Conclusions: This case illustrates the feasibility and efficacy of allo-HSCT in a young adult with NBS, achieving simultaneous treatment of combined immunodeficiency and high-risk relapsed T-ALL. Given the very high risk of haematological malignancies in NBS, early consideration of allo-HSCT at the stage of confirmed immunodeficiency, before malignant transformation, may be warranted. Multicentre studies are needed to define optimal indications, timing and transplant strategies in this rare but high-risk population.

CLINICAL SIGNIFICANCE OF DONOR–RECIPIENT ABO MISMATCH IN SURVIVAL AND IMMUNE RECONSTITUTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION - SINGLE CENTRE EXPERIENCE (CIC 1085)

Yavor Petrov[1], *Ilina Micheva*[1], *Trifon Chervenkov*[1], *Vladimir Gerov*[1]
[1]*University Hospital "St. Marina", Varna, Bulgaria*

Background: The clinical relevance of donor–recipient ABO incompatibility in allogeneic hematopoietic stem cell transplantation (allo-HSCT) is debated. While mismatch may increase transfusion burden and hemolytic risk, its association with survival and immune reconstitution remains unclear. This study evaluates outcomes according to ABO mismatch type in a single-center cohort.

Methods: A retrospective analysis was performed in 114 allo-HSCT recipients treated at the transplant department of the clinic of Haematology, University Hospital "St. Marina", Varna, Bulgaria (CIC 1085). Recipient and donor ABO groups were standardised and classified as compatible, major mismatch, minor mismatch, or bidirectional mismatch. Outcomes included follow-up duration, overall survival (OS), relapse-free survival (RFS), immune reconstitution (ALC, CD4+, CD8+HLA-DR+CD38+, NK, CD19 at days +100/+180/+270), and transfusion requirements. Kruskal–Wallis and χ^2 tests were used for comparisons.

Results: ABO compatibility categories included compatible (n=59), major mismatch (n=16), minor mismatch (n=22), and bidirectional mismatch (n=17). Median follow-up duration did

not differ significantly among groups (p=0.89). Overall survival (OS) was numerically higher in ABO-compatible transplants (56%) compared with major (40%), minor (47%), and bidirectional mismatches (36%), although this difference was not statistically significant (p=0.51). RFS was comparable among compatible, major, and minor mismatch groups (62.5, 63.4%, and 63.6%) and lower in the bidirectional mismatch group (47.1%), without reaching statistical significance (p=0.68). Notably, recipients of ABO-identical grafts required significantly fewer red blood cell transfusions (median 3 units, IQR 2–3) compared with those receiving minor (median 5 units), major (median 6 units), or bidirectional mismatched grafts (median 7 units; Kruskal–Wallis p<0.001), demonstrating a clear association between ABO incompatibility and increased transfusion burden. Immune reconstitution kinetics showed substantial overlap across all groups, with no consistent or clinically meaningful delay attributable to any mismatch category. Immune recovery analyses demonstrated no significant effect of ABO mismatch on the kinetics of lymphocyte subset reconstitution. Absolute lymphocyte count (ALC) recovery at days +30, +100 and +180 progressed in parallel across all ABO categories, and ABO incompatibility was not associated with delayed ALC normalization (Cox HR 1.08, 95% CI 0.82–1.41; p=0.56). CD4+ T-cell reconstitution showed modest numerical variation, with compatible transplants displaying slightly higher median CD4+ values at day +100; however, ABO status did not predict time to CD4+ ≥200/µL (HR 1.12, 95% CI 0.79–1.58; p=0.48). Activated CD8+HLA-DR+CD38+ T-cell levels exhibited the expected early post-transplant elevation in all groups without ABO-specific differences (Kruskal–Wallis p=0.61), and time to CD8+ recovery ≥150/µL was unaffected (HR 0.94; 95% CI 0.66–1.32; p=0.71). NK-cell expansion, typically rapid, showed nearly identical trajectories across compatibility groups, with no delay attributable to ABO mismatch (HR 1.05; p=0.78). Late B-cell (CD19+) recovery demonstrated substantial interpatient variability but no clustering by ABO type (Kruskal–Wallis p=0.67; HR 1.09, p=0.64). Overall, ABO mismatch was not an independent determinant of early T-, B- or NK-cell immune reconstitution following allo-HSCT.

Conclusions: ABO incompatibility did not significantly affect OS, RFS or immune reconstitution, but was strongly associated with increased transfusion requirements. ABO mismatch should not limit donor selection when HLA compatibility is prioritized, although higher transfusion needs should be anticipated.

B-CELL IMMUNE RECONSTITUTION AFTER ALLO-HSCT IN PEDIATRIC PATIENTS: PRELIMINARY RESULTS FROM A LONGITUDINAL FLOW CYTOMETRY ANALYSIS

Elvira Musaeva[1], Susanna Arakelyan[1], Mariia Fadeeva[1], Mariia Igonina[1], Viktoria Vedmedskaia[1], Oyuna Lodoeva[1], Tatiana Sozonova[1], Elizaveta Samykina[1], Andrey Russiyanov[1], Ekaterina Malakhova[1], Elena Kulakovskaya[1], Kirill Butov[1], Ivan Zvyagin[2], Larisa Shelikhova[1], Yulia Skvortsova[1], Dmitry Balashov[1], ***Dmitry Pershin***[1]*, Alexey Maschan[1], Michael Maschan[1]*

[1]Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology, and Immunology, Moscow, Russian Federation (the), [2]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, Moscow, Russian Federation (the)

Background: Immune reconstitution is a critical determinant of HSCT outcomes. While most monitoring strategies focus on T-cell recovery, B-cell reconstitution remains less investigated. According to EUROClass (Wehr et al.,2008) and our pediatric reference data (Sozonova et al.,2025), switched memory B-cell levels <5% indicate impaired or incomplete maturation, whereas ≤2% reflect a severely deficient memory compartment. A reliable surrogate of functional humoral immunity after HSCT has not been fully established; however, the recovery of class-switched memory B cells is increasingly recognized as a key indicator of effective germinal center activity and long-term antibody competence. Here we present preliminary results of our prospective study at 1.5 years follow-up, aiming to characterize B-cell maturation dynamics in pediatric patients after HSCT.

Methods: The interim analysis of our prospective study included 51 pediatric patients that underwent HSCT for hematological malignancies (median age 9 years).
Peripheral blood(PB) samples were collected at days 30, 60, 100, 180, 365, and 540 after HSCT. B-cell subpopulations were analyzed by FC using the DURAClone IM B Cells Tube (Beckman Coulter) when absolute B-cells count exceeded 50cells/μl. The following subsets were assessed: naive, transitional, natural effector, IgM-only, switched memory, plasmablasts, plasma cells. In four patients B-cell precursors (pro-B, pre-BI, pre-BII and immature subsets) were assessed in the bone marrow(BM) samples at days 30 and 100 after HSCT according to EuroFlow recommendations.

Characteristics	**Number of patients (%)**
Diagnosis B-ALL	21 (41%)
T-ALL	5 (10%)
AML	16 (31%)
aBLL	4 (8%)
MDS	5 (10%)
Type of donor Haploidentical	31 (61%)
MSD	13 (25%)
MUD	7 (14%)

Source of stem cells BM	41 (80%)
PBSC	10 (20%)
Conditioning regiment Flu+VP+Treo	16 (31%)
Flu+Thio+Treo	4 (8%)
Flu+VP+TBI	22 (43%)
Flu+Thio+TBI	2 (4%)
Flu+VP+TMLI	4 (8%)
Flu+VP+Bu	1 (2%)
Flu+Timo+Treo+Rituximab	1 (2%)
Flu+VP+Treo+Timo	1 (2%)
GvHD prophylaxis Cyclophosphamide, vedolizumab, abatacept, baricitinib/ruxolitinib	23 (45%) / 28 (55%)

Results: Ten patients (19,6%) were excluded due to disease relapse, graft rejection or tyrosine kinase inhibitors, anti-CD20 or adoptive cell therapy.
Because B-cell maturation is initiated in the bone marrow through tightly regulated transitions from pro-B to pre-B and immature stages, assessing BM precursors provides essential upstream insight into the capacity for downstream peripheral B-cell reconstitution. Consistently, at day 30 the BM samples demonstrated predominance of pre-BI subset (72.6–86.6%) while median absolute B-cell count in PB was 1cell/µl (range 0–33). By day 100, the distribution had shifted toward pre-BII (41.6–51%) and immature (24–37%) populations, accompanied by an increase in PB B-cell count to 143cells/µl (0–892).
All patients demonstrated B-cell recovery by one year (median 480cells/µl, range 128–1148). Among B-cell subsets, the emergence of naive (median 89% at 1.5 years) and natural effector cells (median 3.6% at 1.5 years) followed by the reconstitution of switched memory B cells most closely reflects successful maturation and functional humoral recovery. At 1.5 years post-HSCT, switched memory B-cells remained markedly deficient (median 2.3%, range 0.9-5.7%), with most patients below age-adjusted lower limits and a half of patients persisting at ≤2%, consistent with severely impaired GC-dependent maturation. Only three patients achieved >5% and >25cells/µl of switched B-cells: one – at the 1-year follow-up, two – at 1.5-years, B-cell receptor repertoire assessment is currently in progress for these patients.

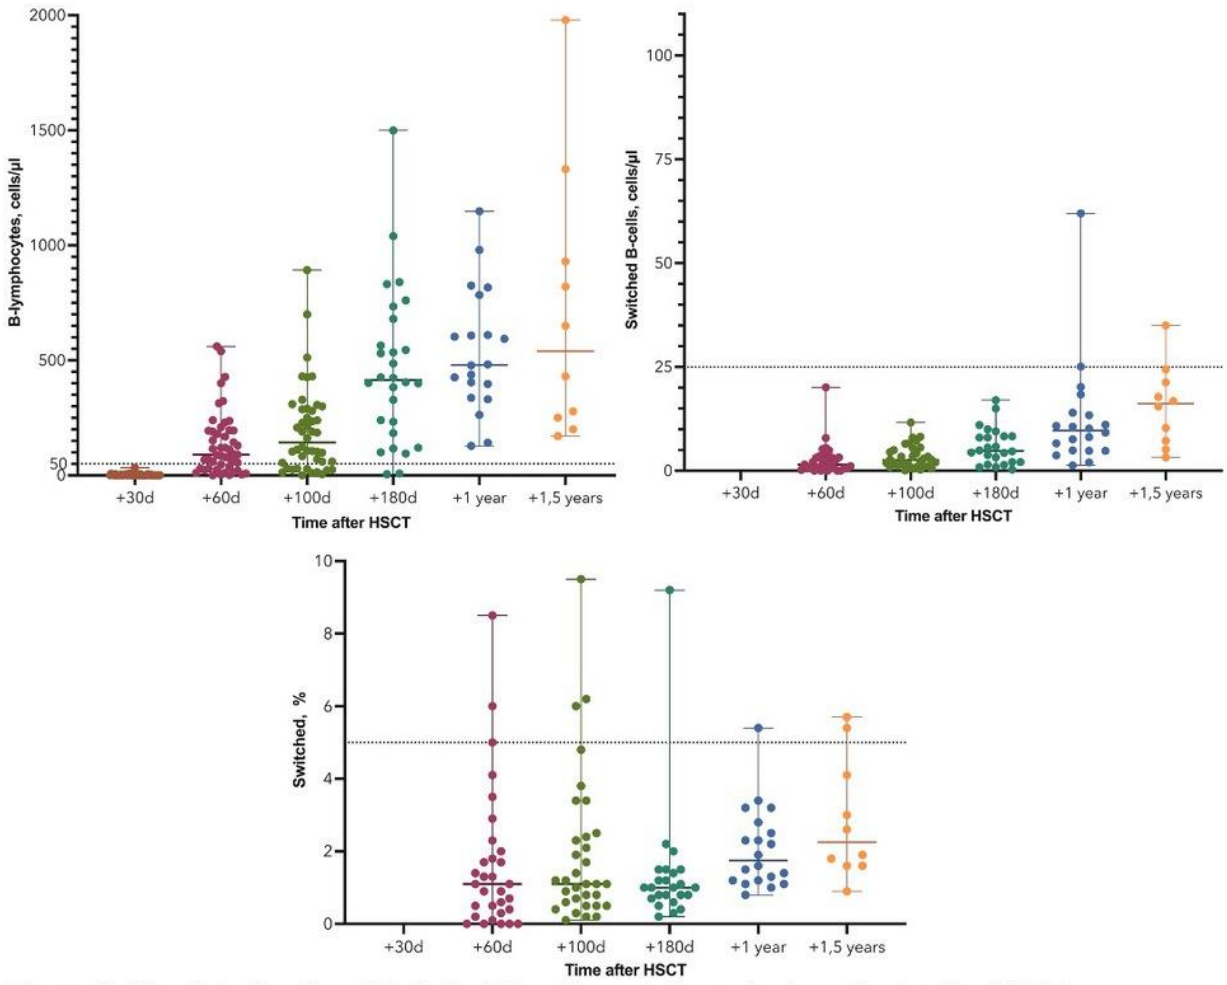

Figure 1. Absolute B-cell and Switched B-cell count dynamics in patients after HSCT.

Conclusions: The data obtained through detailed FC assessment of lymphocyte subpopulations, combined with immunoglobulin profiling, B-cell receptor repertoire analysis and clinical data will help establish a comprehensive and robust framework for evaluating humoral immune competence after HSCT. The observed delay in switched memory B-cell recovery directly impacts clinical decisions regarding IgRT continuation, prophylaxis withdrawal and vaccination readiness.

P209

IMMUNE RECONSTITUTION DYNAMICS AND CLINICAL CORRELATES AFTER PEDIATRIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A SINGLE-CENTER REAL-WORLD EXPERIENCE

*Mucahit Bulut[1], **Suar Caki Kilic**[1], Hayrunnisa Bozkurt[1], Gizem Zengin Ersoy[1], Begum Sirin Koc[1], Funda Tekkesin[1]*
[1]Health Sciences University Umraniye Research and Training Hospital, İstanbul, Turkey

Background: Hematopoietic stem cell transplantation (HSCT) is a curative treatment for a wide range of malignant and non-malignant diseases in children. Successful immune reconstitution (IR) after HSCT is a critical determinant of long-term outcomes, as delayed or impaired IR is associated with severe infections, graft-versus-host disease (GVHD), mixed chimerism, disease relapse, and secondary malignancies. However, real-world data describing immune recovery patterns and their clinical implications in pediatric HSCT recipients remain limited.
The aim of this study was to comprehensively evaluate post-transplant immune reconstitution in children undergoing HSCT, to characterize lymphocyte subset recovery, and to explore the associations between immune parameters, chimerism status, and GVHD.

Methods: This retrospective single-center study included pediatric patients (<18 years) who underwent autologous or allogeneic HSCT between March 2019 and June 2023 at the Pediatric Bone Marrow Transplantation Unit of University of Health Sciences Ümraniye Training and Research Hospital. Patients who received a second transplant, died within the first year post-transplant, or were lost to follow-up before one year were excluded.
Immune reconstitution was assessed using lymphocyte subset analysis (CD3+, CD4+, CD8+, CD19+, CD16+/56+ cells) and correlated with chimerism status and clinical outcomes. Statistical analyses were performed using IBM SPSS version 25.0, with $p<0.05$ considered statistically significant.

Results: A total of 55 patients were analyzed, of whom 52.7% were male. The mean age at transplantation was 81.3±68.0 months. Allogeneic HSCT was performed in 49 patients (89.1%), while 6 patients (10.9%) received autologous HSCT. Indications included non-malignant diseases in 67.3% and malignant diseases in 32.7% of patients. Bone marrow was the stem cell source in 65.5%, and peripheral blood in 34.5% of cases.
Significant associations were observed between immune reconstitution parameters and chimerism status. Patients with low CD3+ T-cell counts had a significantly higher rate of mixed chimerism (<95%) compared to those with normal CD3+ counts (50% vs. 14.6%, $p=0.044$). Similarly, low CD4+, CD8+, and CD19+ cell counts were each significantly associated with increased rates of mixed chimerism ($p=0.022$, $p=0.023$, and $p=0.023$, respectively).
Furthermore, a low CD16+/56+ (NK cell) percentage was significantly associated with a higher incidence of GVHD (71.4% vs. 20.8%, $p=0.013$).

Conclusions: Our findings demonstrate that delayed or impaired immune reconstitution, particularly involving T- and B-cell compartments, is strongly associated with mixed chimerism and GVHD in pediatric HSCT recipients. Systematic monitoring of lymphocyte

subsets may enable early identification of high-risk patients and support individualized post-transplant management strategies. These results underscore the clinical relevance of immune reconstitution profiling in improving long-term outcomes after pediatric HSCT.

IMMUNE RECONSTITUTION ASSESSMENT IN PATIENTS WITH CHRONIC GRAFT VERSUS HOST DISEASE

Victor Iván Salinas-Herrera[1], *Rosa Adriana Alvidrez-González*[1], *Mistral Castellanos-Mares*[1], *Andres Yesid Bonilla-Salcedo*[1], *Vicky Margarita Moncada-Gadea*[1], *Grecia Pamela Martínez-Vázquez*[1], *Irma Karen Pellón-Tellez*[1], *Luis Manuel Valero-Saldaña*[1]
[1]*Instituto Nacional de Cancerologia, Mexico City, Mexico*

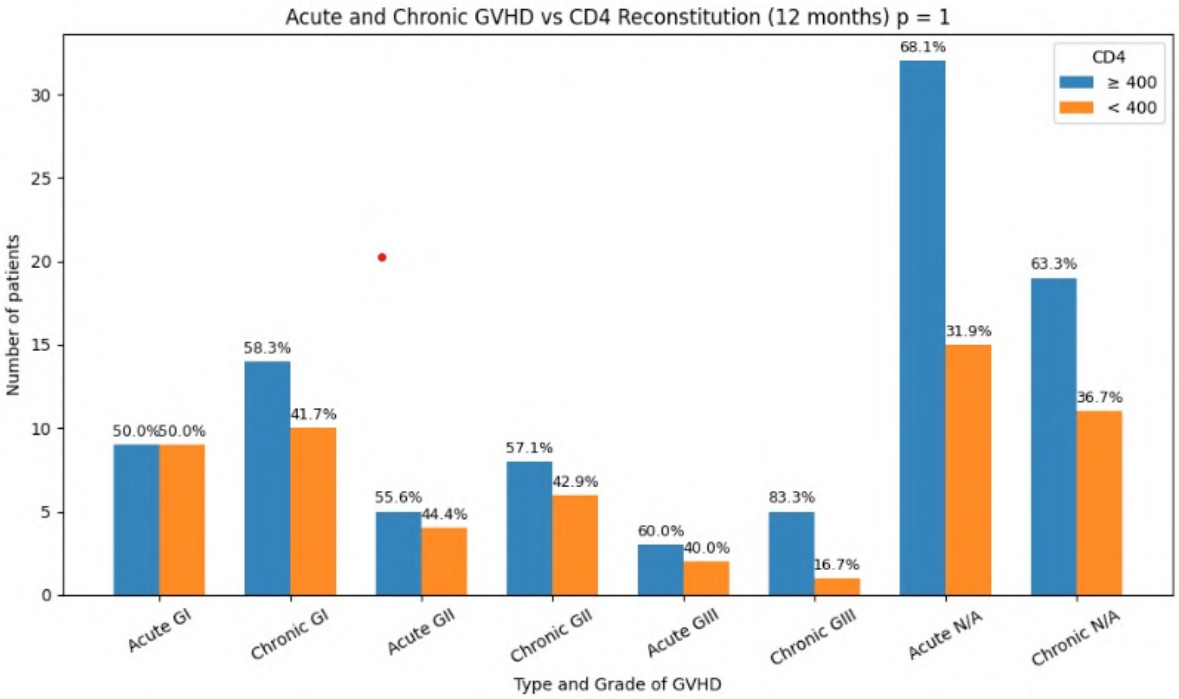
Background: Bone marrow trasplantacion (BMT), also know as Hematopoietic Stem Cell Trasplantation, is a therapeutic process which is fundamental in many malignant and non-malignant diseases, also in oncologic and autoinmune diseases. Graft-versus-host disease (GVHD) is a main complication following BMT, either acute or chronic. This condition can affect multple organs and systems, impacting the patient´s quality of life and long-term survival. GVHD is characterized by an immune response of the alloreactive T lymphocytes. Immune reconsitution is the process in which the immune systeme recovers following BMT and depends on factors such as the graft source, conditioning regiment – myeloablative (MAC) or reduced-intensity conditionin (RIC), the inmunosupresion agents, donor age and sex, graft failure and/or dysfunction, among others. This process involves de recovery of B, T and NK cells. This evaluation is performed through lymphocyte subpopoulation, a blood analysis. Poor immune reconsitution is associated with an incresed risk of infections, relapse and progression of GVHD; therefore; its monitoring and study are of great importance.

Methods: A single-center, retrospective, observational study was conducted in patients who underwent allogeneic BMT and subsequently developed chronic GVHD, compared with those who did not develop GVHD and those who developed acute GVHD, from 2017 to 2024. Clinical, demographic, and laboratory data were collected to analyze the timing of immune reconstitution, taking into account conditioning regimen, transplant type (haploidentical or HLA-identical), donor-related factors, and post-transplant complications that may impact immune recovery.

Results: A statistically significant trend (p=0.0532) was observed between transplant type and immunosuppression at 6 months. Patients with HLA-identical transplants and those using methotrexate-based regimens showed a trend toward better CD4 recovery (53.6% in the >400 group vs. 31.4% in the <400 group). Conversely, post-transplant cyclophosphamide use (common in haploidentical transplant recipients) was more frequent in the group with insufficient reconstitution (68.6%).
Also in the analysis based on our data base, we observed that immune reconstitution is affected by different variables; the most relevant was de association with acute GVHD.

Although there were other items with important significance like CMV reactivation and bacterial infections.

Variable	Total (N=79)	>400 CD4/mcl 6 months (N=28)	<400 CD4 months (N=51)	P Value	>400 CD4/mcl 12months (N=49)	<400 CD4/mcl 12 months (N=30)	P Value
Age	33 (25.5-43)	31.5 (26.25-42)	34 (25.5-44.5)	0.7466	32 (26-41)	39.5 (25.5-48)	0.4334
HLA Identical trasplant HLA Haploidentical trasplant	48 (60.8) 31.39.2	13 (46.4) 15 (53.6)	35 (68.6) 16 (31.4)	0.0532	27 (55.1) 22 (44.9)	21 (70) 9 (30)	0.1881
CMV reactivation Present Absente	49 (62) 30 (38)	20 (41.4) 8 (26.6)	29 (56.9) 22 (43.1)	0.202	32 (65.3) 17 (34.7)	17 (56.7) 13 (43.3)	0.4426
Inmunosupresion Cs + MMF +MTX (HLA Identical) Cs + MMF + CyPT (HLA Haploidentical)	31 (39.2) 48 (60.8)	15 (53.6) 13 (46.4)	16(31.4) 35 (68.6)	0.0532	22 (44.9) 27 (55.1)	9 (30) 21 (70)	0.1881
Acute GVHD Present Absent	46 (58.2) 33 (41.8)	18 (64.3) 10 (35.7)	28 (54.9) 23 (45.1)	0.418	31 (63.3) 18 (36.7)	15(50) 15 (50)	0.2459
Chronic GVHD Present Abscent	30 (38) 49 (62)	13 (46.4) 15 (53.6)	17 (33.3) 34 (66.7)	0.2513	19 (38.8) 30 (61.2)	11 (36.7) 19 (63.3)	0.8513



Conclusions: In this work we can confirm that immune reconstitution is a dynamic process in which every variable have a role in this process. Now that cyclophosphamide is being used post-transplant in HLA-identical patients, it will be interesting to evaluate immune reconstitution with this therapy and compare it to the methotrexate standard.

Disclosure: Nothing to declare.

P212

PRELIMINARY ANALYSIS OF B-CELL IMMUNORECONSTITUTION IN CHILDREN WITH HEMATOLOGICAL MALIGNANCIES AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE

Susanna Arakelyan[1], *Elvira Musaeva*[1], *Alexandra Shutova*[1], *Dmitriy Pershin*[1], *Larisa Shelikhova*[1], *Dmitry Balashov*[1], *Michael Maschan*[1], *Yulia Skvortsova*[1]
[1]*Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology, and Immunology, Moscow, Russian Federation (the)*

Background: Allogeneic HSCT is a curative treatment for severe pediatric hematologic and immunologic diseases; however, delayed immune reconstitution remains a major contributor

to post-transplant morbidity. B-cell recovery is particularly slow and often functionally insufficient, increasing the risk of prolonged hypogammaglobulinemia and recurrent infections. Multiple transplant-related factors including GVHD, prolonged immunosuppression, prior B-cell targeted therapy, and conditioning intensity may further disrupt B-cell maturation. Despite numerical recovery within the first year, full restoration of humoral immunity may be delayed. Understanding determinants of impaired B-cell reconstitution after allo-HSCT with post-transplant cyclophosphamide (PTCy) remains essential for optimizing long-term immune recovery.

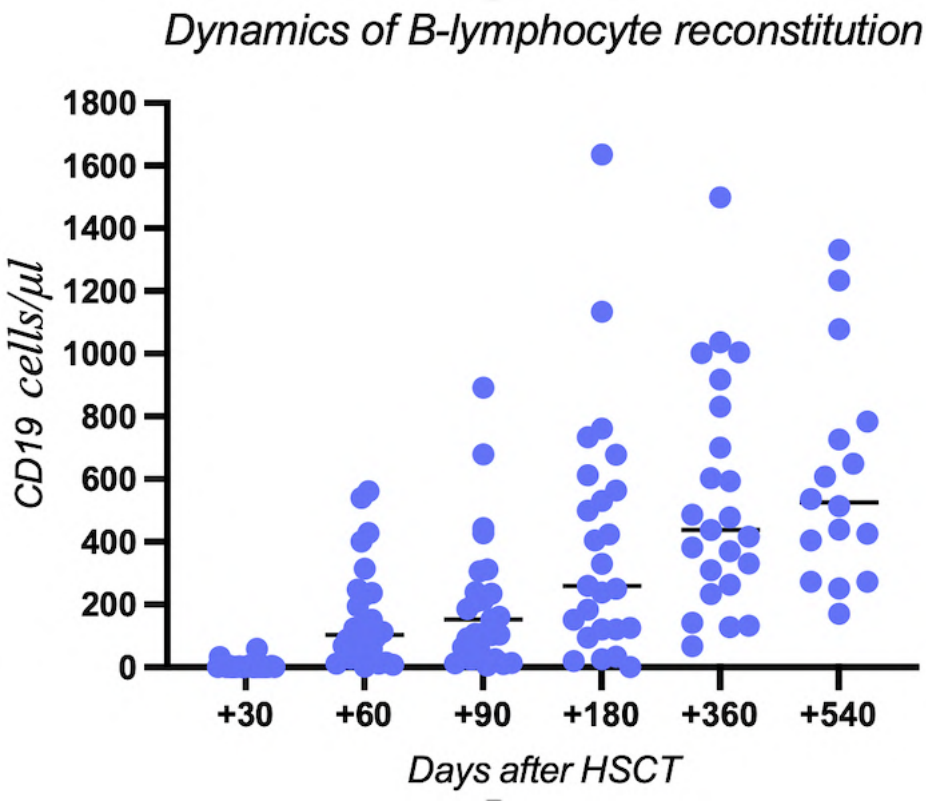
Methods: Here we demonstrate the analysis of 36 pediatric patients with acute leukemias who underwent allo-HSCT with PTCy in 2024 and reached the 1-year or longer milestone. The median age was 9 years (range 1–17 years), 27 boys, 9 girls, 18 ALL, 13 AML, 2 ABLL, 3 MDS. Patients characteristics are presented at Table 1. Seven of 27 children received blinatumomab, 1 - inotuzumab, and 1 got CAR-T cells prior to allo-HSCT. Immunophenotyping was performed by flow cytometry (CytoFLEX, Beckman Coulter). Nine patients were excluded due to relapse, adoptive cell therapy, severe complications or aplasia requiring donor cell infusion, leaving 27 in the final analysis. Detailed B-cell phenotyping ≥ 1 year post-transplant was performed in 17 patients.

Table 1. Patients characteristics

Characteristics	Number of patients (%)
Diagnosis	
ALL (B/T)	18 (50%) (14/4)
AML	13 (36%)
ABLL	2 (6%)
MDS	3 (8%)
Type of donor	
Haploidentical	22 (61%)
MUD	7 (19.5%)
MSD	7 (19.5%)
GVHD prophylaxis	
Baricitinib + Abatacept + Vedolizumab	24 (67%)
Ruxolitinib + Abatacept + Vedolizumab	12(33%)
Conditioning regimen	
TBI-based/TMLI-based (12 Gr) + VP/Thiotepa	18 (50%) (17/1)

Treo-based + VP/Thiotepa	16 (44%) (15/1)
Rituximab in conditioning	2 (6%)
Source of stem cells	
BM	31 (86%)
PBSC	5 (14%)

Results: All patients engrafted in time and had full donor chimerism. Among 27 patients, 12 (44%) developed acute GVHD: grade 1-2 in 75%, grade 3 in 25%. Chronic GVHD was observed in 5 patients (18%). Eight of children with GVHD (57%) received prolonged systemic immunosuppressive therapy (≥ 3 months). Rituximab was employed only in one case of immune-related complications (AIHA). Four of 27 patients (15%) had CMV-viremia. No other serious infections were detected, only a few respiratory episodes. Detailed B-cell phenotyping at ≥1 year after allo-HSCT has been done in 17 patients, in 7 cases switched B-memory cells (IgD-IgM-CD27+) did not exceed 2%, but nobody of them required replacement immunoglobulin therapy. The immunoglobulin M level was within reference values at more than 6 months in almost all patients.
In one (4%) of 27 patients, B-lymphocyte levels reached 50 cells/μL by day +30 after HSCT, in 70% by day +60, in 4% - +90 day, in 8% - +180 day, and in 14% - +360 post-HSCT (Figure 1). Only the patient who received rituximab post-HSCT underwent regular replacement therapy; the remaining patients underwent single intravenous immunoglobulin (IVIG) infusions as indicated (IgG <4 g/L) until B-cell immunoreconstition occurred (first 3 months after HSCT). No-one received replacement therapy with SCIG.
Figure 1. Kinetics of B-lymphocyte recovery.



Conclusions: Allo-HSCT with PTCy as GVHD prophylaxis supports an adequate quantitative and functional B-cell recovery in most pediatric recipients, despite a subset exhibiting persistently low switched memory B-cell levels. No patients required immunoglobulin administration, warranting investigation into the minimum number of switched B cells required for protective clinical efficacy. Further studies are needed to characterize B-cell repertoire evolution and to define transplant-related factors influencing long-term immune competence.

Disclosure: Nothing to declare.

P213

TÜRKİYE TRANSPLANT CENTRES CHIMERISM APPROACH SURVEY STUDY

*İrfan Yavaşoğlu[1], Atakan Turgutkaya[1], **Ayşe Hilal Eroğlu Küçükdiler**[1], Sencer Küçük[1], Yusufcan Aygül[1], Ali Zahit Bolaman[1]*
[1]Adnan Menderes University Medical Faculty, Division of Hematology, Aydın, Turkey

Background: Monitoring donor chimerism after allogeneic haematopoietic stem cell transplantation (Allo-HSCT) is important in terms of engraftment and relapse. Chimerism testing practices may vary from centre to centre. In this study, a survey was conducted targeting transplant centres with Allo-SCT experience in Turkey, and the results were evaluated.

Methods: A survey consisting of 15 questions, some multiple-choice and some open-ended, was conducted for paediatric and adult transplant centres in Turkey with allo-SCT experience(Survey link: **https://forms.gle/1Mg4wAs4z1inHUVv7**). Prior to the study, approval was obtained from the Non-Interventional Clinical Research Ethics Committee of Aydın Adnan Menderes University (2025/72) and announced on the official website of the Turkish Haematology Association. The opinions of the participants who completed the questionnaire regarding the test practice and the questionnaire itself were also obtained from the doctors who wished to provide feedback through an open-ended question.

Results: The study included 30 centres consisting of 17 (56.7%) university hospitals, 3 (10%) teaching and research hospitals, 1 (3.3%) city hospital, and 9 (30%) private hospitals. Of these centres, 23 centres (76.7%) actively perform Allo-SCT on adult patients, and 7 centres (23.3%) actively perform Allo-SCT on paediatric patients. Twenty (66.7%) centres perform related, unrelated, and haploidentical allo-SCT. Six (20%) centres can also perform cord blood-derived Allo-SCT in addition to these. The proportion of centres capable of performing haploidentical Allo-SCT is 90%. Regarding the timing of chimeric state testing, 17 (56.7%) centres have adopted testing within the first month post-transplant, followed by testing at 3 months, 6 months, and 1 year. Regarding the time to achieve chimerism, 21 (70%) centres reported obtaining results within the first 15 days, while 8 (26.7%) centres reported obtaining results between 16 and 30 days. Regarding the cell source, 14 (46.7%) centres used only peripheral blood, while 16 (53.3%) centres used peripheral blood and/or bone marrow. Twenty-three (76.7%) centres do not examine chimerism in a specific population; 5 (16.7%) centres examine the T-cell series, and 2 (6.7%) centres examine the CD34 cell population. The most frequently used method for chimeric state research is short tandem repeats (STR) (50%). Twenty cases (66.7%) stated that they obtained the test result from an accredited laboratory. Twenty-six (86.7%) centres stated that they did not use the HLA relapse loss test.

Conclusions: This survey study, which aims to determine the practices of centres performing allo-SCT in Türkiye regarding chimerism, provides results that will guide future, larger-scale studies. The proliferation of international studies involving a larger number of centres and determining more parameters will improve clinicians' approach to performing and interpreting chimerism tests.

PERI-TRANSPLANT GUT MICROBIOME INJURY AND ENTEROCOCCUS FAECIUM DOMINATION ARE ASSOCIATED WITH INCREASED MORTALITY IN PEDIATRIC ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

Enrico Velardi[1], *Oriana Miltiadous*[2], *Nicholas Waters*[2], *Steven Siegel*[3], *Lanying Ma*[2], *Askarbek Orakov*[3], *Federica Galaverna*[1], *Karissa Whiting*[2], *Chi Nguyen*[2], *Teng Fei*[2], *Nadia Brijmohan*[2], *Elizabeth Klein*[2], *Ana Catarina Gradissimo De Oliveira*[2], *Luigi Amoretti*[2], *Jennifer Haber*[2], *Pietro Merli*[1], *Paola Tabares*[3], *Andrew Kung*[2], *Leslie Kean*[3], *Eric Pamer*[4], *Susan Prockop*[3], *Jonathan Peled*[2], *Ivan Maillard*[2], *Jaap Jan Boelens*[2], *Seth Rakoff-Nahoum*[3], *Marcel van den Brink*[5], *Franco Locatelli*[1]
[1]*Bambino Gesu Children Hospital, Rome, Italy,* [2]*Memorial Sloan Kettering Cancer Center (MSKCC), New York, United States of America (the),* [3]*Dana Farber/Boston Children's Hospital, Boston, United States of America (the),* [4]*University of Chicago, Chicago, United States of America (the),* [5]*City of Hope, Los Angeles, United States of America (the)*

Background: Allogeneic hematopoietic cell transplantation (allo-HCT) is a potentially curative therapy for a wide range of pediatric diseases, yet transplant-related complications remain a major cause of morbidity and mortality. Increasing evidence from adult cohorts suggests that gut microbiome diversity and composition influence post-transplant outcomes; nevertheless, pediatric patients have distinct age-related characteristics in microbiome development, immune maturation, and transplant indications. The contribution of gut microbiome dynamics to outcomes after pediatric allo-HCT remains insufficiently understood.

Methods: We conducted a longitudinal, multicenter study of pediatric patients receiving allo-HCT at Memorial Sloan Kettering Cancer Center (New York, USA), Bambino Gesu Children's hospital (Rome, Italy), and Boston Children's Hospital (Boston, USA). Stool samples were collected from day −30 to 2 years post-transplant. Shotgun metagenomic sequencing with external microbial spike-in controls was used to quantify microbiome composition and absolute abundance across kingdoms. Associations between clinical variables, microbiome features, and transplant outcomes were systematically evaluated.

Results: A total of 349 patients were enrolled, contributing 1,699 stool samples. Median age at transplantation was 8.1 years (IQR 4.2–14.1), and 66% underwent allo-HCT for malignant indications. Females accounted for 36% of the cohort (n=124). T-cell depletion (TCD) was applied in 110 allografts (32%), including alpha/beta TCD in 81 patients. Bone marrow was the most frequently used stem cell source (n=207, 59%), followed by peripheral blood stem cells (n=122, 35%) and umbilical cord blood (n=16, 5%). Most patients (94%) underwent allo-HCT for the first time, while a minority received a subsequent transplant. After a median follow-up of 2.6 years (IQR 1.7–3.8), relapse occurred in 42 patients, corresponding to 18% of those transplanted for malignant indications. Acute GVHD occurred in 31% of the cohort, and overall mortality was 17%, with non-relapse mortality accounting for 6% of deaths.

During the peri-transplant period, gut microbiome α-diversity declined significantly after transplantation (median Simpson reciprocal index 4.0 pre-HCT vs. 2.1 post-HCT, p<0.001), accompanied by an approximately five-fold reduction in total bacterial load. Younger age (<3 years), malignant indication, and use of TCD grafts were associated with lower α-diversity over time (p<0.001). Across the peri-transplant period, bacterial absolute abundance varied significantly by transplant center and underlying disease indication (p<0.001). Microbiome composition analysis revealed frequent low-diversity states, with taxonomic domination (≥30% relative abundance) observed in 97% of patients by day +28. Among dominant taxa, Enterococcus was most frequently observed (26% of samples), followed by Streptococcus (9%). Multivariable analyses were performed to explore clinical determinants of microbiome domination. Malignant disease and piperacillin/tazobactam prophylaxis were associated with increased *Enterococcus* domination and abundance.
In multivariable Cox analysis of first-time recipients (n=192), greater gut microbiome α-diversity during the peri-engraftment period predicted lower all-cause mortality (HR 0.40, 95% CI 0.17–0.95; p=0.038). FLORAL was implemented to identify gut microbiome taxa associated with outcomes, which identified *Enterococcus faecium* as positively associated with mortality.

Conclusions: This multicenter study demonstrates pronounced age- and center-related heterogeneity in the pediatric HCT microbiome. Reduced α-diversity and Enterococcus faecium domination were associated with increased mortality, supporting the prognostic importance of peri-transplant microbiome characteristics.

HLA-DRB1 MISMATCHING ENHANCES GVL EFFECT IN PEDIATRIC ACUTE LEUKEMIA UNDERGOING G-CSF/ATG-BASED HAPLOIDENTICAL TRANSPLANTATION : THE CRITICAL ROLE OF POSITION 86 DIMORPHISM

Yanhui Luo[1], Xiaobo Li[2], Ziqi Wang[2], Bin Wang[1], Chenguang Jia[1], Xian Zhang[3], Yimei Feng[4], Weijie Zhang[5], Dao Wang[6], Benshan Zhang[7], Hao Xiong[8], Liping Dou[9], Jing Cheng[10], Jingbo Wang[5], Xi Zhang[4], Xingyu Cao[3], Guanghua Zhu[1], Maoquan Qin[1], ***Xiangjun Liu***[2]

Background: The impact of HLA-DRB1 mismatching in haploidentical hematopoietic stem cell transplantation (haplo-HSCT) is increasingly recognized in post-transplant cyclophosphamide (PTCy) platforms. Recent investigations led by Petersdorf et al. demonstrated that the amino acid dimorphism at position 86 (p86) of the HLA-DRB1 antigen-binding groove—specifically the Glycine/Glycine (GG) genotype—predicts reduced relapse after haplo-HSCT with PTCy. However, this immunogenetic association remains understudied in pediatric patients treated with the G-CSF/ATG-based protocol (the Beijing Protocol).

Methods: A total of 690 pediatric patients who received haplo-HSCT (5–8/10 HLA matched) with G-CSF/ATG-based conditioning across multicenters in China from 2015 to 2023 were included in this retrospective study. The overall cohort had a median age of 9 years (IQR: 5–13 years), and was composed of 347 AML patients and 343 ALL patients. In terms of disease status at transplantation, 72 cases were categorized as refractory/relapsed (RR) disease, while the remaining 618 were classified as non-RR cases. We evaluated the association between HLA-A/B/C/DRB1/DQB1 matching and clinical outcomes—including disease-free survival (DFS), overall survival (OS), cumulative incidence of relapse (CIR), non-relapse mortality (NRM) and relapse-related mortality (RRM)—using Cox regression models. Additionally, we investigated the immunomodulatory impact of the DRB1 p86 dimorphism (Glycine/Valine), specifically evaluating the prognostic value of DRB1 mismatching within patient GG, GV, and VV subgroups.

Results: HLA-DRB1 matching was significantly associated with inferior outcomes compared to mismatching in the non-RR cohort (Fig. 1a). This effect was not observed in the RR cohort (Fig. 1b). In the non-RR cohort (Fig. 1c), patients matched at DRB1 exhibited lower DFS (HR=1.95, p=0.0002) and OS (HR=1.92, p=0.0021). This survival disadvantage was primarily attributed to a higher cumulative incidence of relapse (HR=2.11, p=0.0006) and

RRM (HR=2.25, p=0.0033), with no significant difference in NRM (HR=1.62, p=0.1484). Structural stratification revealed that the protective effect of DRB1 mismatching is modulated by p86 dimorphism in a disease-specific manner. While the impact of DRB1 mismatch within the p86-GG subgroup showed only marginal association with RRM in the overall cohort (p=0.0472), disease-specific stratification revealed distinct patterns. In AML (Fig. 1d), the DFS benefit was pronounced in the p86-VV subgroup (p=0.0018). Notably, although the p86-GV subgroup showed a significant reduction in relapse risk (p=0.03), it failed to achieve a statistical improvement in DFS. In contrast, in ALL (Fig. 1e), the protective efficacy was prominent in the p86-GV genotype (predicting superior DFS, p=0.0224, and lower RRM, p=0.0305). In multivariate analysis, DRB1 mismatch was identified as an independent predictor of DFS, whereas mismatches at other loci showed no significant association.

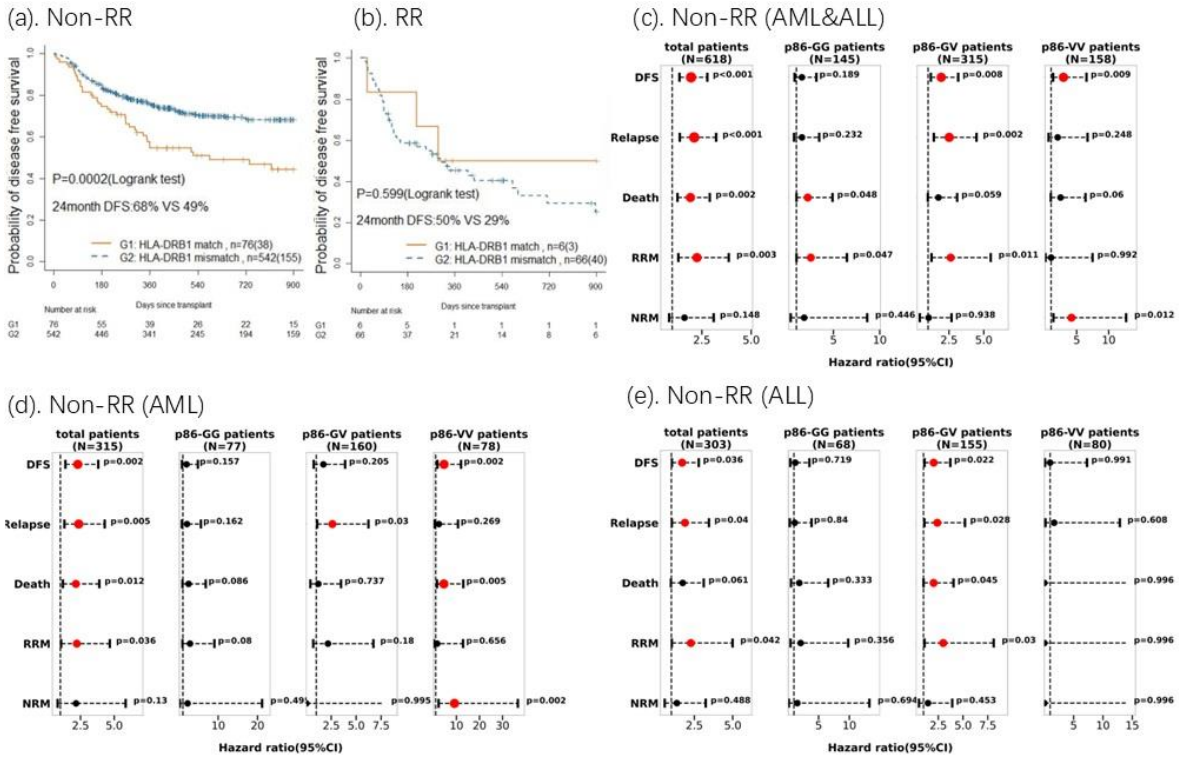

Figure 1. **HLA-DRB1 matching-associated DFS Kaplan-Meier curves and risks stratified by patient amino acid dimorphism at position 86 of DRB1.** (a),(b) Kaplan-Meier curves of DFS for the non-RR and RR subgroups. (c) Forest plot of risks for non-RR (AML&ALL). (d) Forest plot of risks for non-RR (AML). (e) Forest plot of risks for non-RR (ALL).

Conclusions: This multicenter study suggests that HLA-DRB1 matching generally attenuates GVL efficacy in pediatric patients with lower tumor burden (non-RR) undergoing haplo-HSCT. Furthermore, our data indicate that the outcomes are significantly modulated by the Valine/Glycine dimorphism at position 86 . While the survival advantage of DRB1 mismatching is mainly attributed to enhanced GVL, the distinct patterns observed (especially in the p86-VV subgroup) imply that p86 dimorphism also alters immunogenicity, thereby influencing the risk of NRM. These findings highlight the utility of integrating p86 polymorphism into donor selection strategies.

OS14-04

TCR ALPHA/BETA DEPLETION IN HAPLOIDENTICAL TRANSPLANTATION FOR PEDIATRIC PATIENTS

Ajmeera Azeez[1], *Pooja Mallya*[1], *Niveditha Reddy*[1], *Shobha Badiger*[1], *Ravi Joshi*[1], *Murugaiyan Nedunchezhian*[2], *Prathip Kumar*[1], *Sunil Bhat*[1]
[1]*Narayana Health City, Bangalore, India,* [2]*Cytocare Technologies, Hyderabad, India*

Background: TCRαβ-depleted haploidentical HSCT is effective for children without matched donors across benign and malignant diseases. Ex-vivo T-cell depletion of graft- versus -host disease (GvHD) causing subsets- TCR αβ and CD45RA cells – and adoptive transfer with memory (CD45RO) cells have significantly improved the outcomes with low GvHD rates and acceptable viral reactivation.

Methods: We retrospectively analyzed 397 pediatric patients who underwent TCR αβ depleted haplo-HSCTs from January 2013 to September 2025 in a tertiary care center for benign (n= 332) and malignant (n=65) indications. The stem cell product underwent ex-vivo depletion of CD19 (n=46) or CD45RA (n= 350) along with TCR αβ depletion. Patients with CD45RA depletion were given sequential donor lymphocyte infusion (DLI) of CD45RO cells post–transplant.

Results: Cohort characteristics: Median age – 6.08 years with 61% males and 39% females. Benign transplants included transfusion dependent thalassemia (n=253), metabolic disorders (n=32), primary immunodeficiencies (n=26), inherited bone marrow failure syndromes (n=12). Malignant indications included high risk or relapsed acute lymphoblastic leukemia (n=43), high risk or relapsed acute myeloid leukemia (n=14), juvenile myelomonocytic leukemia (n=3) –and other rare hematolymphoid malignancies (n=5).
Transplant procedure: Conditioning regimen used was predominantly myeloablative in 75% and reduced-toxicity in 23% transplants. T haplo-HSCT grafts were of parental origin in 94 %, siblings in 4 % and other relatives in 2 %. Immunosuppression with calcineurin inhibitors given typically for a month. Median CD34 cell dose was 15.4 X 10^6 cells/kg, TCRαβ dose, 0.02 x 10^6 cells/kg, and TCRγδ dose, 10.55 x 10^6 cells/kg.
Transplant outcomes: Median time to both neutrophil and platelet engraftment was 11 days. Graft failure occurred in 31 (7.8%) patients, primary in 24, secondary in 7. Six percent of benign transplants had graft failure. Incidence of acute grade III –IV was 5.5% with 5.1% in benign and 7.7% in malignant transplants. The incidence of any chronic GVHD was 16.8 %, with severe disease in 2.6%.
The incidence of viral reactivation was 54 %, with clinically significant CMV infection in 40 %, adenoviral infection in 13%, and symptomatic BK viral reactivation in 9 %. Twenty percent had bacterial infection and 3% had probable fungal infection. Eighty patients (20%) died in this cohort. Cause of mortality led with infections in 55% (half of whom had proven bacterial sepsis), graft rejection in 21 % and GvHD in 10%. Cumulative incidence of relapse in malignant transplants was 18.5%.

With a median follow up of 18 months, OS and EFS in benign transplants were 81.2% and 79.1% respectively and in malignant transplants was an OS of 65% and EFS of 48%.

Table 1: Transplant characteristics and patient outcomes	
CHARACTERISTICS OF BENIGN PEDIATRIC TRANSPLANTS	
Indications [N(%)]

IMMUNE CELL THERAPY AFTER TCRAB$^+$/CD19$^+$-DEPLETED HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION IN RELAPSED HIGH-RISK NEUROBLASTOMA: A PHASE 2 SINGLE-CENTER STUDY

Stefano Giardino[1], *Massimo Conte*[1], *Michela Falco*[1], *Alessandra Dondero*[1], *Roberta Castriconi*[1], *Filomena Pierri*[1], *Giulia Ferrando*[1], *Sara Pestarino*[1], *Francesca Dagliano*[1], *Michela Lupia*[1], *Marina Lanciotti*[1], *Marco Risso*[1], *Federica Sabatini*[1], *Claudia Cocco*[1], *Francesca Parisi*[1], *Stefania Sorrentino*[1], *Maria Teresa Battaglia*[1], *Carla Manzitti*[1], *Alberto Garaventa*[1], *Maura Faraci*[1]
[1]*IRCCS Istituto Giannina Gaslini, Genova, Italy*

Background: Despite recent advances in immunotherapies in neuroblastoma(NB), the prognosis of relapsed high-risk(HR) patients remains dismal, with historical 5-year survival rates below 20%.
Recently, treatment of relapsed patients with a combination of chemotherapy and dinuximab-β immunotherapy has proven effective in inducing high response rates; however, these responses tend to wane over time, pointing the need for effective consolidation therapies to enhance immunological control of the disease.
At IRCCS Gaslini, a prospective, single-center phase 2 clinical trial with immune-Cell therapy is ongoing in this patient population, aiming to report the feasibility and activity of the proposed approach.

Methods: Eligible patients included those with relapsed HR-NB achieving at least stable disease per INRC criteria and having an available haploidentical parental donor suitable for peripheral blood stem cell harvest. Among parental donors, selection followed an algorithm that integrated the donor's KIR phenotype, NK alloreactivity, the percentage of circulating donor-derived NK cells, and their in-vitro degranulation and cytotoxicity against NB cell lines, both alone and in the presence of anti-GD2 mAb. The treatment protocol consists of a sequential approach involving TCRαβ$^+$/CD19$^+$-depleted haploidentical hematopoietic stem cell transplantation (haplo-HSCT), followed by five courses of post-transplant immunotherapy with dinutuximab beta. Starting from the second course, donor-derived natural killer cell

infusions(NKIs) are administered prior to each cycle (Table 1).

Table 1	
Inclusion criteria	1. Relapsed neuroblastoma after first-line therapy; 2. Disease response ≥ stable disease (according to INRC criteri 3. Age between 0 and 25 years; 4. Availability of a haploidentical family donor eligible for PBS
Donor selection and management	- KIR phenotyping, NK alloreactivity assessment, percentage c vitro degranulatiobn and cytotoxicity in the presence of anti-C - One (or two) lymphocytoapheresis sessions for NK cell manu - G-CSF–mobilized PBSC collection.
Haploidentical HSCT	**Conditioning regimen:** Thiotepa, Fludarabine, Melphalar **In vivo T/B-cell depletion:** ATG, Rituximab. **Graft manipulation:** Negative selection of TCRαβ⁺/CD
ImmunoCell therapy	**Dinutuximab beta:** 5 courses from day +35, every 35 days, 1 **NK cell infusions (NKI):** from the 2nd to the 5th course, cell d
Disease Response Evaluation Schedule	1st: after haplo-HSCT and the first 2 courses of immunotherap 2nd: after the 5th course of immunotherapy 3rd: every 3 months during the first year afetr haploHSCT 4th: every 6 months from the second year after haploHSCT
Immunomonitoring	- Immunophenotyping of circulating immune cells. - Cytokine profiling during immunotherapy. - In vitro evaluation of NK cell functional activity.

Results: As of this report, eight patients have undergone haplo-HSCT. Cellular product manufacturing (TCRαβ⁺/CD19⁺-depleted grafts;NK cells) was successful in all cases, meeting

predefined release criteria. Engraftment was achieved in 7/8 patients, with full donor chimerism. One patient experienced primary graft rejection and was excluded from the protocol. No grade >2 acute or chronic graft-versus-host disease (GvHD) was observed. Among the seven engrafted patients, six have completed the post-transplant immunoCell therapy program, and one is about to begin it. A total of 24 immunotherapy courses were administered post-transplant so far, 17 of which included NKIs, and 12 were completed via home care. Twenty-nine adverse events were reported, all graded <3 (mild to moderate, CTCAE v5.0).
At the end of the treatment, all patients achieved a complete disease response (INRC). Among the six patients with at least 1 year of follow-up, five are alive at a median follow-up of 2.1 years (0.99–2.7) (OS 83%). Two patients are disease-free at 1 and 2.7 years after haplo-HSCT, respectively; two experienced local relapse at 10 and 11 months after haplo-HSCT and started local radiotherapy plus temozolomide, which is ongoing; and one patient developed a local relapse 13 months after haplo-HSCT and achieved a second complete remission following local radiotherapy, topotecan, and consolidation with anti-GD2 CAR-T therapy, remaining stable 14 months after relapse. Only one patient died due to disease progression, 5 months after a metastatic relapse that occurred 20 months post–haplo-HSCT.

Conclusions: Preliminary data demonstrate the feasibility and safety of haplo-HSCT followed by immunotherapy with dinutuximab beta and NK cell infusions in relapsed HR neuroblastoma. This approach shows promise for improving immune control of disease. Long-term efficacy will be assessed with a larger cohort and extended follow-up.

Clinical Trial Registry: Not applicable

HAPLOIDENTICAL STEM CELL TRANSPLANT WITH TCR-ALPHA/BETA DEPLETION IN TRANSFUSION DEPENDENT THALASSEMIA POST PRE TRANSPLANT IMMUNOSUPPRESSION

Sunil Bhat[1], *Ajmeera Azeez*[1], *Niveditha Reddy*[1], *Ravi Joshi*[1], *Shobha Badiger*[1], *Prathip Kumar*[1], *Shreyas AC*[1], *Murugaiyan Nedunchezhian*[2], *Pooja Mallya*[1]
[1]*Narayana Health City, Bangalore, India,* [2]*Cytocare Technologies, Hyderabad, India*

Background: Haploidentical hematopoietic stem cell transplantation (Haplo-HSCT) is an option for treating patients of transfusion-dependent thalassemia (TDT) who lack a full-matched donor. Ex-vivo T-cell depletion of graft-versus-host disease (GvHD) causing subsets-TCR αβ and adoptive transfer with memory (CD45RO) cells have significantly improved the outcomes of haploidentical HSCT.

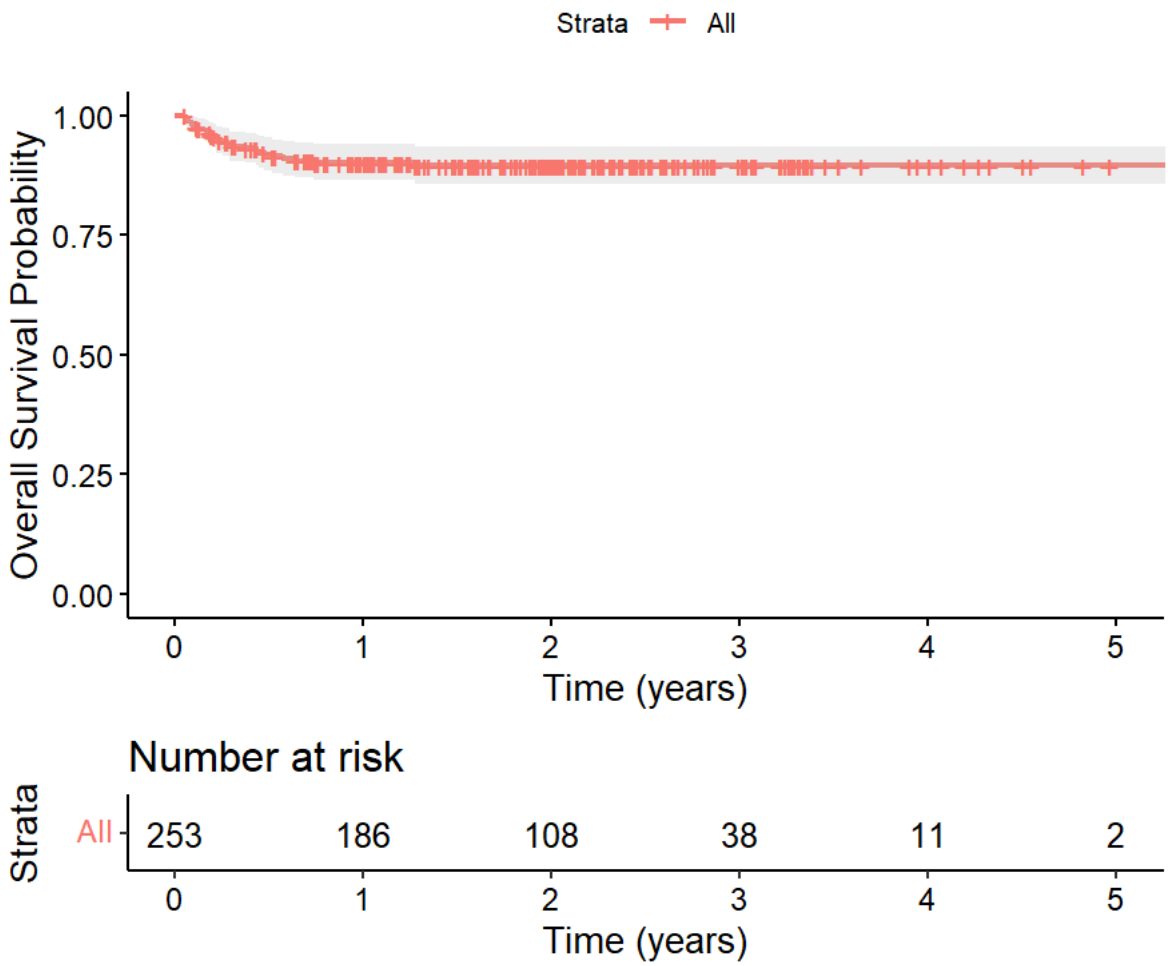
Methods: We prospectively followed up 253 pediatric patients of TDT who underwent TCR αβ depleted haplo-HSCTs from January 2013 to September 2025. The stem cell product underwent ex-vivo manipulation with depletion of CD19 (n=13) or CD45RA (n=240) along

with TCR αβ depletion. Patients with CD45RA depletion were given sequential donor lymphocyte infusion (DLI) of CD45RO cells post–transplant.

Results: Cohort characteristics: Two hundred fifty – three patients with median age of 6.5 (IQR 4.08-10.25) years, 59% males and 41% females. Thirty-four (13.5%) patients were categorized as Pesaro Class I, 150 (59.2%) to class II, and 69 (27.3%) to Class III. Ninety-six percent were CMV serostatus positive. Only 5% of transplants were CMV serostatus mismatched.
Transplant procedure: All patients received pretransplant immunosuppression with 3 cycles of Cyclophosphamide, Fludarabine and Dexamethasone. Myeloablative conditioning with Fludarabine, Busulfan and Cyclophosphamide was used in 195 patients. 58 patients received reduced toxicity- conditioning with Treosulfan. Total body irradiation (TBI) of 2 Gy employed in children older than 3 years (n=164). ATG was used as a strategy to minimize graft rejection and GvHD in younger children, and in Pesaro Class III (n=89). T haplo-HSCT grafts were of parental origin in 93%, siblings in 5% and other relatives in 2%.
Immunosuppression with calcineurin inhibitors given typically for a month.
Transplant characteristics: Median CD34 cell dose was 15.3 X 10^{6} cells/kg. Median time for both neutrophil and platelet engraftment was 11 days. Graft failure occurred in 15 (5.9 %). Incidence of veno-occlusive disease was 29% in Busulfan group and only 7% in Treosulfan ($p < 0.001$).
The incidence of viral reactivation was 50.2%, with clinically significant CMV infection in 34%, adenoviral infection in 12%, and symptomatic BK viral reactivation in 11%. Nineteen percent had proven bacterial infection and 4% had proven or probable fungal infection. Use of ATG was not significantly associated with any infection or viral reactivation.
Acute GVHD grade II- IV in 23.7%, grade III –IV in 5.1 %. The incidence of any chronic GVHD was 18.6%, of which 2.2% was severe.
Twenty-five patients died, with 15 early transplant-related mortality. Infections remained the biggest killer (56%, with bacterial sepsis in three-fourth), followed by graft rejection (24%), severe VOD (16%) and GvHD (4%). With a median follow-up of 22 months the overall survival (OS) at 3 years was 89% and thalassemia-free survival (TFS) at 3 years was 86 %. TFS was 94%, 86%, and 84% in Pesaro Class I, Class II and Class III (p=0.38).

Table 1: Transplant and outcome characteristics		
Characteristics	Descriptive statistics	P value
Donor [N (%)] Male Female	 193 (76%) 60 (24%)	
Median CD34 [median (IQR)]	15.3 x 106 cells/kg (12.12 - 19.45)	
TCR AB dose [median (IQR)]	0.02 x 106 cells/kg (0.01 – 0.04)	
TCR gamma-delta dose [median (IQR)]	9.8 x 106 cells/kg (5.38 – 18.8)	

Table 1: Transplant and outcome characteristics		
Conditioning regimen [N (%)] Busulfan Treosulfan	 195 (77%) 58 (23%)	
Median days to neutrophil engraftment [median (IQR)]	11 (10-12 days)	
Median days to platelet engraftment [median (IQR)]	11 (10 –13 days)	
Rejection [N (%)] Primary Secondary	15 (5.9%) 11 (4.3%) 4 (1.6%)	
Mixed chimerism [N (%)] Busulfan group Treosulfan group	18 out of 232 assessed (7.8%) 17 /169 (10%) 1/51 (2%)	 0.08
Use of ATG [N (%)] Yes No Any infection (ATG vs. No ATG) Viral reactivation (ATG vs. No ATG)	 89 (35%) 164 (65%) 62.1% vs. 57.1% 58.4% vs 46%	 0.36 0.06
Chronic GvHD [N (%)] Mild Moderate Severe	43 out of 231 assessed (18.6%) 36 (15.6%) 2 (0.8%) 5 (2.2%)	



Conclusions: TCR-αβ depleted haplo-HSCTs offer an excellent curative option for TDT patients with acceptable survival and low rates of graft failure and GvHD. CD45RO DLIs are an effective strategy to enhance immune reconstitution and combat the expected viral reactivation in T-cell depleted haplo-HSCT.

Background: Serotherapy with anti-T lymphocyte globulins (ATG) is used to prevent severe acute and chronic GVHD and rejection after unrelated-donor HSCT. The two main ATGs – ATLG-Grafalon® (Neovii) and ATG-Thymoglobulin® (Sanofi) – are polyclonal antibodies generated by immunizing rabbits with Jurkat T-cells or human thymocytes, respectively. Both are lymphodepleting yet differ in antibody quantity, antigen recognition, and effects on lymphocyte subsets. This study compares outcomes of children with ALL who received Grafalon or Thymoglobulin before matched-unrelated-donor (MUD) HSCT in the prospective international ALL SCTped 2012 FORUM1 trial.

Methods: Patients were transplanted from a 9/10 or 10/10 MUD and received serotherapy with either Grafalon (45 mg/kg total) or Thymoglobulin (7.5 mg/kg total) from d-3 to d-1. Patients ≥4 years were conditioned with either total-body irradiation (TBI 12Gy and etoposide, cohort1) or chemo-conditioning with either busulfan or treosulfan combined with thiotepa and fludarabine (cohort2). All patients <4 years received chemo-conditioning (cohort3).

Results: Within each cohort, Grafalon and Thymoglobulin groups were evenly matched in disease and transplant characteristics.
In cohort1 (≥4y TBI) we observed similar 3-year overall (OS) and event-free survival (EFS) of 84% vs 78% and 74% vs 74% with Grafalon (n=343) and Thymoglobulin (n=137), respectively. 3-year incidence of relapse (CIR) was comparable (16% vs 14%), as was non-relapse mortality (NRM) (7% vs 12%). After Grafalon, there was a trend toward faster lymphocyte recovery at day 28, while platelet engraftment was delayed (p<0.0001). 100-day cumulative incidence of CMV and EBV infection/disease was lower after Grafalon (26% vs 46%, p<0.001). We observed no difference in grade ≥2 acute GVHD at day 100 (28% vs 34%), but a lower 3-year incidence of any chronic GVHD after Grafalon (8% vs 16%, p=0.015). Although outcomes were comparable for bone-marrow grafts, substantial differences were seen with PBSCs (n=189): 3-year NRM was lower after Grafalon (6% vs 25%, p=0.001) with similar CIR, resulting in a higher 3-year OS (85% vs 66%, p=0.012) and EFS (76% vs. 59%, p=0.022)
In cohort2 (≥4y chemo-conditioning) no significant differences were seen between the two serotherapies (n=139 vs n=48) regarding OS, EFS, CIR or NRM, as well as engraftment, GVHD and infection.
In cohort3 (<4y chemo-conditioning, n=91 vs n=24) we observed higher 3-year EFS (59% vs 37%, p=0.029) and a trend towards higher 3-year OS (76% vs 60%) after Grafalon. Comparable, high rates of relapse (39% vs 55%) and low NRM (2% vs 8%) were seen in both groups. No difference was observed in rates of engraftment, GVHD, or infection.

Conclusions: In patients ≥4y who received TBI-based conditioning – current standard of care – outcomes were excellent following either serotherapy. Differences emerged only for PBSC grafts, where Thymoglobulin was associated with higher NRM and lower OS and EFS. Among patients >4y conditioned with chemotherapy, outcomes did not differ by serotherapy. In patients <4y – characterized by higher risk of relapse – we observed higher EFS after Grafalon. Taken together, our data suggest that Grafalon may be preferable in those ALL patients at higher risk of NRM (PBSC transplant recipients ≥4y) or relapse (children <4y).

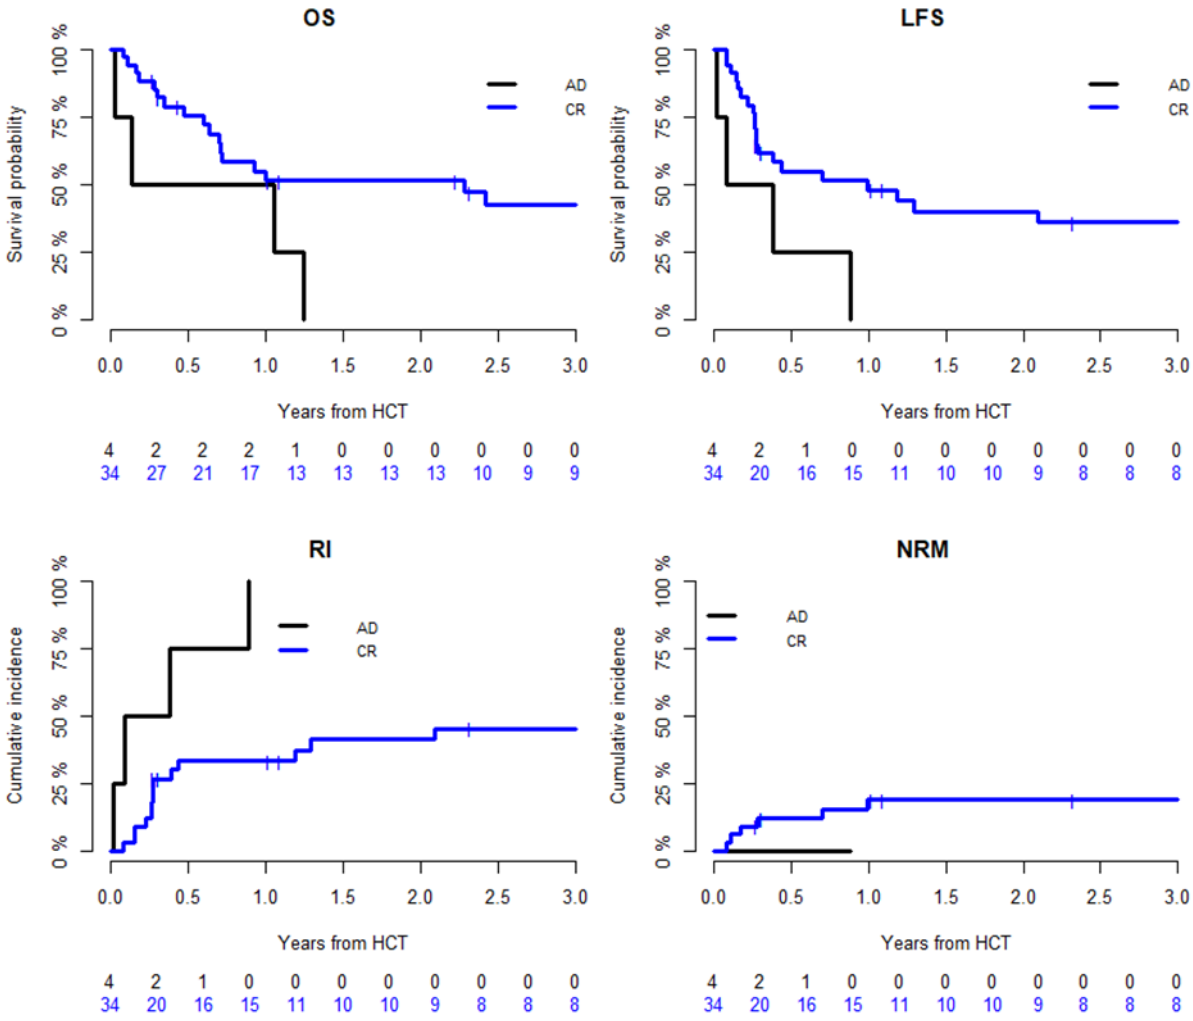
Background: The *CBFA2T3–GLIS2* fusion gene characterizes a paediatric-specific subtype of AML occurring in infants, toddlers and very young children. It is the most frequent chimeric oncogene identified in non–Down syndrome acute megakaryocytic leukaemia and is associated with an extremely poor clinical outcome.

Methods: In this retrospective study, we analyzed outcomes of children undergoing allogeneic haematopoietic stem cell transplantation (alloHSCT) for GLIS2+ AML between

2013 and 2024 at EBMT centres. The primary objectives were to assess overall survival (OS) and leukaemia-free survival (LFS).

Results: Thirty-eight patients (20 female,18male) were included. The majority (30/38, 78.9%) were under 3 years of age at presentation. Isolated bone marrow disease was the most common presentation (20/29, 69%; data missing for 9 patients). Median age at alloHSCT was 1.8 years (range 0.7–17.5). Thirty-two patients (84%) underwent transplantation in CR1, two in CR2, and four had active disease at alloHSCT. Among patients in CR, MRD was negative in 19/22 (data missing for 12).
All patients received myeloablative conditioning, predominantly Busulfan-based regimens (31/38, 81.6%). Serotherapy with ATG was given in 21 patients, while 17 received none. Most children received ciclosporin (± MMF/MTX) as GVHD prophylaxis. Donors included matched and mismatched unrelated donors (29/38, 76%), matched related donors (3/38, 8%), and HLA haploidentical family donors (6/38, 16%). Cord blood was the predominant stem cell source (16/37, 43%; one missing), followed by bone marrow (14/37, 38%) and peripheral blood (7/37, 19%).
At a median follow-up of 3.2 years (95% CI 2.2–4.7), the 2-year probability of OS and LFS was 44.9% (27.7–60.7) and 35.2% (19.7–51.2) respectively. All 4 patients transplanted with active disease relapsed and died. Relapse was the major cause of treatment failure (48.1%, 30.2–63.9). The day-100 incidence of grade II–IV and grade III–IV acute GVHD was 41.2% and 17.6%, respectively. The 2-year incidence of chronic GVHD was 11.6% (2.6-28). Non-relapse mortality at 2 years was 16.7%. The 2-year cumulative incidence of second alloHSCT was 13% (3.9–27.8).

Overall Survival, Leukaemia Free Survival and Relapse Incidence



Conclusions: In the largest cohort to date of children with GLIS2+ AML undergoing alloHSCT, outcomes are confirmed to be poor, with relapse being the predominant cause of treatment failure. This occurred despite most patients being in CR at transplantation and despite a high incidence of significant GVHD. These findings highlight an urgent need for targeted post-transplant therapies, such as the anti–folate receptor-α antibody–drug conjugate luveltamab tazevibulin (STRO-002) or CAR-T cells targeted against this target, in this high-risk group.

Background: TCRαβ/CD19-cell depletion (TCRαβ-depl) and post-transplant cyclophosphamide (PT-Cy) are the two most used platforms for haploHSCT in children. Despite their wide use, however, neither direct prospective comparison, nor retrospective analysis is available for children affected by acute leukemia (AL). The EBMT-PDWP conducted a registry study to compare the outcomes of patients given either of these two approaches.

Methods: All patients affected by AML or ALL, transplanted from an HLA-haploidentical donor with either of the 2 techniques between 2010 and 2022 and registered in the EBMT database were considered. Among more than 1000 patients, a 1:1 matched-pair analysis was performed, using type of disease (AML or ALL) and disease status (complete remission, CR, or non-CR) for exact matching, and patient age and sex, disease risk index (DRI), Lansky score, donor sex, and use of total body irradiation (TBI) in the conditioning regimen for propensity score matching (caliper set=0.2). The impact of the two approaches was estimated using a Cox model with a cluster effect on matching subgroups.

Results: The final cohort was composed of 506 patients (253 patients per group), the median year of HSCT being 2019 (range, January 2010-December 2022); median age at HSCT was 8.4 years (range, 0.4-18). Details on patients and transplant characteristics are

reported in Table 1. Because of the difference in the 2 approaches, as expected, PT-Cy patients received a significantly lower number of $CD34^+$ cells/kg and more $CD3^+$cells/kg. All other transplant variables were comparable between the 2 groups, except for a slightly younger donor age.The median follow-up for surviving patients was 4.4 years. Projected 4-yr relapse incidence and non-relapse mortality (NRM) were 37.1% and 13.4%, respectively. Regarding acute graft-versus-host disease (GVHD), the overall cumulative incidence of grade III-IV GVHD and extensive chronic GVHD were 10.1% and 14.6%; in the TCRαβ-depl group, the cumulative incidence of grade III-IV acute GVHD and extensive chronic GVHD were 7.2% and 10%, respectively, while in children receiving PT-Cy they were 13.1% and 19.5%. The 4-yr overall survival (OS) and leukemia-free survival (LFS) for the TCRαβ-depl and PT-Cy group were 58.5% versus 52.8%, and 54.4% versus 44.8%, respectively. The GVHD/relapse-free survival (GRFS) in the 2 groups were 46.7% for TCRαβ-depl and 30.8% for PT-Cy, respectively. The Cox model (Figure 1) showed that, using TCRαβ- depl as reference population, patients receiving PT-Cy had higher NRM, grade III-IV acute GVHD, chronic GVHD and extensive chronic GVHD, as well as worse LFS and GRFS. In particular, PT-Cy recipients had a higher incidence of death due to GvHD, infections and graft failure.

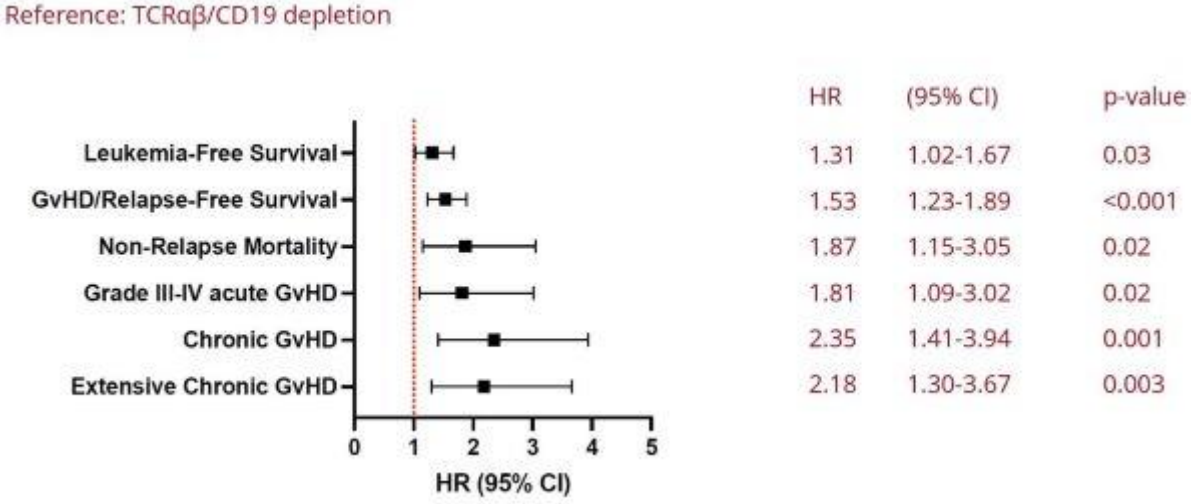
Median donor age (range), years	37.0 (5.7-59.3)	38.2 (6.7-59.3)	36 (5.7-55.5)	*<0.001*
Median year of HSCT (range)	2019 (2010-2022)	2019 (2010-2022)	2018 (2010-2022)	*Pair-match factor*



Conclusions: This large retrospective, registry-based study shows that both platforms are a suitable option for children with AL needing HSCT and lacking a suitable HLA-matched donor or with an urgent transplant indication. Notably, the TCRαβ-depl platform is characterized by lower incidence of severe acute and chronic GVHD, lower risk of NRM and better LFS and GRFS as compared to PT-Cy. Pharmacoeconomic studies are needed to further elucidate the differences between the two platforms in children with AL.

Background: Refractory cytopenia of childhood (RCC) is a well-defined subgroup of pediatric bone marrow (BM) failure, characterized by persistent peripheral cytopenia, dysplasia, and a distinctive BM histology. It can successfully be treated with hematopoietic stem cell transplantation (HSCT). Following the observation of a high rate of graft-failure (GF) after HSCT with a conditioning regimen consisting of thiotepa (Thio) and fludarabine (Flu), a treosulfan (Treo)-Flu regimen had been introduced in our study group.

Methods: We analyzed 373 patients with RCC and normal karyotype enrolled in EWOG-MDS and transplanted between 2007 and 2024 following conditioning with Thio-Flu (n=239) or Treo-Flu (n=134). Median age was 10.4 years (0.8-22.8), and donors were matched siblings (MSD, n=95), 10/10 HLA-matched unrelated donors (MUD, n=190) or 9/10 HLA-matched unrelated donors (MMUD, n=88). There was no difference in donor distribution in the two groups. The main stem cell source was BM (BM 81% vs peripheral blood (PB) 19%) with a higher use of PB in the Treo-Flu group (Treo-Flu 27% PB vs Thio-Flu 15% PB, p=<0.01). Different types of serotherapy were used in unrelated HSCT (ATG Grafalon 88%, Thymoglobulin 7%, alemtuzumab 5%), and 36% of MSD recipients received ATG (ATG Grafalon 82%, Thymoglobulin 18%).

Results: Five-year overall survival (OS) was 0.94 (0.91-0.97) and 0.96 (0.92-1.00) for the Thio-Flu and Treo-Flu group (p=n.s.), respectively. There were significant differences in the incidence of GF (Thio-Flu 0.17 [0.13-0.23] vs Treo-Flu 0.09 [0.04-0.21], p<0.01) and moderate/severe chronic GvHD (cGVHD) (Thio-Flu 0.16 [0.12-0.22] vs Treo-Flu 0.08 [0.04-0.141], p=0.03) resulting in a better cGvHD-GF-free-survival (cGRFS) in the Treo-Flu group (Thio-Flu 0.74 [0.68-0.80] vs Treo-Flu 0.84 [0.75-0.93], p<0.01). The impact of the conditioning regimen on cGRFS was confirmed in multivariate analysis (Thio-Flu vs Treo-Flu relative risk (RR) 2.04, p< 0.01). Additional factors associated with an inferior cGRFS were the use of a MMUD (9/10) compared to a MUD or MSD (MMUD vs MUD RR 1.76, p=0.03; MSD vs MUD RR 1.07, p=n.s.) and a CMV positive recipient (CMV pos vs. CMV neg RR 1.64; p=0.04). In MSD-HSCT the addition of ATG to the conditioning did not result in a difference in GF, aGVHD, cGVHD or OS. In contrast, the use of a higher dose of ATG was associated with a higher incidence of GF and cGVHD resulting in a lower cGRFS in patients conditioned with Thio-Flu for unrelated donor HSCT (ATG Grafalon 60 mg/kg vs 45 mg/kg 0.68 [0.58-0.78] vs 0.80 [0.70-0.90], p< 0.01).

Conclusions: Although both regimens offered an excellent OS for patients with RCC, the Treo-Flu regimen resulted in superior engraftment and lower rates of cGVHD. Serotherapy provided no benefit in MSD-HSCT and a higher-dose ATG Grafalon adversely affected outcomes in unrelated HSCT with Thio-Flu likely through impaired immune reconstitution.

Comprehensive evaluation of long-term consequences, including fertility outcomes, is required.

Disclosure: Nothing to declare.

Paed3-06

IMPACT OF EX-VIVO T-CELL DEPLETION IN UNRELATED DONOR HSCT FOR PEDIATRIC MALIGNANT DISEASES: A MULTICENTER RETROSPECTIVE COMPARATIVE STUDY ON BEHALF OF SPANISH GETH-TC PED GROUP

Luisa Sisinni[1], *Sara Vinagre Enríquez*[2], *Maria Isabel Benitez Carabante*[3], *Blanca Molina Angulo*[2], *Maria Luz Uria Oficialdegui*[3], *Laura Alonso García*[3], *Ivan López Torija*[4], *Mercedes Plaza Fornieles*[5], *Odelaisy León-Triana*[6], *Antonio Pérez-Martínez*[1], *Marta Gonzalez-Vicent*[2], *Cristina Díaz de Heredia*[3]
[1]*La Paz University Hospital, Madrid, Spain,* [2]*Niño Jesús University Hospital, Madrid, Spain,* [3]*Vall d'Hebron University Hospital, Barcelona, Spain,* [4]*Santa Creu i Sant Pau University Hospital, Barcelona, Spain,* [5]*Virgen de la Arrixaca University Hospital, Murcia, Spain,* [6]*Institute for Health Research (IdiPAZ), Madrid, Spain*

Background: Ex-vivo selective T-cell depletion (TCD) has emerged as a strategy to reduce graft-versus-host disease (GvHD) while preserving immune recovery. Although widely implemented in haploidentical transplantation, evidence in unrelated donor (URD) pediatric HSCT remains limited.

Methods: We performed a retrospective observational study across GETH-TC pediatric transplant centers including patients transplanted between 2016–2023. Eligible patients had malignant diseases and received a URD HSCT (9/10 or 10/10 HLA match). Two groups were analyzed: ex-vivo TCD (αβ or CD45RA$^+$) versus conventional non-manipulated grafts. Outcomes included engraftment, acute and chronic GvHD, infections, relapse, TRM, overall survival (OS), disease-free survival (DFS), and GvHD-/relapse-free survival (GRFS). Survival was calculated using Kaplan–Meier; cumulative incidences were analyzed in a competing-risk framework using Gray's test; prognostic factors were evaluated with Cox regression.

Results: A total of 96 patients were included: 49 conventional HSCT and 47 TCD (24 αβ; 23 CD45RA$^+$). Baseline characteristics were largely balanced.
Engraftment: TCD significantly accelerated neutrophil and platelet recovery (median 11 vs 20 days and 12 vs 22 days, both p <0.001). Mixed chimerism was more frequent in TCD (34.8% vs 8.5%, p = 0.002).
Acute and chronic GvHD: TCD reduced the incidence of any-grade aGvHD (46.8% vs 77.6%, p = 0.002). Cumulative incidence of grade II–IV aGvHD showed a non-significant trend toward reduction with TCD (12-month: 37% vs 57%, p = 0.068). Chronic GvHD rates were similar between groups (27.7% vs 24.5%, p = 0.72).
Infectious complications: TCD patients had fewer infections between days 101–180 (14.6% vs 35.6%, p=0.026) and beyond day +365 (2.8% vs 29.3%, p = 0.002).

Relapse and TRM: Relapse cumulative incidence was identical in both groups (18% at 48 months, Gray p = 0.9). TRM at 12 months showed no significant differences (14% vs 11%, p = 0.4).
Survival: Overall survival (OS) and disease-free survival (DFS) did not differ significantly between groups. At 48 months, OS was 80% in the TCD cohort and 61% in the conventional cohort, without reaching statistical significance (p = 0.08). DFS showed a similar pattern, with 69% vs 60% survival at 48 months (p = 0.4). GRFS was also comparable between groups (approx. 50% at 48 months, p > 0.9).
In multivariate Cox analysis for DFS, several disease-related factors emerged as independent predictors: T-ALL diagnosis (HR 6.71, p = 0.016) and disease status ≥CR2 showed worse outcomes (CR2: HR 6.48; ≥CR3: HR 5.60; both p = 0.02). Conversely, negative molecular status (HR 0.37, p = 0.022) and RIC conditioning (HR 0.31, p=0.033) were associated with improved DFS.

Conclusions: In this multicenter real-world pediatric cohort, ex-vivo TCD in URD-HSCT was associated with a reduction in early post-transplant complications—particularly acute GvHD and selected infectious events—while maintaining comparable rates of relapse, TRM, OS, DFS and GRFS relative to conventional grafts. These findings support the safety of ex-vivo TCD approach in pediatric malignant indications, although definitive benefits cannot be established from this retrospective cohort.

REAL-WORLD OUTCOMES OF MESENCHYMAL STROMAL CELL THERAPY IN HEAVILY PRE-TREATED PAEDIATRIC PATIENTS WITH REFRACTORY ACUTE GRAFT-VERSUS-HOST DISEASE

Peter Bader[1], *Felix Zirngibl*[2,3], *Markus Mezger*[4], *Csaba Kassa*[5], *Jana Ernst*[6], *Johann Greil*[7], *Britta Maecker-Kolhoff*[8], *Oliver Basu*[9], *Pascale Schneider*[10], *Andrea Jarisch*[1], *Matthias Wölfl*[11], *Kathrin Vogelsang*[1], *Jean-Hugues Dalle*[12], *Elena Osswald*[13], *Michael Tribanek*[13], *Maria Lazarou-Wild*[13], *Peter Lang*[4], *Arend von Stackelberg*[2]
[1]*Goethe University, Frankfurt am Main, Germany,* [2]*Charité – Universitätsmedizin Berlin, Berlin, Germany,* [3]*Berlin Institute of Health at Charité, Berlin, Germany,* [4]*Children's University Hospital Tübingen, Tübingen, Germany,* [5]*National Institute of Hematology and Infectious Diseases, Budapest, Hungary,* [6]*University Hospital Jena, Jena, Germany,* [7]*University Hospital Heidelberg, Heidelberg, Germany,* [8]*Hannover Medical School, Hannover, Germany,* [9]*Children's University Hospital Essen, Essen, Germany,* [10]*University Hospital of Rouen, Rouen, France,* [11]*Children's Hospital, University of Würzburg, Würzburg, Germany,* [12]*Robert-Debre Hospital, GHU AP-HP Nord Université Paris Cité, Paris, France,* [13]*medac GmbH, Wedel, Germany*

Background: Patients with aGvHD who fail to respond to steroids and/or ruxolitinib face a poor prognosis.

Methods: We conducted a retrospective analysis of real-world data from 140 paediatric aGvHD patients who received the random-donor mesenchymal stromal cell (MSC) preparation MSC-FFM, manufactured from pooled human allogeneic bone marrow-derived mononuclear cells of 8 different donors. The product is distributed via Hospital Exemption in Germany (under the name Obnitix®) and Named Patient Use elsewhere. MSC-FFM is administered as an intravenous infusion; at a recommended dose of 1 to 2 million MSCs/kg BW in 4 once-weekly doses. At baseline, 60.0% had an underlying malignant disease and were severely ill, with 31.4% Grade III and 44.3% with Grade IV aGvHD. Most Grade III/IV cases had lower GI involvement. Patients received a median of 3.5 (maximum: 11) prior lines of therapy; 54.3% were pre-treated with ruxolitinib. The majority (72.9%) received 1 to 2 million MSCs/kg BW and 67.1% received 4 to 6 infusions. Treatment response was assessed at Days 28 and 60.

Results: At Day 28, the overall response rate (OR) was 62.9%, (complete response [CR]: 22.1%, partial response [PR]: 40.7%) with rates of 74.1%, 75.0%, and 53.2% for Grade II, III, and IV aGvHD, respectively. At Day 60 the overall response rate, and in particular CR, improved for all grades to 66.9% (CR: 44.9%, PR: 22.1%). The organ stage in patients with skin, liver, lower gut, and upper gut involvement improved at Day 28 in 69.4%, 57.5%, 58.6%, and 39.5% of the patients, respectively. Response and survival were better in patients with non-malignant disease compared to patients with a malignant disease. Younger patients showed a trend toward better responses and survival. Patients with Grade III and IV, pre-treated with ruxolitinib, had an OR at Day 28 of 63.5% and at Day 60 of 59.7%, and overall survival rates at 6 and 12 months of 61.0% vs 50.3%, respectively.
Overall survival correlated with overall response at Day 28, with 72.9% and 64.2% in responders and 49.1% and 39.7% in non-responders at 6 and 12 months, respectively. Survival probability at 6 months in patients with Grade I/II was 83.9%, Grade III 76.1%, and Grade IV 49.3% (Figure 1).
Four adverse drug reactions were reported in 3 patients (3 serious, 1 non-serious). The good safety profile of MSC-FFM was consistent with prior MSC reports. Most frequently reported causes of death were GvHD (20.9%) and infections (18.4%), with GvHD-related deaths more common in patients pre-treated with ruxolitinib (26.3% vs 14.3%).

Figure 1: → **Kaplan-Meier estimates of overall survival by aGvHD grade prior to first infusion (paediatric aGvHD patients with aGvHD assessment prior to first infusion)**

	Grade I/II	Grade III	Grade IV
Number of patients	28	44	61
Events	6 (21.4%)	13 (29.5%)	38 (62.3%)
Censored	22 (78.6%)	31 (70.5%)	23 (37.7%)
Rate at 6 months[a] [%]	83.9	76.1	49.3
95% CI	(62.3, 93.7)	(60.0, 86.4)	(36.0, 61.2)

[a] based on Kaplan-Meier estimates

Conclusions: Despite limitations of real-world data, MSC-FFM demonstrated good responses with a favourable safety profile in treatment-refractory paediatric aGvHD patients, including those previously exposed to ruxolitinib. Favourable prognostic factors for overall survival are young age, low-grade aGvHD, response at Day 28, and a non-malignant disease. A prospective randomised trial BALDER (NCT06075706) is underway to clarify the efficacy and safety of MSC-FFM in the treatment of steroid-refractory paediatric aGvHD.

Disclosure: Peter Bader receives patent and royalties for MSC-FFM from medac GmbH. Elena Osswald, Michael Tribanek, and Maria Lazarou-Wild are all employees of medac GmbH. The remaining authors declare no conflicts of interest.

ADAPT TO ENDURE: SUSTAINING PEDIATRIC HCT THROUGH WARTIME DISRUPTION IN UKRAINE

Oleksandr Istomin[1], Nina Kostiukova[2], Tetiana Tryliska[3], Yevhen Hrohul[4], Natalia Trofimova[5], Dmytro Koval[2], Alex Müller[6], Krzysztof Kałwak[7], ***Oleksandr Lysytsia***[1]
[1]HCT and Immunotherapy, NSCH "Ohmatdyt", Kyiv, Ukraine, [2]Specialized State Institution "Ukrainian Transplant Coordination Center", Kyiv, Ukraine, [3]Hematology Expert Lab, NSCH "Ohmatdyt", Kyiv, Ukraine, [4]HLA typing Lab, NSCH "Ohmatdyt", Kyiv, Ukraine, [5]Oncogenetic Expert Lab, NSCH "Ohmatdyt", Kyiv, Ukraine, [6]St.Jude GLobal "SAFER Ukraine", Memphis, United States of America (the), [7]Wroclaw Medical University, Wroclaw, Poland

Background: Healthcare reforms in 2019 expanded hematopoietic cell transplantation (HCT) in Ukraine with the promising growth of transplant activity nationwide. To date, the National Specialized Children's Hospital "Ohmatdyt" (NSCH) remains Ukraine's largest pediatric hematology-oncology (PHO) center, offering comprehensive care with its expert reference laboratory and all types of HCT available. It was the first in Ukraine to perform a matched unrelated donor transplant in a 2-year-old with ADA-deficiency during the COVID-19 pandemic.
The full-scale war in 2022 triggered a humanitarian crisis that severely disrupted the healthcare system, with the PHO sector among the most affected. Evacuation efforts, most notably the St. Jude Global SAFER Ukraine initiative, enabled around 1,400 children to continue care abroad. However, resource constraints, safety concerns, mass migration, and a sharp decline in newly diagnosed cases pushed Ukraine's pediatric HCT program to the verge of collapse.
Here we present the first comprehensive analysis of transplant activity in Ukraine during wartime, focusing on the experience of the largest PHO/HCT facility and highlighting epidemiologic shifts, challenges, and key insights for pediatric transplant centers.

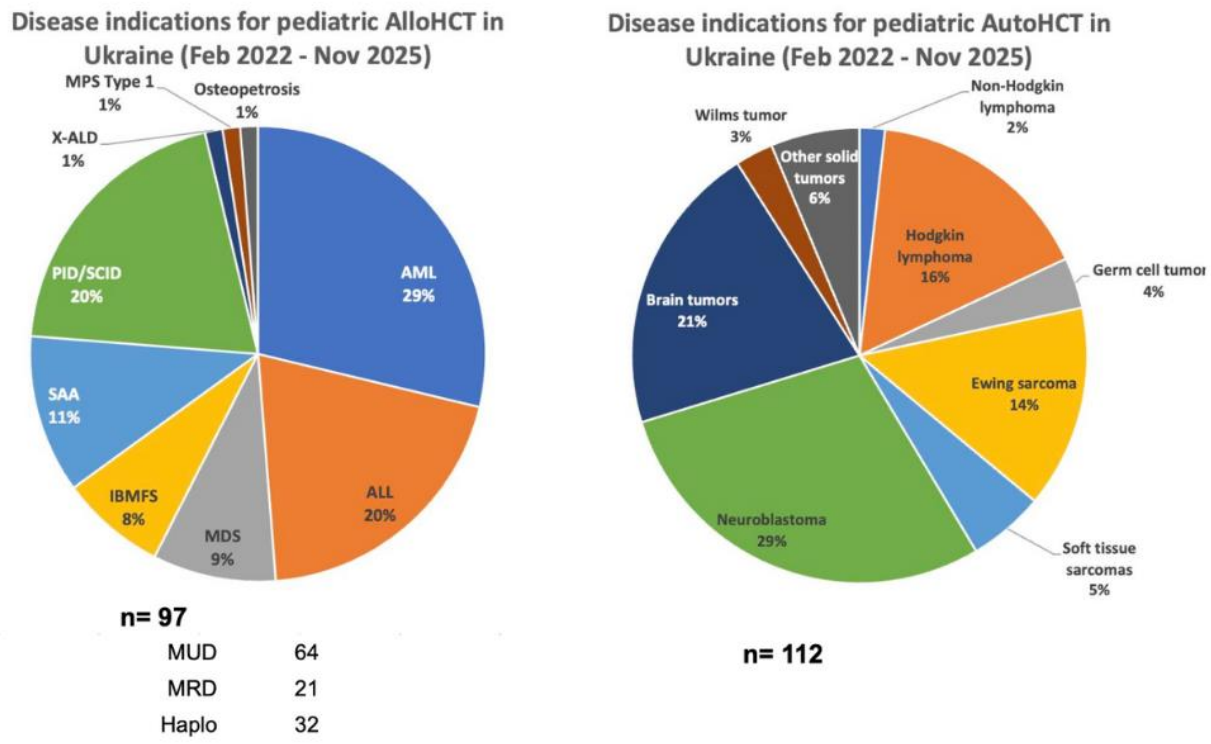
Methods: We retrospectively analyzed national HCT data from February 2022 to November 2025, obtained upon request from the Specialized State Institution 'Ukrainian Transplant Coordination Center' (UTCC), established in mid-2021 to oversee quality control, data collection, and nationwide transplant coordination. UTCC provided annual transplant volumes, the number of operating centers, and HCT distribution by donor type, stratified by pediatric (<18 years) and adult (≥18 years) populations. Data prior to 2022 on pediatric HCT activity were extracted from the internal registry of NSCH's HCT program. All data were analyzed descriptively to evaluate patient demographics and year-by-year trends, with institutional adaptation strategies described in the Results and Summary sections.

Results:

As of December 2025, 13 HCT centers were operating in Ukraine, six of which were formally accredited for transplant activity. Among these, only two performed allogeneic HCT, with NSCH contributing the majority. Expanding transplant eligibility to adult patients allowed more individuals to receive life-saving care while reinforcing NSCH's institutional resilience (see Table 1)

Table 1.				
Year	**Location**	**Total # HCT**	**Total # HCT in children (%)**	**Total # AlloHCT in children (%)**
2022	Ukraine	200	24 (12%)	17
	NSCH	36	17 (47%)	17 (100%)
2023	Ukraine	342	53 (15%)	21
	NSCH	64	32 (50%)	20 (95%)
2024	Ukraine	404	58 (14%)	27
	NSCH	81	36 (44%)	26 (96%)
2025 (Jan-Nov)	Ukraine	443	74 (17%)	34
	NSCH	96	46 (48%)	33 (97%)
Total	Ukraine	1389	209	99
	NSCH	**277**	**131**	**94**
	%	**19,94%**	**62,68%**	**96,91%**

Epidemiologic shifts in pediatric HCT are also notable, with an unusual predominance of acute myeloid leukemia over acute lymphoblastic leukemia - a likely consequence of evacuation programs prioritization patterns towards advanced therapeutic options that are unavailable in Ukraine.



AML - acute myeloid leukemia, **ALL** - acute lymphoblastic leukemia, **PID/SCID** - primary/severe immunodeficiency syndrome, **SAA** - severe aplastic anemia, **IBMFS** - inherited bone marrow failure syndrome, **MDS** - myelodysplastic syndrome, **MPS** - mucopolysacharridoses, **X-ALD** - x-linked adrenoleukodystrophy; **MUD** - matched unrelated donor, **MRD** - matched related donor, **Haplo** - haploidentical

Conclusions:

NSCH leveraged its HCT expertise, crisis management skills, and global partnerships to maintain and expand transplant activity during wartime, becoming a key contributor to Ukraine's national program, covering nearly all pediatric alloHCT and accounting for one-fifth of the country's total volume. Recognizing the fragility of evacuation-based strategies in prolonged crises, NSCH swiftly adapted by extending services to adult patients. This move required complex legislative approvals, additional staff training, and standardization of practices. Collaborations with global institutions such as St. Jude Global and European clinics

enabled evacuation in acute phase patient access to advanced therapies like CAR-T cell treatment abroad. This experience highlights the importance of cross-disciplinary collaboration, international partnerships, and flexible adaptation in sustaining healthcare services in countries affected by war.

Background: Transplantation-associated thrombotic microangiopathy (TA-TMA) is a severe complication after hematopoietic stem cell transplantation (HCT), associated with high morbidity and mortality. Treatment remains controversial, often guided by complement inhibitors, but access is limited by cost, monitoring requirements, and lack of randomized trials. Defibrotide may protect small-vessel endothelium from TA-TMA-related damage.To describe management and outcomes of TA-TMA in a pediatric cohort and evaluate treatment strategies.

Methods: This retrospective study by the UK Pediatric Hematopoietic Stem Cell Transplantation Group analyzed 42 patients (from 55 cases) across seven centers who developed TA-TMA after HCT between January 2016 and May 2025.

Results:

N/N all data completed	55/42
Gender, Male/Female and age, median (IQR)	27/15 and 8 (9)

Disease, malignant/non-malignant	15/40
Donor, MRD/MUD/MMUD/CB/Haplo	11/15/3/8/5
Source, BM, PB, CB	23/11/8
Conditioning, MAC/RTC/RIC	20/11/11
GvHD II-IV, n (%)	26 (62)
Virus reactivation, CMV/EBV/ADV	10/9/14
Day TA-TMA after HCT, median (IQR)	108 (132)
De novo anemia/ thrombocytopenia	28/29
Schystocytes, n (%)	34 (81)
HBP, n (%)	38 (90)
sC5b9 ng/ml, median (IQR)	434 (229)
sC5b9 greater than ULN, n (%)	21 (50)
rUPCR ≥1g/mmol, median (IQR)	0.65 (1)
rUPCR ≥1g/mmol, n (%)	14 (33)
LDH (U/L), median (IQR)	848 (884)
LDH ≥2x ULN, n (%)	33 78)
2/5-year OS (CI95%)	62 (46-84)/21 (8-53)
Alive, n (%) and follow up, median (IQR)	19 (45) and 745 (1046)

The cohort included 42 patients (median age, 8 years; interquartile range [IQR], 9) who underwent either a first (n=39) or second (n=3) allogeneic HCT for malignant (n=14) or

nonmalignant (n=28) conditions. Donors were matched in 26 cases (11 related) and mismatched in 16 cases, including 5 haploidentical and 8 cord blood transplants. Pharmacological graft-versus-host disease (GvHD) prophylaxis was administered in 41 of 42 transplants, predominantly with calcineurin inhibitors (n=37). Acute GvHD grade > I occurred in 26 patients (62%), with a median onset at day 39 (IQR, 66) post-HCT. The median time to TA-TMA diagnosis was 108 days (IQR, 132).
Extra-renal involvement was observed in 28 patients (66%), including pulmonary (n=21), serositis (n=16), central nervous system (n=11), and gastrointestinal (n=8) manifestations. Biopsies confirmed TA-TMA in renal (n=11), pulmonary (n=6), and gastrointestinal (n=2) sites. Twenty-eight patients (66%) required admission to the pediatric intensive care unit for a median of 11 days (IQR, 28), primarily for respiratory support (n=22), inotropic therapy (n=9), and renal replacement therapy (n=10).
Regarding treatment, 6 patients (14%) received defibrotide alone; 18 (43%) received complement inhibitors (predominantly eculizumab, with one case each of ravulizumab and nomacopan); 16 (38%) received defibrotide followed by a complement inhibitor (including one concomitant administration); and 3 (5%) received complement inhibitors followed by defibrotide. The median number of eculizumab doses was 8 (IQR, 12), and the median duration of defibrotide therapy was 16 days (IQR, 35). Soluble C5b-9 (sC5b-9) was elevated in 21 of 31 patients tested (57%; median, 434 ng/mL). Among these, complement inhibitors achieved an overall response rate (ORR) of 63% (7 responders, including 4 complete remissions [CR]); defibrotide achieved an ORR of 70% (including 3 CR). In patients with normal sC5b-9, complement inhibitors achieved 3 CR and 1 partial remission (PR), while defibrotide achieved 2 PR. All unresolved TA-TMA cases were fatal. Overall, 27 patients (63%) responded, and 16 (38%) achieved CR. At last follow-up, 19 patients (45%) were alive. Five-year overall survival was 21% (95% CI, 7.9–53.4%). Causes of death included TA-TMA (65%), GvHD (9%), infection (9%), and relapse (17%).

Conclusions: TA-TMA is a highly aggressive complication following HCT. Both defibrotide and complement inhibitors demonstrated similar ORR; however, complement inhibitors achieved more CR across sC5b-9 strata. Complement inhibitors should be considered first-line therapy, even when sC5b-9 levels are not elevated. Defibrotide remains a reasonable alternative when complement inhibitors are not immediately available, particularly in complement-driven TA-TMA.

COMPARATIVE ANALYSIS ON ANTI-THYMOCYTE GLOBULIN (ATG) *VS* ANTI-T-LYMPHOCYTE GLOBULIN (ATLG) IN PEDIATRIC PATIENTS WITH MALIGNANT DISEASES RECEIVING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE STUDY

*Alessio Tomatis[1,2], **Francesco Saglio**[2], Vincenzo Apolito[2], Valeria Ceolin[2], Manuela Spadea[1,2], Marta Barone[2], Paola Quarello[1,2], Franca Fagioli[1,2]*
[1]University of Turin, Torino, Italy, [2]Regina Margherita Children's Hospital, Torino, Italy

Background: Owing to different manufacturing processes, anti-thymocyte globulin (ATG) and anti-T-lymphocyte globulin (ATLG) diverge in ligand specificities, potency, dosing, and pharmacokinetics.

Methods: We retrospectively compared the global outcome of a cohort of pediatric patients (n=117) with malignant diseases undergoing allogeneic hematopoietic stem cell

transplantation receiving either ATG (n=82) or ATLG (n=35) as part of GvHD prophylaxis (see Table 1 Patient and Transplant Characteristics).

Table 1 Patient and Transplant Characteristics

Variable	**ATG** (n = 82)	**ATLG** (n = 35)	***p*-value**
Sex, [n (%)] Male Female	 45 (55%) 37 (45%)	 18 (51%) 17 (49%)	0.88
Age at transplantation, median (range), years	10.3 (0.6–24.9)	12.6 (1.1–21.3)	0.19
Disease, [n (%)] ALL AML NHL MDS	 44 (54%) 28 (34%) 3 (4%) 7 (8%)	 19 (54%) 12 (34%) 2 (6%) 2 (6%)	0.82

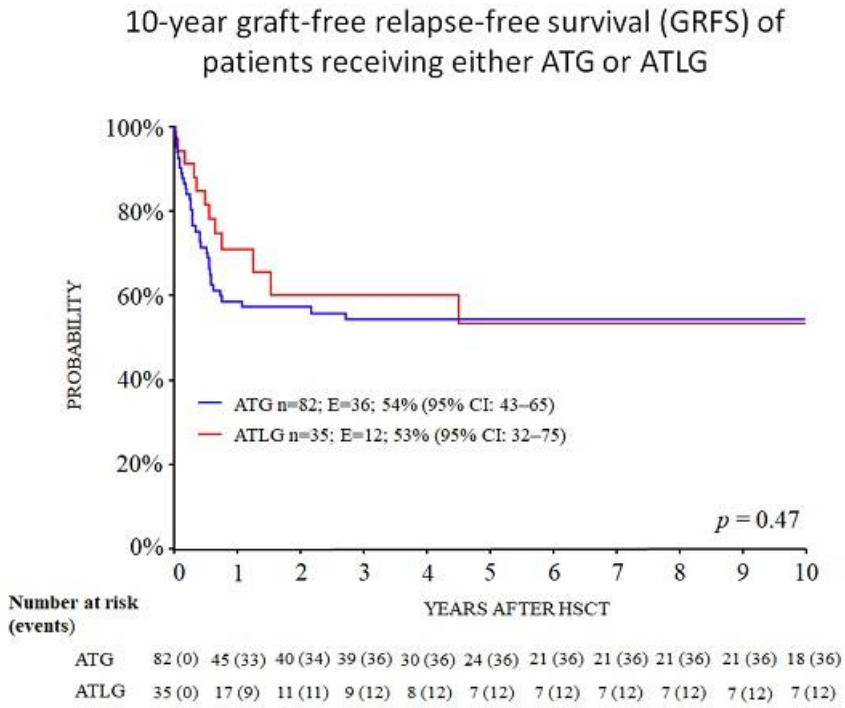
CMV serostatus, [n (%)] Positive Negative	 54 (66%) 28 (34%)	 18 (52%) 17 (49%)	0.14
Blood type, [n (%)] No ABO mismatch Major ABO incompatibility Minor ABO incompatibility Bidirectional ABO incompatibility	 25 (30%) 21 (26%) 29 (35%) 7 (9%)	 17 (49%) 10 (29%) 4 (11%) 4 (11%)	0.06

Results: The median follow-up for the whole study population was 5.9 years (IQR 2.9–12.4), with no differences between the two groups [ATG 9.9 years (IQR 4.3–11.9), ATLG 1.7 years (IQR 1.3–13.9) (p = 0.33)]. The primary, composite endpoint of ten-year graft-free relapse-free survival (GRFS) was 54% (95% confidence interval [CI]: 43–65%) in ATG patients and 53% (95% CI: 32–75%) in ATLG patients (p = 0.47) (see Figure 1). In multivariable analysis only patient age showed a statistical impact on the rate of GRFS, with younger recipients having a better graft-free relapse-free survival compared to the older counterpart (HR 1.97, 95% CI: 1.08–3.58, p = 0.03). The ten-year overall survival (OS) was 64% (95% CI: 54–75%) in the ATG group and 72% in the ATLG group (95% CI: 55–90%) (p = 0.41). The ten-year event-free survival (EFS) was 64% (95% CI: 53–74%) among patients receiving ATG and 67% (95% CI: 48–87%) among patients given ATLG (p = 0.42). The ten-year cumulative incidence of relapse did not differ in the two study populations, being 25% (95% CI: 17–36%) for the ATG group and 27% (95% CI: 13–54%) for the ATLG group (p = 0.74). The 100-day cumulative incidence of grade III-IV acute GvHD was 9% (95% CI: 4–18%) among patients receiving ATG and 6% (95% CI: 1–22%) in patients receiving ATLG (p = 0.58). Statistical significance was observed neither for the cumulative incidence of ten-year non-relapse mortality (NRM) [ATG group 15% (95% CI: 9–25%), ATLG group 6% (95% CI: 1–22%) (p = 0.23)] nor for the cumulative incidence of chronic GvHD [ATG cohort 11% (95% CI: 6–20%), ATLG cohort 21% (95% CI: 10–43%) (p = 0.29)]. The 500-day cumulative incidence of viral infections/reactivations was significantly lower among patients treated with ATLG [41% (95% CI: 26–64%)] compared to those receiving ATG [81% (95% CI: 70–94%)] (p = 0.0003). Such a protective effect towards viral infections/reactivations was confirmed by multivariable analysis. With the exception of $CD16^{+}CD56^{+}$ NK cell immune reconstitution at one year post-transplant (ATG: median 211 cells/μL, ATLG: median 113 cells/μL, p = 0.006), ATG and ATLG patients showed a similar

immune recovery at different timepoints.



Conclusions: ATG and ATLG produce similar outcomes in terms of graft-free relapse-free survival, overall survival, event-free survival, acute and chronic GvHD, relapse, non-relapse mortality and immune reconstitution. Notably, ATLG is strongly associated with a reduced rate of viral infections/reactivations. Future randomized and prospective studies may aid in better defining the optimal dosing and pre- and post-transplant exposure to ATG and ATLG, aiming at improving the transplant-related outcomes.

PRETRANSPLANT ENDOTHELIAL ACTIVATION AND STRESS INDEX (EASIX) PREDICTS NON-RELAPSE MORTALITY AFTER ALLO-HSCT IN A MULTICENTRIC PEDIATRIC ALL COHORT WITH INCREASING RISK FOR OLDER PATIENTS

Dorothea Bauer[1,2], *Evgenia Glogova*[3], *Jan Heusel*[4], *Monika Mielcarek-Siedziuk*[5], *Petr Riha*[6], *Tiphaine Piovesan*[7], *Herbert Pichler*[2], *Christina Peters*[2,1], *Burak Caliskan*[2], *Ulrike Poetschger*[3], *Anita Lawitschka*[2,3]

Austria, [4]University Clinic Frankfurt, Frankfurt, Germany, [5]University Hospital Wroclav, Wroclav, Poland, [6]University Hospital Prague, Prague, Czechia, [7]Université Paris Cité, Paris, France

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a potentially curative treatment for many children with acute lymphoblastic leukemia (ALL); however, non-relapse mortality (NRM) remains a substantial limitation. Reliable early prognostic tools to identify patients at increased risk are therefore needed. The Endothelial Activation and Stress Index (EASIX; LDH × creatinine / thrombocyte count) has been shown to predict post-transplant outcomes in adults and, in our pediatric single-center preliminary analysis, NRM and overall survival (OS). To validate these findings, we conducted the present multicenter study.

Methods: We retrospectively analyzed 206 patients with ALL who underwent allo-HSCT within the FORUM-trial at five pediatric transplant centers (Frankfurt/Main, Paris, Prague, Vienna, Wroclav). Pre-HSCT EASIX was computed at prespecified time points (days −30, -3 and 0). Patients were stratified by cohort-median EASIX at each time point. Primary endpoints were OS and NRM, event-free survival (EFS) was secondary. Kaplan–Meier and log-rank tests compared survival; NRM was analyzed with competing risks methods.

Results:

Table: Patient and transplant characteristics						
	N	%				
Total	206	100%				Total
Male	127	62%				Remission status
Female	79	38%				CR1
			%EASIX	%EASIX	p-value	CR2
Age at HSCT			low	high		>CR2
						Immunophenotype
<4 years	31	15%	27%	4%		BCP
4-10 years	84	41%	44%	38%	<0,001	T-ALL
10-14 years	43	21%	19%	22%		other
>14 years	48	23%	10%	35%		Stem cell donors
Conditioning Regimen						MUD

FLU/THIO/BU	26	13%	15%	10%	0,069	MMD
FLU/THIO/TREO	44	21%	27%	16%		Blinatumomab prior to HS
Stem cell source						aGVHD
BM	126	61%	68%	55%		Grades II-IV
PBSCs	75	36%	27%	45%	0,003	Grades III-IV
CB	5	3%	5%	0%		cGVHD

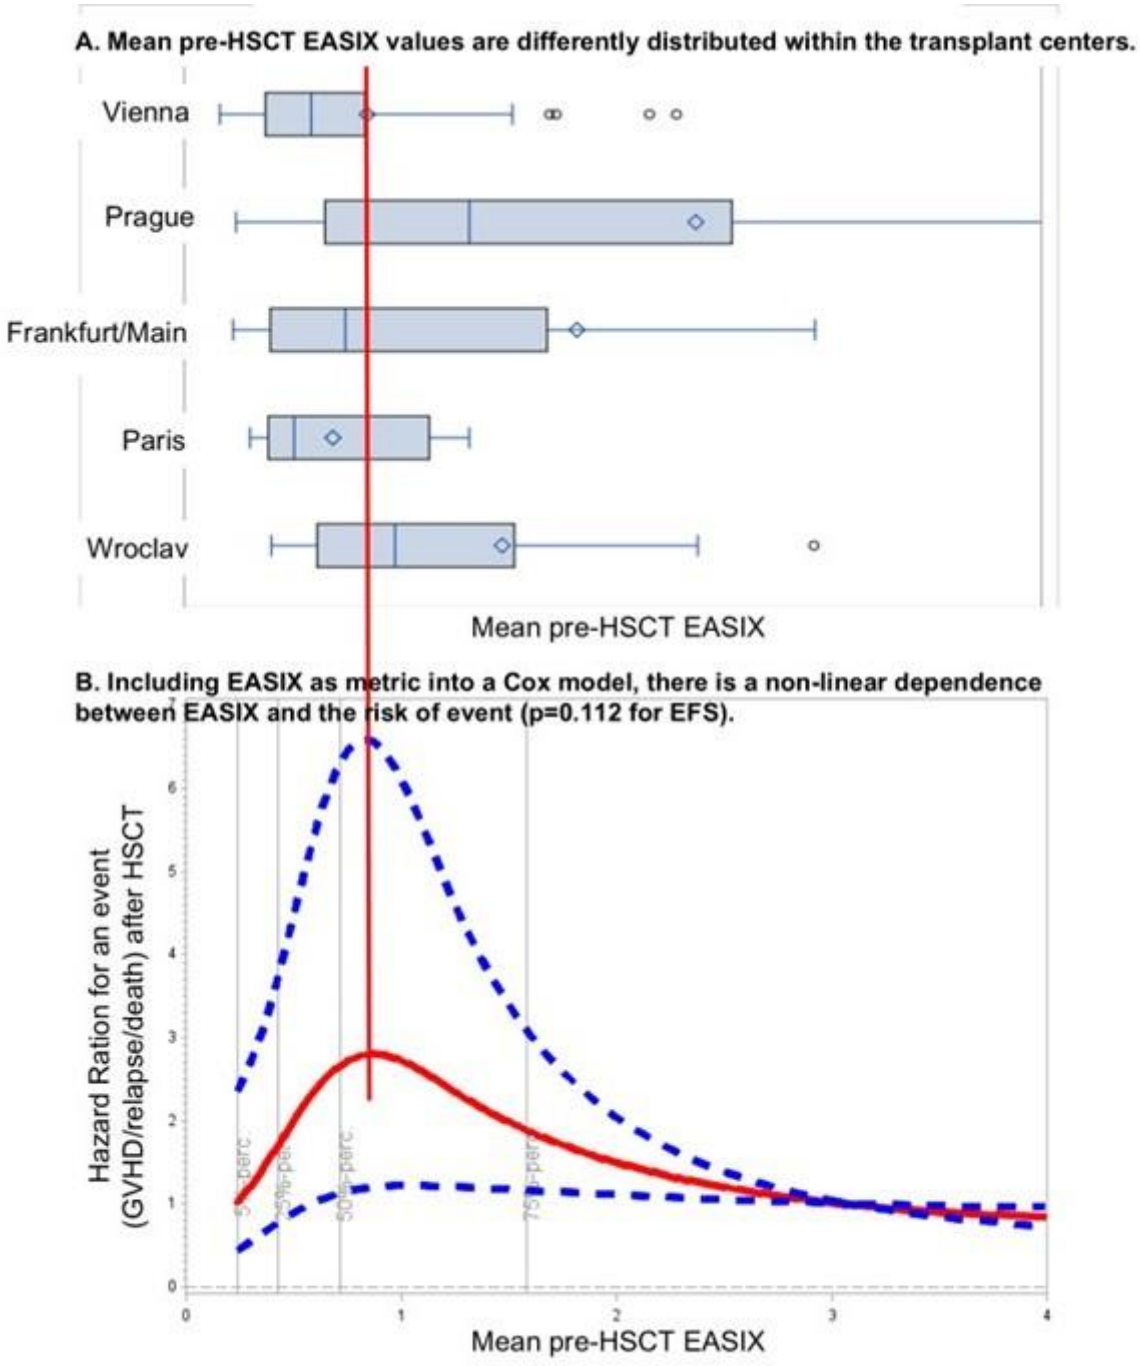

Figure A/B: Only for low EASIX values there is a positive linear dependence between pre-HSCT EASIX and risk.

HSCT was conducted predominantly from matched unrelated donors (74%) with bone marrow as stem cell source (61%) and TBI-containing conditioning regimen (66%). Fifty-six percent of patients were transplanted in first complete remission; the underlying ALL was a

precursor B-cell ALL in 73%. In terms of patient characteristics, immunophenotype and remission status did not correlate significantly with EASIX. An adverse effect of TBI-containing conditioning was borderline significant. Increasing age and peripheral blood as stem cell source were significantly associated with a higher risk of elevated EASIX values (Table).
When patients were dichotomized by mean pre-HSCT EASIX (day−30 to day0), the 5-year NRM was 4% in the low-EASIX group compared with 15% in the high-EASIX group (p = 0.019). Mean pre-HSCT EASIX was not associated with 5-year OS. In contrast, EASIX measured at day −3 showed a clearer separation in outcomes, with a 5-year OS of 72% in the low-EASIX group compared with 84% in the high-EASIX group, indicating a trend toward significance (p = 0.072). The association between mean pre-HSCT EASIX and 5-year EFS observed in the single-center study was not confirmed in the multicenter cohort. However, modeling EASIX as a continuous variable suggested a non-linear relationship with event risk (p = 0.112), indicating that any adverse association may be limited to cohorts with lower mean EASIX values (Figure).
Notably, substantial inter-center variability in mean pre-HSCT EASIX values was observed across the five transplant centers (Figure).

Conclusions: In this multicenter pediatric ALL transplant cohort, elevated pre-HSCT EASIX robustly identified patients at increased risk of NRM, thereby confirming our previous single-center findings. Variability in results across transplant centers may reflect differences in national patient populations and center-specific transplant procedures including supportive care. The analysis including modifications of the EASIX-score as well as post-transplant values is ongoing. The observation of higher pre-HSCT EASIX values in older patients is consistent with the increased NRM reported in adolescents and young adults in the FORUM trial. Prospective integration of EASIX into pediatric pretransplant assessment and early post-transplant monitoring is feasible and may facilitate more effective risk-adapted supportive care.

Background: HSCT is the only widely available curative treatment option for sickle cell disease (SCD), with HLA-matched sibling donor (MSD)-HSCT representing the standard-of-care. We aimed to evaluate outcome of transplant activity for SCD in Germany in recent years across all donor types and conditioning regimens.

Methods: We analysed overall (OS), SCD-free (SFS), and persistent chronic GVHD SCD-free (GSFS) rates as well as risk factors for mixed chimersim (MC) in a retrospective, multicentre analysis of the German paediatric stem cell transplantation and SCD registries, including 146 patients receiving a first HSCT between 2011 and 2022.

Results: The table shows transplant characteristics and outcome according to donor. All patients received reduced-toxicity protocols (RTPs), which were predominantly treosulfan-fludarabine-thiotepa-based (69.9%). Four-year OS and GSFS did not differ significantly between conditioning regimens (treosulfan-based: 97.1% and 82.8%; busulfan-based: 95.2% and 89.2%; melphalan-based: 100.0% and 77.8%). Matched family donor (MFD)-HSCT (88 MSD; 5 other MFD) showed a tendency towards better 4-year-OS (98.9%, p=0.09, table) and represented a protective factor for inferior SFS (91.6%, HR=0.38, p=0.04) and GSFS (91.6%, HR=0.26, p=0.002,), whereas reduced myeloablation (treosulfan 36g/m^2 or without thiotepa) acted as risk factor (SFS: HR=3.4, p=0.03; GSFS: HR=4.3, p=0.005). Multivariate Cox regression analysis identified MUD (HR=27.9, p=0.003), MMUD (HR=14.5, p=0.002) and Ferritin ≥2500µg/l (HR=32.2, p=0.001) as hazard factors for aGVHD II-IV (N=20, table), with a trend towards older recipient age (≥12 years; HR=3.7, p=0.07). Graft failure (GF, N=17) predominantly occurred in treosulfan-based regimens (4-y-cumulative incidence: treosulfan 12.4%, busulfan 3.0%, p=0.14) and frequently in patients undergoing reduced myeloablation (p=0.005). Likewise, MC below 75% appeared more frequently in treosulfan-based regimens (32.4%) compared to busulfan (8.8%, p=0.007). 16 patients received donor lymphocyte infusions, all after treosulfan-based conditioning.
We performed multivariate logistic regression analysis to assess the risk of MC at day+30, +60 (<95% donor chimerism (DC)) and day+100, +180 and +365 post HSCT (<75% DC). Serotherapy with Thymoglobulin® was main risk factor at day+30 (p=0.04). This corresponded to a faster reduction (median day: Thymoglobulin® 73, ATG-Fresenius 124 (p<0.001)) and discontinuation (Thymoglobulin® 115, ATG-Fresenius 162 (p<0.001)) of calcineurin inhibitors in this subgroup. High mean targeted trough level of cyclosporine A (CSA≥150µg/l) combined with MFD-HSCT represented main risk factor at day+60 (p=0.03) and day+100 (p=0.01). From day+100 onwards, young recipient age at transplant (<6 years) was significantly associated with drop in DC to <75% (day+100: p=0.02; day+180: p=0.005; day+365: p=0.004) as well as reduced myeloablation (day+180: p=0.05; day+365: p=0.02). These risk factors originate from a homogenous subgroup of

treosulfan(42g/m^2)-fludarabine-thiotepa-ATG-based MFD-HSCTs (N=62; Thymoglobulin® (day+30: p=0.18); CSA≥150µg/l (day+60: p=0.03; d+100: p=0.03); age<6 years (day+180: p=0.02; day+365: p=0.02)). This subgroup was characterised by minor GvHD problems (no aGvHD III-IV, 4.8% aGvHD II; 1.6% temporary mild cGVHD).

4-y overall survival, %	98.9	94.1	86.8	100.0	0.09
4-y sickle cell disease (SCD)-free survival, %	91.6	76.5	81.3	76.5	0.09
4-y persistent cGvHD- and SCD-free survival, %	91.6	64.2	76.6	70.6	0.004

Conclusions: The results of our detailed, multicentre data analysis confirm excellent OS across all donor types, but significantly better GSFS after MFD HSCT for SCD. We identified risk factors (Thymoglobulin®, CSA≥150µg/l, age<6 years, reduced myeloablation) for the development of MC in treosulfan-based conditioning regimens. These data should assist in risk-adapted optimization of RTPs especially in the setting of MFD-HSCT.

Background: Allogeneic haematopoietic stem cell transplantation (HSCT) is the treatment of choice to cure high risk and relapsed or refractory paediatric AML, however, relapse remains the leading cause of treatment failure. Outcomes for children who relapse after HSCT have been poor historically, particularly for those who experience early relapse (i.e. within 6 months after the allograft), yet data specifically evaluating early relapse in the paediatric AML setting is very limited. We sought to evaluate outcomes for children with AML who relapse within 6 months post-transplant in the largest international registry-based study focusing on this cohort to date.

Methods: We conducted a retrospective study from the EBMT Paediatric Diseases Working Party (PDWP) of all patients transplanted in complete remission (CR) for AML, and aged under 18 years at time of transplant, who relapse within 6 months post first allo-HSCT, over a 15-year study period from 2010-2024. Overall survival (OS) was evaluated from date of relapse post HCT to death or last follow-up. A Cox multivariable model was used to evaluate factors influencing OS.

Results: 469 patients were included in analysis, 288 in CR1 and 181 in CR2 or more, median follow up was 3.2 years after relapse (95%CI 2.1-4.1). The median age for the entire cohort was 6.0 years, (range 1.1-14.8) and 190 were female. Overall survival at 1- and 3-years post relapse was 15.4% (95%CI 12.1-19.2) and 9.1% (95%CI 6.4-12.4) respectively, figure 1. Time from HSCT to relapse, Lansky performance status, and year of HSCT were all shown to adversely impact outcomes on multivariable analysis, table 1.
The 3y cumulative incidence of allo HSCT post relapse was 14.3%, corresponding to 61 pts. Median time of second allo HSCT after relapse was 105 days. At time of second allo HSCT, 31 were transplanted in CR and 27 in active disease (3 missing).
Three patients have no follow-up after the second allo HSCT. Regarding the 58 remaining patients: 1- and 3- year OS was 45.9% (95%CI 32.1 - 58.7) and 30.3% (95%CI 18 - 43.5), respectively. 1- and 3- year leukaemia free survival (LFS) was 34.1% (95%CI 21.7 - 46.9) and 24.6% (95%CI 13.5 - 37.4), respectively.1- year relapse incidence (RI) 53% (95%CI

38.6 - 65.5) and 3-year RI was 60.3% (95%CI 45 - 72.6). Non relapse mortality (NRM) was 12.9% at 1 year (95%CI 5.5 - 23.3) and 15.1% (95%CI 6.9 - 26.3) at 3 years.

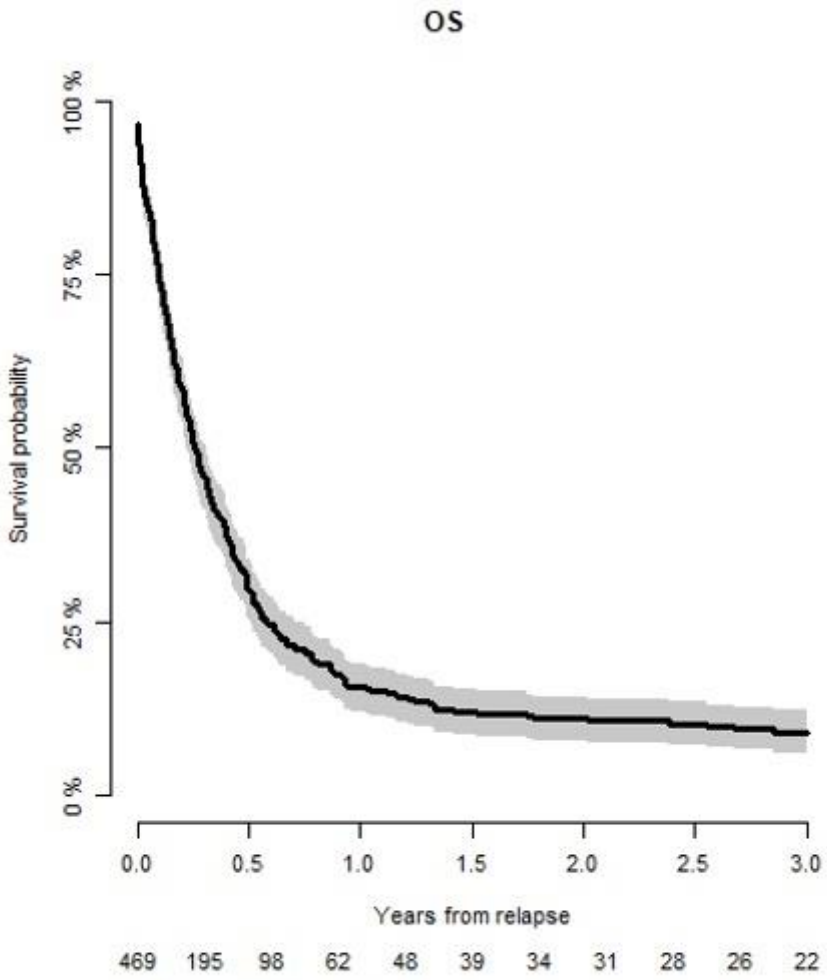

Figure 1: OS of entire cohort

Table 1: Multivariable Cox model on OS

Variables	Parameters	HR (95% CI)	P value
Time from HSCT to relapse	4 to 6 months	1	
	Within 3 months	1.20 (1.21-1.87)	<0.001

Lansky	90 and 100	1	
	≤80	1.43 (1.12-1.84)	0.004
Year of HSCT (5y unit)	After 2016	1	
	Before 2016	1.29. (1.04-1.60)	0.03
Donor type	Matched related	1	
	Mismatched related	1.24 (0.89-1.73)	0.19
	Unrelated donor	1.11 (0.85-1.45)	0.43
	CB	1.38 (0.99-1.82)	0.052
Disease status at HSCT	CR1	1	
	CR2+	1.02 (0.8201.28)	0.85
Age at HSCT (5y unit)		1.04 (0.95-1.14)	0.4
ELN 2022 cyto	Fav/int	1	
	Adverse	0.80 (0.62-1.04)	0.1
	Missing	0.83 (0.64-1.07)	0.14

Conclusions: Our study, representing the largest reported cohort of this specific population to date, shows that outcomes of children with AML who relapse within 6 months after allogeneic HSCT are abysmal using standard transplant approaches. This remains true regardless of whether transplantation occurred in first or second remission. These data highlight the urgent need for innovative and experimental therapeutic strategies to be explored in this setting and serve as a benchmark for future prospective trials evaluating novel approaches to improve outcomes.

COMPARISON OF BONE MARROW VS PERIPHERAL BLOOD STEM CELLS FOR HAPLOIDENTICAL HSCT WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE IN CHILDREN: A CIBMTR ANALYSIS

Anand Srinivasan[1], Sarthak Kumar[2], Kwang Woo Ahn[3,2], Akshay Sharma[4], Takuto Takahashi[5], Parinda Mehta[6], Christine Phillips[6], Hemalatha Rangarajan[7], Larisa Broglie[2,8], ***Joerg Krueger***[9]

[1]Mayo Clinic, Rochester, United States of America (the), [2]CIBMTR® (Center for International Blood and Marrow Transplant Research), Medical College of Wisconsin, Milwaukee, United States of America (the), [3]Division of Biostatistics, Data Science Institute, Medical College of Wisconsin, Milwaukee, United States of America (the), [4]St. Jude Children's Research Hospital, Memphis, United States of America (the), [5]University of Minnesota, Minneapolis, United States of America (the), [6]Cincinnati Children's Hospital, Cincinnati, United States of America (the), [7]Nationwide Children's Hospital, Ohio, United States of America (the), [8]Division of Pediatric Hematology/Oncology/Blood and Marrow Transplant, Department of Pediatrics, Medical College of Wisconsin, Milwaukee, United States of America (the), [9]Hospital for Sick Children, Toronto, Canada

Background: Post-transplant cyclophosphamide has dramatically changed the landscape of hematopoietic cell transplant (HCT) for adults with malignancies, significantly reducing GVHD rates when either BM or PBSC is used as a graft source. In many pediatric programs, bone marrow (BM) remains the preferred graft source due to low rates of graft-versus-host disease (GVHD) when calcineurin inhibitor-based prophylaxis is used; data using peripheral blood stem cells (PBSC) grafts for children in the PTCy setting is limited. We aimed to compare outcomes between BM and PBSC grafts in pediatric patients with hematological malignancies receiving PTCy based haploHCT.

Methods: Children ≤21 years (y) with acute lymphoblastic leukemia (ALL) or acute myeloid leukemia (AML) who received their first myeloablative haploHCT with PTCy between 2015-2022 were identified in the CIBMTR registry. Primary outcome was chronic graft-versus-host disease-free relapse free survival (CRFS) defined as patients who have not experienced extensive cGVHD or relapse of their primary disease at 2 years post-HCT. Secondary outcomes were overall survival (OS), incidence of relapse and acute/chronic GVHD. Survival was estimated using Kaplan-Meier analysis and graft sources compared using log-rank testing. Multivariable analysis assessed the effect of graft source on outcomes, adjusting for other significant covariates (variables tested: recipient age, donor relationship, disease, disease status, conditioning regimen, year of transplant, and disease risk index scoring). Statistical significance was defined as $p < 0.05$.

Results: In our cohort of 836 patients, 532 patients received BM, 304 PBSC. Demographics were comparably, except for an older age receiving PBSC (median age for PBSC 15.3 vs 9.7 for BM; $p<0.01$).
Although there was no difference in CRFS by graft source (PBSC 44.4% vs BM 49.8% at 2 years, p=0.101), cGVHD was significantly higher in those receiving PBSC, particularly extensive cGVHD (PBSC 26.6% vs BM 13.4%; p=<0.001). There was no difference in the incidence of grade 3-4 aGVHD (PBSC 3.6% vs BM 3.3%; p=0.835). The cumulative incidence of relapse was lower with PBSC grafts (PBSC 21.9% vs BM 29.5%; p=0.045), but the OS was similar (PBSC 71.2% vs BM 70.9%; p=0.360).
Multivariate analysis showed inferior CRFS with PBSC (HR 1.23; 95% CI 1.01-1.58; p=0.04). OS (HR 0.93; 95% CI: 0.72-1.21; p=0.60) and DFS (HR 0.98; 95% CI: 0.77-1.25; p=0.89) were comparable for both stem cell sources. The decrease in CRFS was due to the increased incidence of extensive cGVHD (HR: 1.89; 95% CI: 1.46-2.46; p=<0.0001) with PBSC. There were no differences in incidence of grade 3-4 aGVHD (PB HR: 1.67; 95% CI: 0.70-3.97;

p=0.25); relapse (PB HR: 0.88; 95% CI: 0.65-1.17; p=0.37) and transplant related mortality (PB HR: 1.23; 95% CI: 0.82-1.83; p=0.32).

Conclusions: In this large contemporary comparison of BM and PBSC grafts in haploHCT utilizing PTCy, the use of PBSC conveys a higher risk of cGVHD with mildly inferior CRFS. This suggests that PTCy does not fully mitigate the PBSC associated cGvHD risk. Patients receiving PBSC had a lower relapse rate in univariate analysis, but this finding did not persist when other covariates were adjusted for in multivariate analysis. Prospective studies are needed to further optimize haploHCT for pediatric patients.

EFFICACY ANALYSIS OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PEDIATRIC ACUTE MYELOID LEUKEMIA: A 15-YEAR CLINICAL STUDY FROM CHINA

*Qingwei Wang[1,2], Li Gao[1,2], Senlin Zhang[1], Shengqin Cheng[1,2], Peifang Xiao[1,2], Jun Lu[1,2], Jie Li[1,2], **Shaoyan Hu**[1,2]*
[1]Children's Hospital of Soochow University, Suzhou, China, [2]Jiangsu Provincial Center for Pediatric Hematology and Oncology, Suzhou, China

Background: In recent years, transplantation techniques for pediatric acute myeloid leukemia (AML) have advanced significantly; however, post-transplant relapse remains the primary challenge affecting prognosis. This study aims to analyze the evolution of transplant outcomes over 15 years and explore the impact of specific molecular subtypes and clinical factors on relapse.

Methods: A retrospective analysis was conducted on 452 children with AML who underwent their first allo-HSCT at the Children's Hospital of Soochow University between 2011 and 2025. Patients were divided into two groups based on the transplant era (pre-2019 vs. post-2019). Outcomes, including overall survival (OS), event-free survival (EFS), cumulative incidence of relapse (CIR), non-relapse mortality (NRM), and incidence of acute graft-versus-host disease (aGVHD), were compared between the groups. Furthermore, based on clinical data such as molecular characteristics at initial diagnosis, response to chemotherapy, and donor-recipient profiles, multivariate analysis was performed to identify independent prognostic factors.

Results: Among the 452 patients (248 males, 204 females), the median age was 90 months (range: 4.7-205). There were 105 transplants performed before 2019 and 347 after 2019. The two groups showed no significant differences in baseline characteristics, including peripheral blood counts at diagnosis, age at transplant, gender, nutritional status, blood group compatibility, or donor-recipient gender. Notably, the post-2019 era saw an increase in haploidentical transplants and a decrease in cord blood transplants. With a median follow-up of 27 months (range: 1-101) post-transplant, patients transplanted after 2019 showed trends towards improved 3-year OS (81.5% vs. 74.6%, P=0.16) and EFS (79.8% vs. 75.0%, P=0.43), significantly lower NRM (9.2% vs. 18.4%, P=0.011), and a significantly reduced incidence of grade 2-4 aGVHD (10.5% vs. 26.0%, P<0.001). However, CIR did not show significant improvement (13.3% vs. 9.7%, P=0.220). Molecular analysis revealed that patients with*CBFA2T3::GLIS2* or *TLS::ERG* fusion genes derived minimal benefit from transplantation, with post-transplant relapse rates exceeding 80%. Patients with *KMT2A::AF10* rearrangement had limited benefit (relapse rate 19.0%, 4/21), while those

with spliceosome mutations showed excellent outcomes (relapse rate 4.2%, 1/54). Multivariate Cox analysis identified myeloid sarcoma (vs. non-M7, HR=9.0, P=0.045), M7 (vs. non-M7, HR=8.112, P=0.001), failure to achieve remission after first induction (NR vs. CR/CRi, HR=2.433, P=0.045), and non-complete remission status pre-transplant (PR/NR vs. CR1, HR=3.237, P=0.017) as independent risk factors for poorer OS. Transplantation in the post-2019 era (HR=0.262, P=0.004) was a protective factor for OS. For relapse-free survival (RFS), M7 (vs. non-M7, HR=8.379, P=0.001) and pre-transplant PR/NR status (HR=3.427, P=0.005) were risk factors, while transplantation post-2019 (HR=0.346, P=0.018) and younger donor age (HR=1.03, P=0.038) were protective factors.

Conclusions: Advances in transplantation techniques, particularly the optimization of haploidentical protocols, have significantly reduced NRM and severe aGVHD, contributing to a trend towards improved survival in pediatric AML. However, relapse remains a major challenge. Patients with specific molecular subtypes (e.g., *CBFA2T3::GLIS2, TLS::ERG*) have extremely poor outcomes, whereas those with spliceosome mutations derive significant benefit. Additionally, myeloid sarcoma, M7, and failure to achieve complete remission prior to transplant are important adverse prognostic factors. Selecting younger donors may help improve RFS.

B209

THE COMBINATION OF VENETOCLAX AND DECITABINE AS MAINTENANCE THERAPY AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR CHILDREN WITH VERY HIGH-RISK ACUTE MYELOID LEUKEMIA

Jonathan P. Gross[1,2,3], *Karin M. Cabanillas Stanchi*[4,5], *Michaela Döring*[4,5], *Sandra Cyrull*[1], *Jan R. Dörr*[1,2], *Michael Launspach*[1,2], *Johannes H. Schulte*[1,4], *Tim Flaadt*[4], *Peter Lang*[4], *Dirk Reinhardt*[6,7], *Arend von Stackelberg*[1], *Felix Zirngibl*[1,2]
[1]*Charité – Universitätsmedizin Berlin, Berlin, Germany,* [2]*Berlin Institute of Health at Charité - Universitätsmedizin Berlin, Berlin, Germany,* [3]*German Center for Child and Adolescent Health (DZKJ), Berlin, Germany,* [4]*Eberhard Karls University Tuebingen, University Children's Hospital, Tuebingen, Germany,* [5]*Nachsorgeklinik Tannheim Gemeinnützige GmbH, Vs-Tannheim, Germany,* [6]*University Hospital of Essen, Essen, Germany,* [7]*AML-BFM Study Group, Essen, Germany*

Background: Relapse of AML remains the leading cause of treatment failure and mortality after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Venetoclax combined with decitabine has shown efficacy as post-HSCT maintenance therapy in adult AML, but pediatric data are scarce. This retrospective case series evaluates venetoclax/decitabine maintenance as an individualized post-HSCT strategy in children with AML and very high-risk (VHR) for post-HSCT relapse.

Methods: We retrospectively analyzed 12 pediatric AML patients treated between March 2022 and November 2025 at two German HSCT centers (Charité Universitätsmedizin Berlin and Universitätsklinikum Tübingen). Eligibility criteria defined VHR-AML by adverse cytogenetics, refractory disease, relapse after prior allo-HSCT, and/or minimal residual disease (MRD) reappearance post-HSCT.
The maintenance regimen was adapted from Wei et al. (Cancer Science, 2021). Therapy was initiated between day +45 to +200 after HSCT, in the absence of active infection, grade III–IV acute GvHD, or relevant transplant-related toxicities. Each 21-day cycle consisted of decitabine 15 mg/m² on days 1–3 and venetoclax up to 200 mg daily on days 1–21 (dose-adjusted for body weight and drug interactions). Cycles were repeated every 8 weeks for up

to 10 cycles or a maximum of 24 months post-HSCT. Dose modifications were applied for cytopenias.
Primary endpoints were relapse-free survival (RFS) and overall survival (OS), calculated from the day of last HSCT. Secondary endpoints included non-relapse mortality, incidence and severity of acute and chronic GvHD, feasibility, and tolerability. Analyses were performed both intention-to-treat and per protocol (>2 cycles).

Results: Median age at diagnosis was 5.7 years (range 2 months–15 years). Patients were heavily pretreated, including multiple chemotherapy lines, targeted agents, and prior HSCTs. Disease status before HSCT was heterogeneous: 6/12 patients (50%) proceeded to transplantation in CR, whereas 6 patients had refractory disease (2/12, 16.7%) or empty marrow (4/12, 33%), reflecting advanced, therapy-resistant disease.
Conditioning regimens were treosulfan- (6/12, 50%), melphalan- (4/12, 33%) or busulfan- -based (2/12, 16.7%). Median time from HSCT to maintenance initiation was 96 days (range 45-209 days). Six patients (50%) completed all planned cycles, four (33%) remain on therapy, and two patients discontinued early, one due to relapse, another due to withdrawal of health insurance reimbursement. Two patients additionally received DLI. Eleven out of 12 evaluable patients (92%) completed >2 cycles.
The most common grade III adverse events were febrile neutropenia or fever without neutropenia where patients had to be hospitalized (9 events), all transient and reversible. No grade IV toxicities and no severe (≥grade III) acute or chronic GvHD were observed.
At a median follow-up of 24 months, 2-year RFS was 83% (10/12) in the intention-to-treat analysis and 91% (10/11) in patients receiving >2 cycles. Corresponding OS rates were 92% (11/12) and 100% (11/11), respectively.

Table 1. Demographic and clinical characteristics.
Abbreviations: AML - acute myeloid leukemia; N - sample size; VENDEC - combination of venetoclax and decitabine; HSCT – hematopoietic stem cell transplantation; VHR – very high risk; MRD - minimal residual disease; CR – complete remission; MUD – matched unrelated donor; MSD – matched sibling donor; MMFD – mismatched family donor.

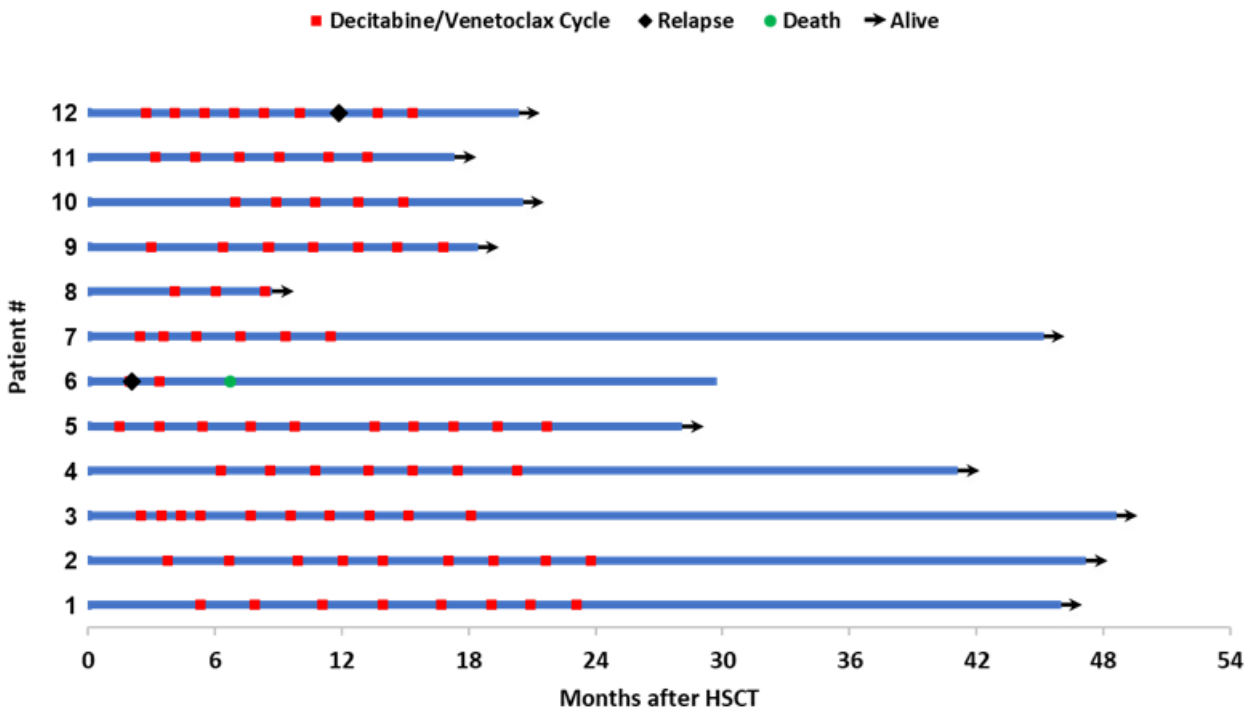
Table 1. Demographic and clinical characteristics.
Abbreviations: AML - acute myeloid leukemia; N - sample size; VENDEC - combination of venetoclax and decitabine; HSCT – hematopoietic stem cell transplantation; VHR – very high risk; MRD - minimal residual disease; CR – complete remission; MUD – matched unrelated donor; MSD – matched sibling donor; MMFD – mismatched family donor.

	MRD-Persistence	1 (8)
Prior HSCT, N(%)	0	8 (67)
	1	4 (33)
Remission status before HSCT, N (%)	Empty marrow	4 (33)
	Persistent blasts	2 (17)
	CR with pos. MRD	2 (17)
	CR with neg. MRD	4 (33)
Donor Type, N (%)	9/10 MUD	1 (8)
	10/10 MUD	4 (33)
	MSD	2 (17)
	5/10 MMFD (Haplo)	5 (42)
Number of VENDEC cycles, N	Median (Range)	7 (1-10)



Conclusions: Venetoclax plus decitabine appears feasible and well tolerated as post-HSCT maintenance in children with VHR-AML, with encouraging survival outcomes compared with an expected EFS of <30% in this population. Despite limitations related to small sample size and retrospective design, these data support prospective studies to define personalized, risk-adapted maintenance strategies in pediatric AML.

Disclosure: Nothing to declare.

MMUD VS MATCHED DONORS IN PEDIATRIC HSCT SETTING: TIME TO RE-THINK GVHD PROPHYLAXIS STRATEGIES?

EBMT 52nd Annual Meeting
Madrid, Spain
22-25 March 2026
#EBMT26
Advancing the Art of Patient Care

Chiara Mainardi[1], *Manuela Tumino*[1], *Maria Gabelli*[1], *Antonio Marzollo*[1], *Marta Pillon*[1], *Linda Rossini*[1], *Giulia Reggiani*[1], *Alessandra Biffi*[1,2]
[1]*Padova University Hospital, Padova, Italy,* [2]*Padova University, Padova, Italy*

Background: The use of Mismatched unrelated donors (MMUD), a subgroup of the so-called "alternative donors", although increasingly widespread in adult and pediatric HSCT, raises concerns about transplant outcome, since GvHD risk might be increased. Optimizing GvHD prophylaxis in MMUD HSCT is crucial, especially in hematological disease where no graft-versus-leukemia effect is of interest.The present study aims to detect any differences in transplant outcomes according to the donor used (MMUD vs matched) in a single Institution's pediatric dataset.

Methods: A large cohort of pediatric patients, who underwent MUD HSCT for malignant and non-malignant disease with an homogeneous GvHD prophylaxis regimen (r-ATG, Ciclosporin A and short course Methotrexate) was reviewed. Patients were categorized according to stem cell donor as "Matched" (10/10 HLA matching at loci HLA-A, B, C, DRB1, DQB1) or "MMUD" (9/10 or lower HLA matching at the same loci) and and the groups were compared in terms of engraftment times, acute and chronic GvHD prevalence, transplant-related mortality (TRM) and OS and EFS, considering relapse and graft failure as events. Patients were not censored according to the number of transplants (1 or > 1). Groups were compared for categoric variables using the Chi-squared test with Yates correction. The probability of OS and DFS was estimated using the Kaplan–Meier method. NRM, relapse incidence and GvHD occurrence were expressed as cumulative incidence (CI) curves. The log-rank test was used to estimate differences between curves.

Results:

Patients' characteristics are summarized in Table 1.

TABLE 1.

		a) Malignant diseases				**b) Non-malignant diseases**

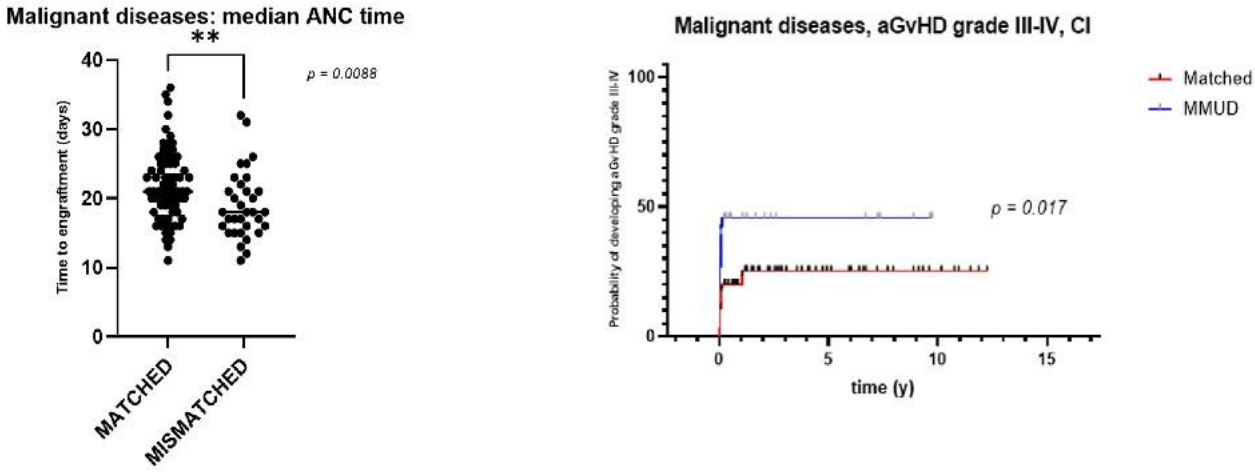
median engraftment time PTL (days)		24	25			29	25
aGvHD any grade		24/33 (72.7%)	47/75 (62.7%)			5/18 (27.8%)	11/29 (37.9%)
aGvHD gr. III-IV		15/33 (45.4%)	18/75 (24%)			1/18 (5.6%)	4/29 (13.8%)
cGvHD		6/33 (18.18%)	16/75 (21.3%)			0/18	2/29 (6.9%)
cGvHD severe		2/33 (6%)	5/75 (6.6%)			0/18	1/29 (3.4%)
death		10/33 (30.3%)	23/73 (31.5%)			2/18 (11.1%)	2/27 (7.4%)
relapse		6/33 (18.18%)	21/73 (28.7%)	**graft failure**		1/18 (5.6%)	4/29 (13.4%)
death due to TRM		6/10 (60%)	7/23 (30.4%)			2/2 (100%)	2/2 (100%)
death due to relapse		4/10 (40%)	16/23 (69.6%)				

108 MUD HSCT were performed in 106 patients affected by malignant disease in a 15 year interval, with the main indication being ALL. The majority (nearly 70%) were transplanted from a matched donor. In the same timespan, 47 MUD HSCT were performed in 45 patients with non malignant disease, mostly severe aplastic anemia (AAS) and immunodeficiencies. 61.7% of them received HSCT from a matched donor. ANC recovery time resulted significantly shorter in the Matched group for malignant diseases (p = 0.0088, figure 1a), while no difference was observed for platelets recovery. This finding was not confirmed for non-malignant diseases. CI of grade III-IV aGvHD was significantly higher in the MMUD group for malignant diseases (p = 0.017, figure 1b) , while no difference was observed in OS, EFS, CI of cGvHD and TRM either in malignant and non-malignant diseases.

Figure 1
a) b)



Conclusions: Our data show that the use of MMUD donors is associated with higher probability of severe aGvHD in malignant diseases. This does not result in an increased TRM, suggesting that GvHD can be successfully cured, but such observation raises the question whether our own GvHD prophylaxis policy in pediatric patients undergoing HSCT from MMUD donors should be modified, i.e. with the use of PT-Cy and Abatacept, as many adult centers are already doing even outside the haplo-setting.

Disclosure: Nothing to disclose.

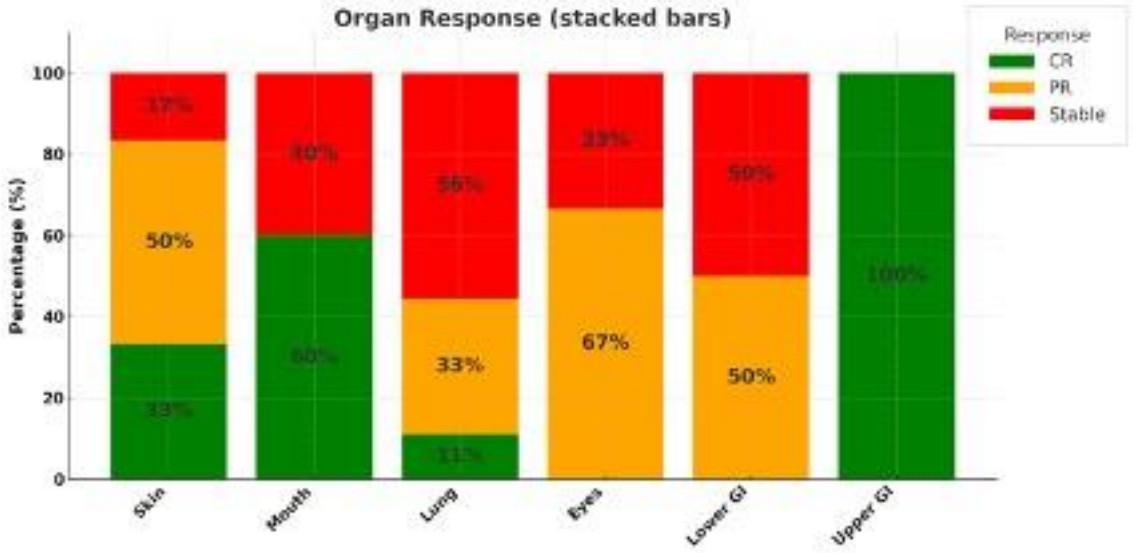
BELUMOSUDIL USE FOR CHRONIC GRAFT-VERSUS-HOST DISEASE IN CHILDREN: EXPERIENCE FROM THE PEDIATRIC SUBCOMMITTEE OF THE SPANISH GROUP FOR HSCT AND CELL THERAPY (GETH)

Marta Gonzalez Vicent[1], *Blanca Molina*[1], *María Luz Uria*[2], *Helena Martinez*[3], *María Jesús Pascual*[4], *Sara Vinagre*[1], *Laura Alonso*[2], *Luisa Sisinni*[5], *Iván López*[6], *Lucía Castilla*[7], *Julia Marsal*[8], *Cristina Diaz de Heredia*[2]
[1]*Hospital Niño Jesus, Madrid, Spain,* [2]*Hospital Vall de Hebrón, Barcelona, Spain,* [3]*Hospital La Fe, Valencia, Spain,* [4]*Hospital Regional de Málaga, Malaga, Spain,* [5]*Hospital La Paz, Madrid, Spain,* [6]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain,* [7]*Hospital Gregorio Marañón, Madrid, Spain,* [8]*Hospital San Joan de Deu, Barcelona, Spain*

Background: Belumosudil is a selective inhibitor of the kinase ROCK2 (Rho-associated coiled-coil kinase 2), approved by FDA for the treatment of chronic GVHD in patients 12 years of age or older who have received at least two prior lines of therapy. In children, experience is limited to clinical case reports because it is still in the trial phase.

Methods: We conducted a retrospective study including 15 children in 8 Spanish centers within the Pediatric group of GETH who received belumosudil as third or subsequent line for cGVHD treatment between May 2023 and August 2025.

Results: Median age at belumosudil start was 14 years (range, 11-20) and half of patients were boys. Most of patients have acute leukemia (5 AML and 4 ALL) and the remainder six patients have a non-malignant disease. Nine children were transplanted from a HLA-identical donor and 6 from an haploidentical donor. GVHD prophylaxis consisted of cyclosporine and methotrexate in 6 cases, post-transplant cyclophosphamide in 6 cases, and T-cell depletion in 3 cases. Median time from allo-HSCT to belumosudil start was 3 years (range, 1-10 years) and median time from cGVHD diagnosis to belumosudil start was 2 years (range, 5 months-10 years). At belumosudil start, cGVHD was moderate in 9 and severe in 6 patients according to 2014 NIH criteria. Patients had received a median of 4 prior lines of therapy for cGVHD (range, 2-8) including steroids in 15, ruxolitinib in 14, extracorporeal photopheresis in 12, mesenchymal cells in 5 and ibrutinib in 4 patients.
Median follow-up after belumosudil treatment was 7 months (range, 3-30)**.** Twelve patients received 200 mg/d, 2 patients 400 mg/d and 1 patient 200 mg/48h**.** Two patients discontinued treatment after a median of 4 months, 1 because lack of efficacy and 1 due to suspected adverse events**.** Overall survival was 92%. Only one patient died by IFI.
Overall response rate (ORR) was 60%**,** all were partial responses. There were no cases of progression. Median time to response was 6 months. Nine children discontinued their concomitant treatments. The best responses were achieved in the skin, mouth, and upper gastrointestinal tract (Figure 1). It is important to highlight the overall lung response of 44%.



Conclusions: In pediatric patients, belumosudil treatment was safe and cGVHD response was obtained in 60% of cases. Now it is necessary to determine the appropriate dosage in children through clinical trials.

Disclosure: Nothing to declare.

B212

A PILOT MULTICENTRE FEASIBILITY STUDY OF REAL-TIME PHARMACOKINETIC-GUIDED FLUDARABINE DOSING IN CHILDREN RECEIVING CD19-DIRECTED CAR T-CELL THERAPY FOR RELAPSED/REFRACTORY B-CELL LEUKAEMIA

Emma Barlow[1], *Su Han Lum*[1,2], *Geoff Shenton*[2], *Denise Bonney*[3], *Rachael Hough*[4], *Sophie Hambleton*[1,2], *Gareth Veal*[1], *Shelby Barnett*[1]
[1]*Newcastle University, Newcastle upon Tyne, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Newcastle upon Tyne Hospital NHS Foundation Trust, Newcastle upon Tyne, United Kingdom of Great Britain and Northern Ireland (the),* [3]*Manchester University NHS Foundation Trust, Manchester, United Kingdom of Great Britain and Northern Ireland (the),* [4]*University College London Hospitals NHS Foundation Trust, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Tisagenlecleucel, a CD19-directed CAR T-cell therapy, has transformed the treatment of relapsed or refractory (R/R) paediatric B-cell acute lymphoblastic leukaemia (ALL). In the UK paediatric cohort, ~90% of patients achieve complete remission following CAR T-cell infusion but ~50% of responders subsequently experience treatment failure including frank/MRD relapse or loss of B-cell aplasia. Lymphodepleting chemotherapy with

fludarabine and cyclophosphamide is critical for promoting CAR T expansion and persistence. Prior studies have demonstrated that achieving minimum fludarabine exposure thresholds (cumulative area under the curve (cAUC) >14mg.h/L) enhances patient outcome. In children, substantial interpatient variability in fludarabine pharmacokinetics is observed when body surface area (BSA)–based dosing is utilised, therefore therapeutic drug monitoring (TDM) to individualise exposure may improve patient outcomes.

Methods: Children (<18 years) with R/R B-ALL receiving CAR T-cell therapy were prospectively enrolled in the NCCPG TDM 2018 clinical trial across 3 paediatric CAR T-cell treatment centres in the UK (Newcastle, Manchester, UCL). All patients received standard lymphodepletion consisting of fludarabine (30mg/m^2 on days -6, -5, -4 and -3) and cyclophosphamide (500mg/m^2 on days -6 and -5). Fludarabine was given over 30 minutes and PK samples were taken at 0, 1, 3 and 6 hours post end of fludarabine infusion. A fully validated liquid chromatography-tandem mass spectrometry assay was used to measure fludarabine concentrations. PK analysis was conducted using a 3-compartment population PK model using InsightRX. Real-time analysis was conducted to enable dose adjustments of 3rd and 4th fludarabine doses to target a cAUC of 16-20mg.h/L. For a subset of patients, further PK analysis was conducted on day 4 following dose adjustment.

Results: Twenty-one patients were included with a median age of 13.2 years (range 1.3 - 18). All except one (Obicel) received tisagenlecleucel. The median cAUC was 18.1 (10.2-26mg.h/L) (Table 1). Nine patients (43%) achieved exposures <16mg.h/L, increasing the risk of CAR T failure. Eight patients (38%) achieved exposures >20mg.h/L, increasing the risk of drug toxicity. Required dose adjustments to target a cAUC of 18mg.h/L ranged from 59.7 - 187% of the total protocol dose and all dose adjustments were implemented in real-time. Three patients underwent additional TDM to validate dose adjustments, with final predicted AUCs within 6% of the targeted exposure (figure 1B).
Model-predicted exposures (median 15.4 (13.2 - 25.6mg.h/L) were significantly different from the measured-predicted exposures after incorporating concentration-time data into the model (median 18.1 (10.2 - 26mg.h/L) ($p<0.05$) with no pattern of over or under prediction. Had model-based dosing (MBD) alone been utilised, potentially suboptimal exposures would have been missed for 10/21 patients (47%).

Table 1

	Patient Age (Years)	
	1-13 (n= 10)	**³ 13 (n= 11)**
Weight (kg), Median (range)	23.1 (9.2 - 49.8)	42.5 (21.1 - 71.6)
BSA (m^2), Median (range)	0.88 (0.46 - 1.4)	1.35 (0.82 - 1.88)

Creatinine (mmol/L), Median (range)	27.5 (10 - 47)	41 (16 - 60)
cAUC (mg.h/L), Median (range)	17 (10.2 - 24)	18.1 (13.2 - 26)
Patients with cAUC 16-20 mg.h/L n (%)	2 (20)	2 (18)
Patients with cAUC <16 mg.h/L n (%)	5 (50)	4 (36)
Patients with cAUC >20 mg.h/L n (%)	3 (30)	5 (45)
MBD dosing cAUC (mg.h/L), Median (range)	15 (13.2-29.9)	15.7 (14.6-25.6)
Percentage difference between measured PK and MBD cAUC, Median (range)	6.4 (-22.7 - 69.6)	8.1 (-12 - 64)

Figure 1

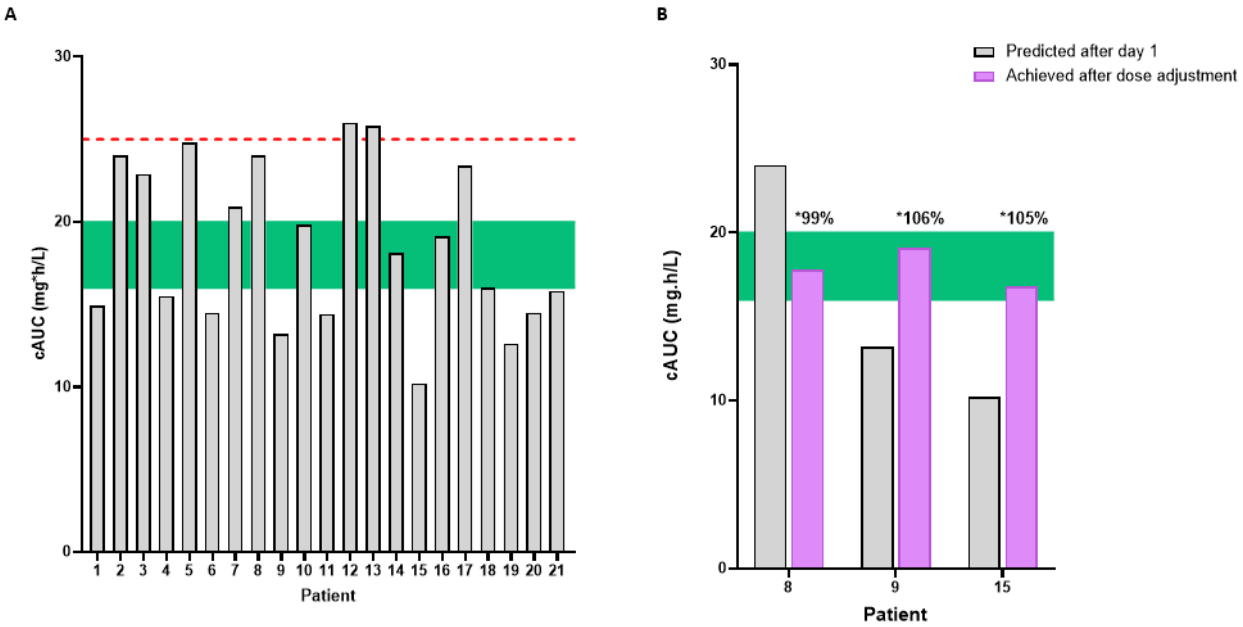


*Figure 1 A) cAUC achieved at a dose of 30 mg/m2/day x 4 (mg.h/L) (n=20). Shaded green area represents the proposed therapeutic window. Red dashed line represents a potential exposure toxicity threshold. B) cAUC achieved for 3 patients on day 1 and day 4 of treatment following a dose adjustment. *Indicates the % of the target AUC achieved following dose adjustment.*

Conclusions: These pilot data indicate considerable interpatient variability in fludarabine exposure in paediatric patients with R/R B-ALL receiving CAR T-cell therapy. BSA and model-based precision dosing were insufficient to reliably achieve target exposures, demonstrating the need for adaptive dosing strategies. Real-time therapeutic drug monitoring is feasible. Building on these findings, a dedicated clinical trial (Goldilocks) is now opening across all UK paediatric CAR T centres to implement real time PK-guided fludarabine dosing for children undergoing CD19-directed CAR T-cell therapy.

SURFACTANT PROTEIN D IN PLASMA MAY PREDICT BRONCHIOLITIS OBLITERANS AFTER PEDIATRIC HSCT

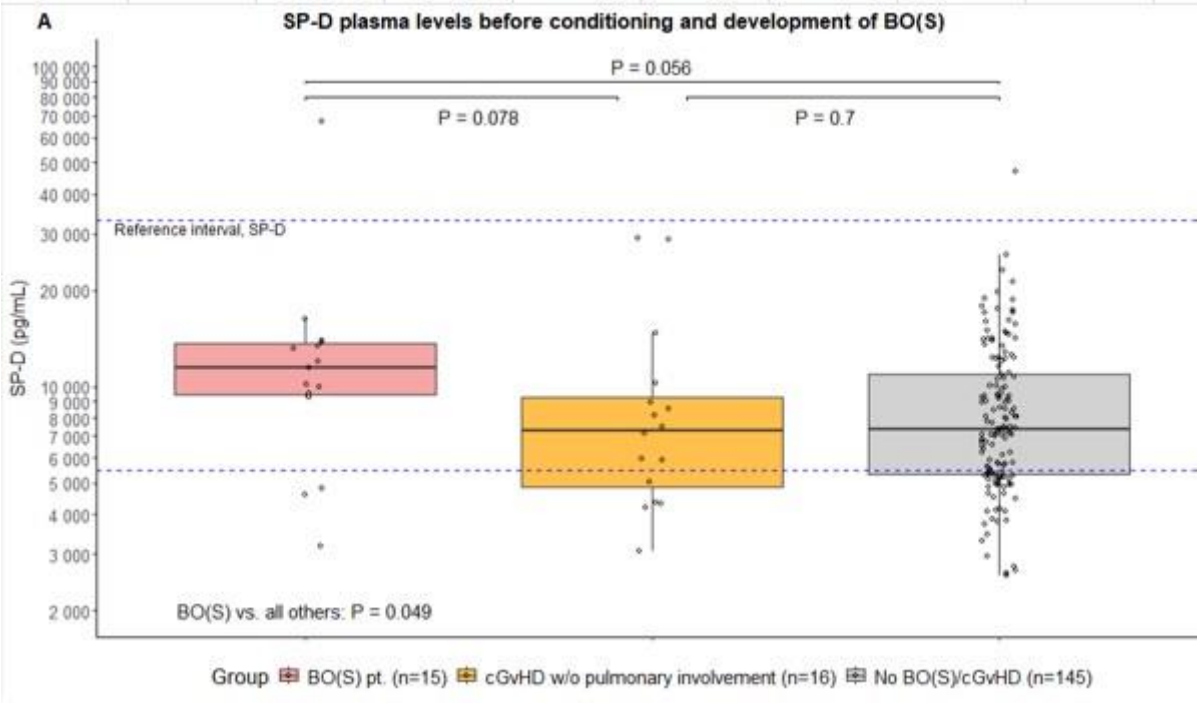
Amalie Christence Sennels[1], *Hilde Hylland Uhlving*[1], *Tania Masmas*[1], *Victoria Bloch Blytt Sandstad*[1], *Jens-Christian Holm*[2], *Claus H. Nielsen*[1], *Frederik Fouirnaies Buchvald*[1], *Kim Gjerum Nielsen*[1], *Klaus Müller*[1,3], *Katrine Kielsen*[1]
[1]*Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark,* [2]*Holbæk Hospital, Holbæk, Denmark,* [3]*University of Copenhagen, Copenhagen, Denmark*

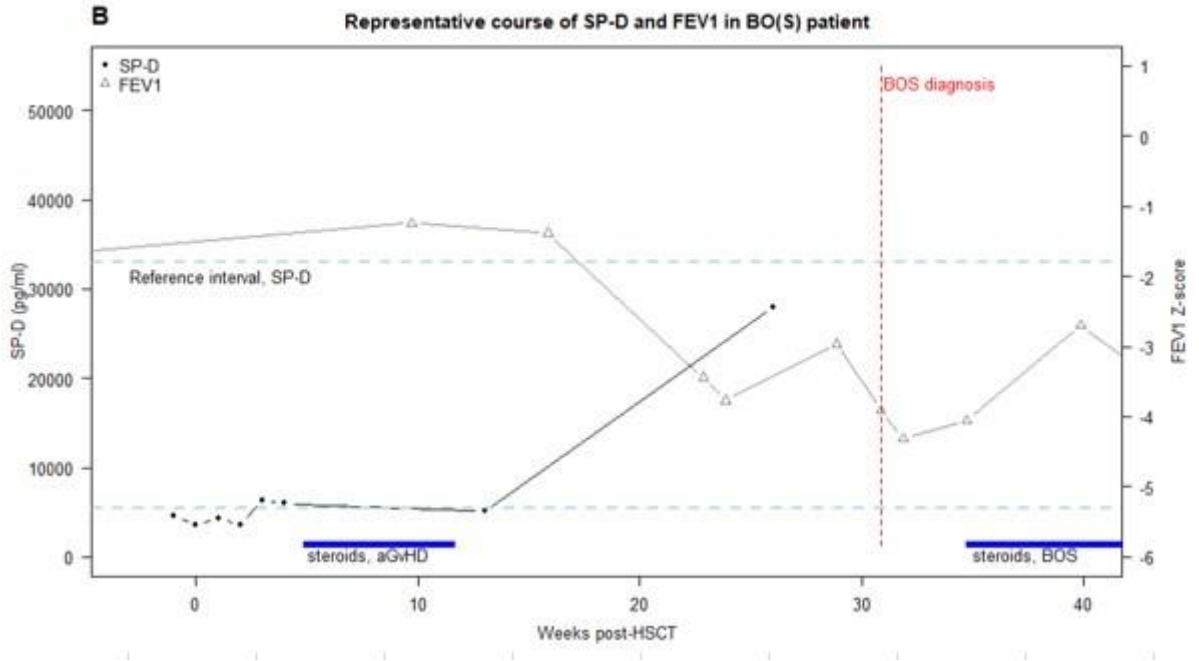
Background: Bronchiolitis obliterans and bronchiolitis obliterans syndrome (BO(S)) are severe and potentially life-threatening pulmonary complications after HSCT. Early treatment is crucial to prevent irreversible lung damage, but definitive diagnosis relies on invasive procedures such as lung biopsy and/or HRCT combined with pulmonary function tests - methods that can be challenging in young children and may fail to detect early disease. This calls for less invasive diagnostic tools, including biomarkers.
Surfactant protein D (SP-D), a component of the pulmonary innate immune system, shows elevated plasma levels during viral lower respiratory tract infections and exacerbations of COPD. We investigated SP-D as a potential biomarker for BO(S) in pediatric HSCT.

Methods: We prospectively included 178 children undergoing their first HSCT from 2010-2023 (Table), and 200 healthy children as controls (median age (range): 11.7 years (6-18.8)). BO(S) diagnosis was based on modified NIH guidelines and defined as either cGvHD in lung biopsies or the combination of >10% decrease in FEV1 from baseline, FEV1/FVC <0.7, and air trapping on HRCT.
Plasma levels of SP-D were measured by Luminex before conditioning and on days 0, +7, +14, +21, +30, +60, +90, +180 and +365 post-HSCT.

Results: Pre-conditioning SP-D levels were significantly lower in HSCT recipients than in healthy children (7620 vs. 12898 pg/mL, P<0.0001), although variability was high in both groups. SP-D levels were not associated with age, sex, diagnosis, conditioning regimen, donor type, or graft type at any timepoint.

Children who developed aGvHD grade II-IV, (n=56), had significantly higher SP-D levels pre-conditioning, and on day 0 and +14 compared to patients with aGvHD grade 0-I (pre-conditioning: 9209 vs. 7347, p=0.026), but not at later time points. SP-D levels were influenced by use of systemic corticosteroids, declining after initiation of treatment and increasing after discontinuation. Of the patients with aGvHD grade II-IV, 12 (21.4%) later developed BO(S) (P=0.0001).
15 patients (8.4%) developed BO(S) at median day +181 (range: 70-342) post-HSCT; including two fatal outcomes. Pre-conditioning SP-D levels were significantly elevated in patients who later developed BO(S) compared to those who did not (P=0.049) and patients who developed cGvHD without pulmonary involvement (P=0.078) (figure A). No association was found between pre-conditioning SP-D levels and pre-existing or current respiratory disease, including active infection, radiological abnormalities, and FEV1 Z-score (all P≥0.05). In patients with BO(S), post-HSCT SP-D levels and FEV1 Z-scores showed a tendency towards inverse correlation (Figure B). Leading up to the BO(S) diagnosis, SP-D levels increased in patients not actively treated with steroids (n=7). In all BO(S) patients, SP-D levels generally declined after initiation of steroid treatment, except for the two fatal cases where SP-D levels initially fell but subsequently rose again.





Characteristics	N=178

Recipient age (years), median (range)	8.7 (1.1-17.9)
Female recipient sex, no. (%)	71 (39.9%)

Conditioning regimen, no. (%)	
12 Gy TBI + VP16/Cy	35 (19.7%)
Cy + Bu + Mel	36 (20.2%)
Flu + Thio + Bu/Treo	42 (23.6%)
Other chemotherapy-based regimes (MAC)	45 (25.3%)
RIC (Cy / Cy+Flu / TBI 2 Gy + Cy)	20 (11.2%)

Anti-thymocyte globulin as part of conditioning, no. (%)	141 (79.2%)
Sex mismatch (female donor to male recipient)**, no. (%)**	39 (21.9%)
Pulmonary function prior to HSCT (n=110), median (range) FEV1 (Z-score) FVC (Z-score)	-0.92 (-3.59 – 5.55) -0.66 (-3.75 – 3.34)

Conclusions: Elevated plasma levels of SP-D before conditioning were associated with the development of BO(S), but not cGvHD without pulmonary involvement, nor pre-exiting pulmonary disease. These findings suggest that elevated SP-D pre-conditioning may reflect low-grade pulmonary inflammation that either directly or indirectly predisposes to BO(S) and indicate that SP-D may be a potential biomarker for the risk of BO(S) in pediatric HSCT.

HAPLOIDENTICAL HAEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHILDREN USING CD3/CD19 DEPLETED GRAFTS: RESULTS OF A MULTICENTRE PHASE I/II STUDY

Background: The objective of our study was to investigate the clinical feasibility of haploidentical hematopoietic stem cell transplantation (HSCT) in children using CD3+ and CD19+ depletion of the graft, combined with a reduced-toxicity conditioning regimen. We aimed to assess the effects of both the depletion method and the conditioning regimen on

transplant success, toxicity and potential complications. As survival rates improve, late effects of transplants become increasingly significant and must be considered when evaluating the transplant approach.

Methods: Between 2003 and 2013, children and adolescents with both malignant and non-malignant diseases were included in the study and underwent transplantation at seven centers in Germany and Austria. CD3+ and CD19+ depletion of PBSC grafts was performed using the CliniMACS system with magnetic microbeads. A primarily melphalan-based conditioning protocol with reduced toxicity was applied, alongside standard conditioning protocols. In 2024, aftercare clinics, as well as patients and their families, were contacted to assess late effects.

Results: A total of 157 transplants were performed as part of the study. Stable engraftment was achieved in 85% of patients (primary engraftment 95.5%, secondary graft failure 10.8%). Natural killer (NK) cells recovered rapidly, reaching a mean of 300/µl by day +14, while CD3+ cells recovered more slowly, reaching 186/µl after 3 months. The cumulative incidence (CI) of aGvHD III-IV° was 6.4%. Among patients with malignant disease, 55.5% experienced relapse, which was particularly influenced by pre-transplant remission status. Event-free survival at 1 year was 34%, with relapses being the most frequent event. Non-relapse mortality at 1 year was 7.9%. Reactivation of CMV or ADV in the blood was detected in 17.2% and 10.8% of patients, respectively, but less than half developed clinical symptoms. In the long term, serious infections barely occurred. Overall survival was 40%, with a median follow-up of over 12 years. Long-term sequelae were not increased compared to allogeneic HSCT from matched donors. On the contrary, reduced conditioning toxicity and the avoidance of TBI might have reduced certain late sequelae (CI of secondary malignancies 7.7%).

Conclusions: Haploidentical HSCT with CD3/CD19-depleted grafts is feasible and safe in children. Graft manipulation was effective, resulting in low levels of transplanted CD3+ cells, which led to a reduced incidence of critical aGvHD. Rigorous monitoring for viral reactivation, combined with pre-emptive therapy, largely prevented clinical disease. Immune reconstitution was satisfactory, and, in the long term, a functioning immune system derived from the donor was established.
The conditioning regimen was well tolerated, even in heavily pre-treated patients, with a low non-relapse mortality. It also appeared to be beneficial in the long term, including a reduced risk of developing secondary malignancies.
For high-risk patients who did not achieve remission pre-transplant and for those with solid tumors, our regimen was insufficient to reduce relapse risk. However, for patients with adequate remission status it might be suitable. Since prolonged post-transplant immunosuppression is no longer required, our approach represents an optimal platform for several pre-emptive strategies to prevent relapse. These results strongly support the potential role of this haplo-HSCT approach and its evolution, including TCR-alpha/beta and CD45RA depletion.

EMAPALUMAB FOR THE TREATMENT OR PROPHYLAXIS FOR GRAFT FAILURE AFTER HSCT IN CHILDREN

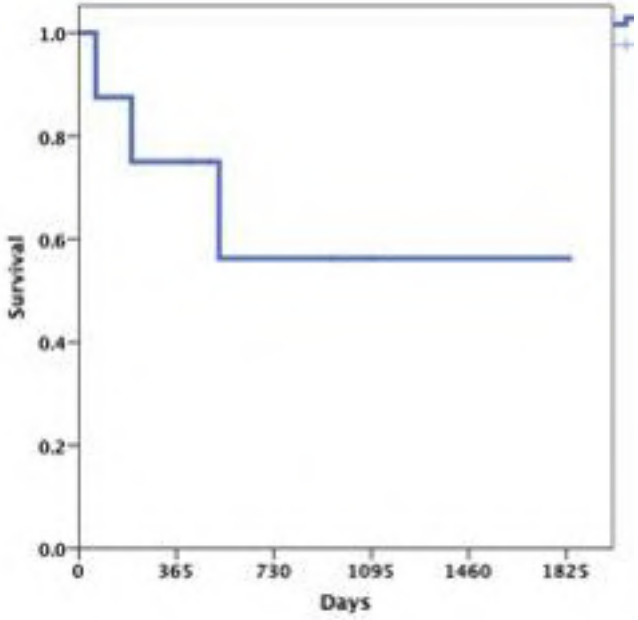
Blanca Molina[1], *Francisco Jose Martinez*[1], *Sara Vinagre*[1], *Marta Gonzalez Vicent*[1]
[1]*Hospital Niño Jesus, Madrid, Spain*

Background: Graft failure (GF) is a severe complication of allogeneic hematopoietic stem cell transplantation (HSCT) and leads to inferior overall survival (OS). The mechanisms involved in this phenomenon are still not completely understood. Interferon gamma (IFNγ) is particularly elevated in graft rejection and prior studies report the essential contribution of IFNγ in this phenomenon. Emapalumab is a fully human IgG1 monoclonal antibody directed against IFN γ and was approved in 2018 by the FDA for primary HLH who have refractory, recurrent or progressive disease or intolerance with conventional HLH therapy. Preliminary efficacy findings suggest Emapalumab merits further study as a potential graft rejection therapy.

Methods: We perform a retrospective study including pediatric patients undergoing HSCT who were treated with emapalumab either as prophylaxis or as treatment for primary or secondary GF since 2022 to 2024. Seven children with a median age of 10 years (range: 2-15) were included. Three was diagnosed of ALL, two of AML and two patients were diagnosed of non-malignant disease. Six patients underwent an haploidentical T-cell depleted peripheral blood transplant and the other one received a bone marrow HLA-identical unrelated donor (UD) transplant. Conditioning regimen was myeloablative in 6 cases and reduce toxicity in one child. Emapalumab was administered for treatment in six patients (5 with secondary GF and 1 with primary GF) and for prophylaxis in the other one with a history of previous GF secondary to HLH. Patients in the "treatment group" (n=6) received Emapalumab once signs and symptoms of graft rejection appeared associated with methylprednisolone and G-CSF. Hemophagocytosis was seen in the bone marrow in 4/6 patients and median ferritine levels at the time of graft failure diagnosis was 6378 ng/ml (range:2358-14255). The other child received Emapalumab for prophylaxis immediately after the graft infusion of the second transplant and continued twice a week until sustained engraftment.

Results: In the treatment group 50% (3/6) of HSCTs achieved engraftment after Emapalumab, while graft rejection occurred in the remaining three patients who received another allogeneic transplantation. In these 3 children Emapalumab was administered for prophylaxis in the second transplant and they all achieved engrafment and full donor chimerism. Across the entire group, the median Emapalumab dose was 3 mg/kg (range 1-6) and the median number of doses was 10 (range 2–26). Emapalumab was well-tolerated in all the cohort. With a median follow-up of 32 months, the overall survival (OS) was 57±10%.

Two patients died from relapse and one from thrombotic microangiopathy.



Conclusions: Currently, there is no effective treatment for graft failure other than a second-transplant. Therefore, Emapalumab could be effective in some patients avoiding the morbidity and mortality associated with a second HSCT. Prospective studies with a larger number of patients are needed to evaluate the efficacy and safety of this drug.

B216

TREOSULFAN OR BUSULFAN: DETERMINANTS OF RELAPSE RISK WITH DIFFERENT CONDITIONING REGIMEN IN CHILDREN WITH ACUTE MYELOID LEUKEMIA

Emanuele Lanino[1,2], *Sofia Giudici*[1,2], *Giovanna Lucchini*[2], *Sonia Bonanomi*[2], *Francesca Vendemini*[2], *Marta Verna*[2], *Pietro Casartelli*[2], *Giulia Prunotto*[2], *Sara Napolitano*[2], *Adriana Cristina Balduzzi*[1,2], *Giorgio Antonio Ottaviano*[2]
[1]*University of Milano Bicocca, Monza, Italy,* [2]*Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy*

Background: Treosulfan-based (TREO) conditioning regimens have increasingly been adopted in pediatric acute myeloid leukemia (AML) undergoing hematopoietic stem cell transplantation (HSCT) as an alternative to busulfan-based (BU) protocols, with the aim of reducing treatment-related toxicity while maintaining anti-leukemic efficacy. Specifically,

children > 12 years-old historically showed higher risk of non-relapse mortality (NRM) with intensive BU-based protocols. However, comparative evidence on post-transplant outcomes remains limited.

Methods: We retrospectively evaluated outcomes of patients with AML undergoing their first allogeneic HSCT at Fondazione IRCCS San Gerardo dei Tintori (Monza, Italy) between 2011 and 2025. BU containing regimens included BuCyMel, BuFlu, BuFluTT and BuCy. TREO containing regimen included TreoFluTT and TreoFlu. Cox proportional-hazards models were used for multivariable analysis. Cumulative incidence of relapse and NRM were calculated using competing-risks methods with Gray's test. Stringent complete remission (sCR) was defined as morphologic CR with negativity for residual disease (MRD) by flow cytometry or PCR. Any MRD positivity was classified as no sCR. cGRFS was defined as time to chronic GVHD, relapse or death.

Results: A total of 77 children met inclusion criteria (median age 9 years, range 0.5–17), with a median post-transplant follow-up of 4.3 years (IQR 1.4–8.7).
Characteristics of the two groups are depicted in Table 1 (BU: n=57; TREO: n=20).

Variable	**Total[1] (n=77)**	**BU-based (n=57)**	**TREO-based (n=20)**	**p-value**
Sex				>0.999
M	44 (57%)	33 (58%)	11 (55%)	
F	33 (43%)	24 (42%)	9 (45%)	
Age at HSCT	9 [3–14]	7 [3–13]	12 [7–16]	0.050
Year of HSCT	2017 [2015–2021]	2016 [2014–2020]	2020 [2020–2022]	0.036
Phase at HSCT				0.442
CR1, MRD–	55 (71%)	40 (70%)	15 (75%)	
CR2, MRD–	8 (10%)	5 (8.8%)	3 (15%)	
No sCR	14 (18%)	12 (21%)	2 (10%)	
Donor type				0.304
Matched	64 (83%)	49 (86%)	15 (75%)	
Mismatched	13 (17%)	8 (14%)	5 (25%)	

Stem cell source				0.647
BM	71 (92%)	53 (93%)	18 (90%)	
PB	6 (7.8%)	4 (7.0%)	2 (10%)	
[1]n (%); Median [Q1–Q3]				

Patients were comparable within the 2 groups for remission status at HSCT, donor matching and stem cells source. Patients receiving TREO were significantly older (median 12 vs 7 years, p=0.05) than those receiving BU. HSCT outcomes showed no significant differences in time to neutrophils/platelet engraftment and risk of aGvHD and cGvHD. 3-year OS was 82.0% (95% CI 72.5–92.8) for BU and 64.6% (95% CI 46.6–89.6) for TREO (p=0.15). 3-year EFS was 76.5% (95% CI 66.1–88.6) for BU and 49.1% (95% CI 31.2–77.3) for TREO (p=0.027). Competing-risks analysis showed a higher 3-year cumulative incidence of relapse in the TREO group (40.9% vs 12.9%; p=0.009), while non-relapse mortality was similar between groups (10.6% vs 10.0%; p=0.945). In multivariable Cox models, conditioning regimen was not significantly associated with OS (HR 2.09, 95% CI 0.78–5.59; p=0.14), however TREO was associated with a lower EFS (HR 2.85, 95% CI 1.19–6.83; p=0.019). 3-year cGRFS was 67.6% (95% CI 56.3–81.2) for BU and 44.4% (95% CI 27.1–72.9) for TREO (p=0.06). sCR status was the strongest independent predictor across all models (OS: HR 2.51, p=0.009; EFS: HR 2.35, p=0.007; GRFS: HR 1.85, p=0.041), whereas age and donor type did not show independent associations with outcomes.

Conclusions: In our cohort, TREO was preferentially used in older patients, and NRM remained comparable between regimens. This observation is consistent with historical reports of higher TRM with BU in adolescents. However, patients receiving TREO had a lower EFS due to a higher cumulative incidence of relapse. Strategies to prevent relapse, including achieving deep remission before HSCT, are highly needed in this subgroup of patients. Confirmation of these findings will require larger multicenter cohorts and randomized studies comparing treosulfan and busulfan.

[1]University of Turin, Turin, Italy, [2]Pediatric Hematology Oncology, Stem Cell Transplantation and Cell Therapy Division, Regina Margherita Children's Hospital, Turinitaly, Italy, [3]IRCCS Istituto G. Gaslini, Genova, Italy, [4]Pediatric Hematology Oncology and Stem Cell Transplantation Unit, Azienda Ospedaliero Universitaria Pisana, Pisa, Italy, [5]Pediatric Hematology, Oncology and Stem Cell Transplant Division, Department of Women's and Children's Health, University Hospital of Padova, Padova, Italy, [6]IRCCS-AOU di Bologna, Policlinico di S. Orsola, Bologna, Italy, [7]Clinical Trial Unit, Regina Margherita Children's Hospital, Turin, Italy

Background: Infections (IDs) and transplant-related complications (TRCs)—including acute GVHD, sinusoidal obstruction syndrome, engraftment/pre-engraftment syndromes, transplant-associated thrombotic microangiopathy, cytokine release post-ATG/ATLG or PTCy—are leading causes of morbidity after pediatric allogeneic HCT and are closely linked to endothelial damage. Differentiating TRCs/IDs from benign 99febrile neutropenia (FN) in the early stages is challenging. Mid-regional proadrenomedullin (Pro-ADM), an endothelial biomarker, improves risk assessment in pediatric FN; however, evidence in HCT is limited.

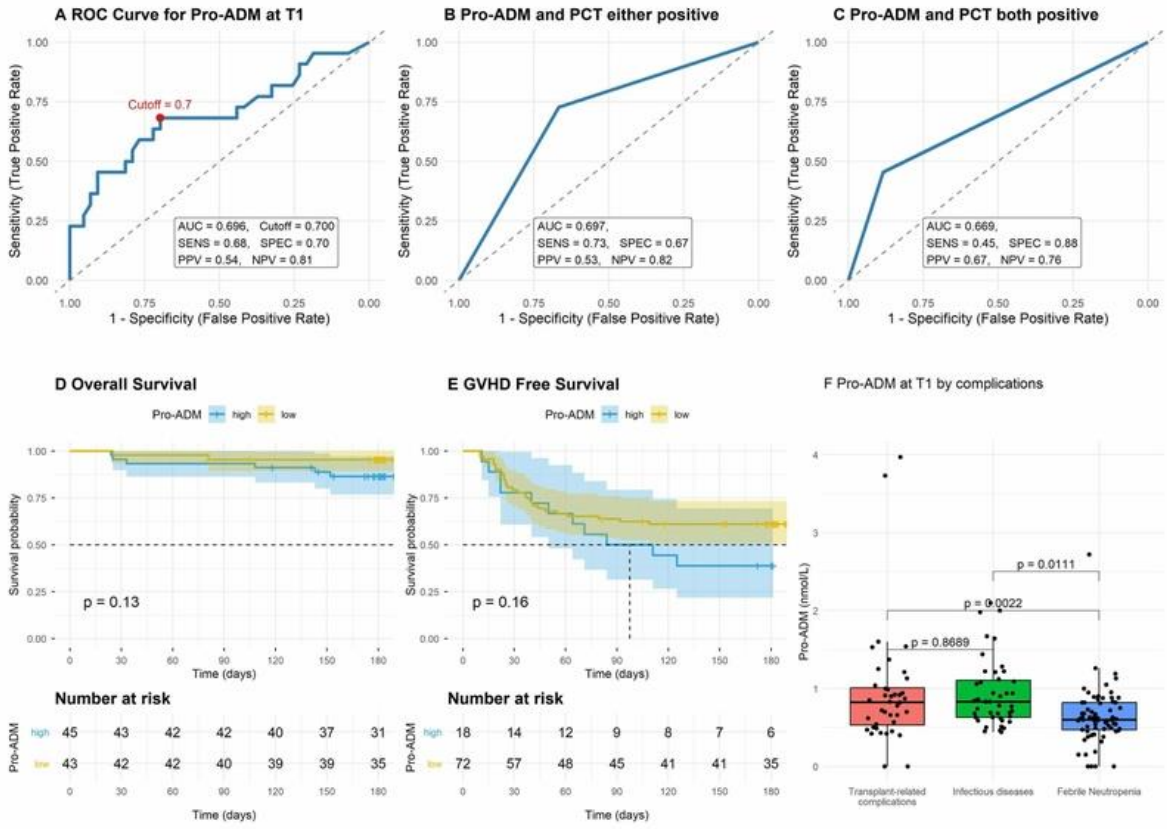
Methods: A multicenter, prospective, observational trial (NCT05523336) involving pediatric allogeneic HCT recipients with serial biomarker sampling. 99 patients enrolled, including 6 screening failures. Pro-ADM (nmol/L) and PCT levels were measured at baseline (before conditioning) and at three predefined time points (T1, T2, T3: days 0, 3, 10) when complications occurred. These were classified as TRCs, IDs, and FN, according to protocol-defined criteria. Linear mixed-effects models with patients as a random effect and Tukey-adjusted pairwise comparisons evaluated biomarker differences among complication types. ROC analyses at T1 assessed Pro-ADM alone and combined Pro-ADM+PCT strategies (either biomarker positive; both positive). Overall survival (OS) and GVHD-related survival were analyzed using Kaplan–Meier curves, stratified by high versus low Pro-ADM, with cutoff points determined via the maximally selected rank statistics.

Results: We examined 98 transplants (see Table 1 for patients' characteristics).

Patients' Characteristics	**1st HCT (N = 89)[1]**	**2nd HCT (N = 9)[1]**
Age ≤ 10 years	46 (50%)	2 (40%)
Malignancy	63 (68%)	5 (100%)
Disease status before HSCT		
CR1	35 (39.4%)	0 (0%)
CR2/CR3	11 (12.3%)	7 (77 %)
Persistent disease	43 (48.3%)	2 (22 %)

Patients' Characteristics	1st HCT (N = 89)[1]	2nd HCT (N = 9)[1]
Myeloablative conditioning regimen	79 (89%)	9 (100%)
Donor		
MFD	16 (18%)	0 (0%)
MMUD/Haplo	24 (27%)	2 (22%)
MUD	49 (55%)	7 (78%)
Stem cell source		
BM	50 (57%)	4 (44%)
PBSC	39 (43%)	5 (55%)
GVHD prophylaxis including ATG	57 (63%)	5 (55%)
GVHD prophylaxis including PTCY	17 (20%)	4 (44%)
[1]n (%)		

We analysed 40 TRCs, 44 IDs, 69 FN episodes. Across serial episodes, median (IQR) Pro-ADM at T1 was higher in TRCs and IDs than in FN: 0.83 (0.52-1.02) and 0.83 (0.63-1.12) versus 0.60 (0.47-0.82) (TRCs vs FN p=0.0022, IDs vs FN p=0.011). At T2, medians were 0.66 (0.52-1.00), 0.79 (0.62-0.92), and 0.55 (0.44-0.65) (TRCs vs FN: p=0.033); at T3, no significant difference was observed. Baseline Pro-ADM levels did not significantly differ among patients with subsequent TRCs, IDs, or FN. ROC analysis at T1 showed Pro-ADM alone had an AUC of 0.696 with a cutoff of 0.70 nmol/L (sensitivity 0.68; specificity 0.70; positive predictive value, PPV 0.54; negative predictive value, NPV 0.81). Combining Pro-ADM and PCT using a either positive rule did not significantly improve performance, whereas the both positive rule approach increased specificity (0.88) and PPV (0.67) while reducing sensitivity (0.45). Time-to-event analyses showed no significant difference in OS between high and low Pro-ADM groups; the cutoff matched the median biomarker value. Similarly, no significant difference was found for the GVHD-related survival endpoint (Figure 1).



Conclusions: In pediatric HCT, Pro-ADM and PCT are practical serial biomarkers that exhibit distinct patterns by episode type. Early measurement of Pro-ADM (T1) offers moderate yet clinically meaningful discrimination between TRCs/IDs and FN. Combining Pro-ADM with PCT in a series approach significantly enhances specificity and PPV for relevant complications, thereby identifying a high-risk group of patients who require closer monitoring and additional diagnostics. Conversely, low Pro-ADM levels support a more conservative treatment approach. Although no impact on short-term survival was observed, these results support the addition of Pro-ADM to early post-HCT assessment protocols and highlight the need for validation in larger cohorts and for future risk-based intervention studies.

REAL-WORLD EXPERIENCE WITH ISAVUCONAZOLE IN ALLOGENEIC STEM CELL TRANSPLANTATION IN PEDIATRIC PATIENTS IN SPAIN

Blanca Molina[1], *Maribel Benitez*[2], *Gloria Miguel*[3], *Eduardo Jesus Bardon*[4], *Yasmina Mozo*[5], *Sara Vinagre*[1], *Marta Gonzalez Vicent*[1], *David Bueno*[5], *Andrea Urtasun*[6], *Ivan Lopez*[7], *Maria Pilar Palomo*[8], *Monica Lopez*[9], *Mercedes Plaza*[10], *Helena Martinez*[11], *Marta Garcia Culebras*[12], *Cristina Diaz De Heredia*[2]
[1]*Hospital Niño Jesus, Madrid, Spain,* [2]*Hospital Vall d'Hebron, Barcelona, Spain,* [3]*Hospital Sant Joan de Deu, Barcelona, Spain,* [4]*Hospital Gregorio Marañon, Madrid, Spain,* [5]*Hospital la Paz, Madrid, Spain,* [6]*Clinica Universitaria de Navarra, Pamplona, Spain,* [7]*Hospital Sant Pau, Barcelona, Spain,* [8]*Hospital Central de Asturias, Oviedo, Spain,* [9]*Hospital Marqués de Valdecilla, Santander, Spain,* [10]*Hospital Virgen de la Arrixaca, Murcia, Spain,* [11]*Hospital la Fe, Valencia, Spain,* [12]*Hospital Virgen del Rocio, Sevilla, Spain*

Background: Fungal infections remain one of the main complications in patients undergoing hematopoietic stem cell transplantation (Alo-HSCT). Isavuconazole (ISV) is a next-generation broad-spectrum triazole that has been recently approved for the treatment for invasive aspergillosis and mucormycosis (when Amphotericin B is not appropriate) in children aged >1 year. The objective of our study is to share our national experience in terms of effectiveness and safety with the use of this drug in pediatric population undergoing Alo-HSCT, both in treatment and in prophylaxis for invasive fungal infections.

Methods: We present a retrospective, multicenter and observational study conducted in 12 hospitals of Spanish Group of HSCT and Cell Therapy (GETH-TC). Our objective was to evaluate the efficacy and safety of ISV use in patients <21 years undergoing Alo-HSCT from January 2019 to June 2025. One hundred patients (63 male, 37 female) with a median of 11 years (range:1-21) were included. The main diagnoses were ALL (36 %), non-malignant disease (34%), and AML (22%). Regarding the type of donor, 44 patients received an haploidentical transplantation, 23 match unrelated donor, 20 matched related donor and 13 mismatched unrelated donor. Most of patients received a mieloablative conditioning regimen (66%) and ICT was administered in 24% of the patients. For 80% was the first Alo-HSCT.

Results: In 70% of patients ISV was used as treatment and in 30% as prophylaxis. Thirty patients had acute graft versus-host-disease (aGVHD) and 20 had chronic GVHD when ISV was started. In the treatment group a total of 70 patients were included. The main reasons for selecting ISV were as second-line treatment due to toxicity with prior treatments (37%) but up to 30% of patients ISV was selected as first-line treatment. Infections were classified as probable in 33 patients (47%), possible in 27 patients (38%) and proven in 10 patients (14%). The most frequent diagnoses were Invasive Aspergillosis (n = 41; 58%). At the end of ISV treatment, 56 of 70 (80%) patients presented with a favourable response (51 complete response and 5 parcial). In the prophylaxis group a total of 30 patients were included, 17 (56%) as primary prophylaxis and 13 (44%) as secondary. Reasons for selecting ISV were a more favorable toxicity profile in 19 patients (63%). The rate of breakthrough IFI was 10% (n = 3). Therapeutic drug monitoring was performed in 69/100 patients. The median ISV dose to reach adequate levels was 6 mg/kg/day (range 2,6-16,6). In 33 patients, the dose had to be increased. Adverse events were reported in 11 patients

(11%) and 9 of them had interrupt the treatment because of it. With a median follow-up of 30 months for the HCST, the overall survival (OS) was 55±11% and only one patient died of invasive fungal infection.

Conclusions: In our experience, ISV appears to be safe and effective for treatment and prophylaxis of IFI in paediatric patients and shows a favorable toxicity profile. A significant proportion of patients showed ISV plasma levels out of the therapeutic range, highlighting the importance of monitoring levels in this population.

BANDICOOT: AN ADAPTIVE PLATFORM TRIAL DESIGNED TO IMPROVE THE COMPLICATIONS, COST-EFFECTIVENESS AND HEALTH OUTCOMES FOR CHILDREN RECEIVING A STEM CELL TRANSPLANT

Hannah Walker[1,2,3], *Chris Selman*[1], *Li-yin Goh*[2], *Katherine Lee*[1,3], *Kristene Rimblado*[2], *Lorna McLeman*[1,2,3], *Peter Summers*[2], *Julian Stolper*[1], *Diane Hanna*[2,3], *David Hughes*[2], *Stacie Wang*[2], *Claudia Toro*[1,2,3], *Deborah Meyran*[1,2,3], *Elizabeth Williams*[1], *Roxanne Dyas*[1], *Lori Chait-Rubinek*[2], *Kaitlyn Taylor*[1], *Tom Snelling*[4], *Theresa Cole*[1,2,3], *Amanda Gwee*[1,2,3], *Anneke Grobler*[1,3], *Rachel Conyers*[1,2,3]
[1]*Murdoch Children's Research Institute, Melbourne, Australia,* [2]*The Royal Children's Hospital, Melbourne, Australia,* [3]*University of Melbourne, Melbourne, Australia,* [4]*University of Sydney, Sydney, Australia*

Background: Multiple challenges face haematopoietic stem cell transplant (HCT) clinical researchers, many of which are unique to this field. Importantly, traditional two-arm randomised trials using frequentist analysis might no longer be fit for purpose for HCT. Adaptive platform trials, which evaluate multiple interventions simultaneously, offer a solution, but rely on a shared primary endpoint that can be used for all interventions/subgroups. No such short-term outcome currently exists in the HCT literature. We designed and evaluated a novel ordinal endpoint within the first 100 days post-transplant for use in an APT, 'BANDICOOT: AN adaptive platform trial Designed to Improve the Complications, cost-effectiveness and health Outcomes for children receiving a stem cell Transplant'.

Methods: A multi-disciplinary working group co-designed and validated a novel ordinal endpoint through literature review, focus groups, and blinded expert input. The endpoint was then evaluated using data from *n*=202 paediatric HCT recipients at The Royal Children's Hospital in Melbourne by (i) examining the distribution of patients across endpoint categories; (ii) assessing the association with long-term outcomes; (iii) evaluating if exposures with known efficacy had the expected associations with endpoints in a multivariate analysis adjusting for pre-transplant factors; and; (iv) assessing feasibility of collection from a clinician and consumer perspective.

Results: Through co-design with clinicians and individuals with lived experience, a primary ordinal endpoint that includes (i) CD4+ reconstitution; (ii) viral infection; CMV, EBV, HHV6 and adenovirus (at viral threshold and viraemia duration) and (iii) major and minor organ support was established (Table in Figure below). This novel endpoint utilises the combination of clinical outcomes; (viral reactivation, immune reconstitution (CD4 count) and organ support) to rank a patient from a good score (level 1) through to a poor score (level 5). The endpoint was evenly distributed across categories when applied to the HCT cohort of 202 patients. Associations with key exposures (e.g. donor type and cell source) were mostly in the expected direction e.g. patients who received a matched sibling donor transplant scored lower in the ordinal endpoint compared to patients who received haploidentical donor transplants. Importantly, the endpoint (censored at Day 100) correlated with traditional long-term HCT complications, including relapse, chronic-graft-versus-host disease, and death up to 5 years post HCT. These results, coupled with expert feedback from clinicians and family representatives identified that that the endpoint, was both feasible and relevant for use in BANDICOOT.

Novel Ordinal Endpoint

Worse outcome

Best outcome

Category	Criteria in the first 100 days post HCT
5	**Any of** (i) Death (ii) Graft loss requiring second HCT (iii) Relapse* (iv) Multi-organ support ≥ 14 days
4	**Any of:** (i) Persistent significant viraemia for any of adenovirus, CMV, EBV or HHV6 for ≥21 days and/or >1 viral reactivation for > 14 days# (ii) highest CD4+ T cells < 0.05 $CD4^+$ X 10^9/L (iii) Multi-organ support < 14 days.
3	**Any of** (i) Moderate duration of significant viraemia for any of adenovirus, CMV, EBV or HHV6 for 14- <21 days (inclusive) and/or >1 viral reactivation 14 days or less#. (ii) highest CD4+ T cells 0.05 - < 0.1 X 10^9/L (iii) Single organ support ≥ 10 days
2	**Any of:** (i) Short duration of significant viraemia for any of adenovirus, CMV, EBV or HHV6 for (ii) highest CD4+ T cells 0.1 - < 0.3 X 10^9/L (iii) Single organ support < 10 days
1	**All of:** (i) No significant viraemia (ii) highest CD4+ T cells ≥ 0.3 X 10^9/L (iii) No organ support.

Relapse defined as: minimal residual disease positivity > 10^{-4} or image confirmed extramedullary relapse. Significant viraemia defined as: HHV6 > 10^4, adenovirus positive on 2 occasions at least a week apart and/or EBV > 10^4 and/or CMV > 10^3

#>1 viral reactivation do not have to occur concurrently. All measures are counted from HCT admission.

Results

- Endpoint outcomes: day 100 post HCT for each patient
- This showed that 10% of patients had the worst outcome (category 5) and 12% of patients had the best outcome (category 1)

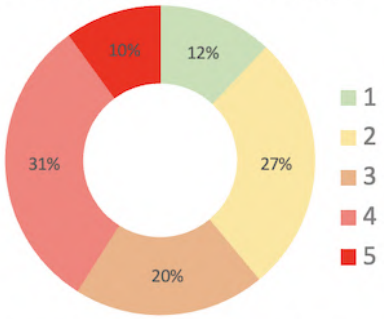

Figure 1: Distribution of patients across each category of the best performing ordinal endpoint (shown in Table 1)

Figure 2: Probability of developing cGVHD based on a patients score in the primary ordinal endpoint

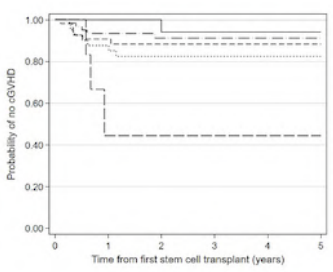

Figure 3: Probability of survival based on a patients score in the primary ordinal endpoint

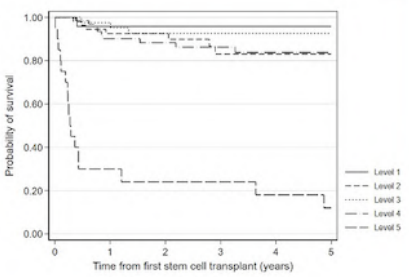

- *Each endpoint category was associated with longer term HCT outcomes*
- *Category 5 patients had increased risk of adverse outcomes beyond day 100.*
- *The final endpoint was based on statistical performance and stakeholder feasibility.*

Conclusions: Our novel ordinal endpoint , measured at day 100 post HCT, is a paradigm shift away from traditional binary endpoints such as overall survival, graft versus host disease free survival and relapse free survival, which do not sufficiently incorporate the patient voice or accurately depict a patients worst outcome, often only the first. The BANDICOOT APT will transform paediatric HCT research, introducing a novel ordinal endpoint applicable across multiple outcomes. Future HCT advancements require global collaboration. The APT model accelerates progress, enabling rapid evaluation and refinement of interventions. BANDICOOT provides a scalable framework, ensuring faster access to optimal, evidence-based care for children.

ORAL SUPPLEMENTATION VS ENTERAL VIA NASO-GASTRIC TUBE VS PARENTERAL NUTRITION AS NUTRITIONAL SUPPORT AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE STUDY

Francesco Paolo Tambaro[1], *Francesco Fabozzi*[1], *Riccardo Masetti*[2], *Fabiana Cacace*[1], *Gennaro Pagano*[2], *Valeria Caprioli*[1], *Francesco Cecere*[1], *Maria Rosaria D'Amico*[1], *Giuseppina De Simone*[1], *Emanuela Rossitti*[1], *Davide Leardini*[2], *Edoardo Muratore*[2], *Maria Simona Sabbatino*[1]
[1]*AORN Santobono Pausilipon, Naples, Italy,* [2]*Azienda Ospedaliero-Universitaria di Bologna Policlinico di Sant'Orsola, Bologna, Italy*

Background: Deterioration of nutritional status in recipients of allogeneic hematopoietic stem cell transplantation (HSCT) is associated with increased morbidity. Although enteral nutrition (EN) has been favorably associated with improved outcomes compared with total parenteral nutrition (TPN), TPN remains first-line nutritional support in many pediatric transplant centers, mainly due to physician- and caregiver-related barriers. Oral nutritional supplementation (ON) may represent a feasible alternative capable of overcoming these limitations. However, evidence supporting the adequacy of ON in pediatric HSCT recipients remains limited.

Methods: We retrospectively evaluated the impact of three nutritional support modalities, oral nutrition (ON), enteral nutrition (EN), and total parenteral nutrition (TPN)—on nutritional status in children undergoing allogeneic HSCT. Nutritional status was assessed by body mass index (BMI) at ward admission and at day +30 post-transplant.
Patients were treated at two Italian pediatric centers: Santobono-Pausilipon Children's Hospital (Naples) between 2014 and 2023, and IRCCS Sant'Orsola (Bologna) between 2020 and 2023.
Secondary endpoints included associations between nutritional modality and HSCT outcomes: time to neutrophil and platelet engraftment (defined as the first of three

consecutive days with absolute neutrophil count >500/mm³ and platelet count >20,000/mm³ without transfusion support, respectively), length of hospitalization, and incidence of grade III–IV acute graft-versus-host disease (aGVHD) according to MAGIC criteria.

Results: Patient characteristics are summarized in Table 1. A decrease in BMI was observed across all groups after HSCT, with a median change of −0.6 kg/m² (range −9.86 to +12.29; IQR −1.34 to −0.04). BMI reduction was greater in males ($p<0.05$) and directly correlated with age ($p=0.0017$).
Patients receiving EN experienced a significantly smaller BMI decrease compared with other groups (median −0.45 kg/m²; range −2.18 to +3.95; IQR −0.67 to −0.15; $p<0.05$). In contrast, patients supported with TPN showed the greatest BMI reduction (median −1.1 kg/m²; range −9.86 to +0.58; IQR −1.78 to −0.36; $p<0.05$ vs all other groups). Notably, ON resulted in an intermediate outcome (median −0.91 kg/m²; range −4.09 to +12.29; IQR −1.66 to −0.06), neither significantly worse than EN ($p=0.0785$) nor better than TPN ($p=0.514$).
Median length of hospitalization was significantly associated with nutritional modality ($p<0.001$). EN was associated with the shortest hospital stay (median 35 days; range 25–193; IQR 30–44), while TPN resulted in the longest hospitalization (median 55 days; range 32–135; IQR 44–70). Patients receiving ON had a median hospitalization of 42 days (range 27–147; IQR 36–53), significantly shorter than TPN ($p<0.001$) and longer than EN ($p<0.05$).
Severe aGVHD (grade III–IV) occurred in 6/47 patients receiving ON, 5/41 receiving TPN, and 7/37 receiving EN. Nutritional modality was not significantly associated with severe aGVHD incidence ($p=0.691$).

	Overall (N=125)	Total Parenteral Nutrition (N=41)	Oral Nutrition (N=47)	Enteral Nutrition (NGT) (N=37)	P-value
Median age at HSCT [range, IQR], years	8.8 [0.3-20.7; 4.3-13.1]	10.1 [0.8-18.6; 4.5-13.7]	8.4 [0.3-18; 3.5-12.8]	8.5 [3.1-20.7; 4.7-12.5]	p = 0.67*
Sex:					
Male (%)	83 (66%)	23 (56%)	33 (70%)	27 (74%)	p = 0.234^
Female (%)	42 (34%)	18 (44%)	14(30%)	10 (26%)	
Disease:					
Malignant (%)	93 (74%)	31 (76%)	30 (64%)	31 (83%)	p = 0.12^
Not Malignant (%)	33 (26%)	10 (24%)	17 (36%)	6 (16%)	
Median weight before HSCT [range, IQR], kg	28 [5.5-85; 16-48.5]	27.3 [5.5-85; 16-54]	28 [5.52-76.7; 14.25-43.975]	30 [13-90; 19-58.4]	p = 0.485*
Median weight after HSCT [range, IQR], kg	25.5 [5.5-79.7; 16.1-45.4]	24.3 [5.45-79.7; 15.7-49]	26.3 [5.6-72.5; 14.4-41.1]	28 [12.8-77.5; 18.4-50.3]	p = 0.429*
Median BMI before HSCT [range, IQR]	17.1 [6-33.7; 15.3-20.4]	16.9 [6-33.7; 14.7- 21.1]	17.3 [8-27.1; 15.4-20]	17.6 [12.7-27; 15.7-20]	p = 0.912*
Median BMI after HSCT [range, IQR]	16.7 [6-32.6;14.6-19.1]	16.3 [5.6-32.6; 13.9-19.1]	17.2 [12.6-26.8; 15.3-18.9]	17 [13.2-27.2; 14.8-19.6]	p = 0.435*

Similarly, no significant differences were observed among groups in time to neutrophil or platelet engraftment.

Conclusions: ON supplementation showed intermediate outcomes, comparable to EN and superior to TPN in terms of length of stay, without negatively affecting engraftment or severe aGVHD. When supported by high-calorie supplements, ON may represent a feasible alternative to enteral feeding in selected patients when clinical conditions or compliance do not allow tube feeding.

Disclosure: NO COI

POST-TRANSPLANT LYMPHOPROLIFERATIVE DISEASE IN PEDIATRIC PATIENTS RECEIVING LETERMOVIR AS CMV INFECTION PROPHYLAXIS

Katarzyna Smalisz[1], *Anna Zaniewska-Tekieli*[1], *Anna Sarnecka-Paruch*[1], *Magdalena Wozniak*[1], *Aleksandra Krasowska-Kwiecien*[1], *Oktawiusz Wiecha*[1], *Sylwia Bartyzel-Palinska*[1], *Jolanta Gozdzik*[1]
[1]*Jagiellonian University Medical College, Cracow, Poland*

Background: Among patients after allogeneic hematopoietic stem cell transplantation (HSCT), EBV can cause the development of a serious complication known as post-transplant lymphoproliferative disorder. (PTLD). In patients receiving letermovir prophylaxis, a higher risk of EBV reactivation is observed, including PTLD symptoms.The aim of this study is to assess the occurrence of EBV infection reactivation and its severity in children receiving letermovir for CMV prophylaxis after HSCT.

Methods: The population of children undergoing alloHSCT at the Department of Hematopoietic Stem Cell Transplantation, University Children's Hospital in Cracow, Poland, between 2023 and 2025 was analyzed. In total, 72 alloHSCT procedures were included in the analysis. Letermovir prophylaxis was administered to 34 children. EBV infection was identified in 6 children receiving letermovir. The analysis included patients who experienced EBV reactivation requiring preemptive therapy.

Results: The frequency of EBV reactivation was 18% (6/34). The time of EBV reactivation ranged from +39 to +123 days after HSCT, with a median of +79 days. Reactivation occurred in children aged 3-18 years, with a median age of 14. Only in 1 patient was the infection asymptomatic and detected solely during routine post-HSCT testing. In 83% (5/6) of patients, PTLD was diagnosed, presenting with massive painful lymphadenopathy, fever, and pancytopenia. All patients (100%, 6/6) were treated with Rituximab. In 2 patients, progression to non-Hodgkin lymphoma occurred in the course of PTLD, and R-CHOP chemotherapy was initiated. No deaths related to PTLD were observed in the study group.

Conclusions: CMV prophylaxis with letermovir may increase the risk of severe EBV reactivation. Intensive monitoring of patients receiving letermovir for EBV reactivation is recommended, particularly around 3 months after HSCT, especially in children over 14 years of age.

Disclosure: No conflict of interests.

TREOSULFAN-BASED CONDITIONING REGIMENS ARE SAME EFFECTIVE, BUT LESS TOXIC IN COMPARISON WITH BUSULFAN-BASED IN PEDIATRIC SOLID TUMORS: RESULTS OF RETROSPECTIVE ANALYSIS FROM 148 PATIENTS

Teimur Aliev[1], *Kirill Kirgizov*[1], *Ilya Kazantsev*[2], *Marina Rubanskaya*[1], *Elena Machneva*[1], *Irina Kostareva*[1], *Nara Stepanyan*[1], *Natalia Burlaka*[1], *Olga Romantsova*[1], *Daria Smirnova*[1], *Karina Sergeenko*[1], *Maria Malova*[1], *Anatoly Kazantsev*[1], *Garik Sagoyan*[1], *Amina Suleymanova*[1], *Alexey Slinin*[3], *Lyudmila Zubairovskaya*[2], *Svetlana Varfolomeeva*[1]
[1]*Lev Durnov Research Institute of Pediatric Oncology and Hematology of N.N. Blokhin National Medical Research Centre of Oncology, Moscow, Russian Federation (the),* [2]*First Pavlov State Medical University of St. Petersburg, Saint Petersburg, Russian Federation (the),* [3]*Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Im-munology, Moscow, Russian Federation (the)*

Background: Autologous hematopoietic stem cell transplantation (aHSCT) is effective way of consolidation therapy in neuroblastoma (NB) and Ewing sarcoma (ES). Balance between toxicity and efficacy is important.
We aimed to present the data of retrospective analysis from 2 centres describing toxicity and efficacy of aHSCT for the patients with NB and ES.

Methods: Our retrospective study includes 148 patients with NB (n=116, 78%) and ES (n=32, 22%). M:F=62(46%):86(54%). All patients received aHSCT with treosulfan/melphalan or busulfan/melphalan conditioning in 2021-2023. Age median was 5.1 y.o. [8 months – 17 y.o.]. The majority of patients (73.6%) received aHSCT as a part of first-line therapy with complete response in 72.9% cases. HSCT with Treosulfan-based conditioning regimen received 89 patients (60.1%) and Busulfan-based – 59 (39.9%). Median infused dose of CD34+ cells was 7.1*10 6 /kg. Toxicity as well as overall survival and relapse-free survival estimated.

Results: All patients engrafted. Median day of engraftment was better in treosulfan group (11 vs 15). Toxicity rates were better in treosulfan group both mucositis and neutropenia: grade 3-4 – 12% in treosulfan group and 25% in busulfan group ($p<0.005$). Toxic deaths: treosulfan: n=2 (2.24%) and busulfan n=2 (3.4%). No differences were found in nutrition insufficiency, viral reactivations and hemorrhagic complications. At the median of FU of 2 years OS was higher in treosulfan group (78.1% vs 73.1%) as well as RFS (65.3% vs 59.8%), but no statistical difference found.

Conclusions: Treosulfan-based conditioning regimen is safe and effective for NB and ES. Less organ toxicity found in patients with treosulfan-based conditioning regimen in comparison with busulfan-based conditioning. Large multicenter studies required.

Disclosure: There are no conflicts of interest.

Background: Unrelated cord blood transplantation (CBT) is a well-established treatment approach for pediatric patients with acute leukemia. While both Europe and Japan have accumulated extensive CBT experience and have robust programs, differences in clinical practice and patient characteristics exist. However, studies directly comparing European and Japanese pediatric populations, side by side, are limited. This study uniquely evaluates CBT from both regions, allowing easy comparison of outcomes and prognostic factors of single-unit CBT for children with acute leukemia between these two distinct populations.

Methods: Retrospective analysis of patients aged <18 years who underwent first single-unit CBT for acute lymphoblastic leukemia (ALL) or acute myeloid leukemia (AML) between 2005 and 2020. Clinical data were retrieved from Eurocord/EBMT and JSTCT (Japan Society for Transplantation and Cellular Therapy) registries. Multivariate analyses (MVA) were performed separately for each registry, using Cox regression or Fine-Gray regression as appropriate.

Results: A total of: 1,645 from Europe and 1,131 from Japan were included in the analyses. The proportion of more advanced disease status at CBT was higher in Japan than in Europe (30% vs. 7%). The infused cell dose was significantly higher in Europe (median TNC 7.1 vs.

5.2 $\times 10^7$/kg; $CD34^+$ 2.6 vs. 1.7 $\times 10^5$/kg), while the use of total body irradiation (TBI) in conditioning regimens was more frequent in Japan (64% vs. 38%). Anti-thymocyte globulin (ATG) was used in 65% of European patients but only in 3% of Japanese patients.
Five-year OS was 62% (95% CI, 59-65%) in the Japanese cohort and 55% (52-57%) in the European cohort ($p<0.001$). In MVA, advanced disease status was associated with higher mortality in both cohorts. In Japan, lower CD34+ cell dose, multiple HLA mismatches, and earlier transplant year were also significant risk factors, whereas in Europe, ALL diagnosis and CMV positivity were significant predictors of higher mortality.
The cumulative incidence of aGVHD grades II-IV was 37% (95% CI, 34-40%) in Japan and 32% (95% CI, 29-34%) in Europe. In MVA, factors associated with higher aGVHD included higher TNC dose, MAC regimens, TBI use, and greater HLA mismatches in Japan, while male gender, younger age at CBT, and conditioning without ATG were significant in Europe. The CI of cGVHD was 22% (95% CI, 19-25%) in Japan and it was 14% (95% CI, 12-16%) in Europe.
The 5-year CI of relapse was slightly higher in Japan (31% vs 26% in Europe, $p=0.00121$). Conversely, 5-year NRM was higher in Europe than Japan (22% vs 11%, $p<0.001$).

Conclusions: This joint study of pediatric single-unit cord blood transplantation for acute leukemia reveals distinct transplant practices, as well as different outcome patterns and prognostic factors between Japanese and European cohorts. While OS was higher in Japan compared to Europe, relapse rates were lower for patients in the European cohort. Advanced disease status emerged as a consistent predictor of poor outcomes across both regions. However, other risk factors impacted the individual cohorts differently. These findings emphasize the importance of tailoring transplant strategies to regional practices to optimize outcomes in pediatric acute leukemia.

ENTERAL VERSUS PARENTERAL NUTRITION IN PEDIATRIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE EVALUATION OF FEASIBILITY, CLINICAL OUTCOMES, AND RESOURCE UTILIZATION

Noura Alamri[1], Viqaruddin Mohammed[1], Sawsan Albalawi[1], Muhammad Zulfiqar[1], Syed Jafri[1], Abdullah Aljefri[1], Awatif Alanazi[1], Saadiya Khan[1], Ali AlAhmari[1], Mouhab Ayas[1], Reuof Alrumeih[1], Fatimah Hakami[1], Sarah Abahussain[1], Rafat Malkawi[1], ***Hawazen Alsaedi***[1]
[1]*King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia*

Background: Children undergoing hematopoietic stem cell transplantation (HSCT) are vulnerable to early post-transplant malnutrition due to impaired oral intake and treatment-related toxicities. Optimal nutritional support—enteral nutrition (EN) versus parenteral nutrition (PN)—remains a subject of debate in pediatric HSCT practice. EN is physiologic, maintains gut integrity, and may reduce infectious complications, whereas PN is often used when EN is assumed to be poorly tolerated. This study evaluates the tolerability of EN and compares its impact on clinical outcomes, early toxicities, and healthcare resource utilization during the first 100 days post-HSCT.

Methods: A retrospective cohort analysis was conducted following a shift prioritizing EN. Pediatric patients aged ≤14 years who underwent HSCT between 2015 and 2024 were included. The PN cohort comprised patients transplanted from 2015–2019, while the EN cohort included those transplanted from 2020–2024. Patients undergoing subsequent transplants were excluded. Clinical outcomes assessed included time to neutrophil and platelet engraftment, infectious complications, mucositis, graft-versus-host disease (GVHD), day-100 mortality, and length of stay. Data were extracted from institutional databases and analyzed using standard comparative statistics.

Results: A total of 1,246 pediatric HSCT patients met inclusion criteria, with a median age of 4.66 years (range 0.1–14.4). Females represented 56% (n=693), and males 44% (n=553). Most procedures were allogeneic HSCT (92%, n=1,150), with autologous HSCT accounting for 8% (n=96). Non-malignant disorders constituted 76% of indications, while malignant conditions comprised 24%. Among allogeneic recipients, 66% (n=757) received matched-related donor grafts, 23% (n=263) haploidentical grafts, and 11% (n=130) matched-unrelated donor grafts. Bone marrow was the predominant graft source (81%). Overall, 51% (n=632) received PN, and 49% (n=614) received EN, yielding a control-to-intervention ratio of 1.03:1. EN was associated with significantly faster neutrophil recovery (15.3 vs. 16.7 days; $p<0.001$) and platelet engraftment (28.5 vs. 33.4 days; $p<0.001$). EN recipients had lower rates of bacterial infections (190 vs. 262; $p<0.001$) and mucositis (157 vs. 214; $p<0.001$). Among allogeneic HSCT patients, the EN recipients showed a significantly lower incidence of Grade II – IV, GVHD compared to the PN (38 vs. 20; $p=0.044$. Overall day-100 mortality was 9%, with lower mortality in the EN group compared with PN (48 vs. 65 deaths; $p=0.535$). Resource utilization analysis demonstrated a significantly shorter average length of stay among EN recipients (29 vs. 49 days; $p=0.038$), reflecting reduced toxicities and improved recovery trajectories. Institutionally, this project was presented as a quality

improvement initiative and received the Performance Improvement Award for its measurable clinical and cost-saving impact.

Conclusions: Enteral nutrition was well tolerated in pediatric HSCT and associated with faster engraftment, reduced infectious and mucosal toxicities, and lower healthcare resource utilization compared with PN. Gut GVHD rates were lower in the EN group continues to decline with ongoing practice refinement as follow-up data demonstrates a further declining trend in acute GVHD during 2025. These findings support EN as a safe, feasible, and potentially superior nutritional strategy in pediatric HSCT. Future multi-center studies are needed to validate these results and guide standardized nutritional-support recommendations and its impact on healthcare resource utilization.

Clinical Trial Registry: Not Applicable.

Disclosure: Nothing to Declare.

DAY +60 B LYMPHOCYTES POST-TRANSPLANT AS AN EARLY PREDICTOR OF CHRONIC GVHD

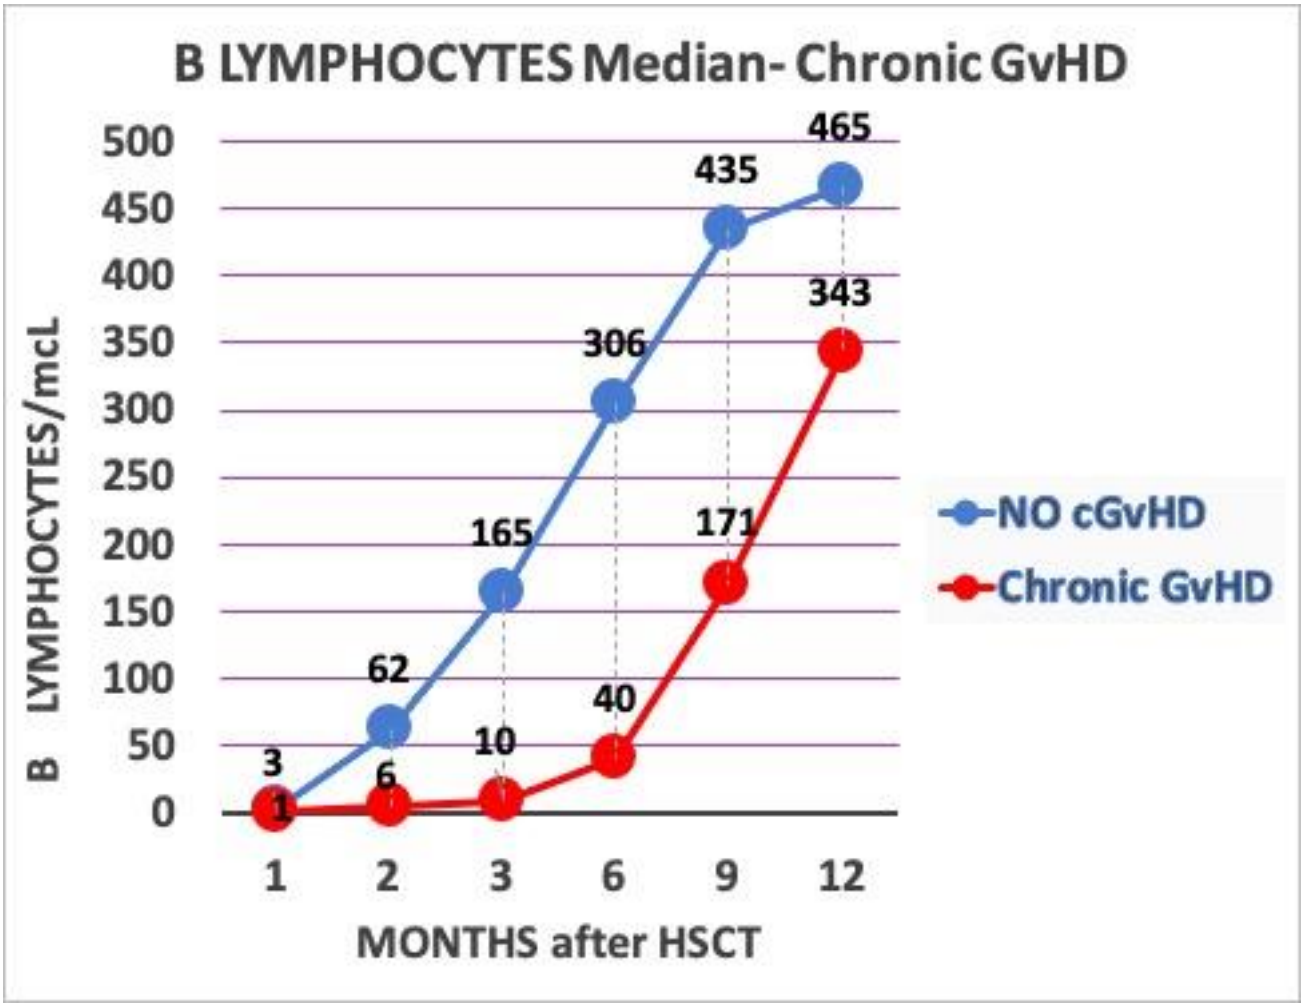
Marta Gonzalez Vicent[1], *Blanca Molina*[1], *Sara Vinagre*[1], *Elena Sebastian*[1], *Guzman Lopez De Hontanar*[1], *Jorge Verdejo*[1], *Josune Zubicaray*[1], *Ana Castillo*[1], *Julian Sevilla*[1], *Manuel Ramirez*[1], *Miguel Angel Diaz*[1]
[1]*Hospital Niño Jesus, Madrid, Spain*

Background: Risk biomarker analyses for chronic GVHD (cGVHD) after HSCT in children are scarce. Recently, a 5-biomarker panel (IL1RL1, REG3α, MMP3, DKK3, and sCD163) measured 3 months post-HSCT was shown to predict susceptibility to cGVHD and was associated with TRM. However, these biomarkers are not routinely available in most centres. Therefore, we evaluated a more accessible approach based on post-transplant lymphocyte subset recovery.

Methods: We conducted a retrospective study of children with leukaemia who underwent haploidentical HSCT with T-cell depletion between 2005 and 2020. A total of 159 children were included, with a median age of 9 years (range, 1–19), diagnosed with ALL (n = 80) or AML (n = 79). One hundred and six were male (67%) and 53 were female (33%). Forty patients were in CR1 (25%), 66 in CR2 (42%), and 53 in ≥CR3 or had active disease (33%). The median donor age was 40 years (range, 2–54). Donors were parents in 143 cases and siblings in 16 cases. Most donors (84%) had a KIR-B genotype. Conditioning was mainly based on fludarabine, busulfan, and thiotepa. Patients received a T-cell–depleted peripheral blood graft containing a median CD34+ dose of 8 × 10^6/kg.
The primary objective was to identify risk factors for cGVHD. Secondary objectives included analysis of TRM and OS.

Results: The cumulative incidence (CI) of acute GVHD was 33 ± 6% at a median onset of 30 days, with 18% being grade III–IV. The CI of cGVHD was 27 ± 5% at a median onset of 120 days, with 7% being moderate or severe.

We evaluated lymphocyte subsets on day +60 as potential predictors of cGVHD.
In univariate analysis, both prior acute GVHD (55 ± 7% vs 15 ± 4%, p = 0.0001) and as early as day +60 B-cell counts (≤ median 15/µL: 59 ± 8% vs > median: 22 ± 6%, p = 0.00001, Figure 1) were associated with cGVHD risk.



In multivariate analysis, prior acute GVHD (yes vs no; HR 2.27, 95% CI 1.1–4.9, p = 0.042) and B-cell counts at day +60 (≤ median vs > median; HR 3.5, 95% CI 1.6–7.5, p = 0.001) independently predicted cGVHD development.
With a median follow-up of 6 years (range, 1–16), TRM and OS varied according to the day +60 B-cell count, below median it was TRM 35 ± 7%, OS 44 ± 7% vs above median: TRM 9 ± 4% and OS 70 ± 6%.
We developed a risk score for cGVHD based on Cox regression HR (0, 1, or 2 points), incorporating prior acute GVHD and day +60 B-cell count: 0 points: cGVHD 15 ± 6%, 1 point: cGVHD 32 ± 6% and 2 points: cGVHD 78 ± 10% (p = 0.001).

Conclusions: The incorporation of these readily accessible clinical and immunological risk factors enables early prediction of chronic GVHD and informs clinical management as early as day +60 post-transplant.

Background: Chronic graft-versus-host disease (cGvHD) is a major cause of late morbidity and mortality following allogeneic hematopoietic stem cell transplantation (aHSCT) and remains a major focus within the European Society for Blood and Marrow Transplantation (EBMT). In pediatric and young adult patients, effective treatments beyond first-line corticosteroids is particularly challenging due to cumulative toxicity, and limited availability of evidence-based second-line options. Belumosudil, a selective ROCK2 inhibitor, has shown promising results in adult steroid-refractory (SR) cGvHD; however, pediatric data are scarce,

and European practices have not yet been systematically described. As EBMT updates its guidelines for GvHD management, real-world pediatric experiences are essential to shape consensus and address gaps in access and implementation.
Objective: To characterize current real-world use of belumosudil in children and young adults with SR cGvHD across European EBMT centres, including indications, dosing, timing of initiation, combination therapies, and observed safety signals.

Methods: The Pediatric Diseases Working Party (PDWP) conducted a retrospective survey to EBMT centres collecting information on belumosudil use in pediatric and young adult patients. The survey captures centre-level prescribing patterns and patient-level safety data.

Results: Twenty-seven centres reported their experience with 100 patients treated with belumosudil. Most patients (n=78) received belumosudil specifically for SR cGvHD. The majority of centres (65%) initiated belumosudil after inadequate response to two previous lines of therapy, and 61.5% reported use after two or more lines. Nine centres also reported organ-specific indications for belumosudil. Across centres, the number of treated patients ranged from 1 to 20. The most frequently used total daily dose was 200 mg (85% of centres), followed by 100 mg (three centres) and 400 mg (one centre). Therapy was started 6–12 months after cGvHD diagnosis in 46% of centres, 3–6 months in 32%, 1–3 months in 11%, and at SR cGvHD diagnosis in 11%. Most centres (94%) defined SR cGvHD as progression despite adequate steroid exposure, while 42% reported using multiple criteria, including incomplete response after 4–8 weeks of steroid treatment or steroid intolerance. Belumosudil was commonly used alongside ECP, ruxolitinib, sirolimus, or other immunomodulatory approaches. All experienced centres agreed to participate in a retrospective patient-level study. With reported use in children (0–12 years; 18 centres (72%)), adolescents (13–17 years; 10 centre (40%), and young adults (18–21 years; n=9 centres (33%)). These centres are in the process of being contacted, and detailed data will be made available at the meeting. Reported centre-level significant adverse events included nausea (48%), fatigue (37%), infections (30%), diarrhea (22%), liver toxicity (22%), renal impairment (15%), and headache, thrombocytopenia and visual disturbances one centre each.

Conclusions: This PDWP survey reveals widespread yet heterogeneous use of belumosudil for pediatric and young adult SR cGvHD across centres in Europe, with a generally manageable safety profile. These findings emphasize the need for harmonized EBMT guidance, highlight barriers such as limited drug availability in some countries, and serve as a vital foundation for upcoming EBMT recommendations and patient-level outcome studies.

THE DONOR'S FINGERPRINT: PEDIATRIC DONOR CELL LEUKEMIA

Aharon Gefen[1], *Hanan Ashkar*[1], *Dina Rosenberg*[1], *Hazim Khatib*[1], *Mariam Daher*[1], *Adi Shapira*[1], *Avigail Eisenberg Wygoda*[1], *Nira Arad-Cohen*[1]
[1]*Rambam Health Care Campus, Haifa, Israel*

Background: Most relapses of acute leukemia after allogeneic HSCT reflect re-emergence of the patient's original malignant clone. Donor Cell Leukemia (DCL) is a rare post-transplant relapse arising from donor-derived cells, identified by donor-specific mutations or cytogenetic markers (e.g., XX/XY in sex-mismatched transplants) present in donor and leukemic cells, but absent in the original leukemia. Proposed pathogenic mechanisms include transmission of a pre-malignant donor clone, host bone marrow microenvironment dysfunction, or multifactorial donor–host interactions. The incidence is 2–5% of relapses. The true incidence of pediatric DCL (pDCL) is presumed to be lower.

Methods: We describe a pDCL case occurring after allogeneic HSCT, including serial molecular analysis of recipient and donor samples. Retrospective testing of stored bone marrow specimens was performed to track clonal evolution over time. In addition, a literature review of previously reported pDCL cases was conducted.

Results: A 7-year-old boy was diagnosed in October 2020 with Ph-like pre–B- ALL. He achieved complete remission with chemotherapy and tyrosine kinase inhibitor therapy but experienced an early relapse with isolated CNS involvement and MRD-positive bone marrow. In December 2021, he underwent haploidentical HSCT from his apparently healthy father and achieved sustained molecular remission with full donor chimerism.
In April 2024, while maintaining complete donor chimerism, he developed a second leukemia- AML. Next-generation sequencing revealed mutations in DNMT3A R882C (41% variant allele frequency [VAF]) and two presumed biallelic RUNX1 (W106L and G199W; VAF 24% and 26%). Peripheral blood testing of the donor demonstrated the identical DNMT3A mutation (20% VAF), consistent with a pre-leukemic donor clone, while RUNX1 mutations were absent. The donor remains clinically healthy with normal blood counts.
Retrospective analysis of stored recipient bone marrow samples identified the DNMT3A mutation approximately 10 months prior to AML diagnosis, whereas RUNX1 mutations emerged only 2 months before diagnosis, supporting stepwise leukemic transformation of donor-derived cells. Following treatment with azacitidine and venetoclax, the patient achieved morphological remission but with persistent molecular disease. In July 2024, he underwent a second HSCT from a matched unrelated female donor. As of November 2025, he remains in molecular complete remission, with full second-donor chimerism and no detectable DNMT3A or RUNX1 mutations (NGS sensitivity 0.5%). Table presents a literature review of pDCL, including current case. Figure illustrates the clinical and molecular data of this patient.

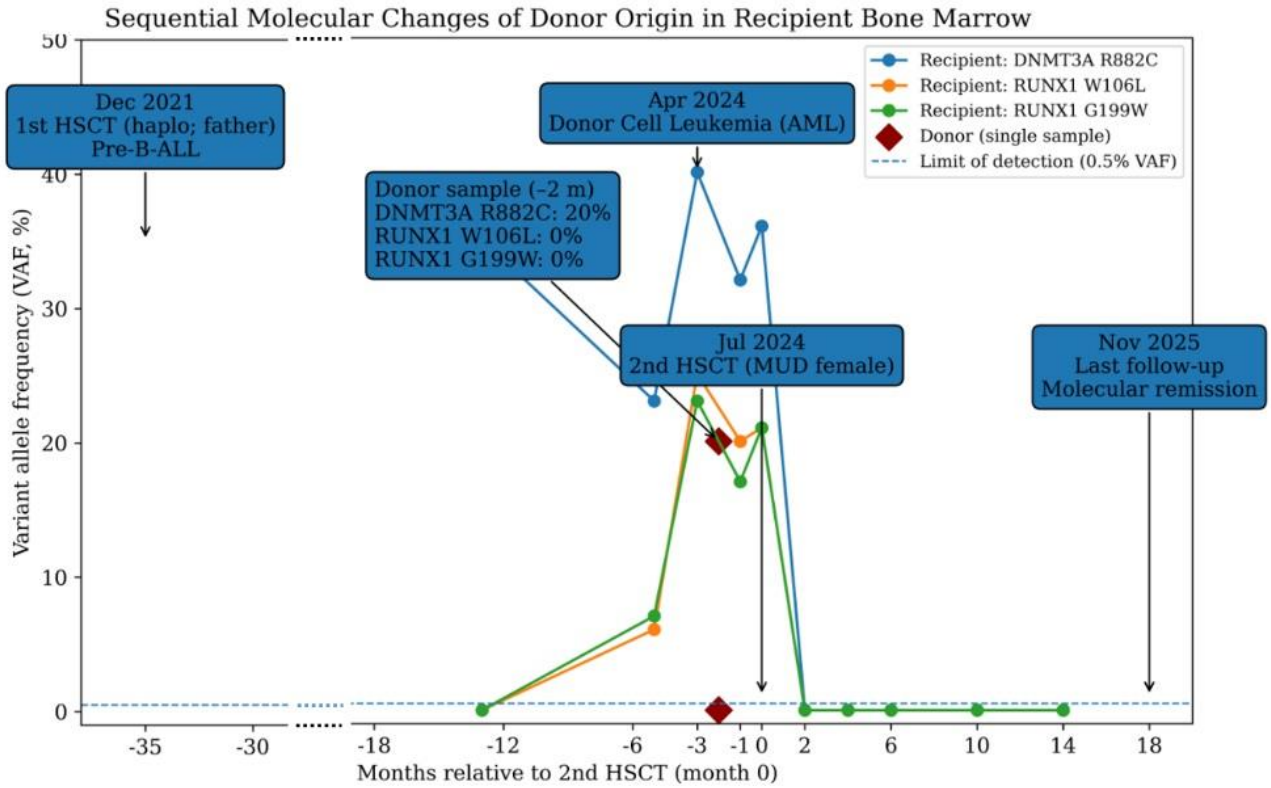
ALL: acute lymphoblastic leukemia, AML: acute myeloid leukemia, BM: bone marrow, CGD: chronic granulomatous disease, Chr: chromosome, DCL: donor cell leukemia, del: deletion, F: female, FA: Fanconi Anemia, Haplo: haploidentical, HSCT: hematopoietic stem cell transplantation, M: male, MSD: matched sibling donor, MUD: matched unrelated donor, NR: not reported, Ph: Philadelphia, SAA: severe aplastic anemia, t: translocation, UCB: unrelated cord blood



Conclusions: To date, only a limited number of pDCL cases have been reported. pDCL has been described following HSCT for both malignant and non-malignant disorders, with latency ranging from a few months to more than a decade. Reported cytogenetic abnormalities are heterogeneous and distinct from the original disease, including monosomy 7, del(9q), KMT2A rearrangements. Donor genetic data are largely unavailable in most published reports.
Our case uniquely demonstrates stepwise donor-derived clonal evolution preceding overt AML, providing direct molecular evidence of leukemic transformation originating from donor hematopoietic cells. These findings underscore the potential relevance of donor-related genetic factors and highlight the importance of careful donor selection, including pre-transplant donor molecular evaluation. Further studies are needed to better define the underlying biological mechanisms of pDCL.

Background: Chronic GVHD (cGVHD) is a serious complication after allogeneic HCT in children. Belumosudil is one of the promising drug for treatment of advanced forms of cGVHD with an inhibitory mechanism of action ROCK-path. The drug is approved for the treatment of patients ≥12 yo after ≥2 prior lines of therapy. However, data on its effectiveness in pediatric patients is limited, especially in children under 12 yo.

Methods: We present a multicenter retrospective analysis of 43 children (<18 years) with steroid-refractory cGVHD treated with belumosudil across 9 HCT centers in Russia. Diagnosis, grading and response were assessed per NIH 2014 criteria.

Results:

Response rate	All pts	Age,12<yo	Age, 12>yo	Adverse events/Site toxicity	All pts	Age<12yo	Age>12yo
N of pts	N=43	N=24	N=19		N=43	N=24	N=19
Overall	28, 65%	17, 71%	11, 58%	Overall AE	30, 70%	16, 67%	14, 74%
Compele	2, 5%	2, 8%	0, 0%	Severe AE	16, 37%	11, 46%	5, 26%

Partial	26, 60%	15, 63%	11, 58%	Infections	24, 56%	13, 54%	11, 58%
No response	8, 19%	4, 17%	4, 21%	Kidney	7, 16%	2, 8%	5, 26%
Prigression	7, 16%	3, 12%	4, 21%	Neurological	9, 21%	6, 25%	3, 16%
				Liver	9, 21%	6, 25%	3, 16%
				GIT	8, 19%	4, 17%	4, 21%
				Hematological	16, 37%	9, 37.5%	7, 37%

Analysis included 30 boys (70%) and 13 girls (30%). Median age at belumosudil initiation was 12 yo (range 2-18), 24 patients (56%) < 12 yo. Median weight was 29 kg (5.5-80). Indications for allogeneic HCT were: acute leukemias (n=33, 77%), myelodysplastic syndrome (n=1, 2%), solid tumors (n=2, 5%), and non-malignant disorders (n=7, 16%). Donor types were: haploidentical (n=29, 67.5%), MUD (n=13, 30.5%), and MSD (n=1, 2%). A second allo-HCT performed in 13 patients (30.5%). Prior acute GVHD was documented in 25 patients (58%).
Median time to cGVHD onset was 180 days (54-1062); 13 patients (30.5%) had overlap syndrome. Patients were heavily cGVHD pre-treated: one prior line of systemic therapy received 5 (11.5%), two – 13 (30.5%), and three or more - 25 patients (58%), including corticosteroids (n=38, 88%), ruxolitinib (n=36, 84%), calcineurin inhibitors (n=22, 51%), mTOR inhibitors (n=17, 39.5%), extracorporeal photopheresis (n=19, 44%), rituximab (n=10, 23%), abatacept (n=9, 21%), etanercept (n=8, 19%), ibrutinib (n=6, 14%), and mycophenolate mofetil (n=4, 9%), and others (n=15, 35%).
At belumosudil initiation, NIH global severity was moderate in 5 patients (12%), severe in 38 (88%). Involved organ sites were: skin (n=35, 81%; sclerotic features in 24), oral mucosa (n=26, 60.5%), eyes (n=22, 51%), lungs (n=26, 60.5%), joints (n=15, 35%), gastrointestinal tract (n=11, 26%), liver (n=11, 26%), and genitalia (n=2, 5%).
Starting dose was weight-based: ≤15 kg received 50 mg/day, 15-40 kg received 100 mg/day, and >40 kg received 200 mg/day. The overall response rate (ORR=CR+PR) was 65% (28/43), including complete response in 2 (5%) and partial response in 26 patients (60%). No response was observed in 8 patients (19%), and 7 (16%) had progressive disease. Median time to response was 35 days (7-183). At data cutoff, 28 patients (65.1%) continued therapy with a median treatment duration of 148 days (14-1005). Adverse events occurred in 30 patients (70%), with serious adverse events in 16 (37%). Tabl.1 Dose reduction, temporary interruption, or permanent discontinuation due to an adverse event were required in 15 (35%), 9 (21%), and 8 patients (19%), respectively.

Conclusions: This is the large real-world series of belumosudil use in pediatric cGVHD. It demonstrates clinically meaningful efficacy in a heavily pre-treated population with predominantly severe, multi-organ disease, including children under 12 years. The safety profile was manageable. These findings support the therapeutic potential of belumosudil in pediatric cGVHD and highlight the need for prospective trials.

Disclosure: Nothing to declare.

PLATFORM-SPECIFIC PATTERNS OF IMMUNE RECONSTITUTION AFTER PEDIATRIC ALLOGENEIC HSCT: COMPARATIVE ANALYSIS OF TCRAB/CD19⁺ DEPLETION AND POST-TRANSPLANT CYCLOPHOSPHAMIDE

*Anna Vlasova[1], **Larisa Vakhonina**[1,2], Dmitriy Klevakin[1], Daria Kostenko[1], Zhan Permikin[1,3], Tatiana Verzhbitskaya[1], Alexander Ponomarev[1], Grigory Tsaur[1,2,3], Larisa Fechina[1,2]*
[1]Regional Children's Hospital, Ekaterinburg, Russian Federation (the), [2]Institute of Medical Cellular Technologies, Ekaterinburg, Russian Federation (the), [3]Ural State Medical University, Ekaterinburg, Russian Federation (the)

Background: Immune reconstitution is a critical determinant of post-transplant infectious risk and graft-versus-host disease (GVHD) in children undergoing allogeneic HSCT. Ex vivo TCRαβ/CD19⁺ depletion (TCR) and in vivo post-transplant cyclophosphamide (PTCY) represent two widely used approaches to alloreactivity control, yet comparative data on their immunological consequences in pediatric patients remain limited. Understanding platform-specific recovery patterns may support individualized GVHD prophylaxis and infection risk stratification.

Methods: We conducted a retrospective single-center analysis of 151 pediatric patients with acute lymphoblastic leukemia (ALL, n=93) and acute myeloid leukemia (AML, n=58) undergoing allogeneic HSCT between 2017 and 2024. Donor types included haploidentical (n=132), matched related (n=1) and matched unrelated (n=18). Conditioning regimens were MAC or RIC; ATG was used in 42 patients in the TCR group.
Patients were categorized into either TCRαβ/CD19⁺ depletion group (n=78) or PTCY — n=73 (50 mg/kg on days +3/+4). Gender, age, disease distribution were similar between these two groups ($p<0.05$ in each category).
Immune reconstitution of CD3⁺, CD4⁺, CD8⁺, CD19⁺ and NK cells was assessed at days +60, +100 and +180.Secondary endpoints included CMV reactivation, CD8⁺ dynamics in the context of viraemia, and associations between immune recovery and acute GVHD.

Results: At day +60, immune recovery profiles were comparable between groups ($p<0.05$ for parameter).
At day +100, distinct platform-specific patterns emerged: PTCY was associated with significantly higher CD3⁺ ($p=0.002$) and CD8⁺ ($p=0.003$) counts, while TCR led to significantly higher CD4⁺ recovery. By day +180, these trends persisted but lost statistical significance.
The overall incidence of CMV reactivation was comparable between the two groups. CMV reactivation was linked to a marked CD8⁺ expansion, most pronounced in the PTCY group (*$p=0.012$*), highlighting potential differences in antiviral T-cell responses across platforms.
The incidence of acute GVHD was significantly higher in the PTCY cohort (69.2% vs 30.6%,

p=0.0013). Within the TCR group, elevated $CD3^+$ levels at day +100 were associated with higher incidence of aGVHD (*p=0.047*), whereas no significant associations between T-cell subsets and aGVHD were identified in PTCY recipients. This divergence suggests distinct alloimmune dynamics between platforms.

Conclusions: Distinct patterns of immune reconstitution were observed between the two platforms. PTCY was associated with higher $CD3^+/CD8^+$ counts at day +100 and more pronounced $CD8^+$ expansion during CMV reactivation, whereas $TCR\alpha\beta/CD19^+$ depletion showed trends toward enhanced B-cell and NK-cell recovery. These findings indicate that immune recovery after pediatric HSCT is highly platform-dependent, with clinically relevant implications for infectious risk, alloimmune activation and GVHD. Our results support the need for platform-specific immune monitoring and may inform individualized selection of GVHD prophylaxis strategies in pediatric HSCT.

ROMIPLOSTIM IN PEDIATRIC PATIENTS POST HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR EARLY PLATELET ENGRAFTMENT- AN OPEN LABEL RANDOMISED CONTROLLED TRIAL

Sanjana Sarangarajan[1], *Aditya Kumar Gupta*[1], *Jagdish Prasad Meena*[1], *Sameer Bakhshi*[1], *Deepam Pushpam*[1], *Sheffali Gulati*[1], *Prashant Jauhari*[1], *Biswaroop Chakrabarty*[1], *Neerja Gupta*[1], *Poonam Coshic*[1], *Sujata Mohanty*[1], *Priyanka Naranje*[1], *Rachna Seth*[1]
[1]*All India Institute of Medical Sciences, New Delhi, India*

Background: Delayed platelet engraftment following HSCT contributes substantially to post-transplant morbidity, transfusion dependence, and prolonged hospitalization in children. Thrombopoietin receptor agonists such as **romiplostim** have been used as rescue in delayed platelet engraftment and for secondary failure of platelet recovery. There is limited data, especially in the pediatric population, on its early use to enhance platelet engraftment. This study aimed to evaluate whether romiplostim administration accelerates platelet engraftment following HSCT in children.

Methods: A prospective, open-label, randomized controlled trial was conducted at the Department of Pediatric Oncology, All India Institute of Medical Sciences, New Delhi, between March 2024 and October 2025. Children aged 1–18 years undergoing autologous or allogeneic HSCT were randomized (1:1) to receive **romiplostim 5 µg/kg** subcutaneously on days +1 and +8 post-HSCT (day +5 and +12 for haploidentical PtCy transplants) or standard of care. The **primary endpoint** was days to platelet engraftment (first of three consecutive days with platelet count ≥20 × 10^9/L without transfusion). **Secondary endpoints** included platelet transfusion requirements, platelet count at day +28, platelet nadir, days to platelet ≥50 × 10^9/L, and safety. Exploratory analyses assessed neutrophil engraftment and multivariate predictors of engraftment.

Results: Thirty children (17 in the intervention arm, 13 controls) were enrolled, with a median age of 8 years (IQR 5–12); 57% underwent allogeneic HSCT and 77% had malignant indications. The median time to platelet engraftment was **12.0 (IQR 11–18.75) days** in the intervention group and **12.5 (IQR 11–18.5) days** in controls (p = 0.88), with **Kaplan–Meier analysis** confirming no significant difference (log-rank p = 0.66). Subgroup analyses across autologous, allogeneic, and malignant transplants similarly revealed no difference in engraftment times.
The **median platelet transfusion requirement** was comparable between groups (14 vs 17 mL/kg, p = 1.00). However, patients receiving romiplostim demonstrated a trend towards **higher platelet counts at day +28** [175,000 (94,000–365,000) vs 145,000 (56,500–175,000); p = 0.16], with a statistically **significant advantage in the allogeneic HSCT subgroup** [290,000 vs 165,000; p = 0.048]. The platelet nadir and days to platelet ≥50 × 10^9/L were similar between groups (p = 0.78 and p = 0.69, respectively). No grade ≥3 bleeding or thrombotic events occurred, confirming the **safety and tolerability of romiplostim** in this setting.
Exploratory analysis demonstrated no significant difference in median time to neutrophil engraftment [13 (10.75–16.75) vs 12 (11.75–14.5) days; p = 0.80]; however, **day +28 absolute neutrophil counts were significantly higher in the intervention group** within **autologous and malignant subgroups (p = 0.04)**.

Conclusions: Romiplostim was **safe and well tolerated** following pediatric HSCT. While it did **not significantly shorten platelet engraftment time**, the **intervention group demonstrated higher platelet and neutrophil counts by day +28**, particularly among **allogeneic and malignant subgroups**. These findings support the feasibility of romiplostim use post-HSCT and warrant larger multicenter trials to establish its efficacy in the pediatric population.

Santobono - Pausilipon, Napoli, Italy, [12]Azienda "A. Meyer", Firenze, Italy, [13]A.O.U. Città della Salute e della Scienza di Torino, Torino, Italy, [14]Catholic University of the Sacred Heart, Rome, Italy

Background: The prognosis of children with severe acute graft-versus-host disease (aGVHD) who fail to respond to first-line systemic corticosteroids remains poor. However, the proportion of pediatric recipients requiring second-line therapy and the associated risk of non-relapse mortality (NRM) are not well defined. We performed a retrospective, registry-based analysis of children and adolescents undergoing allogeneic hematopoietic cell transplantation (allo-HCT) at AIEOP (Italian Association of Pediatric Hematology and Oncology) centers between 2010 and 2020, prior to the routine use of ruxolitinib in the pediatric setting, to estimate the frequency of steroid-refractory aGVHD requiring second-line treatment and to describe salvage therapies and clinical outcomes.

Methods: We analyzed 2,663 pediatric patients (41% female) who underwent allo-HCT between 2010 and 2020. Median age at transplant was 7.6 years (range, 0.1–18). Donor type was matched related donor (MRD) in 675 (25%), matched unrelated donor (MUD) in 1,315 (50%), and mismatched/haploidentical related donor in 673 (25%). Stem cell source was bone marrow in 64%, peripheral blood in 30%, and cord blood in 6%. *Ex vivo* T-cell depletion was used as GVHD prophylaxis/graft manipulation in 21% of cases.

Results: Overall, 756/2,663 patients (29%) developed grade II–IV aGVHD, with a cumulative incidence of 29% (95% CI, 28–31). Among these, 383/756 (51%) required second-line therapy (14% of the entire cohort). aGVHD requiring second-line therapy occurred more frequently after MUD transplantation compared with MRD or mismatched/haploidentical related transplantation (20% vs 8% vs 11%, respectively; $P<0.01$). It was also more frequent after cord blood transplantation compared with bone marrow or peripheral blood transplantation (25% vs 9% vs 10%, respectively; $P<0.001$). Second-line treatments included extracorporeal photopheresis (60%), mycophenolate mofetil (46%), mesenchymal stromal cells (12%), monoclonal antibodies (5%), and other therapies (28%); 32% of patients received ≥ 2 second-line treatments. The overall 1-year non-relapse mortality (NRM) in the study population was 10% (95% CI, 9–11). The 1-year NRM was 8% (95% CI, 7–10) in patients with grade 0–I aGVHD, 10% (95% CI, 7–14) in those with grade II–IV aGVHD responding to steroids, and 16% (95% CI, 13–20) in those with grade II–IV aGVHD requiring second-line therapy ($P = 0.005$). The overall cumulative incidence (CI) of chronic GVHD (cGVHD) was 13% (95% CI, 12–14). The CI of cGVHD was 5% (95% CI, 4–6) in patients with grade 0–I aGVHD, 21% (95% CI, 18–25) in those with grade II–IV aGVHD responding to steroids, and 36% (95% CI, 32–40) in those with grade II–IV aGVHD requiring second-line therapy ($P < 0.001$).

Conclusions: Children and adolescents with grade II–IV aGVHD requiring second-line therapy after failure of first-line corticosteroids experienced higher NRM and inferior outcomes compared with steroid responders. In this pre-ruxolitinib era cohort, available second-line approaches did not appear to mitigate the adverse prognostic impact of steroid refractoriness, supporting steroid-refractory aGVHD as a major determinant of transplant-

related mortality. This large, homogeneous registry-based dataset provides a benchmark against which contemporary and emerging therapeutic strategies can be compared.

Disclosure: No potential conflict of interest to disclose.

POST-TRANSPLANT CYCLOPHOSPHAMIDE IN PEDIATRIC HEMOGLOBINOPATHIES: EXPANDING ACCESS TO ALLOGENEIC STEM CELL TRANSPLANTATION

*Luca Marie Beermann[1], **Manon Queudeville**[1], Wiebke Jünemann[1], Ysabel Alessa Schwietzer[1], Ingo Müller[1]*
[1]Universitätsklinikum Hamburg-Eppendorf (UKE), Hamburg, Germany

Background: Sickle cell disease (SCD) and thalassemia (TM) are two of the most prevalent genetic disorders globally. Despite the improvement in supportive medication, those affected nevertheless experience severe morbidity and early mortality. In addition to the recently approved gene therapy, haematopoietic stem cell transplantation (HSCT) remains the only curative treatment option. The overall survival rate following a HLA-identical related donor transplant (MRD) exceeds 97%, while the disease-free survival rate is 91%[MI1] (1-2). However, only a small proportion of patients have a suitable family donor, emphasizing the need for improvements in unrelated donor transplantations. HSCT from unrelated donors are accompanied with an elevated risk of graft-versus-host disease (GvHD) and rejection. To improve GvHD prophylaxis in (M)MUD transplantations, we changed our standard from CNI/MMF to CNI/Cy. Here, we report key outcome parameters of this cohort.

Methods: We retrospectively analyzed 70 patients who underwent allogeneic HSCT at our institution between 2018 and 2025. All patients received the same conditioning regimen consisting of treosulfan, fludarabine, thiotepa and ATLG.GvHD prophylaxis consisted of either calcineurin inhibitor (CNI) combined with mycophenolate mofetil (MMF) (n = 37) for the MRD group, or CNI with post-transplant cyclophosphamide (ptCy) in the UD cohort (n = 33).

Results: There was no significant difference in overall survival between the two groups (p = 0.17) with a Median follow up of 380 days (90-1105) for the ptCy group and 681 days (103-2310) for the CNI/MMF group. Grades II–IV acute GVHD occurred in 18.2% (95% CI, 7.0–35.5) versus 16.7% (95% CI, 6.4–32.8) (p = 1.00), and severe (grade III–IV) acute GVHD in 12.1% (95% CI, 3.4–28.2) versus 8.3% (95% CI, 1.8–22.5) (p = 0.70), respectively. The cumulative incidence of chronic GVHD was comparable between both groups (9.1% vs 8.3%, p = 1.00) (see Figure 1).
Hematopoietic recovery was rapid and comparable across groups and there was no difference in the usage of immunosuppressive agents. Immune reconstitution dynamics were comparable between groups across all lymphocyte subsets ($CD3^+$, $CD4^+$, $CD8^+$, $CD56^+/CD16^+$, and $CD19^+$). Infectious complications occurred in 57 patients overall, with comparable frequencies between the CNI/ptCy group (88%) and the CNI/MMF group (84%, p = 0.74). A total of 126 infections were documented (57 in CNI/ptCy and 69 in CNI/MMF

recipients, p= 0,88, 95% CI 0,67 – 1,36). The distribution by grade and timing was comparable between groups, with most infections occurring before day 30. The median number of infectious episodes per patient was two in both treatment arms.
GvHD prophylaxis using CNI/ptCy equilized the most important outcome parameters for hemoglobinopathy patients transplanted from a MRD versus MUD. The analysis revealed no significant difference in terms of overall survival (OS), event-free survival (EFS) and the proportion of patients who did not require transfusions (TFS). In addition, our data did not show a significant impairment of immune reconstitution or higher rates of viral reactivations in the ptCy group.

Conclusions: Overall, we conclude that CNI + ptCy as a GvHD prophylaxis could be a safe option for SCT and TM patients with no available family donor.

Disclosure: Nothing to declare.

B236

MULTIFACETED ROLE OF ELTROMBOPAG FOR POOR GRAFT FUNCTION IN PEDIATRIC ALLOGENEIC HSCT RECIPIENTS

Natalia Maximova[1], *Stefania Braidotti*[1], *Debora Curci*[1]
[1]*Institute for Maternal and Child Health-IRCCS Burlo Garofolo, Trieste, Italy*

Background: Poor Graft Function (PGF) is a life-threatening complication of allogeneic hematopoietic stem cell transplantation (allo-HSCT) (5-27% incidence), and is defined by the development of two or three linear cytopenias with full donor chimerism and no disease relapse. Risk factors include low CD34+ cell dose in the graft, high donor-specific antibody titers, damaged bone marrow microenvironment, cytomegalovirus infection, graft-versus-host disease (GVHD), splenomegaly, and iron overload. Eltrombopag, a thrombopoietin receptor agonist, shows promise as a therapeutic option for PGF treatment due to its multilineage hematopoietic effects and ability to reduce inflammation and chelate intracellular iron with an affinity comparable to that of chelators such as deferoxamine.

Methods: We conducted a retrospective, single-centre, observational study at the pediatric Bone Marrow Transplant Centre of the Institute for Maternal and Child Health—IRCCS "Burlo Garofolo" in Trieste, Italy, from April 2018 to May 2025 (IRB approval: RC 44/24). This study involved 30 patients (mean age 8.76 years, IQR: 15.87, 73.3% males). The study evaluated the efficacy and safety of eltrombopag for PGF in pediatric allo-HSCT recipients, assessing clinical outcomes as transfusion independence, adverse events (infections and GVHD), and overall survival. Its ability to modify pro-inflammatory cytokine production and its chelating activity was evaluated either alone or in combined therapy with deferoxamine.

Results: The median duration of eltrombopag treatment is 136.5 days (IQR, 93.3 days). A complete hematological improvement was observed in 24 patients (80.0%), a partial response in 2 patients (6.7%), while 4 patients (13.3%) did not respond. Significant increases were seen in median neutrophil counts (from 636/mm³ to 2,675/mm³), platelets (from 113,500/mm³ to 218,500/mm³), and hemoglobin (from 9.35 g/dl to 11.35 g/dl).

Patients showed decreased transfusion dependence. Non-response was associated with significant viral infections (all 4 non-responders). Severe acute GVHD (grade 3–4) occurred in 4 patients (13.3%); moderate-to-severe chronic GVHD in 5 patient (16.7%). At the 1,281-day mean follow-up, 27 patient (90%) were alive.
Severe siderosis before eltrombopag treatment (15 patients, 50%) did not hinder hematologic response, and liver iron concentration was markedly reduced (median 298 mg Fe/g, IQR: 111.0 mg Fe/g to 88 mg Fe/g IQR: 44..0 mg Fe/g dry weight). Seven patients (23.3%) with severe siderosis received eltrombopag combined with deferoxamine. Double chelation therapy demonstrated a synergistic effect, significantly reducing treatment duration compared to deferoxamine (160 days, IQR: 17.5 vs. 355 days, IQR: 28.5; p=0.001) and Eltrombopag alone (160 days, IQR: 17.5 vs. 290 days, IQR: 153; p=0.010). Cytokine analysis suggested potential immunomodulatory effects: five cytokines (TNF-α, TNF-β, SDF1-α, SCGF-β, IL-9) showed a significant change after Eltrombopag treatment ($p<0.05$).

Conclusions: In conclusion, our finding supports the use of Eltrombopag as a safe and effective treatment option for managing PGF in the pediatric population, even when combined with other iron-chelating agents, potentially contributing to improved clinical outcomes. Cytokine profile suggests that Eltrombopag may exert immunomodulatory effects beyond megakaryopoiesis stimulation, potentially contributing to hematologic recovery by regulating the bone marrow niche. Further research is needed to validate these findings and to better define the optimal criteria for its use in the paediatric setting.

Disclosure: Nothing to declare

B237

HIGH VIRAL LOAD BK VIRURIA IS COMMON AFTER PAEDIATRIC HAEMATOPOIETIC STEM CELL TRANSPLANT AND DOES NOT PREDICT SYMPTOMATIC HAEMORRHAGIC CYSTITIS

Hilary Cahill[1], *Nathan Jeffreys*[1], *Malcolm Guiver*[1], *Ramya Hanasoge-Nataraj*[1], *Claire Horgan*[1], *Oana Mirci-Danicar*[1], *Omima Mustafa*[1], *Srividhya Senthil*[1], *Robert Wynn*[1]
[1]*Manchester University NHS Foundation Trust, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: BK virus is the most common cause for haemorrhagic cystitis (HC) in paediatric haematopoietic stem cell transplant (HSCT) patients. HC is associated with prolonged hospitalisation, poorer quality of life, and treatment related mortality, with an estimated incidence of 8-25% in paediatric HSCT recipients. HC typically develops 2-8 weeks post HSCT, and is associated with a triad of macroscopic haematuria, clinical signs and symptoms of cystitis, and demonstration of BKV viruria.
BK viruria alone is common, seen in up to 80% of paediatric transplant patients, but can occur in the absence of HC, and is not predictive of HC onset or severity. Risk factors associated with BK-associated HC include UCB source, BK viraemia, older age (>5 years), and use of ATG.

Methods: A retrospective review was performed of children undergoing HSCT at a single UK transplant centre between 1 January 2015 and 31 December 2024, who were identified to have BKV viruria detected by quantitative polymerase chain reaction (PCR) testing. Associated demographic data was collected, including donor, cell source, use of serotherapy in conditioning, and number of urine samples sent for BKV PCR. Patients were considered to have BKV-associated haemorrhagic cystitis if symptoms were reported and noted in the medical record on the day of the highest viral load detected by quantitative PCR, and documented by common terminology criteria for adverse events (CTCAE) cystitis grading.

Results: 502 transplants were performed during the 10-year period, and a total of 163 patients (2 of which had 2 transplants) developed BK viruria. The incidence of BKV viruria in this population was 33%. 126/165 (76%) were from unrelated donors 33/165 (20%) were matched family donors. Donor source was predominantly bone marrow (88/165, 53%), followed by cord (48/165, 29%), and PBSC (29/165 (17%). 84/165 (51%) received serotherapy as part of their conditioning regimen. There was no relationship between viral load and serotherapy received.
BKV in urine was measured either due to screening for BKV, or due to clinical symptoms such as haematuria, dysuria or urinary frequency. The median number of BKV PCR samples sent per patient was 4 (1-44). The median date post-transplant of peak BKV PCR result was day +26 (1-346). Median BKV copies/ml detected was $1.0x10^9$, ($9.2x10^1$ – $2.8x10^{11}$). Median BKV log was 9.06^{10} (1.96^{10} – 11.94^{10}).
Grade 1-2 haemorrhagic cystitis symptoms were reported in 7/45 patients transplanted between 2022 and 2025, with no significant difference in viral load between the patients who developed haemorrhagic cystitis and those who did not. Peak BKV log did not correlate with severity of haemorrhagic cystitis.

Conclusions: BK viruria is common in paediatric HSCT recipients, however peak BKV viruria does not predict the development HC. There is a poor relationship between urine BKV viral load and clinical symptoms, and peak BKV viruria is not predictive of the severity of cystitis.

Disclosure: Nothing to declare

B238

DONOR SELECTION STRATEGY IS CRITICAL IN DETERMINING OUTCOMES OF HIGH-RISK, PAEDIATRIC, RELAPSED, MRD POSITIVE T-ALL HSCT

Srividhya Senthil[1], *Shirin Elshikh*[2], *Caroline Furness*[2], *Robert Wynn*[1]
[1]*Royal Manchester Children's Hospital, Manchester, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Royal Marsden Hospital, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Haematopoietic stem cell transplantation (HSCT) outcomes for T-cell acute lymphoblastic leukaemia (T-ALL) remain inferior to those for B-ALL due to the aggressive biology of T-ALL, higher relapse risk, limited options for targeted minimal residual disease

(MRD) control, and the lack of effective chimeric antigen receptor (CAR)-T programmes. Pre-transplant MRD is an independent predictor of poor relapse-free survival (RFS) and overall survival (OS) in T-ALL HSCT. We hypothesised that graft-versus-leukaemia (GVL) activity may play a particularly important role in T-ALL biology and could translate into improved outcomes with non-serotherapy–based HSCT. We examined the impact of transplant type and donor source on outcomes in a multicentre cohort.

Methods: We retrospectively reviewed children with T-ALL who underwent HSCT at two major UK paediatric transplant centres between 2014 and 2024. Clinical records were analysed for patient, donor, transplant characteristics, OS and relapse outcomes.Differences in RFS by donor type were assessed using the log-rank test, with multivariable Cox regression adjusting for MRD.

Results: Thirty-nine children (36 boys, 3 girls) aged 8–18 years (median 13) underwent HSCT. Nineteen had primary refractory T-ALL, of whom 10 were MRD-positive pre-transplant (10^{-4} to 10^{-6}). Twenty patients had relapsed T-ALL; 14 of these were MRD-positive at transplant. All except one received TBI-based myeloablative conditioning: approximately half received etoposide with 12 Gy TBI, and the remainder cyclophosphamide with 14.4 Gy TBI. Serotherapy was used only in matched unrelated donor (MUD) transplants using BM/PBSC as HSC source. Cord blood transplants were T-cell-replete (TRCBT) with ciclosporin ± mycophenolate mofetil as GVHD prophylaxis. Matched sibling donor (MSD) transplants used methotrexate plus ciclosporin as GVHD prophylaxis.
Of 39 patients, 11 received MSD bone-marrow grafts. The remaining 28 received unrelated donor grafts: 11 cord blood and 17 PBSC/BM. With a median follow-up of 6 years 5 months (range 1.5–11.2 years), 29 patients (74.3%) are alive. Relapse accounted for 9 of 10 deaths; one additional death occurred from transplant-related mortality (TRM) after TRCBT. All relapses occurred within one-year post-HSCT.
OS and RFS were 89.5% and 60% for transplants performed in CR1 and CR2, respectively. Pre-transplant MRD strongly influenced outcomes in CR2 patients: RFS was 50% in MRD-positive versus 83% in MRD-negative CR2 recipients. In contrast, MRD positivity appeared less impactful in CR1 transplants.
Outcomes varied markedly by donor type. MSD HSCT and TRCBT showed significantly superior post-transplant remission rates (90% and 80%, respectively) (log rank p=0.002) compared with a markedly lower RFS of 33% after MUD HSCT. Among MRD-negative recipients, differences were less pronounced: RFS was 100% for MSD (n=3) and TRCBT (n=1), and 81.8% for MUD (n=11).

Conclusions: Relapse remains the leading cause of HSCT failure in T-ALL, particularly in CR2 patients with persistent pre-transplant MRD. Where disease is chemo responsive, deeper pre-transplant cytoreduction—such as with nelarabine—may be beneficial. Our data suggest that in cases of refractory MRD, prioritising non-serotherapy platforms like MSD HSCT or TRCBT may better harness GVL and improve RFS and OS. Larger studies are warranted to validate these findings, inform donor-selection strategies, and improve outcomes in this high-risk population.

Disclosure: nil

Background: Hematopoietic stem cell transplantation (HSCT) remains a life-saving intervention for numerous malignant and non-malignant hematologic disorders in childhood. Advances in assisted reproductive technologies have enabled the intentional conception of HLA-matched "savior siblings," born with the potential to serve as stem cell donors for an affected child. While this practice has markedly improved transplant feasibility and outcomes, it simultaneously raises complex psychosocial and ethical questions concerning consent, identity formation, familial expectations, and moral responsibility. Existing literature has

largely emphasized clinical success and ethical debate, whereas qualitative studies capturing the lived experiences of both savior siblings and recipient children—within their familial and cultural contexts—remain scarce. This study aimed to explore these experiences in depth, focusing on psychosocial meanings and ethical perceptions across the HSCT trajectory.

Methods: A descriptive phenomenological qualitative design was employed. The study sample included savior siblings, transplanted children, and their parents. Data were collected through online semi-structured in-depth interviews guided by open-ended questions designed to elicit personal meanings and emotional experiences. Interviews were audio-recorded, transcribed verbatim, and analyzed using DataBeeg 1.0 qualitative analysis software. Colaizzi's seven-step method guided data analysis. Methodological rigor was ensured through participant validation, peer debriefing, and transparent documentation of analytic decisions, enhancing credibility and transferability of the findings. The study was conducted in accordance with the Declaration of Helsinki. Ethical approval was obtained from the institutional ethics committee, and written informed consent was obtained from all parents. Only families in whom savior siblings and recipient children had received structured, age-appropriate information regarding the donation and transplantation process were included.

Results: Participants' narratives revealed a multidimensional experience shaped by four themes: (1) diagnosis and treatment journey, (2) meanings attributed to having a savior sibling, (3) coping strategies, and (4) reflections. The diagnosis and treatment phase involved urgency, long hospitalizations, and major emotional and physical strain on families, particularly mothers undergoing assisted reproduction, often disrupting family roles and social life. Savior siblings viewed donation as an act of healing and belonging, strengthening sibling bonds and family unity. Recipient children described transplantation as a turning point symbolizing survival and renewal. Parents voiced ethical concerns about informed consent at young ages and potential risks to the donor child. Coping relied on family and social support, trust in healthcare teams, continuous information, and maintaining hope, while some avoided recalling the experience as psychological self-protection.

Conclusions: This study demonstrates that savior siblings and recipient children experience HSCT not solely as a medical intervention but as a profound psychosocial and ethical life event. The findings highlight the need for longitudinal, family-centered psychosocial support embedded within pediatric transplant programs. Given the culturally sensitive and ethically complex nature of savior sibling practices, transplant physicians and nurses should proactively assess and address the evolving emotional and moral needs of both donor and recipient children. Although based on a single-center cohort, the depth and consistency of narratives suggest transferable insights relevant to pediatric HSCT programs across diverse cultural and religious contexts.

SECONDARY MALIGNANCIES IN SURVIVORS OF CHILDHOOD CANCER

Hilary Cahill[1], *Karen Johnston*[1], *Rachael Baldwin*[1], *Cecilia Oswald*[1], *Adam Nelson*[1,2]
[1]*Sydney Children's Hospital, Randwick, Australia,* [2]*University of New South Wales, Randwick, Australia*

Background: Over the past 60 years, treatment and supportive care of children with cancer has improved, increasing the number of survivors living to adulthood. Treatment regimens have been modified to improve outcomes and reduce long-term sequelae. Secondary malignancies (SMN) contribute to high morbidity and mortality and the estimated 25-year cumulative incidence in one study of nearly 50,000 survivors was 5.4%. In haematopoietic stem cell transplant (HSCT) patients, the 30-year cumulative incidence of any SMN was 9.9%.

Methods: We performed a retrospective review of a database of patients treated by a single institution and followed up in the long term follow up clinic who self-reported SMNs following treatment with chemotherapy or radiation for malignant and non-malignant conditions. Patients included in the dataset include those treated as early as 1968 when the oncology unit was first opened, and were known to the LFTU service. Descriptive statistical analysis was used to describe characteristics of patients with SMNs.

Results: 95 patients had self-reported SMNs (59% female, 41% male). The majority were between the ages of 1-4 years when treated for their primary condition, with 28% patients having a primary diagnosis of acute lymphoblastic leukaemia. 81% were diagnosed before the year 2000. The most common reported SMN was thyroid cancer (18%), followed by sarcoma (11%) and meningioma (10%). 33% of patients had experienced multiple malignancies. 67% of patients had received radiation during their primary therapy.
41 patients who reported SMN had previously undergone HSCT for treatment of their primary condition (80% malignant disease, 20% non-malignant disease), of a total of ~1000 patients who had undergone HSCT at our institution (4%). 60% of patients had been transplanted before the year 2000, and 20% had died due to their SMN, with some SMN reported as late as 30 years post HSCT. Underlying germline cancer predisposition syndromes were reported in 1 patient.

Conclusions: SMNs contribute to significant health burden in survivors of childhood cancer, often contributing to early mortality. A challenge is the long latency period between the original diagnosis (often when the child is very young), and development of the SMN, often in early adulthood. The introduction of risk-adapted therapies has contributed to the changing nature of SMNs reported, as radiation has been removed from the majority of upfront ALL therapies.
The growing survivorship cohort requires specific and early SMN surveillance, and a patient-adapted approach is essential to consider underlying cancer predisposition syndromes, and use of more contemporary treatments such as targeted therapies.

PERI-TRANSPLANT RUXOLITINIB FOR GRAFT-VS-HOST-DISEASE (GVHD) PREVENTION IN PEDIATRIC AND YOUNG ADULT PATIENTS UNDERGOING MYELOABLATIVE HEMATOPOIETIC CELL TRANSPLANTATION (HCT): INTERIM ANALYSIS

Nicole Karras[1], *Anna Pawlowska*[1], *Dongyun Yang*[1], *Sally Mokhtari*[1], *Xin-Zi Emily Tang*[1], *YunZu Michele Wang*[1], *Jerry C. Cheng*[2], *Hisham Abdel-Azim*[3], *Monzr M. Al Malki*[1], *Haris Ali*[1]
[1]*City of Hope, Duarte, United States of America (the),* [2]*Southern California Permanente Medical Group, Los Angeles, United States of America (the),* [3]*Loma Linda University Health, Loma Linda, United States of America (the)*

Background: Ruxolitinib, a JAK 1/2 inhibitor, has been proven to be safe and effective in treating steroid refractory acute and chronic graft-versus-host disease (GVHD) in pediatric and adult patients after allogeneic hematopoietic cell transplant (HCT). However, it has not been studied upfront for GVHD prevention in pediatric patients. We previously reported peri-HCT ruxolitinib administration is safe and promotes engraftment in adults with myelofibrosis undergoing HCT. Similarly, our group showed that peri-HCT itacitinib, another JAK 1 inhibitor, is safe when added to tacrolimus/sirolimus as GVHD prophylaxis, with 100% engraftment and low rates of acute/chronic GVHD in adults. Peri-HCT ruxolitinib may be a strategy to reduce conditioning intensity. We are conducting a pilot study (NCT06128070) adding ruxolitinib to tacrolimus/methotrexate for GVHD prophylaxis in pediatric and young adult patients undergoing myeloablative HCT, with the primary objectives of evaluating safety, feasibility/tolerability and preliminary efficacy based on grades 3-4 acute GVHD-free survival.

Methods: This open-label study has a safety lead-in segment (n=6) with a modified rolling 6 phase 1 design, monitoring unacceptable toxicities (UT) until day 30 post-HCT. Upon confirming safety, the trial will proceed to the randomized segment (n=40), with patients randomized 1:1 to receive standard HCT care with or without ruxolitinib. UTs are defined as grade 3-4 non-hematologic toxicities per Bearman criteria, and grade 4 hematologic toxicities per CTCAE v5.0 at least possibly related to ruxolitinib. Patients ≤22-years-old, weight ≥25 kg, with a history of acute leukemia, myelodysplastic syndromes, or lymphomas receiving myeloablative HCT from an 8/8 matched donor are eligible. Ruxolitinib (5mg, twice a day) is administered from day -1 pre-HCT until day 100 post-HCT.

Results: To date, we have enrolled 6 patients. Median age was 15 years (range: 11-17). All patients received marrow stem cells; patient and transplant characteristics are shown in Table 1. All 6 patients achieved neutrophil engraftment (median 22 days, range: 14-26), 5 achieved platelet engraftment (median 24 days, range: 14-36). One patient passed on day 21 before platelet engraftment due to causes unrelated to ruxolitinib and was not evaluable for UTs. Of the 5 evaluable patients, none experienced UTs. Grade ≥3 adverse events (AEs) at least possibly related to ruxolitinib included anemia (n=1), elevated ALT and AST (n=1), and decreased lymphocyte count (n=1). By day 100 post-HCT, 3 patients had bacterial infections, 2 of which were disseminated, all resolved. Of the two with disseminated bacterial infections, one also had viral gastrointestinal infection and the other also had yeast infection (cause of death). Between days 100-130 post-HCT, 1 patient reported 2 episodes of viral

infections, both resolved. No patients experienced clinical CMV reactivation.
With a median follow-up duration of 120 days (range: 59-386), acute GVHD occurred in 2 patients (both Grade 2). One patient had NRM, and none have experienced relapse or chronic GVHD so far.

Table 1 Patient and Transplant Characteristics

	Total (N=6)
Gender	
Female	2 (33.3%)
Male	4 (66.7%)
Ethnicity	
Caucasian Hispanic or Latino	1 (16.7%)
Caucasian Non-Hispanic or Non-Latino	1 (16.7%)
Asian	4 (66.7%)
Diagnosis	
Acute myeloid leukemia	2 (33.3%)
Acute lymphoblastic leukemia	4 (66.6%)
KPS/Lansky Score	
60	1 (16.7%)
80-90	5 (83.3%)
Donor type	
Allogeneic, related	1 (16.7%)
Allogeneic, unrelated	5 (83.3%)
Conditioning Regimen	
BUSULFAN/CYCLOPHOSPHAMIDE	1 (16.7%)
FTBI/CYCLOPHOSPHAMIDE	5 (83.3%)

Conclusions: We show that peri-HCT ruxolitinib did not interfere with engraftment post-HCT. In addition, our data supports the safety and feasibility of adding ruxolitinib to tacrolimus/methotrexate as GVHD prophylaxis in young patients receiving HCT. Accrual is ongoing.

PROPHYLACTIC DLI IN PEDIATRIC PATIENTS WITH HIGH RISK HEMATOLOGICAL MALIGNANCIES – A SINGLE CENTER EXPERIENCE

Denise Epple[1]
[1]*Technical University of Munich, Munich, Germany*

Background:

Allogeneic stem cell transplantation (allo-SCT) and donor lymphocyte infusions (DLI) can elicit a graft-versus-leukemia (GvL) effect in pediatric patients with hematological malignancies. We report our single-center experience with prophylactic DLI in high- risk pediatric patients with leukemia or lymphoma, focusing on feasibility, safety and efficacy.

Methods:

In total, 10 high-risk patients received prophylactic DLI following allo-SCT. Donors were either matched (n=5) or haploidentical (n=5). CD3+ T-cell doses of up to 1×107cells/kg body weight were administered, in some cases over extended periods exceeding three years.

Results:

The treatment was associated with a favourable toxicity profile. In our cohort, 40% of patients developed moderate acute (n=2) or chronic (n=2) graft-versus-host disease (GvHD), no cases of severe or high grade GvHD occurred. Given the high-risk profile of our cohort, outcomes were encouraging, with relapse-free survival (RFS) of 70% and overall survival (OS) of 80% at a median follow-up of 20.5 months. Especially the two subgroups of patients with acute myeloid leukemia (AML) after relapse and patients who were transplanted in first complete remission (CR1) showed outcomes superior to currently reported data. One AML-patient, who had experienced three relapses, received prophylactic DLI after a third allo-SCT and remains in complete remission (CR), more than three years after the last allo-SCT.

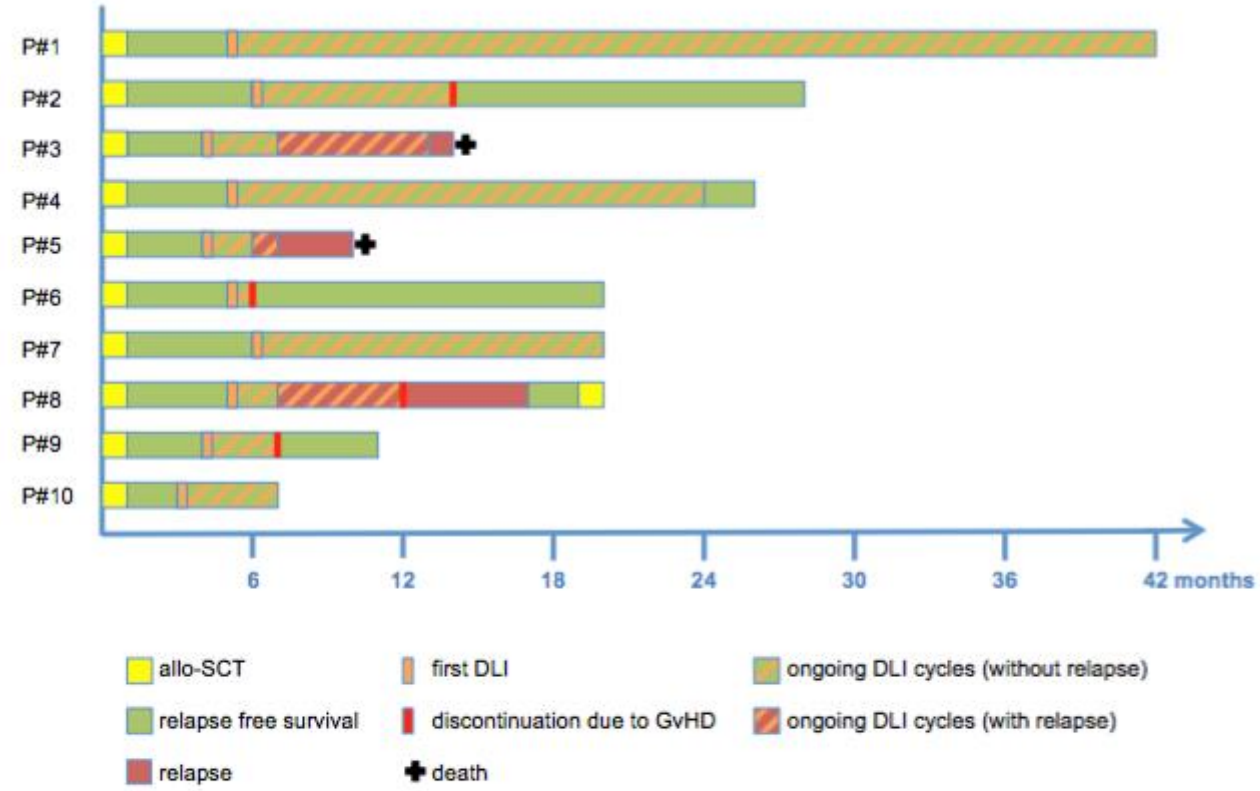

Figure 1 Clinical outcomes and survival of patients

Conclusions:

These data suggest that prophylactic DLI may represent a safe and effective treatment option for pediatric patients with hematological malignancies at high risk of post-transplant relapse.

Background: Hematopoietic stem cell transplantation (HCT) has been investigated as a strategy to induce mixed chimerism in solid organ transplantation (SOT), aiming to promote tolerance and reduce long-term immunosuppression. Cadaveric donors represent a valuable source of hematopoietic progenitors and other immune cell populations. We hypothesize that grafts containing $CD34^+$ cells, $CD45RA^-$ T cells, and regulatory T cells (Tregs) from cadaveric donors can safely induce transient chimerism and improve graft acceptance. The addition of thymic tissue or Tregs may further reduce alloreactivity. We report our initial experience with four $CD34^+$ cell collections harvested from vertebral bodies of cadaveric donors (two brain-dead, two circulatory-dead). Additionally, we aimed to isolate $CD45RO^+/RA^-$ T cells from peripheral blood and generate Tregs from thymic tissue.

Methods: Harvest was done in vertebral corps and $CD34^+$ cells were isolated using CliniMACS Plus. $CD45RO^+/RA^-$ T cells were obtained from the $CD34^-$ fraction and peripheral blood. Tregs were generated by mechanical thymus disaggregation (GentleMACS), $CD25^+$ selection with magnetic beads, and one-week culture with cytokines. To model tolerance, we developed a rat small bowel transplant rejection model.

Results: $CD34^+$ cells were successfully obtained from all four donors. Median harvested volume was 96 mL (IQR, 65), yielding 1.25×10^8/kg total nucleated cells and 1.455×10^6/kg $CD34^+$ cells; after selection, 0.645×10^6/kg $CD34^+$ cells were recovered. $CD45RA^-$ T cells were isolated from the two older donors, while younger donors (1.6 years and 1 month)

had scarce memory T cells but provided thymic tissue for Treg isolation.
One patient (#1), with prior multivisceral transplant (MVT) rejections, received non-myeloablative conditioning followed by a graft containing naïve and memory T cells 88 days post-MVT from a mismatched deceased donor. No graft-versus-host disease or HCT-related toxicity occurred. The patient achieved transient mixed chimerism ($CD3^+$ cells 0.05–5.1% during the first year), a peak in Tregs at day 90, and remains stable >5 years on monotherapy without rejection. One patient (#2) died from surgical complications before HCT. Two patients (#3 and #4) are enrolled in the DUALGRAFT trial (NCT06997471) and awaiting HCT.
In rats, Brown Norway small bowel was transplanted into Lewis recipients under tacrolimus (Tac) alone or Tac plus delayed infusion of $CD90^+$ progenitors. Tac+$CD90^+$ animals showed increased chimerism and delayed lymphoid infiltration, but severe rejection persisted at day 21. We hypothesize that adding thymic tissue or Tregs to progenitor cells may improve outcomes.

IMPACT OF ANTI-THYMOCYTE GLOBULIN DOSE ON SURVIVAL, RELAPSE AND IMMUNE RECOVERY IN PEDIATRIC ALLOGENEIC HSCT FOR MYELOID MALIGNANCIES

Zuzanna Gamrot[1], Natalia Haze[2], Jowita Frączkiewicz[1], Karolina Liszka[1], Monika Mielcarek-Siedziuk[1], Joanna Owoc-Lempach[1], Elżbieta Wawrzyniak-Dzierżek[1], Krzysztof Kałwak[1], ***Marek Ussowicz***[1]
[1]*Wroclaw Medical University, Wrocław, Poland,* [2]*University Clinical Hospital, Wrocław, Poland*

Background: Anti-thymocyte globulin (ATG) is widely used in pediatric allogeneic HSCT to prevent graft-versus-host disease (GvHD), but its optimal dose and impact on immune reconstitution remain uncertain. We evaluated dose-dependent effects of ATG on survival, relapse, viral complications and lymphocyte subset recovery in children transplanted for myeloid malignancies.

Methods: We retrospectively analysed 90 allogeneic HSCTs in children with AML (n=51), MDS (n=28) and JMML (n=11). Most procedures used matched unrelated donors (MD, 84.4%), and matched sibling donors (MSD) accounted for 15.6%. ATG was administered at 45 mg/kg (n=48) or 30 mg/kg (n=30) in MD transplants, while 12 MSD recipients received no ATG. Outcomes included overall survival (OS), relapse, viral infections, acute and chronic GvHD, and longitudinal recovery of cell subsets up to 36 months. Kaplan–Meier/log-rank and chi-square tests were used for univariable analyses.

Results: After a median follow-up of 62.0 months, 2- and 5-year OS were 87.8% and 79.7%, respectively. Relapse occurred in 20.0% and was the most significant adverse predictor of OS (5-year OS 90.2% without relapse vs 36.2% with relapse, $p<0.001$). ATG dose showed a modest association with early OS (2-year OS 91.7%, 96.7% and 81.2% for 0, 30 and 45 mg/kg, $p=0.024$), but differences diminished by 5 years ($p=0.487$). Relapse rates were not increased with higher ATG dosing (33.3%, 20.0% and 16.7% for 0, 30 and 45 mg/kg, $p=0.435$). EBV reactivation rose with ATG dose (0%, 13.3% and 37.5%, $p=0.006$), while other viral reactivations and GvHD rates showed no clear dose–response after adjusting for donor type. ATG demonstrated a significant, dose-dependent delay in early $CD4^+$ T-cell and B-cell reconstitution, with median counts at day +30 and +90 markedly lower in the 45 mg/kg group and only partial convergence by 12–24 months. Total and $CD8^+$ T-cell recovery was also delayed, although to a lesser extent, whereas NK-cell reconstitution was rapid and largely preserved across ATG dosing levels.

Conclusions: In pediatric HSCT for myeloid malignancies, higher ATG doses delay recovery of $CD4^+$ T cells and B cells, but do not clearly worsen long-term survival or increase relapse risk. These data highlight the need to individualise dosing to balance GvHD prophylaxis, infection and EBV risk, and timely immune reconstitution.

Disclosure: Nothing to declare.

THE EFFECT OF ALLOGENEIC HSCT ON PEDIATRIC NON–DOWN SYNDROME AMKL: RESULTS FROM A MULTICENTER CALD-AMKL-18 TRIAL

Shengqin Cheng[1], Yixin Hu[1], Peifang Xiao[1], Xiaowen Zhai[2], Hua Jiang[3], Ningling Wang[4], XiuLi Ju[5], Yong Zhuang[5], Xueju Xu[6], Ning Liao[7], Fang Xu[8], Liangchun Yang[9], ***Shaoyan Hu***[10]
[1]Children's Hospital of Soochow University, Soochow, China, [2]Children's Hospital of Fudan University, Shanghai, China, [3]Guangzhou Women and Children's Medical Center, Guangzhou, China, [4]The Second Affiliated Hospital of Anhui Medical University, Hefei, China, [5]Qilu Hospital of Shandong University, Jinan, China, [6]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China, [7]The First Affiliated Hospital of Guangxi Medical University, Guangxi, China, [8]The First Affiliated Hospital of USTC, Hefei, China, [9]Xiangya Hospital, Changsha, China, [10]Children's Hospital of Soochow University, Soochow, China*

Background: Pediatric non–Down syndrome acute megakaryoblastic leukemia (non-DS AMKL) is a rare, high-risk AML subtype with poor outcomes. In this study we investigated the effect of allogeneic hematopoietic stem cell transplantation (HSCT) on the outcome of non-DS AMKL.

Methods: CALD-AMKL-18 is a prospective multicenter trial using a low-dose HAG induction backbone (low-dose of homoharringtonine and cytarabine, routine dose of G-CSF) for newly diagnosed pediatric non-DS AMKL at 9 Chinese centers. All patients received at least one HAG induction cycle followed by risk-adapted consolidation; those in first complete remission (CR1) either proceeded to HSCT or continued chemotherapy, and a minority underwent HSCT after relapse. Measurable residual disease (MRD) was monitored by multiparameter flow cytometry after each induction and, when applicable, immediately before HSCT. Survival was estimated by Kaplan–Meier; subgroup analyses by HSCT, fusion status and MRD were exploratory.

Results: From 2017 to 2022, 51 patients (median age 40 months) were enrolled. The most frequent lesions were *CBFA2T3::GLIS2*(15.7%), *NUP98::KDM5A* (15.7%), *KMT2A::MLLT3* (9.8%), *HOXr* (7.8%) and *RBM15::MRTFA* (7.8%). Eight patients (15.7%) carried infrequent or novel fusions (including *PICALM::MLLT10*, *TNIP1::CSF1R*, *ZEB2::RUNX1*, *MYB::GATA1*, *CCDC6::BCKDHB*, *ETV6::TLL2*, *EED::PRKAR1A*), and 14 (27.5%) were negative. After two HAG cycles, the CR/CRi rate was 76.5%; induction was very safe, with no early deaths and an overall treatment-related mortality of 2.0% (one fatal infection during consolidation). Overall, 27/51 patients (52.9%) underwent HSCT in CR1 or after consolidation, while 24/51 (47.1%) received chemotherapy alone. For the entire cohort, 5-year overall survival (OS) and event-free survival (EFS) were 42.7 ± 7.3% and 41.9 ± 7.6%. Relapse occurred in 16/51 (31.4%): 8/27 (29.6%) after CR1/early HSCT and 8/24 (33.3%) with chemotherapy alone, and was concentrated in patients with canonical adverse lesions (*CBFA2T3::GLIS2*, *NUP98::KDM5A*, *KMT2A::MLLT3*, monosomy 7/del(7q)). Many high-risk patients, particularly those with *NUP98::KDM5A* or *CBFA2T3::GLIS2*, had refractory or continuously progressive disease and died before they could proceed to HSCT. Fusion-stratified analyses showed that CR1 HSCT did not improve overall outcome in *CBFA2T3::GLIS2* patients (4/4 transplanted

relapsed and died), but appeared to convert a uniformly fatal course into long-term survival for half of *NUP98::KDM5A* cases (2/4 long-term survivors vs. 4/4 deaths with chemotherapy alone) and was associated with excellent disease control in *KMT2A::MLLT3* and monosomy 7/del(7q) disease (6/6 transplanted patients alive in first CR). Only two fusion-negative patients received salvage HSCT after relapse; one achieved durable second remission. MRD ≥0.1% after Induction II predicted markedly inferior OS/EFS, and pre-HSCT MRD negativity was associated with superior post-transplant survival.

Conclusions: CR1 HSCT appeared to improve survival for some adverse genotypes. These data support a risk-adapted HSCT strategy built on a low-toxicity HAG backbone, but also highlight the need for "low-dose chemotherapy (LDC) + X" approaches that integrate targeted agents and MRD-guided HSCT to overcome fusion-driven resistance in pediatric non-DS AMKL.

PEDIATRIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) IN BRAZIL: A REGIONAL CHALLENGE

Beatrice Duarte[1], *Fernando Barroso Duarte*[2]
[1]*UNIFESP/EPM, São Paulo, Brazil,* [2]*UFC, Fortaleza, Brazil*

Background: Hematopoietic stem cell transplantation (HSCT) is an advanced therapeutic modality that has revolutionized the treatment of several severe hematologic and immunologic diseases. In Brazil, HSCT has gained increasing relevance over recent years, consolidating its role as an effective and potentially curative option for multiple clinical conditions.
Nationwide, HSCT is performed in specialized centers supported by highly trained multidisciplinary teams. However, these centers are unevenly distributed, with a marked concentration in the South and Southeast regions, particularly in cities such as São Paulo and Curitiba. Although Brazil's Unified Health System (SUS) provides coverage for HSCT in several indications, the geographic distribution of services remains a significant barrier to equitable access.
We aim to demonstrate the disparity in the distribution of pediatric HSCT centers in Brazil, highlighting the disproportion between service availability and the incidence of diseases requiring transplantation.

Methods: This is a cross-sectional, retrospective, descriptive, and qualitative study based on data from the Brazilian Transplant Registry (ABTO). Pediatric HSCTs performed in 2023 across the different regions of Brazil were analyzed. Additionally, an attempt was made to collect data for the year 2024 from the Brazilian Transplant Registry; however, these data were not available or published at the time of analysis.

Results: In 2023, data from the Brazilian Transplant Registry revealed pronounced regional disparities in the performance of pediatric HSCT. The state of São Paulo accounted for 357 pediatric transplants, whereas the state of Ceará registered only one procedure during the same period. These findings stand in marked contrast to DATASUS data, which reported approximately 415 new cases of pediatric leukemia in the Northeast region in 2023—conditions that, when associated with poor prognosis, may indicate HSCT.
An even more critical situation was observed in the Northern region, where no pediatric HSCT centers were registered, despite the diagnosis of approximately 376 new cases of pediatric leukemia in the same year according to DATASUS.
The attempt to obtain data for 2024 from ABTO revealed the absence of published information, limiting more recent temporal analyses and suggesting weaknesses in transparency and prioritization of national monitoring of this therapy. Complementary data from the Summary Slides of the Brazilian Society of Cell Therapy and Bone Marrow Transplantation (SBTMO), published in 2025, report 42 HSCT centers in Brazil, of which 26 are located in the Southeast and 8 in the South, while only 3 centers are located in the Northeast and none in the North.

Conclusions: The distribution of pediatric HSCT centers in Brazil is markedly unequal, with a strong concentration in the South and Southeast regions, contrasting with the high incidence of pediatric hematologic diseases in other parts of the country. The lack of published ABTO data for 2024 limits updated analyses and highlights weaknesses in national HSCT monitoring. Data from the SBTMO further confirm that the North and Northeast regions remain extremely underserved in terms of pediatric transplant centers. Expanding and redistributing the HSCT network, along with improving transparency in national registries, is essential to ensure equitable access and improve clinical outcomes for Brazilian children.

Disclosure: No disclosures.

DOSE REDUCTION IMPROVES THE OUTCOMES OF HEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHILDREN WITH WILMS TUMOR: DATA FROM RETROSPECTIVE TRIAL FROM TWO CENTRS

Teimur Aliev[1], *Ilya Kazantsev*[2], *Kirill Kirgizov*[1], *Marina Rubanskaya*[1], *Elena Machneva*[1], *Irina Kostareva*[1], *Nara Stepanyan*[1], *Karina Sergeenko*[1], *Daria Smirnova*[1], *Natalia Burlaka*[1], *Maria Malova*[1], *Anatoly Kazantsev*[1], *Garik Sagoyan*[1], *Amina Suleymanova*[1], *Alexey Slinin*[3], *Lyudmila Zubairovskaya*[4], *Svetlana Varfolomeeva*[1]

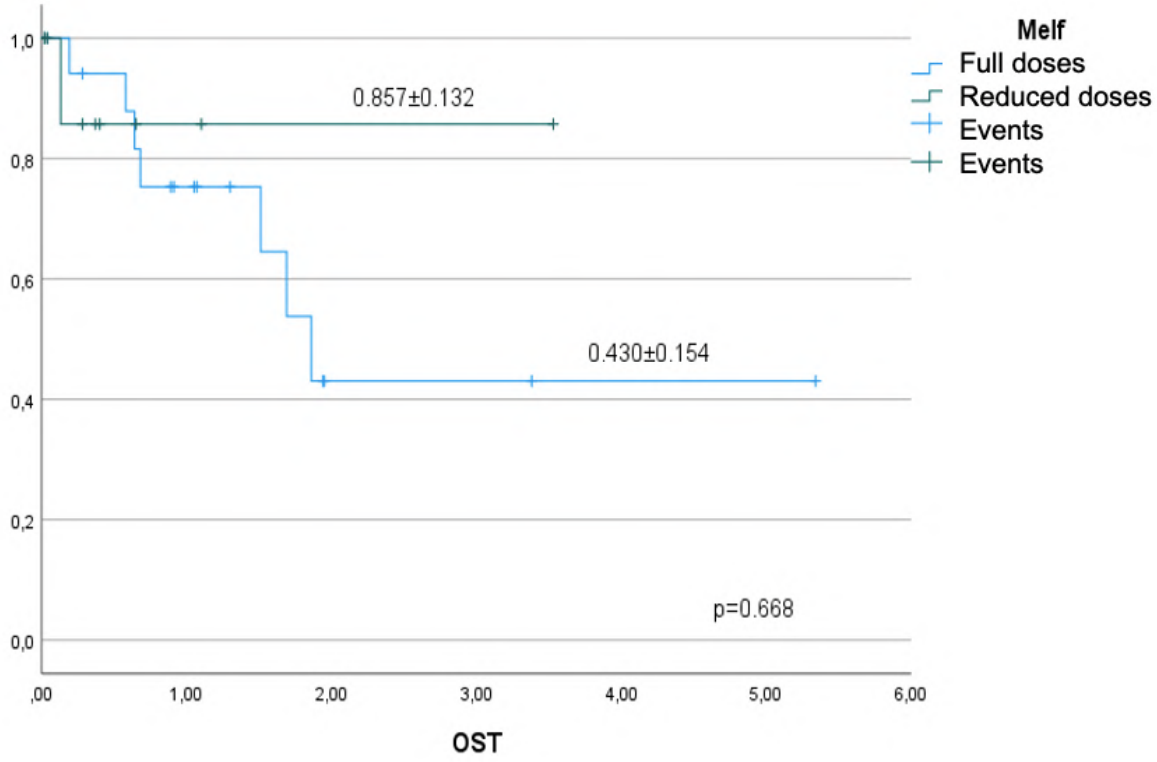
Pavlov State Medical University of St. Petersburg, Saint Petersburg, Russian Federation (the), [3]Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Im-munology, Moscow, Russian Federation (the), [4]First Pavlov State Medical University of St. Petersburg, Moscow, Russian Federation (the)

Background: High-risk Wilms tumor (WT) requires autologous hematopoietic stem cell transplantation (aHSCT) as a part of treatment plan. High-dose chemotherapy with melphalan is associated with high mortality and morbidity.
We presenting retrospective analysis of children with WT received aHSCT in different dosing regimen of melphalan.

Methods: A retrospective study analyzed the results of treatment of 27 children with WT (M/F ratio 15/12) belonging to the group of extremely high risk (group D, n = 3, 11.1%), disease progression/recurrence (n=24, 88.9%). Nineteen patients (70.4%) received two lines of induction, and 5 (18.5%) three or more lines of therapy (SIOP RTSG 2016 protocol). Median of age was 6 years 5 months. Peripheral blood stem cell apheresis (PBSC) was performed in all patients: 24 (89%) patients required one apheresis, 3 (11%) two or more. Full dose of Melphalan (single dose of 200 mg/sq.m.) was used in 17 (63.0%) cases (group 1), and reduced dose (140 mg/sq.m.) – in 10 (37.0%) cases (group 2). The median of infused CD34+ cells was 4.9 × 10 6/kg.

Results: All patients engrafted. Median of neutrophils recovery were faster in group 2 (7 days) in the contrast of group 2 (17 days). Toxicity rates were same in both groups, but no mucositis of gr. 3-4 was found in group 2. With a median follow-up of 1.5 years, 19/27 patients are alive in both groups. Overall survival: group 1 – 43.0%, group 2 – 85.7%. Disease-free survival: group 1 – 36%, group 2 – 78%. Causes of mortality in group 1: toxicity – 4, progression – 2; in group 2: toxicity – 1, progression – 1.



Conclusions: Autologous HSCT is an effective method of consolidation in case of WT of unfavorable prognosis in children. Our study showed that reduction of doses of Melphalan improves both overall and disease-free survival. Future large multicenter trials required.

Disclosure: There are no conflicts of interest.

NEUROIMMUNOLOGICAL MORBIDITY AFTER PEDIATRIC ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A MULTICENTER ANALYSIS ON BEHALF OF THE PEDIATRIC SUBCOMMITTEE OF GETH (GRUPO ESPAÑOL DE TRASPLANTE HEMATOPOYÉTICO)

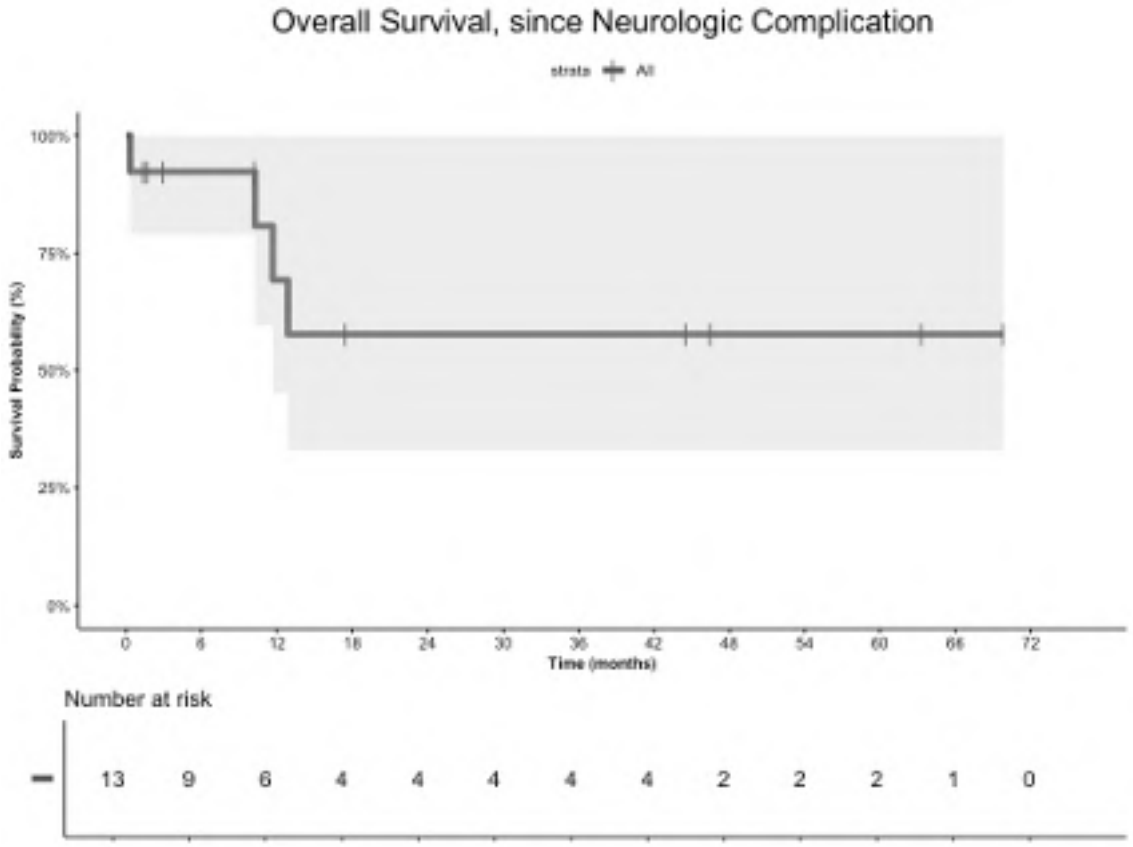
Angélica Villanueva Freije[1], *Lorea Vicente Elcano*[1], *Yasmina Mozo del Castillo*[1], *Blanca Molina Angulo*[2], *Helena Martínez Sánchez*[3], *Laia Garcia Marzo*[4], *Andrea Urtasun Erburu*[5], *Mercedes Plaza Fornieles*[6], *M. Luz Uria Oficialdegui*[7], *Marina Ascunce Abad*[1], *Odelaisy León Triana*[1], *Mª del Mar García Romero*[1], *David Bueno Sánchez*[1], *Luisa Sisinni*[1], *Pilar Nozal*[1], *Cristina Verdú*[1], *Cristina Díaz de Heredia*[7], *Antonio Pérez Martínez*[1]

[1]Hospital Universitario La Paz, Madrid, Spain, [2]Hospital Universitario Niño Jesús, Madrid, Spain, [3]Hospital Universitario La Fe, Valencia, Spain, [4]Hospital Sant Joan de Dèu, Barcelona, Spain, [5]Clínica Universitaria de Navarra, Pamplona, Spain, [6]Hospital Virgen de la Arrixaca, Murcia, Spain, [7]Hospital Universitario Vall D' Hebron, Barcelona, Spain

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is the only curative treatment for certain hematological malignancies and non-malignant disorders. Conditioning regimens and immunosuppressive therapies induce a profound transient immunodeficiency, which is associated with relapse of malignant diseases, infections, graft versus host disease (GvHD), and immune dysregulation. In recent years, neurological complications secondary to immune dysregulation induced by transplantation have been increasingly recognized. Nevertheless, their typification as atypical manifestations of GvHD remains challenging, and the available literature is limited and predominantly focused on adults.

Methods: The aim of this study was to describe immune-mediated neurological complications (INC) in pediatric HSCT recipients in Spain. We retrospectively analyzed patients under 18 years old who underwent HSCT and subsequently developed neurological complications not attributable to infectious, pharmacologic, or other non-immune causes, between January 2018 and September 2025.

Results: Thirteen patients were included. The majority were male (62%), transplanted because of a malignant disease (69%) from an unrelated (62%) or an haploidentical related donor (31%). The median age at INC diagnosis was 13.5 years (interquartile range [IQR] 10.3–16.4), at a median of 119 days post-HSCT (IQR 82–226). All but two patients (85%) had acute and 54% had chronic GvHD. Prior to the INC, patients were profoundly lymphopenic (median CD4+ 86/mcl [IQR 10-212]; median B cells 8/mcl [IQR 0-57]). INC affected mainly the central nervous system (8/13, 62%): 5/8 encephalitis, 1/8 neuromyelitis optica, 1/8 cerebellitis, and 1/8 transverse myelitis. Peripheral nervous system manifestations (38%) included 3/5 myositis and 2/5 peripheral neuropathies. Diagnostic workups excluded non-immune causes. Specific diagnostic tests (MRI, EEG, EMG, etc.) were tailored to the neurological presentation yielding heterogeneous findings. Half of the patients had no detectable autoantibodies in either serum or cerebrospinal fluid (CSF); in CSF were rarely detected (13% of tested patients), but 100% were anti-GAD. The majority of patients received at least two immunossupressant/immunomodulatory therapies (85%), including steroids (11/13, 85%), IVIg (10/13, 77%), rituximab (5/13, 38%), ruxolitinib (4/13, 31%), and plasmapheresis (4/11, 31%).
Ten patients (77%) developed long-term sequelae. Survival after INC was 69% at a median follow up of 12 months (IQR 3, 44) (figure 1). Death was attributed to NIC in one patient (refractory status epilepticus due to encephalitis). Other causes of death were sepsis in the context of status epilepticus (1/13), and relapse of malignant disease while remaining profoundly disabled (2/13).



Conclusions: Although uncommon, INC following pediatric allogeneic HSCT constitute a significant clinical entity with substantial implications for survival and long-term quality of life.

Disclosure: Nothing to declare.

B249

THE RESULTS OF ALLOGENIC HSCT IN PAEDIATRIC PATIENTS DIAGNOSED WITH MYELOID SARCOMA – A SINGLE CENTRE EXPERIENCE

Agnieszka Sobkowiak-Sobierajska[1], Magdalena Samborska[1], Sandra Rutkowska[1], ***Jacek Wachowiak***[1]*, Katarzyna Derwich[1]*
[1]Poznan University of Medical Sciences, Poznań, Poland

Background: Myeloid sarcoma (MS) is an extramedullary mass consisting of myeloid blasts and it may occur *de novo* or concurrently with acute myeloid leukemia, myelodysplastic

syndrome of myeloproliferative disease. There is no consensus on the treatment of MS, especially its isolated form. Systemic chemotherapy with consideration of allo-HSCT is usually used in paediatric patients.

Methods: We performed a retrospective analysis of 7 paediatric patients (age: 2,5-16,3 years old) with myeloid sarcoma who underwent allogenic HSCT between December 2010 and January 2024 in our institute. One patient had MS de novo, six patients developed MS in course of an underlying disease (AML, n=5; CML, n=1). The extramedullary disease was located in skin (n=2), orbit (n=2) and other organs (n=5). Patients were transplanted in CR1 (n=4; 57,1%), CR2 (n=2; 28,6%) or PR (n=1; 14,3%) and had Lansky or Karnofsky score >80% (n=7; 100%) at HSCT. Most children were transplanted from unrelated donor (n=5; 71,4%), one patient from sibling donor and one from haploidentical donor. The stem cell sources were peripheral blood stem cells (PBSC; n=4) and bone marrow (BM; n=3). The conditioning regimen was treosulfan-based (n=5) or busulfan-based (n=2), combined with different cytostatics, mostly fludarabine (n=6; 85,7%) and cyclophosphamide (n=1; 14,3%).

Results: All patients achieved engraftment (range: 12-23 days after HSCT; median 16 days). One SOS/VOD was diagnosed. Acute graft versus host disease (GvHD) grade II-IV occurred in 2/7 patients. There was no extensive chronic GvHD in our cohort. There was no non-relapse deaths. Relapse occurred in 3/7 patients: 2 months (relapse in skin and BM), 5 months (relapse in skin and BM), and 13 months after HSCT (relapse in BM), respectively. All relapsed patients finally died due to disease progression. Four patients remain in complete remission for 3-15 years after HSCT (median: 6 years).

Conclusions: Allogeneic hematopoietic stem cell transplantation is a feasible and well-tolerated treatment option for pediatric patients with myeloid sarcoma, providing long-term remission in a substantial proportion of cases. Despite acceptable transplant-related toxicity, relapse after HSCT remains common and is associated with dismal outcomes. These findings underscore the importance of careful patient selection and achieving optimal disease control before transplantation and further research to establish indications for allogenic HSCT and its optimal procedure, including optimal conditioning regimen.

Disclosure: Nothing to declare.

POPULATION PHARMACOKINETIC EVALUATION OF EXTENDED INFUSION ACYCLOVIR IN PEDIATRIC HEMATOPOIETIC STEM CELL RECIPIENTS

Natalia Maximova[1], *Stefania Braidotti*[1], *Antonello Di Paolo*[2]
[1]*Institute for Maternal and Child Health-IRCCS Burlo Garofolo, Trieste, Italy,* [2]*University of Pisa, Pisa, Italy*

Background: Acyclovir represents the first-line prophylaxis and therapy for herpes virus infections. However, the pharmacokinetics (PK) of acyclovir in children highlights the risk of

achieving ineffective or toxic drug levels. Understanding its PK is crucial for optimizing antiviral therapy and reducing infectious complications in immunosuppressed patients. Understanding the PK profile is essential for tailoring dosing regimens to achieve optimal plasma concentrations. Adjusting infusion duration based on PK data offers a promising strategy to improve clinical outcomes in this population. Although acyclovir is typically administered as a 1-hour intravenous infusion, limited data exist on the effects of prolonged infusion times on drug PK. This study aimed to characterize and compare the PK parameters of acyclovir administered as a 2-hour intravenous infusion with those of the standard 1-hour regimen in pediatric HSCT recipients, evaluating potential benefits of infusion prolongation on drug exposure and plasma concentration profiles.

Methods: A population PK approach was employed using Monolix version 2024R1 according to standard methods. Individual estimates from the final POP/PK model for the 2-hour infusion group (n=35, 9 [1.2-12.5] years) were compared with those obtained from 99 children receiving 1-hour infusions (Maximova et al., Frontiers Pharmacol, 2022). Key PK metrics assessed included clearance (CL), volume of distribution (V), area under the concentration-time curve (AUC), and peak (Cmax) and trough (Cmin) plasma concentrations. Statistical comparisons were performed using t-tests.

Results: Results showed comparable systemic exposure and clearance between 1-hour and 2-hour infusion regimens, with mean AUC values of 26.0±13.2 and 26.3±17.8 h×mg/L, and CL values of 14.0±5.5 and 14.9±4.5 L/h, respectively ($p > 0.05$, Table 1). Volumes of distribution and Cmax were also comparable. Notably, the 2-hour infusion significantly increased trough concentrations (1.4±1.3 mg/L vs. 0.8±1.0 mg/L, $p=0.002$), which may enhance antiviral efficacy by maintaining higher minimum plasma drug levels.

TABLE 1	1-h infusion q6h			2-h infusion q6h	
	All patients (n=99)			All patients (n=35)	
	Mean±SD	Median	t-test, *p*	Mean±SD	Median
Dose (mg)	334.0±158.2	350.0	n.s.	352.2±195.6	300.0
CL (L/h)	14.0±5.5	14.6	n.s.	14.9±4.5	15.3
AUC (hxmg/L)	26.0±13.2	23.3	n.s.	26.3±17.8	21.5
V (L)	25.4±8.7	26.1	n.s.	31.1±4.4	31.3
Cmax (mg/L)	6.9±4.5	6.3	n.s.	7.4±3.8	7.3
Cmin (mg/L)	0.8±1.0	0.6	0.002	1.4±1.3	1.1

Conclusions: In conclusion, extending acyclovir infusion duration to 2 hours in pediatric transplant patients maintains overall drug exposure while increasing trough concentrations, potentially improving pharmacodynamic outcomes. These findings support considering infusion time extension as a viable approach to optimize antiviral therapy in this vulnerable population.

Disclosure: Nothing to declare

B251

EXCELLENT OUTCOMES OF UNMANIPULATED HLA-HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTS AFTER MINIMALLY INTENSIVE CONDITIONING FOR SALVAGE HSCT IN CHILDREN

Ulrike Zeilhofer[1], *Layla Bauriedl*[1], *Markus Schmugge*[1], *Michael Amrein*[1], *Mathias Hauri*[1], *Matthias Felber*[1], *Tayfun Guengoer*[1]
[1]*University Children's Hospital of Zurich, Zurich, Switzerland*

Background: For children with severe bone marrow (BM) hypoplasia due to graft failure (GF) or bone marrow failure disorders complicated by life-threatening infections, urgent rescue hematopoietic stem cell transplantation (HSCT) is required. If no HLA-matched sibling donor is available, haploidentical HSCT offers the quickest treatment option. Here we demonstrate excellent outcomes of HLA-haploidentical HSCT with unmanipulated grafts after a minimally intensive conditioning regimen, that was described by Rizzieri et al (Rizzieri et al, JCO, 2007) and so far has not been analyzed in children.

Methods: We conducted a retrospective investigation of 12 children with a median age of 11,1 years (range 1,7-17 years) who underwent a nonmyeloablative conditioning comprising fludarabine (120 mg/m2; d-5 to d-2), cyclophosphamide (90 mg/kg, d- 5 to d-2) and alemtuzumab (1.25 mg/kg; d-4 to d 0), followed by T-cell-replete haploidentical grafts from peripheral blood stem cells (PBSC). We analyzed overall survival (OS), event-free survival (EFS; events were defined as death, relapse, graft rejection or stem cell boost (SCB) administration), time to neutrophil and platelet engraftment, incidence of aGvHD ≥ grade 3 and cGvHD, viral complications and immune reconstitution.
Three patients suffered from severe aplastic anemia and life-threatening invasive infections. Two of these patients were transplanted in the intensive care unit (ICU). One patient with Cernunnos Syndrome suffered from intractable autoimmune hemolytic anemia. Nine patients were treated for GF and BM aplasia following their first allogeneic HSCT for various diseases.

Results: The median follow-up was 39 months (range 7-118 months). All 12 patients demonstrated excellent outcomes with 100% 2-year OS and 76.9% 2-year EFS. All patients engrafted, three patients needed unconditioned CD34+positive selected SCBs. The median time to neutrophil engraftment was 10.5 days (range 9-22) and the median time to platelet engraftment was 18 days (range 10-136). Acute GvHD grade 1-2 was observed in eight patients. There were no cases of aGvHD ≥ grade 3 and only one case of mild chronic skin GvHD. Two patients developed secondary autoimmune diseases (acquired hemophilia and immune thrombocytopenia ITP) which resolved after immunosuppressive treatment including rituximab. All patients could be completely weaned off immunosuppression.
Seven patients developed viral reactivations, which resolved following antiviral treatment and in two after additional donor lymphocyte infusions. All patients achieved a satisfactory immune reconstitution, however 2 patients remain on intravenous immunoglobulin replacement therapy. Ten patients demonstrate complete donor chimerism (DC) at last follow

up, one patient had a mixed chimerism with donor cells of >80% on CD14 and CD15 and complete DC on CD3 and CD19. One patient was transferred to his local hospital 7 months after HSCT for chronic granulomatous disease (CGD) with a DHR-test of 97%.

Conclusions: This non-myeloablative protocol for T-cell replete haploidentical salvage HSCT is here investigated for the first time in children. It shows promising outcome results in this extremely high-risk group of patients with stable engraftment and almost absent chemotherapy-associated toxicity. Although viral reactivations were frequent, the rapid neutrophil recovery was life-saving for children suffering from severe bacterial or fungal infections in severe aplasia. Further studies in larger patient cohorts are needed.

Disclosure: Nothing to disclose

B252

EFFICACY OF PROPHYLACTIC LEVOFLOXACIN IN PEDIATRIC AUTOLOGOUS HEMATOPOITIC CELL TRANSPLANTATION: A SINGLE CENTER, RETROSPECTIVE ANALYSIS

Melanie Klemond[1], *Alexis Kuhn*[1], *Catherine Martin*[1], *Paul Galardy*[1], *Laura Dinnes*[1], *Theresa Madigan*[1], *Anand Srinivasan*[1], *Mira Kohorst*[1]
[1]*Mayo Clinic, Rochester, United States of America (the)*

Background: The practice of using prophylactic levofloxacin following hematopoietic cell transplantation remains variable among pediatric centers due to conflicting evidence and practice recommendations. Research is particularly limited in its utility in pediatric autologous hematopoietic cell transplantation (auto-HCT).

Methods: This was a retrospective single center study of pediatric patients who underwent auto-HCT at Mayo Clinic Children's (Rochester, MN) between 2018 to 2025. For patients with multiple transplants, each transplant was treated as a discrete episode. For eligible patients, collected data included: patient and transplant characteristics, antibiotic exposure (prophylaxis and treatment), hospital length of stay, and infectious outcomes. The primary objective was to quantify the impact of levofloxacin prophylaxis on duration of febrile neutropenia. Secondary objectives included evaluating the impact of levofloxacin prophylaxis on duration of empiric IV antibiotic usage, duration of hospital stay, frequency of bacteremia, and incidence of *Clostridioides difficile*-associated diarrhea and multidrug-resistant organisms (MDRO). Continuous variables were compared using two-tailed student's t-tests, and categorical variables were compared using Pearson's chi-squared tests.

Results: Data was analyzed from 67 discrete transplant episodes in 41 patients (median age at transplant of 8.3 years, range 1.4 - 21.7 years). Indications for transplant included CNS tumors (40.4%), neuroblastoma (29.9%), lymphoma (13.4%), germ cell tumors (12.0%), and rhabdoid tumors (3.0%). There was a similar distribution of tandem transplants and transplant indications between the two groups.
From day 0 through date of engraftment, the average days of febrile neutropenia were 2.9

for the prophylaxis group, and 4.3 for the non-prophylaxis group (p=0.036). Average days on empiric IV antibiotics through engraftment were 5.4 for the prophylaxis group, and 8.3 for the non-prophylaxis group (p=0.001). There was no significant difference in the proportion of patients who developed at least one MDRO or had at least one positive blood culture within 21 days of transplant (p=1.000 and 0.355 respectively).
Duration of hospital stay post day 0 approached statistical significance (p=0.063), with an average of 15.5 in the prophylaxis group and 20.3 in the no prophylaxis group. Proportion of patients to develop *C. difficile*-associated diarrhea within 21 days of transplant also neared significance (p=0.054) with 3/36 in the prophylaxis group and 8/31 in the no prophylaxis group.

Table 1. Short-term outcomes of pediatric auto-HCT based on use of prophylactic levofloxacin

	Prophylactic Levofloxacin (N=36)	No-Prophylactic Levofloxacin (N=31)	P-value
Mean days of febrile neutropenia through engraftment	2.9	4.3	0.036
Mean days on empiric IV antibiotics through engraftment	5.4	8.3	0.001
Proportion with a positive blood culture through engraftment	5/36	7/31	0.355
Mean days of hospitalization after transplant	15.1	20.3	0.063
Proportion with C. difficile-associated diarrhea within 21 days of transplant	3/36	8/31	0.054
Proportion with one or more MDRO on culture within 21 days of transplant	3/36	3/31	1.000

Conclusions: In this retrospective analysis, the use of prophylactic levofloxacin was associated with a significantly reduced number of days with febrile neutropenia and days requiring empiric IV broad spectrum antibiotic usage from day 0 through engraftment for pediatric patients undergoing auto-HCT. Length of hospitalization was numerically lower in the prophylaxis group, though this did not reach statistical significance. No statistically significant difference was seen in the proportion of patients who developed *C. difficile*-associated diarrhea or at least one MDRO within 3 weeks of transplant, though *C. difficile* rates were numerically lower in the prophylaxis group, nearing statistical significance. Additional prospective multicenter studies with a larger cohort are needed to confirm these findings.

Disclosure: Nothing to declare.

B254

POST-TRANSPLANT COMPLICATIONS AND MAINTENANCE THERAPY IN CHILDREN UNDERGOING AUTOHSCT DUE TO RELAPSE/PROGRESSION OF HODGKIN'S LYMPHOMA

Katarzyna Smalisz[1], *Tomasz Klekawka*[1], *Anna Zaniewska-Tekieli*[1], *Magdalena Wozniak*[1], *Oktawiusz Wiecha*[1], *Aleksandra Krasowska-Kwiecien*[1], *Sylwia Bartyzel-Palinska*[1], *Jolanta Gozdzik*[1]
[1]*Jagiellonian University Medical College, Cracow, Poland*

Background: Hodgkin's lymphoma (HL) accounts for 5-7% of malignancies in children and 30% of lymphomas in children. The use of hematopoietic stem cell transplantation (HSCT) in the treatment of HL in children remains controversial due to generally good outcomes. So far, there is no unified position regarding the selection of prognostic factors indicating the small group of patients (1–5%) who should undergo such an aggressive line of treatment. High doses of drugs and auto-HSCT are recommended for patients who experience HL progression during initial treatment, in cases of early relapse with inadequate response to therapy, and in subsequent relapses. Objective: To assess complications after auto-HSCT and the impact of maintenance therapy after HSCT in children treated for relapse/progression of HL.

Methods: The process of qualification and the course of the auto HSCT procedure in children hospitalized due to progression/relapse of Hodgkin's lymphoma treated at the Hematopoietic Stem Cell Transplantation Department of the University Children's Hospital in Krakow in the years 2022-2025 was analyzed.

Results: The auto HSCT procedure was performed on 5 children - 3 boys and 2 girls. The age of the patients was 14-18 years, median 17. All children were initially diagnosed with 4 clinical stage , nodular sclerosis type. 4 children were qualified due to progression of Hodgkin's lymphoma, and 1 due to early relapse. Second-line treatment - all children received 4 cycles of IGEV, and 1 girl additionally received 2 cycles of Brentuximab+Bendamustine. PET/CT before the auto HSCT showed the following treatment response levels: Deauville 3 in 4 children, and Deauville 4 in 1 child. Stem cells were collected from the peripheral blood of all children for autoHSCT, and all underwent BEAM megachemotherapy. No severe toxicities were observed in the peri-transplant period; all children experienced grade 2-3 mucositis according to WHO, and 2 children had mild grade 2 hepatotoxicity according to WHO. Conventional radiotherapy was administered to 4 children, and proton therapy to 1 child after autoHSCT. Maintenance therapy with 6 doses of brentuximab was given to 1 child. Early relapse after autoHSCT was observed in 2 patients, at 3 and 5 months post-autoHSCT, respectively. The first patient received 3 cycles of Brentuximab + Bendamustine and was qualified for alloHSCT; the second received Brentuximab + Bendamustine followed by Nivolumab—there was no response to the treatment, and the patient was referred to palliative care. The 4 children remain in remission, currently without late treatment complications.

Conclusions: Children treated for Hodgkin's lymphoma, due to a good response to the applied treatment, rarely require megachemotherapy and autoHSCT. In cases of relapse/progression, autoHSCT in most cases allows for achieving a lasting second remission. In patients with a poorer response to the applied treatment, maintenance therapy after autoHSCT should be considered.

Disclosure: No conflict of interests.

B255

LYMPHOMATOID GRANULOMATOSIS OF A CENTRAL NERVOUS SYSTEM AS THE ONLY MANIFESTATION OF POST- TRANSPLANT LYMPHOPROLIFERATIVE DISORDER AFTER HAPLOIDENTICAL STEM CELL TRANSPLANTATION: A PEDIATRIC CASE REPORT

Maria Polacik[1], *Ines Goppelt*[1], *Tobias Däbritz*[1], *Sasha Brückmann*[2], *Christoph Meissner*[3], *Denis Martin Schewe*[1]
[1]*Faculty of Medicine and University Hospital Carl Gustav Carus, Dresden, Germany,* [2]*Institute of Pathology, Faculty of Medicine and University Hospital Carl Gustav Carus, Dresden, Germany,* [3]*Institute for Diagnostic and Interventional Radiology, Faculty of Medicine and University Hospital Carl Gustav Carus, Dresden, Germany*

Background: Lymphomatoid granulomatosis is a rare Epstein-Barr virus (EBV)- associated B-cell lymphoproliferative disorder. It is characterized by angiocentric and angiodestructive infiltrates, leading to coagulative necrosis. This disease affects typically middle-aged adults. The most common sites of involvement are the lungs, skin, central nervous system (CNS), kidney and liver.

Methods: We present a six-year-old patient, who underwent a haploidentical hematopoietic stem cell transplantation (HSCT) due to relapse of stage 4 neuroblastoma. Conditioning included fludarabine, melphalan and thiotepa. Graft-versus-host-disease (GvHD) prophylaxis included antithymocyte globulin (ATG) and mycophenolate mofetil (MMF). Three months after HSCT she developed an acute GvHD of the skin (grade II) and gut (grade III), requiring systemic immunosuppressive therapy with high-dose steroids, ciclosporine and extracorporeal photopheresis. At day 260 post-transplant, she presented with fever without a clear focus of infection. EBV-PCR in peripheral blood was positive just above the detection limit of the assay. At this time, progressive neurological deterioration was observed, including pupillary difference, right-sided hemiballismus and altered mental status.

Results: MRI of the brain demonstrated involvement of the left basal ganglia and a rounded mass in the left frontal subcortical region with marked perifocal edema and central hemorrhage. Cerebrospinal fluid (CSF) analysis revealed a cell count of 7/µl, total protein of 410 mq/l; glucose of 2,4 mmol/l and a positive EBV-PCR (3 x10^3 copies/ml). Flow cytometry of CSF showed a small population of CD3-positive T-cells and a population of cells expressing CD20 and CD30. Brain biopsy was performed, which demonstrated a vascular lymphoid proliferation, with numerous small, mature- lymphoid cells, as well as blast-like-appearing

cells and areas of necrosis. Immunohistochemical staining confirmed a B-cell origin (PAX-5 positive) with expression of CD20 and CD30. Also, numerous EBV-positive blast cells were detected. A diagnosis of post-transplant lymphoproliferative disorder, specifically a CD30-positive, EBV-positive diffuse large B-cell lymphoma (DBCL) with morphological characteristics of lymphomatoid granulomatosis grade 3 was made. CT/PET scan showed no evidence of nodal or extranodal organ involvement. Immunosuppression with ciclosporine was discontinued. The patient was treated initially with Rituximab (375 mg/m^2) weekly for a total of 4 doses, systemic prednisolone and weekly intrathecal triple therapy with methotrexate, prednisolone and cytarabine. Due to the detection of CD30- positive cells, systemic Brentuximab Vedotine was also administered. Additionally, EBV-specific cytotoxic T lymphocytes were infused. Radiotherapy was not feasible due to previous radiation of the skull at relapse of the initial malignant disease, at this time in complete remission.

Conclusions: This case report describes a manifestation of lymphomatoid granulomatosis (LYG) of the central nervous system after haploidentical stem cell transplantation in a child. Primary CNS involvement is rare and the prognosis of LYG described in literature is poor. Different treatment modalities including steroids, rituximab, chemotherapy and radiotherapy have been reported in isolated CNS-LYG. With this therapy, remission of the disease was achieved, but only partial improvement of neurological symptoms could be observed after five months of therapy.

Disclosure: "Nothing to declare"

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: A POLISH PEADIATRIC EXPERIENCE

*Natalia Haze[1], **Jowita Fraczkiewicz**[1], Anna Panasiuk[2], Karolina Liszka[1], Pawel Marschollek[1], Zuzanna Gamrot[1], Monika Mielcarek-Siedziuk[1], Anna Rodziewicz-Konarska[2], Elzbieta Wawrzyniak-Dzierzek[1], Marek Ussowicz[1], Krzysztof Kalwak[1]*
[1]Clinical Department of Paediatric Bone Marrow Transplantation, Oncology and Haematology, Wroclaw Medical University, Wroclaw, Poland, [2]Clinical Department of Paediatric Bone Marrow Transplantation, Oncology and Haematology, University Hospital in Wroclaw, Wroclaw, Poland

Background: Juvenile Idiopathic Arthritis (JIA) is the most common chronic rheumatologic condition in children, characterized by persistent joint inflammation, pain, and progressive functional impairment. Although substantial advances have been achieved with conventional disease-modifying antirheumatic drugs and biologic therapies, a subset of patients continues experience severe, treatment-refractory disease associated with long-term disability and reduced quality of life. For these patients, allogeneic hematopoietic stem cell transplantation (alloHSCT) may be considered as a rescue strategy due to its potential to reconstitute immune tolerance, supported by emerging evidence from recent studies.

Methods: Between 2022 and 2024, two adolescents with refractory juvenile arthritis underwent alloHSCT at our center in Wrocław, Poland. One patient had systemic JIA (without an identified underlying genetic defect), while the second presented with Blau syndrome (NOD2 mutation) with systemic arthritis manifestations. Both patients were transplanted from 10/10 HLA-matched sibling donors (MSD). Conditioning regimens included treosulfan, fludarabine, melphalan and alemtuzumab. Graft-versus-host disease (GvHD) prophylaxis consisted of methotrexate, tacrolimus or cyclosporine A.

Results: Both patients had prolonged, treatment-resistant disease with multi-joint involvement despite extensive therapy, including glucocorticosteroids, immunosuppressants, and multiple biologics. Early post-transplant complications included mucositis, viral infections, fever of unknown origin, and mild GvHD. Despite these complications, both patients recovered without sequelae. At a follow-up of one year in one patient and three years in the other, both achieved and remained in a complete clinical remission, with marked improvement in mobility, absence of morning stiffness, resolution of joint pain, and return to full physical activity.

Conclusions: AlloHSCT may represent a feasible and effective therapeutic option for selected pediatric patients with refractory arthritis syndromes who fail to respond to pharmacotherapy. In this small cohort, the procedure resulted in meaningful clinical improvement and enhanced quality of life. Nevertheless, the risks of transplant-related complications must be weighed against potential benefits, and long-term follow-up is essential to fully assess the durability of remission.

Disclosure: No

MANAGEMENT OF TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY IN CHILDREN AFTER HSCT WITH RAVULIZUMAB: SINGLE CENTER EXPERIENCE

*Darya Smirnova[1], **Irina Kostareva**[1], Teimur Aliev[1], Nara Stepanyan[1], Yuri Lozovan[1], Karina Sergeenko[1], Tatyana Potemkina[1], Natalya Burlaka[1], Ramil Fatkhullin[1], Mariya Malova[1], Veronika Ermakova[1], Irina Trushkova[1], Elena Machneva[1], Meri Shervashidze[1], Natalia Batmanova[1], Timur Valiev[1], Kirill Kirgizov[1], Svetlana Varfolomeeva[1]*
[1]N.N. Blokhin National Medical Research Center of Oncology, L.A. Durnov Research Institute of Pediatric Oncology and Hematology, Moscow, Russian Federation (the)

Background: Transplant-associated thrombotic microangiopathy (TA-TMA) is severe life-threatening complication of hematopoietic stem cell transplantation (HSCT). Diagnostics and treatment of TA-TMA in pediatric patients is challenging. Ravulizumab (a C5 complement inhibitor) could be used to treat severe refractory TA-TMA. Real-world data on Ravulizumab usage for TA-TMA in pediatric population required.

Methods: Seven children among 347 transplanted pediatric patients in Nikolay Blokhin National Medical Research Center of Oncology in 2023-2024 were diagnosed with TA-TMA according EBMT criterions. Three of these patients were diagnosed with severe refractory TA-TMA without adequate response on eculizumab. Patients received ravulizumab in recommended dose (by weight).

Results: Most of the patients were females (M/F=1/2), pt. 1 (F) was 17 y.o., pt. 2 (F) – 17 y.o. and pt. 3 (M) – 12 y.o. All patients suffered of leukemia (AML – 2 pts., ALL – 1 pt.) and received allogenic HSCT from matched unrelated donor (MUD). ALL patient received TBI-based conditioning regimen combined with VP and Flu and AML patients received Treo/Flu/Mel conditioning regimen. GvHD prophylaxis included ATG, rituximab, abatacept and tacrolimus or ruxolotinib in all cases. TA-TMA in pt. were found on day +77 with combination of renal bleeding. In pt. 2 and pt. 3 TA-TMA were found in the course of severe chronic GvHD with multiple therapy. TA-TMA was found in pt. 2 at day +280 and at pt. 3 at day 273 after HSCT. All patients received eculizumab (median no. of infusions – 4) before ravulizumab. Ravulizumab treatment started due to absence of clinical and laboratory effect of eculizmab. No severe side effects on ravulizamab infusion were found. All patients responded well in TA-TMA for Ravulizumab. Median number of infusions – 4.

Conclusions: TA-TMA is still challenging complication of HSCT. Use of Ravulizumab in refractory cases is promising strategy in pediatric patients. Future multicenter studies required for estimation of safety and efficacy of Ravulizumab in real-world practice.

Disclosure: Nothing to declare.

OUTCOME OF SALVAGE SECOND HAPLOIDENTICAL STEM CELL TRANSPLANTATION FOR CHILDREN WITH HIGH-RISK HEMATOLOGICAL DISORDERS: A SINGLE CENTER EXPERIENCE FROM JORDAN

Ayad Ahmed Hussein[1], *Bayan Majed Alaaraj*[1], *Dyala M. Alfryjat*[1], *Ahmed Mahmoud Rawashdeh*[1], *Ala' Al Qhaiwi*[1], *Bayan Amer Habeeb*[1], *Julia Dawoud*[1], *Tariq Ahmed Abdelghani*[1]
[1]*Bone Marrow and Stem Cell Transplantation Center, Istishari Hospital, Amman, Jordan*

Background: Haploidentical hematopoietic stem cell transplantation (haplo-HSCT) using post-transplant cyclophosphamide (PTCy) has become an important alternative for patients lacking a matched sibling donor. However, it remains associated with significant challenges, including graft failure (GF). Data on salvage second haplo-HSCT are limited.

Methods: This is a retrospective review of the medical files of all patients who underwent second haplo-HSCT at the Bone Marrow and Stem Cell Transplantation Center, Istishari Hospital, Jordan, between June 2016 and June 2025.

Results: Out of 27 patients who received T-replete Haplo-HSCT with PTCy, two required second transplant. The first patient was a 6-year-old female with severe aplastic anemia (SAA) who underwent upfront haplo-HSCT from the mother. The conditioning regimen

consisted of rATG 5 mg/kg, Fludarabine 150 mg/m^2, Cyclophosphamide 29 mg/kg, and 300 cGy TBI in a single fraction. GVHD prophylaxis was with PTCy at 100 mg/kg, mycophenolate Mofetil (MMF) and Tacrolimus. The graft was RBC depleted bone marrow (BM) due to major ABO incompatibility. The infused CD34$^+$ cell dose was 4.1 ×10^6/kg. The patient experienced non-engraftment and underwent a second haplo-HSCT from another donor (brother) 42 days later. The conditioning regimen consisted of Fludarabine 90 mg/m^2 and 300 cGy single fraction TBI. GVHD prophylaxis was with PTCy at 100 mg/kg, MMF and Tacrolimus. The graft was RBC depleted peripheral blood stem cell (PBSC) due to major ABO incompatibility with CD34$^+$ dose of 19.8 ×10^6/kg. Neutrophil and platelet engraftment were documented on day +14 and +16 post-HSCT respectively. The post-transplant course was uneventful. At last follow-up 76 months after second transplant, the patient is well and off immunosuppression. The second patient had high-risk infantile acute lymphoblastic leukemia, and underwent the first haplo-HSCT from the suitable donor (mother) following complete remission. He received myeloablative conditioning with targeted dose IV Busulfan 16 mg/kg and Cyclophosphamide 100 mg/kg. GVHD prophylaxis was with PTCy at 100 mg/kg, MMF and Tacrolimus. The graft was unmanipulated BM with CD34$^+$ dose of 3.5 ×10^6/kg. Neutrophil and platelet engraftment documented on days +14 and +17 respectively. The post-transplant course was complicated by CMV reactivation and grade 3 mucositis. The patient experienced early medullary disease relapse four months post-transplant. He received soft re-induction and consolidation chemotherapy followed by five blinatumomab cycles as bridging therapy. A second haplo-HSCT was performed 16 months after the first transplant from the same donor using PBSC. Conditioning regimen included rATG 5 mg/kg , Thiotepa 10 mg/kg, Fludarabine 150 mg/m^2, Cyclophosphamide 29 mg/kg, and 300 cGy TBI in a single fraction. GVHD prophylaxis was with PTCy at 100 mg/kg, MMF and Tacrolimus. CD34$^+$ cell dose was 10.2 ×10^6/kg. Neutrophil and platelet engraftment documented on days +14 and +15 respectively. Early post-transplant complications included grade 3 mucositis, CMV and HHV-6 reactivation, and grade 3 acute gut GVHD, all of which were successfully managed. The patient is currently doing well and disease-free at 8 months post 2nd transplant.

Conclusions: Saving lives with second Haplo-HSCT with PTCy is a feasible and effective option for complex pediatric cases. Multicenter studies are warranted to examine the best strategies for those patients.

Disclosure: Nothing to declare.

B259

CMV AND BK VIRUS REACTIVATION AFTER ALLOGENEIC HSCT ACCORDING TO DONOR TYPE: A SINGLE-CENTER PEDIATRIC EXPERIENCE

Cristina Jercan[1,2], *Irina Avrămescu*[1,2], *Ana Maria Bică*[1,2], *Andra Marcu*[1,2], *Anda Mocanu*[1,2], *Otilia Niculiță*[1,2], *Matei Coliță*[1,3], *Carmen Călugăroiu*[2], *Alexandra Ichim*[2], *Ileana Constantinescu*[1,2], *Andrei Coliță*[1,3], *Anca Coliță*[1,2]
[1]*Carol Davila University of Medicine and Pharmacy, Bucharest, Romania,* [2]*Fundeni Clinical Institute, Bucharest, Romania,* [3]*Colțea Clinical Hospital, Bucharest, Romania*

Background: Viral reactivation remains a major cause of morbidity after allogeneic hematopoietic stem cell transplantation (allo-HSCT), particularly in pediatric patients. Cytomegalovirus (CMV) and BK virus (BKV) are among the most frequent viral complications, yet data regarding their incidence, clinical impact, and association with donor type in children are limited. We aimed to evaluate the incidence of CMV and BKV reactivation according to donor type and CMV serostatus in a large single-center pediatric allo-HSCT cohort.

Methods: We retrospectively analyzed pediatric patients undergoing allo-HSCT at the Fundeni Clinical Institute between January 2013 and July 2025. CMV reactivation was defined as CMV DNAemia requiring initiation of pre-emptive antiviral therapy. BKV reactivation was defined by detection of viruria and/or viremia, with clinically significant infection defined by the presence of hemorrhagic cystitis (HC) supported by clinical and imaging findings. Donor types included matched sibling donors (MSD), matched unrelated donors (MUD), and haploidentical donors (Haplo). Conditioning regimens were disease-specific. GVHD prophylaxis included methotrexate plus calcineurin inhibitor with or without ATG, post-transplant cyclophosphamide–based regimens, or MMF-based protocols. Associations between viral reactivation, donor type, and CMV serostatus were analyzed using chi-square tests.

Results: A total of 191 patients were included: 42 MSD, 103 MUD, and 46 Haplo transplants. CMV reactivation occurred in 83 patients (43.5%). The incidence was significantly lower in MSD recipients (26.2%) compared with MUD (47.6%) and Haplo (50%) transplants (overall p=0.037). Median time to CMV reactivation was day +25 for MSD, day +18.5 for MUD, and day +30 for Haplo recipients. Recipient CMV seropositivity was strongly associated with CMV reactivation (overall p=0.015), with the highest risk observed in D−/R+ patients (p=0.046). BKV reactivation was observed in 101 patients (52.9%) and showed comparable incidence across donor types (MSD 47.6%, MUD 54.3%, Haplo 54.3%). Clinically significant BKV-associated hemorrhagic cystitis developed in 20 patients (19.8% of BKV-positive cases), with similar proportions across donor groups. Imaging studies, when performed, revealed bladder wall thickening in all evaluated cases and intravesical clots in a subset. Concomitant CMV infection and acute GVHD were observed in a minority of patients with BKV-HC. Severe BKV-related complications, including graft loss, occurred in rare cases.

Conclusions: CMV and BKV reactivations remain frequent complications after pediatric allo-HSCT. CMV reactivation is significantly influenced by donor type and CMV serostatus, with MSD transplantation associated with a lower risk and D−/R+ status representing a major risk factor. In contrast, BKV reactivation is highly prevalent and occurs independently of donor type, while clinically significant hemorrhagic cystitis affects approximately one-fifth of BKV-positive patients. These findings support risk-adapted CMV monitoring strategies and highlight the need for improved preventive and therapeutic approaches for BKV-associated complications in pediatric allo-HSCT recipients.

CMV reactivation by donor type			
Donor type	No. patients	CMV reactivation n (%)	No CMV reactivation n (%)
MSD	42	11 (26.2)	31 (73.8)

THE CLINICAL COURSE OF HAPLOHSCT + DINUTUXIMAB BETA IMMUNOTHERAPY IN POLISH CHILDREN WITH RELAPSING NEUROBLASTOMA

Katarzyna Smalisz[1], *Aleksandra Wieczorek*[1], *Oktawiusz Wiecha*[1], *Magdalena Wozniak*[1], *Anna Zaniewska-Tekieli*[1], *Sylwia Bartyzel-Palinska*[1], *Anna Sarnecka-Paruch*[1], *Jolanta Gozdzik*[1]
[1]*Jagiellonian University Medical College, Cracow, Poland*

Background: Pediatric patients with relapsed neuroblastoma after autologous stem cell transplantation have an extremely poor prognosis. Especially after haploidentical stem cell transplantation anti tumor activity exerted by donor derived NK cells could be demonstrated. Thus, the donor derived immune system post-transplant may be a basis for further immunotherapeutic approaches and anti tumor effects of antibody and cytokine administration are likely. Those effects may help to reduce the relapse rate and to improve the outcome of those patients.

Methods: The aim of the study was to analyse the qualification, toxicity and response to treatment in children with relapsed neuroblastoma undergoing haploHSCT with immunotherapy with dinutuximab beta afer HSCT.

Results: In years 2024-2025 6 children with relapsing neuroblastoma were transplanted from haploidentical donors with 5-8/10 HLA matching. The inclusion criteria were: relapse after autoHSCT, no severe organ toxicities (e.g.nephrotoxicity), no features of progression in MIBG/MRI/PET-CT and agreement of the parents. The procedure included FluMelTT (Fludarabin 4 x 40 mg/m2 BSA, Thiotepa 10 mg/kg body weight, melphalan 2 x 70 mg/m2 BSA) conditioning + ATG Grafalon in dose 30mg/kg with immunosuppresion – mycophenolate of mofetil depending of the T cell level in transplant (600-1200 mg/ kg body weight) and G-CSF support from +4 day after HSCT. The transplantation material was PBSC donated by one of the parents (1-mother, 5-fathers), with alphabetaTdepletion. The material after depletion included 8-24 mln CD 34/ body weight of the recipient. 5 boys and 1 girl were qualificated to haplo HSCT, with number od relapses 1-3. The age of patients was between 3-14 years, median 6,5. 3 patients received 131I MIBG therapy 2-3 weeks before transplantation. The tolerance of chemotherapy was good, with no severe toxicities. Deeper pancytopenia was observed in patients undergoing MIBG therapy. In peri-transplant period all patients demonstrated mild stomatitis 1-2 stage WHO. Severe infection with septic shock was observed in one patient, with no necessity of ICU hospitalization. Engraftement of WBC ctiteria were fulfilled in +10 to + 15 day, median +12. 1The MMF immunosupression was driven from 30 to 60 days depending of the level of T cell in transplant. 1 patient presented the features of acute GvHD with skin and intestine involvement, with good response to methylprednisolone id dose 2 mg/kg/day. 1 patient developed reactivation of CMV and HHV 6 neuroinfection with mild course. Only 1 patient started dinutuximab beta therapy with delay-4 weeks. All these patients completed the dinutuximab beta therapy and remain in remission.

Conclusions: HaploHSCT with dinutuximab beta therapy seems to be encouraging method of treatment for children with relapsing neuroblastoma, connecting chemotherapy and

immunotherapy. This method seems to be well tolerated with no serious toxicities. Although due to posiible toxicities of the method, the patients should be carefully selected to this method of theatment. Also well conducted alphabetaTcell depletion helps to protect patients against GvHD, enables fast withdrawal from immunosupression and continuation of therapy with dinutuximab with no delays.

Disclosure: no conflict of interests

B261

ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHILDREN WITH DIAMOND-BLACKFAN ANAEMIA: A SINGLE-CENTER EXPERIENCE

Renata Formankova[1], *Petra Keslova*[1], *Petr Riha*[1], *Martina Sukova*[1], *Dagmar Pospisilova*[2], *Ondrej Zapletal*[3], *Jan Stary*[1]
[1]*Charles University and Motol University Hospital, Prague, Czechia,* [2]*Palacky University Olomouc, Olomouc, Czechia,* [3]*University Hospital Brno, Brno, Czechia*

Background: Diamond-Blackfan anaemia (DBA) is a rare congenital pure red cell aplasia characterised by macrocytic anaemia, reticulocytopenia, constitutional abnormalities and cancer predispositions, typically diagnosed in the first year of life. Most cases are caused by heterozygous loss-of-function mutations or deletions affecting genes encoding ribosomal proteins (RPs). Standard therapy includes regular red blood cell (RBC) transfusions with iron chelation and corticosteroids from ≥ 1 year of age. Although initial steroid response reaches 80%, long-term efficacy is limited, and only 20% of children become treatment-independent. Allogeneic haematopoietic stem cell transplantation (HSCT) remains the only curative option.

Methods: Between January 1998 and June 2025, a total of 9 patients (2 males, 7 females) with DBA underwent allogeneic HSCT in the Czech Republic. The diagnosis of DBA was established at 1.3-3 months of age based on clinical and laboratory criteria. Among six children born after 2000, pathogenic RP mutations were identified: RPS26 (n=2), RPS19 (n=2), RPL5 (n=1), RPL35A (n=1). Congenital skeletal or craniophacial malformations were present in 4/9 patients. Corticosteroid therapy was initiated in all patients, with transient response in one child and no response in eight. The indication for HSCT was transfusion dependence in all 9 children. All patients received long-term iron chelation (deferoxamine, deferasirox). Before HSCT, 6/9 patients had serum ferritin level >1000 ug/l, and 8/9 showed organ iron overload confirmed by liver biopsy or MRI. Median age at HSCT was 9 years (range 4.4–19.1); the first three patients transplanted before 2000 were > 10 years old. Donors were HLA-identical siblings (n=5), 10/10 HLA-matched unrelated donor (n=3), and 9/10-HLA matched unrelated donor (n=1). Stem cell source was bone marrow in 3 patients, peripheral blood stem cells in 5 patients, and a combined graft in 1 patient. All conditioning regimens were busulfan-based. Before 2000, busulfan was combined with cyclophosphamide; later, the BuFluTT was used. ATG serotherapy was administered in all unrelated donor transplants. Rituximab was included in the conditioning of the last four patients.

Results: Engraftment was achieved in all patients; acute graft-versus-host disease (GVHD) was documented in 6/9 children, with complete response to immunosuppressive therapy in 5/6. One patient transplanted in 1998 at the age of 19 years died from grade IV acute GVHD and infection 3 months post-HSCT. Mild hepatic veno-occlusive disease occured in three patiens without need for therapeutic intervention (defibrotide). One patient developed severe transplant-associated thrombotic microangiopathy managed successfully with eculizumab. Eight of nine children are alive and well, RBC transfusion-independent, with full donor chimerism and no evidence of chronic GVHD, at a median follow-up of 4.9 years (range 0.5–27 years) post-HSCT.

Conclusions: Allogeneic HSCT from matched related or unrelated donors is currently indicated for steroid-non-responsive or transfusion-dependent children with DBA. Our experience confirms high efficacy and acceptable safety, particularly in childern < 10 years, while the decision must be individualised and carefully weighed in older patiens.

B262

CHRONIC GRAFT VERSUS HOST DISEASE DURING 20-YEAR OF MONOCENTRIC EXPERIENCE

Francesca Dagliano[1], Sara Pestarino[1], Giulia Ferrando[1], Francesca Bagnasco[1], Stefano Giardino[1], Filomena Pierri[1], ***Maura Faraci***[1]
[1]*IRCCS Istituto G. Gaslini, Genova, Italy*

Background: Chronic Graft-versus-Host Disease (cGvHD) is one of the most common causes of morbidity and mortality affecting survivors of allogeneic hematopoietic cell transplantation (HCT). The incidence is lower in children (6-33%) than adults. Risk factors are mismatched donor, PBSCs as source, older age, and female donor/male recipient combination. The therapeutic approach of cGvHD is still challenging although new therapeutic approaches has improved the outcome of these patients.

Methods: This single-center retrospective study includes 396 pediatric patients who underwent allogeneic HSCT at IRCCS Giannina Gaslini Institute between 2004 and 2024. The median follow-up is 11.5 years (range 0-21 years). Second transplants performed for relapse of malignant disease were included, while primary and secondary graft failure were excluded. We retrospectively collected data about underlying disease, source of HSC, conditioning regimens, GvHD prophylaxis, onset and grading of acute and cGvHD, organ involvement (according to the 2014 National Institutes of Health consensus criteria), treatments and response to therapies.

Results: We examined 402 transplants (396 first transplants and 6 second transplants for disease relapse) in a cohort of 396 patients with malignant and non-malignant diseases: 85 patients (21.4%) developed cGvHD. The characteristics of the examined population are reported in Table 1.

83.5% (71/85) of patients had cGvHD after a previous acute GvHD and in 69% of them aGvHD was grade 1-2, while in 31% grade 3-4. The 77.5% of patients with aGvHD reached a complete response after a first line therapy with steroid.
Among patients with cGvHD, 15/85 (17.6%) developed grade 1, 40/85 grade 2, and 30/85 grade 3 disease. The most involved organ was the skin which was affected in 76.4 % of patients, followed by GI tract (45.8%), lung (25.8%), liver (22%), eye and oral mucosae (16.4%) and two patients had sierositis as main clinical manifestation of cGvHD. 61.1% of patients showed multiorgan involvement.
Most patients received steroids as first-line treatment (73/85, 85.9%), but it was often necessary to combine other treatments as Extracorporeal Photopheresis (14/85) and JAK inhibitors (imatinib or ruxolitinib) (38/85) to achieve a clinical response. A complete treatment response was reached from the 53% patients, 40% obtained a partial response, while 6 (7%) patients did not respond to any line of treatment.
Of 85 patients 19 died (22.3%) and transplant related mortality was cause of death in 14.%, and cGvHD in 8 patients.

Characteristics	**Patients with cGVHD (n =85)**
Male	51 (60%)
Female	34 (40%)
Malignant	46 (54.1%)
Benign	39 (45.9%)
MSD	22 (25.8%)
Haplo	24 (28.2 %)
MUD	39 (46 %)
Myeloablative	39 (45.8 %)
RIC	46 (54.2%)
BM	60 (70.6%)
PBSC	24 (28.2%)
CORD BLOOD	1 (1.2%)
GVHD prophylaxis	
MTX	39 (45.9%)
ATG	56 (65.9%)
Alemtuzumab	5 (5.9%)

Characteristics	Patients with cGVHD (n =85)
Engraftment	
PMN	85 (100%)
PLT	81 (95.2%)

Conclusions: Chronic GvHD represent as one of the major late complications of allogeneic HSCT, with an incidence comparable to that described in literature. Retrospective analysis of cGvHD is essential to identify the incidence in our population in particular in pediatric patient and it is complex yet extremely useful for guiding the clinical practice; the application of the NIH classification allows us to objectify this complication. The treatment of cGvHD is challenging, requiring the use of steroid therapy as first-line treatment, often in combination with other methods as steroids-sparing strategy.

Clinical Trial Registry: Not applicable.

Disclosure: Nothing to declare.

Background: Infant˙s KMT2A-rearranged acute lymphoblastic leukemia (I-KMT2A-r ALL) is characterized by unique biology: multiple KMT2A partners genes engagement, early B-lineage phenotype predominance; agressive clinical course: initial hyperleukocytosis, central nervous system involvement (CNS pos); high rate of relapses refractory (r/r) to the standard programs of chemotherapy with or without hematopoietic stem cells transplantation (HSCT) Targeting immunotherapy implementation into the infant˙s ALL treatment programs demonstrates very convincing results, but until now, little is known about its effectiveness for the r/r CNS positive KMT2A-r ALL in this age group.

Methods: From 2014 to 2025, 21 uncelected patient (pts) with r/r I-KMT2A-r ALL, who were treated initially by MLL-Baby programm, with median of age 5 months (range: 4 days-10.5 mo) at the time of primary ALL diagnostic , underwent 25 HSCT after complete CSF clearance and hematological remission (CR) achievement in one Pediatric Oncology and

Hematology Center. Depending on CD19 and/or CD22 expression, 28-days blinatumomab (blina) course (5mcg/15mkg/sq.m/day by IV continuous infusion) or inotuzumab ozogamicin (ino) 3 times once a week (0.8-0.5-0.5 mg/sq.m/1 hours IV infusion were applied prior to HSCT in all minimal residual disease positive (MRD(+)) cases (range 0.011-0.4% by flow cytometry). 17 of 21(86.5%) were CNS+, all of them with B-lineage immunophenotype and BI- ALL predominance (62%); KMT2A::AFF1/t(4;11) in 57%, KMT2A::MLLT3/t(9;11) in 24%, KMT2A::MLLT1/t(11;19) and KMT2A::MLLT10/t(10;11) both at 9.5%. 19(76%) pts received haplo HSCT, 5MSD and 1MUD. Treo/Flu/Mel(or Thio) MAC regimens have been applied in all cases, except one with Bu/Flu/Mel with various regimens of immunosupression, TCRαβ /CD19 depletion in 15 and PTCy in 10 cases.

Results: All the transplanted pts achieved MRD(-) CR at the Day(D)+28. 3 pts with MRD reappearance at the D+62, D+83,D+93 have been salvaged by one or two 28D blina courses with 4 DLI each, one of them progressed and died , another 2 pts are survived in MRD(-) CR for 4 and 7 years respectively. One more patient developed graft rejection after first HSCT and died from engraftment failure, despite of the second haplo HSCT. Another one patient died after first HSCT due to the acute GvHD Grade 4.
9(53%) out of 17 CNS positive pts relepsed: 6 developed very early, 1 - early and 2 late BM BM+CNS relapses . It is important to note: all 4 CNS negative pts are alived in MRD(-)CR since its time of achievement
3 patients who were relapsed despite of the bridge immunotherapy and MRD(-) status after first HSCT, underwent secondary HSCT, succsessfully achieved MRD(-)status and alive in CR. EFS in our group of patients with multiple unfavorable factors is 0.47 ±0.2; OS – 0.69± 0.15; RFS – 0.56± 0.19 and CIR 0.43 ±0.1.

Conclusions: Although the combination of immunotherapy and HSCT together with chemotherapy for infant's KMT2A-r demonstrates promising results, treatment of pts with CNS positive KMT2A-r infants R/R ALL still a challenging problem. New CNS-directed curative strategy for this group of patients must be evaluated in the nearest future.

EXTRACORPOREAL PHOTOPHERESIS INWITH DIFFERENT SYSTEMS PERFOREMD; A REAL WORLD SINGLE CENTER REPORT

Volker Witt[1], *Andrea Lietz*[1], *Michael Rittenschober*[1], *Magdalena Russwurm*[1], *Natalia Zubarovskaya*[1], *Anita Lawischka*[1], *Herbert Pichler*[1]
[1]*St. Anna Kinderspital, Vienna, Austria*

Background: Extracorporeal photopheresis (ECP) is still an accepted second line treatment in acute and chronic GVHD. In the adult setting the use of commercial available systems is mostly easy and vascular access is feasable with an experienced team. In pediatric setting this is more challenging. Therefore especially in pediatric centers different systems could be used for treating extrem small children or children in difficult situations. In our centre we

have MINI ECP (manual treatment of 200 ml peripheral blood in under GMP conditions processed), offline Systems (AMICUS™+PIT™, OPTIA™+PIT™) inline systems (UVARXTS™, CELLEX™(historically, AMICUS BLUE™) available. One major impact in using differnet systems might be the cell dose treated (smallest in MINI ECP).We ask our self, if the use of different systems has an impact on outcome of acute or chronic GVHD. Therefore we retrospectively analysed in our patients the use of different systems and the overall outcome, especially when we used MINI ECP, due to different cell doses been treated (the sammlest amount in MINI ECP and the highest in offline ECP).

Methods: We retrospectvely collected data from patients charts used for the documentation of the treatment of acute and chronic GVHD. ECP was used as second line treatment in corticoid refractory situations, or in cirtical situations to avoid massive immunosppressive agents. MINI ECP was performed form 200 ml peripheral blood harvested by either isovolemic hemodilation or exchange. In offline methods the leukapheresis was performed by processing 1000 to 2000 ml peripheral blood, and Reinfusion once or twice on consecutive days. Inline methods were performed in Cellex bei processing 100 to 1500 ml blood, and the same for the AMICUS BLUE inline system. For statistical analysis WinSTAT™ add in for xcel was used. The internal policy to choose the method of ECP was 1.) available vascular access, 2.) absence of critical illness, 3.) willingness of accept a longterm vascular access, if not MINI ECP was preferred, and also for tappering strategies.

Results: We treated from 2011 to 2025 81 patients with episodes of acute (n=50) and chronic GVHD (n=38), median age 9.79 y (min 0.32 to max 25.3) and in median 25 ECP per episode (min 2, max 141) corresponding to n=2228 procedures (MINI ECP 703, AMICUS BLUE 617, offline 679, CELLEX/UVARXTS 206). The five years survival rate for the whole group was 78% (Kaplan-Meier), for the patients with acute GVHD group 78.4% and chronic GVHD 75.4%. Only deaths were directly related to untreatable GVHD (BOOP, GVHD after DLI). A subgroup of patients recieves only MINI ECP (n=23, median age 4.6y) versus patients with combination of MINI ECP with offline or inline systems (n=58, median age 11.7y). ECP was in every case part of an multimodular therapy. This subgroup has not significant dfferent outcome versus the mixed group (87% overall survival versus 74%). Reductions of corticoid and/or immunosuppressive therapy was one of the main results.

Conclusions: Especially in young patients the combination or the only use of MINI ECP instead of standard treatment (offline and inline) can result in faivorable overall outcome.

Disclosure: Nothing to declare.

TACKLING MIXED CHIMERISM WITH WHOLE BLOOD DONOR LYMPHOCYTE INFUSION IN RESOURCE LIMITED SETTING – CASE SERIES

Ranjit Kumar Chatada Srivaishnava[1], *Chaitanya G B*[1], *Anil Aribandi*[1]
[1]*Sindhu Hospitals, Hyderabad, India*

Background: Mixed donor chimerism is increasingly common in the pediatric hematopoietic stem cell transplantation (HSCT) setting because of the increased use of reduced-toxicity preparative regimens for nonmalignant diseases. Mixed chimerism poses a threat to disease relapse and transplant failure. Donor lymphocyte infusion (DLI) is a well established strategy to mitigate the mixed chimerism, however in the resource limited settings and in Low middle income countries which adds the extra financial burden to the family and donors consent for the DLI procedure become difficult, Here in our study we used whole blood DLI for mixed chimerism in 7 pediatric patient and retrospectively analyzed the data and presented.

Methods: This is the retrospective case series data collected from the EMR, our series includes total 7 children we have undergone allogenic stem cell transplantations for the various benign conditions. Chimerism was done by using the VNTR PCR analysis. Whole blood DLI was considered, after the failure of immunosuppression boost, to the children who had mixed and dropping chimerism along with cytopenias. Before whole blood DLI donor peripheral blood CD3 count was enumerated by using flow cytometry and each time before DLI donor Complete blood counts and Differential counts perfomred and Whole blood DLI [W DLI] volume was calculated as per dose required. Following W-DLI, chimerism was performed once every 2weeks and W-DLI was planned until complete donor chimerism.

Results:

	Case-1	Case-2	Case-3	Case-4	Case-5	Case-6	Case-7
Diagnosis	Griscelli syndrome	SCID T-B-NK+ (RAG27+)	Thal Major-class II	Thal Major-Class II	IBMFS-ERCC6L2+	Hyper IgE syndrome-DOCK8+	MPS-type IH & II
Age at HSCT	18mon	5mon	4yrs	5yr	10yr	6yr	15mon
Type of HSCT	MSD	MSD	Haplo/PtCY	Haplo/PTCY	MRD(Father)	Haplo / PtCY	MSD
Conditioning	FTT	FTT	FTTA	FTTA	FTTA	Flu-CTx-TBI	FTTA
GVHD prophylaxis	MTX+CSA	MTX+CSA	PtCY + Tac+MMF	PtCY + Tac +MMF	MTX + Tac	PtCY + Tac+MMF	MTX+Tac

Engraftment [N/P]	10 /17	14/21	18/24	17/22	12/18	14/18	16/20
Day+30 chimerism	98%	97.6%	99%	97.9%	99.25%	99%	86%
Reason for DLI	Cytopenias	Cytopenias	Cytopenia - Transfusion	Cytopenia	Cytopenia	Cytopenia-symptoms	Cytopenia
Strategies before DLI	Withdrwal of immunosuppression	Immunoboost/ Withdrwal	Immunoboost/ Withdrwal	Immunoboost/ Withdrwal	Immunoboost/ Withdrwal	Immunoboost/ Withdrwal	Immunoboost/ Withdrwal
Number of DLI dose	3	7	4 – Secondary GR	8	2	6	2
Post DLI chemirism	FDC	Stable mixed Chimerism -86%; no cytopenia	Secondary graft rejection	FDC	FDC	FDC	FDC
Outcome	Alive -CR	Alive-CR	Alive – Auto recovery	Alive-CR	Alive -CR	Alive-CR	Alive-CR

In our series out of 7children who received W-DLI, 6 were responded and cytopenias and symptoms were controlled, one child had stable mixed chimerism but cytopenias recovered. We have seen 85% success with W-DLI in our series.

Conclusions: Mixed chimerism in benign condition stem cell transplantation poses a threat for disease relapse, DLI has success rate in between 60-85% in the literature, however which as extra financial burden on the families and for repeated doses patient will be exposed to DMSO and storage related challenges. In W- DLI in our series we have seen 85% success rate and easy to use and DLI product is free from DMSO. Therefore in resource limited settings Whole blood DLI is a good alternative for DLI and with at least similar results as conventional DLI.

Clinical Trial Registry: No.

Disclosure: No conflict of interest.

DEVELOPMENT OF A NOVEL SCORING INDEX TO QUANTIFY THE NEED FOR NUTRITIONAL SUPPORT INTERVENTIONS DURING STEM CELL TRANSPLANT AND GENE THERAPY IN CHILDREN

Gerard Gurumurthy[1], *Rebecca Dixon*[2], *Victoria Whiteley*[2], *Claire Horgan*[2], *Omima Mustafa*[2], *Denise Bonney*[2], *Ramya Nataraj*[2], *Oana Mirci-Danacar*[2], *Nicola Williams*[2], *Rob Wynn*[2]
[1]*The University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Royal Manchester Children's Hospital, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Children undergoing haematopoietic stem cell transplant (HSCT), chimeric antigen receptor (CAR-T) therapy, or autologous gene therapy require intensive dietetic input and nutrition support due to treatment-related toxicities to optimise patient outcome. There is no scoring index to quantify the intensity and duration of such dietetic interventions in children despite nutritional status being known to correlate with outcomes. We developed a quantitative score to capture the cumulative intensity and duration of dietetic support delivered over the first 100 days to cell therapy recipients.

Methods: We performed a single-centre retrospective study of 131 children. Nutritional interventions were categorised into five levels: dietetic review (1 point), oral nutritional support (2 points), enteral nutritional support (4 points), parenteral nutritional (PN) support (6 points), and bespoke PN support (7 points). The cumulative nutritional intensity score was calculated by multiplying the intervention points by the duration (in days) and summing across all interventions. The primary endpoint was the cumulative score at day +100. Secondary analyses assessed predictors of ≥PN requirement at day +100 with multivariable logistic regression.

Results: The cohort included allogeneic HSCT (n=109, 83.2%), CAR-T (n=16, 12.2%), and gene therapy (n=6, 4.6%). CAR-T patients showed notably lower median nutritional intensity score (53.0, 95%CI: 30-117) relative to allogeneic (326.0, 95%CI: 282-404) or stem cell gene therapy (124.5, 95%CI: 56-182, $p < 0.05$) recipients. Within allogeneic patients, malignant disease was associated with higher scores than non-malignant disease (444.0 vs 261.5, $p<0.01$). Conditioning with total body irradiation (TBI) had higher scores than non-TBI (476.0 vs 302.0, $p<0.01$). On multivariable analysis, higher nutritional intensity and malignant disease independently predicted ≥PN at day +100 (OR = 2.43 per 100-unit increase). Model discrimination was strong (AUC-ROC: 0.87).

Demographic	**N=131**
Age	
Median Age (IQR)	7 (3-12)
Gender	

Male	86 (65.6%)
Female	45 (34.4%)
Transplant Type	
Allogeneic	109 (83.2%)
CAR-T	16 (12.2%)
Gene therapy	6 (4.6%)
Of those undergoing allogeneic transplant	***N =109***
Allogeneic Cell Source	
Cord Blood	31 (28.4%)
Others	78 (72.6%)
Disease	
Malignant	45 (41.3%)
Non-malignant	64 (59.7%)
Conditioning	
Total body irradiation	14 (12.8%)
Not irradiated	95 (87.2%)

Conclusions: Our nutritional intensity score captures the cumulative burden of dietetic support. Higher scores identify patients at risk of prolonged PN. This tool may enable early risk stratification and inform resource planning. Prospective validation is warranted.

POOR OUTCOMES FOR CHILDREN WITH REFRACTORY POST TRANSPLANT LYMPHOPROLIFERATIVE DISORDER

Kristene Rimbaldo[1], Rachel Conyers[1,2,3], Theresa Cole[1,3,2], Deborah Meyran[1,3,2], Heather Weerdenburg[1,3,2], Lorna McLeman[1,3,2], Stacie Wang[1,2], Diane Hanna[3,1,2], ***Hannah Walker***[1,2,3]
[1]Royal Children's Hospital, Melbourne, Australia, [2]University of Melbourne, Melbourne, Australia, [3]Murdoch Children's Research Institute, Melbourne, Australia

Background: Post-transplant lymphoproliferative disorder (PTLD) is a rare but serious complication of paediatric haematopoietic stem cell transplant (HCT) and solid organ

transplant (SOT). Although most PTLD arises in the setting of Epstein Barr virus (EBV) driven B-cell proliferation, disease biology spans a clinicopathological spectrum from benign hyperplasia to aggressive monomorphic lymphoma. Survival has improved with rituximab based therapies however, refractory or relapsed PTLD remains challenging, with poor survival outcomes and limited paediatric-specific evidence to guide management. This study aimed to describe the natural history, treatment approaches and outcomes of paediatric PTLD according to transplant type, with particular emphasis on relapsed and refractory disease.

Methods: We conducted a retrospective single centre review of paediatric patients (<18 years) diagnosed with PTLD following HCT and SOT at the Royal Children's Hospital (Melbourne, Victoria) from 2016-2024. Clinical, histological and transplant-related variables were extracted from electronic medical records. Overall survival (OS) and event-free survival (EFS) were estimated using Kaplan–Meier methods.

Results: Twenty-five children developed PTLD, eighteen following SOT and seven following HCT. Histological subtypes included hyperplasia (36%), polymorphic PTLD (24%), and monomorphic lymphoma (40%). Advanced (Ann Arbor Stage III/IV) disease was common (69%), including three cases with CNS involvement and four with marrow infiltration. Rituximab and/or reduction in immunosuppression (RIS) was first-line therapy in 64% of patients with a complete response rate of 56%. EBV-specific cytotoxic T lymphocytes (CTLs) were used in 32% of patients with an overall response rate of 87%. Chemotherapy was typically reserved for monomorphic lymphoma or failure of rituximab-based therapy. Refractory disease occurred in 28% of patients (n=7), predominantly in those post HCT (57%) and with monomorphic lymphoma (86%). All deaths (n=5) occurred in this group, all within 12 months of diagnosis. In contrast, relapsed cases (20%), exclusively in SOT recipients, were all successfully salvaged with further therapy. Five-year overall survival was 80% and event-free survival was 52%. Refractory disease, monomorphic lymphoma, and stage IV disease were associated with inferior survival.

Conclusions: Refractory monomorphic PTLD accounted for all deaths in this cohort, highlighting a critical unmet need in paediatric transplant care. These findings highlight a need for clinical trials evaluating earlier risk stratification, integration of CTLs and optimising management strategies for this high-risk population.

Disclosure: Nothing to declare

ULTRA-RAPID CD3/CD45RA-DEPLETED HAPLOIDENTICAL HSCT FOR PEDIATRIC CEREBRAL ALD: FEASIBILITY, ENGRAFTMENT KINETICS, CHIMERISM BEHAVIOR, AND EARLY NEUROLOGIC OUTCOMES IN THREE CASES

Poh Lin Tan[1], *Frances Yeap*[1], *Jann Adriel Chua Sy*[1]
[1]*National University Hospital, Singapore, Singapore*

Background: Cerebral X-linked adrenoleukodystrophy (cALD) is a progressive neuroinflammatory demyelination in boys. Allogeneic HSCT can arrest MRI activity and preserve function when performed early (low Loes scores, minimal neurologic impairment), but donor acquisition delays can be critical in a disease where "time is brain." Haploidentical HSCT offers immediacy; however, ALD-specific data—particularly using ex vivo T-cell–depleted platforms—are sparse and often embedded within broader inherited metabolic disorder cohorts. In parallel, lentiviral gene therapy (elivaldogene autotemcel) is an option for select early-stage patients, but eligibility, access, and time-to-treatment constraints frequently limit real-world use relative to the pace of inflammatory progression. We present an ALD-focused pediatric series using a standardized CD3/CD45RA-depleted haploidentical platform, emphasizing operational timelines, engraftment/chimerism kinetics, safety, and early neurologic outcomes.

Methods: We analyzed three boys with cALD (ages at HSCT 6.7–9.0 years) who underwent paternal haploidentical peripheral blood stem cell transplantation. All grafts were ex vivo CD3/CD45RA-depleted. Conditioning comprised ALC-based Thymoglobuline, model-based Fludarabine and Busulfan, Rituximab, and IVIG; GVHD prophylaxis included Tacrolimus. Pre-HSCT staging captured MRI Loes scores, gadolinium enhancement, and clinical status. Outcomes included timeliness (referral-to-admission and referral-to-transplant), engraftment (ANC and platelets), donor chimerism at predefined timepoints, immune reconstitution (IgG), GVHD, infections, hospital length of stay, and serial clinical neurologic assessments.

Results: Disease spectrum: One symptomatic patient had a Loes score of 7 with extensive enhancement; two were presymptomatic with low Loes scores (1–1.5) and focal enhancement on screening MRI. Operational timeliness: Referral-to-transplant was 23–34 days; referral-to-admission was 9–21 days. Graft/platform: CD34+ doses were high (10.66–25.06 × 10^6/kg) with ultralow CD3 contamination (0.039–0.050 × 10^6/kg). Engraftment: Myeloid recovery occurred on day +8 or +9 in all patients; platelets exceeded 100,000/μL on days +12, +13, and +69. Early chimerism: All achieved ≥95% donor chimerism by day +8–9. Chimerism dynamics: The symptomatic patient maintained 100% donor chimerism through year 2. Both presymptomatic patients developed mixed/declining chimerism, prompting pre-emptive donor lymphocyte infusion (DLI) at day +157 with 7 doses and day +54 with 4 doses, respectively; latest available chimerism stabilized at 0.91 in both. Safety: No grade ≥2 acute GVHD or chronic GVHD occurred; one suspected upper GI aGVHD episode (vomiting) resolved. Infections/toxicity: One CMV DNAemia episode was managed successfully with anti-virals. Regimen-related toxicities were predictable and manageable (nausea/vomiting, mucositis, tacrolimus-related hypomagnesemia; one busulfan-associated

rash; one case of engraftment fevers/rash). Length of stay was 28–37 days. Immune reconstitution: IgG at day +100 was 8.9, 11.3, and 12.6 g/L. Neurologic outcomes: The symptomatic patient showed stabilization with functional gains by year 2. Presymptomatic patients remained clinically stable at early follow-up.

Conclusions: A standardized CD3/CD45RA-depleted haploidentical platform enabled rapid time-to-transplant, ultra-fast engraftment, and low GVHD in pediatric cALD. The recurrent observation of mixed/declining chimerism in early-stage patients—despite robust initial engraftment—highlights a potentially stage- and platform-specific behavior that may benefit from protocolized monitoring and timely DLI. These data support haploidentical HSCT as a timely, feasible option for cALD for multicenter evaluation to refine conditioning intensity, graft composition, and DLI strategies to optimize durable chimerism and neurologic preservation.

P215

TORQUE TENO VIRUS IN PEDIATRIC CAR-T RECIPIENTS

Yasmina Mozo[1], *Carolina del Pino*[1], *María Martín-Lunas*[2], *Berta González*[1], *Víctor Galán*[1], *Isabel Martínez Romera*[1], *Teresa Del Rosal*[1], *Elena Sánchez Zapardiel*[1], *Iker Falces Romero*[1], *Victor Manuel Quintero*[1], *Sonsoles San Román*[1], *Jordi Minguillón*[1], *Itsaso Losantos*[1], *Carmen Cámara*[1], *Eduardo López Granados*[1], *Cristina Calvo*[1], *Antonio Pérez Martínez*[1]
[1]*Hospital Universitario La Paz, Madrid, Spain,* [2]*Hospital Clínico Universitario de Santiago, Santiago de Compostela, Spain*

Background: CART therapy has improved outcomes in relapsed/refractory (R/R) B-acute lymphoblastic leukemia (B-ALL) and diffuse large B-cell lymphoma (DLBCL), although immune-mediated toxicities remain a concern. Torque Teno Virus (TTV) is the main component of human virome. A recent study in adults suggests that plasma TTV viral load (TTV-VL) in CART patients may correlate with immune effector cell-associated neurotoxicity syndrome (ICANS) severity and progression-free survival (Benzaquén, 2024). We aimed to analyze plasma TTV-VL kinetics in pediatric CART recipients, its association with complications, outcome, lymphocytes and CART subsets, and its predictive value.

Methods: Retrospective single center study including <18 years treated with CART CD19 or CD19/22 (2019-2023) for R/R B-cell malignancies. Blood samples were collected pre-lymphodepletion (pre-LD), at CART infusion (0d), +7, +14, +21, +28, +35, +42, +60 and + 90 days (d), and at the onset of immunotoxicities. Immune cell typing was performed by flow cytometry. CART was monitored via HIV qPCR and flow cytometry. TTV in plasma was measured with TTV
R-GENE® (Biomérieux, France).

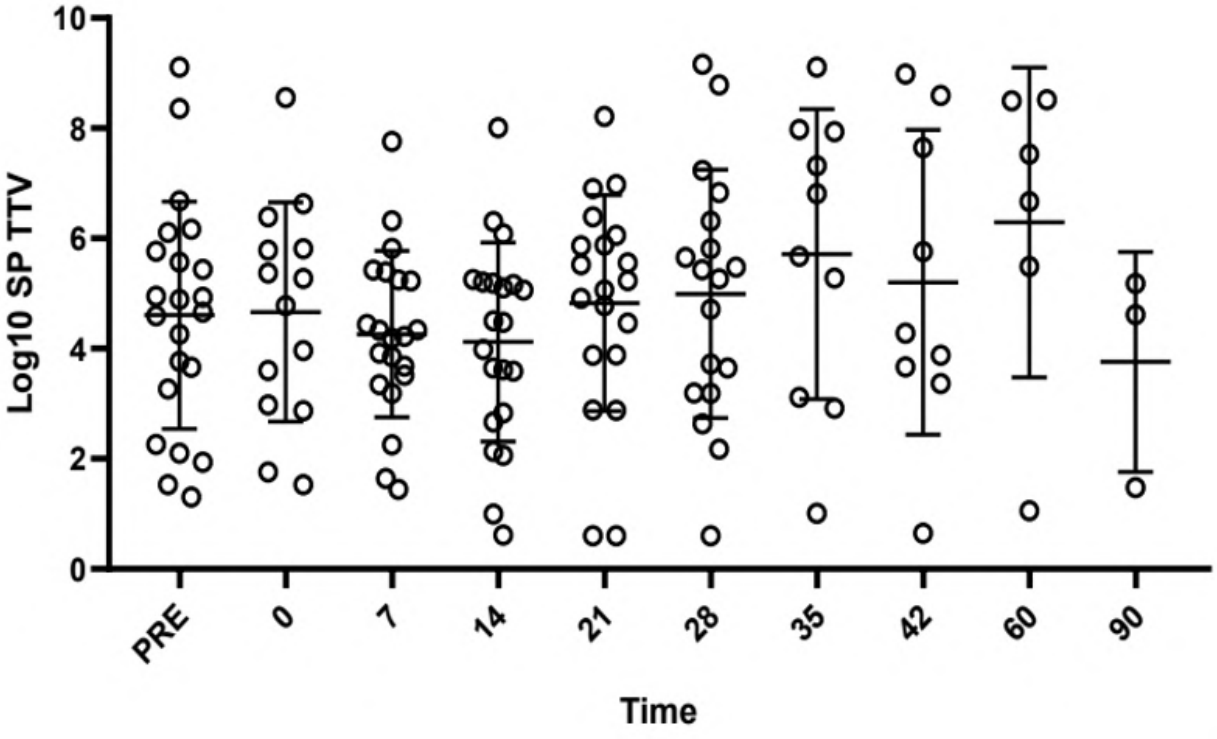
Results: Twenty-seven patients were included, treated with CD19 (70.4%) or CD19/22 (29.6%) CART because of B-ALL (81.5%) or DLBCL (18.5%). Most were male (59.3%),

caucasian (55.6%), mean age 12.5 years (SD 5.6); 18.5% Down Syndrome. Immune-mediated toxicities and other complications are detailed in table 1.

IMMUNOTOXICITIES	n=27
CRS, n (%)	23 (85.2)
Onset day, median [Q1, Q3]	3 [1, 6.5]
Grade 3-4, n (%)	9 (33.3)
ICANS, n (%)	8 (29.6)
Onset day, mean (SD)	8.1 (2.6)
Grade 3-4, n (%)	5 (18.5)
HLH, n (%)	10 (37)
Onset day, mean (SD)	8.1 (2.6)
Treatments, n (%)	
Steroids	13 (48.1)
Tocilizumab	11 (40.7)
Siltuximab	8 (29.6)
Anakinra	9 (33.3)
COMPLICATIONS AT 30 DAYS	n=27
Pancytopenia, n (%)	6 (22.2)
Infections, n (%)	7 (25.9)
PICU admission, n (%)	14 (51.9)

B-cell recovery occurred in 29.6% (mean 92 days, SD 61.4), 40.7% relapsed (mean 139 days, SD 105), and 11.1% had progressive disease (PD). Twenty patients (74.1%) received treatment after CART, 48.1% HSCT. Survival was 55.6% (median follow up 752 days, [134.5,1421]). Main causes of death were PD (64.3%) and HSCT complications (14.3%). TTV was analyzed in 173 samples (figure 1). Pre-LD, it was detectable in 81.5%, with no differences regarding patient characteristics. Receiver Operating Characteristics curve analysis (ROC) at Pre-LD revealed a TTV-VL threshold of 4.91 log copies/ml predicted PICU

admission (AUC 0.77; Sp 70%, Se 75%). Each increase in pre-LD TTV-VL diminished the probability of receiving tocilizumab by 45.1% (p=0.0496).
At 0d, TTV-VL inversely correlated with CRS grade (p=0.0165). ROC showed 6.51 log copies/ml predicted CRS (AUC 0.82; Sp 66.7%, Se 100%) and 2.93 grades 3-4 (AUC 0.96; Sp 91.7%, Se 100%); 3.29 HLH (AUC 0.85; Sp 90%, Se 75%), PICU admission (AUC 0.77; Sp 90%, Se 75%), and steroid treatment (AUC 0.85; Sp 90%, Se 75%). Treatment with tocilizumab was predicted by 3.78 (AUC 1; Sp 100%, Se 100%) and siltuximab by 1.64 log copies/ml (AUC 0.75; Sp 100%, Se 50%).
TTV-VL could predict mortality with 0.75 AUC: 4.99 log copies/ml at +28d (Sp 80%, Se 75%), 4.2 at +35d (Sp 100%, Se 75%), and 3.77 at +42d (Sp 100%, Se 75%).
TTV-VL directly correlated with absolute NK cells count at +7 (p=0.0371), double negative at +21 (p=0.0356), and Treg lymphocytes at +42d (p=0.0386). The correlation resulted inverse with total T lymphocytes at +21d (p=0.0064).
TTV-VL at 0d inversely correlated with HIV qPCR at +28d (p=0.0231). We found no associations with CART flow subsets.



Conclusions: In pediatric CART recipients, TTV-VL does not correlate with CART monitoring methods, but could predict toxicity and outcomes.

Disclosure: Nothing to declare.

P217

A PILOT RANDOMIZED STUDY OF SMOFLIPID VERSUS INTRALIPID IN PEDIATRIC ACUTE LEUKEMIA UNDERGOING HSCT: EARLY ANTHROPOMETRIC, METABOLIC, INFLAMMATORY, AND CLINICAL EFFECTS

Melika Hajimohammadebrahim-Ketabforoush[1], Pejman Rohani[2], Zahra Vahdat Shariatpanahi[1], Maryam Behfar[3], ***Amir Ali Hamidieh[3]***
[1]National Nutrition and Food Technology Research Institute, Shahid Beheshti University of Medical Sciences, Tehran, Iran (Islamic Republic of), [2]Pediatric Gastroenterology and Hepatology Research Center, Children's Medical Center, Tehran University of Medical Sciences, Tehran, Iran (Islamic Republic of), [3]Pediatric Cell and Gene Therapy Research Center, Gene, Cell & Tissue Research Institute, Tehran University of Medical Sciences, Tehran, Iran (Islamic Republic of)

Background: Nutritional management of children undergoing allogeneic hematopoietic stem cell transplantation (HSCT) for acute leukemia remains a challenge and unresolved aspect of care. Although enteral feeding is increasingly advocated, many pediatric patients cannot meet requirements enterally, necessitating parenteral nutrition (PN). The optimal formulation and dosing of PN in this population remain uncertain, as clear evidence or HSCT-specific guidelines are lacking. SMOFlipid has been suggested to offer metabolic benefits over conventional Intralipid; however, it is not FDA-approved for pediatric use, despite adoption clinical practice. To address these uncertainties, we performed a double-blind pilot randomized trial in pediatric HSCT recipients comparing SMOFlipid with Intralipid.

Methods: This double-blind randomized pilot trial enrolled pediatric acute leukemia patients undergoing allogeneic HSCT and assigned them to high-protein PN using either SMOFlipid or Intralipid for a standardized 10-day post-transplant regimen. Oral intakes were concurrently recorded to quantify total energy delivery. Anthropometric, biochemical, inflammatory, and hematological markers were assessed at baseline and predefined follow-up points, and early clinical outcomes were prospectively monitored.

Results: Thirty-one patients were included (13 SMOFlipid, 18 Intralipid; mean age 9.26±3.62 years). Baseline characteristics, estimated energy targets, initial PN composition, oral intake, and appetite scores were comparable. During the first 10 post-transplant days, patients achieved on average 47.35±7.84 % of estimated energy needs parenterally, 33.97±12.20 % orally, and 81.32±11.55 % in total. ANCOVA adjusting for baseline values and key covariates, showed no significant differences between groups on day +15 in the means of 10-day oral energy and protein intakes, appetite, anthropometric indices, lipid profile, glucose, electrolytes, inflammatory markers (IL-6, CRP), engraftment, or other clinical outcomes. Paired t-test analyses showed declines in anthropometric indices in both groups, which were statistically significant only for weight (SL, P=0.003; IL, P=0.01) and BMI (SL, P=0.001; IL, P=0.04). Total cholesterol decreased in both groups (SL, 173.57±23.81 vs, 156.71±23.64; IL, 150.83±52.93 vs, 142.17±27.64), reaching statistical significance only with SMOFlipid (P=0.032). Triglycerides increased significantly in both groups, with a notably larger rise in the Intralipid group (SL, 140.42±55.36 vs,

296.71±82.18, *P*=0.008; IL, 102.50±59.48 vs, 420.0±191.76, *P*=0.006). Fasting glucose increased in both groups (SL: 100.85 ± 9.65 vs. 111.42 ± 52.51; IL: 82.83 ± 5.81 vs. 98.67 ± 18.69), reaching marginal statistical significance only in the Intralipid group (P = 0.07). Electrolytes trended downward, with magnesium showing a significant reduction (P = 0.024) and phosphorus a marginally significant reduction (P = 0.08). Notably, inflammatory markers increased in both groups: IL-6 (SL: 10.41 ± 14.29 vs. 38.92 ± 47.25; IL: 10.85 ± 13.36 vs. 18.64 ± 18.89) and CRP (SL: 12.08 ± 10.10 vs. 58.65 ± 52.42; IL: 14.04 ± 15.09 vs. 40.14 ± 41.26), with marginal significance observed in the SMOFlipid group (P = 0.055).

Conclusions: In this pilot randomized study, SMOFlipid provided no short-term advantage over Intralipid and, unexpectedly, was associated with greater increases in inflammatory markers by day +15. Given the metabolic vulnerability of pediatric HSCT recipients, cautious use of SMOFlipid and careful selection of lipids overall appear warranted. Larger, adequately powered studies are necessary to clarify the safety and clinical implications in this population.

Disclosure: Nothing to declare.

ETOPOSIDE OR FLUDARABINE MAY BE COMBINED WITH 1.200CGY TOTAL BODY IRRADIATION FOR PEDIATRIC HAPLOIDENTICAL HEMATOPOIETIC CELL TRANSPLANTATION TO TREAT ACUTE LYMPHOBLASTIC LEUKEMIA

Ana Carolina Ribeiro Correa[1], *Aline Ferrari Martins*[1], *Raisa Machado Amaral*[1], *Luciana dos Santos Domingues*[1], *Lais Lima Quintino*[1], *Maria Gabriela Alves Dias Matos*[1], *Roseane Vasconcelos Gouveia*[1,2], *Valeria Cortez Ginani*[1,2], *Ana Claudia Ramos Donatelli Bronzoni*[1], *Fernanda de Oliveira Mota*[1], *Maria Estela Shiroma*[1], *Lahis Cardoso de Castro*[1], *Maria de los Angeles Duran Salas*[1], *Yohanna Bastani de Mattos*[1], *Mayara Satsuki Kunii*[1], *Michael Jenwei Chen*[1], *Maria Luisa Sucharski Figueiredo*[1], *Cintia Monteiro Lustosa*[1], *Erica Almeida Viana*[1], *Vanessa Aparecida do Nascimento Varjão*[1], *Camila Margarida Maria Soares de Sousa Parrode*[1], *Olga Margareth Felix*[1], *Adriane dos Santos Ibanez*[1], *Adriana Seber*[2,1]
[1]*Instituto de Oncologia Pediátrica - IOP/GRAACC, SÃO PAULO, Brazil,* [2]*Hospital Samaritano, São Paulo, Brazil*

Background: Acute lymphoblastic leukemia (ALL), is the most common indication for allogeneic pediatric hematopoietic cell transplant (HCT). The superiority of 1,200 cGy Total Body Irradiation-Etoposide (TBI-VP) conditioning was demonstrated by the FORUM trial, but optimal conditioning therapy for Haploidentical HCT (Haplo) with post-transplant cyclophosphamide (PT-Cy) to prevent GVHD is still unknown. We have initiated the Haplo program 25 years ago using TBI-Fludarabine (Flu) (*Solomon et al,* 2012) but in the past three years have adopted TBI-VP based on the FORUM experience (*Peters et al, 2020*). Since a direct comparison of both conditioning regimens has not been performed yet, our objective

is to compare overall survival (OS) and event-free survival (EFS) of consecutive pediatric patients with ALL undergoing Haplo-HCT with TBI-Flu and TBI-VP.

Methods: Retrospective analysis of all consecutive pediatric ALL patients undergoing Haplo with Flu 90 mg/m2 -TBI 1,200cGy or TBI-VP 60 mg/kg. All used GvHD prophylaxis with post-transplant Cyclophosphamide (PTCy) 50 mg/kg and MMF 15 mg/kg TID. TBI-Flu also used Tacro and TBI-VP, Cyclosporine.

Results: Between February 2020 and June 2025, we performed 58 Haplo for ALL with a median follow-up of 2.4 years (3.6 for TBI-Flu and 1.7 for TBI-VP). 88% of cases were B-cell ALL; 35/58 (60%) received Flu-TBI, and 23 (40%), TBI-VP. VP had a 2-day delay to neutrophil engraftment: median 15 days with Flu (13-21) and 17 days with VP (12-24), (p=0.003). Peripheral blood grafts were used in 63% of the patients with Flu-TBI and in 2 TBI-VP (9%). With Flu-TBI, 69% had GvHD: 22/35 aGvHD and 14/35 cGvHD; 34% relapsed and 23% died of TRM. Four underwent a second HCT and all unfortunately died. With Flu-TBI, the EFS was 43% and OS 65% at 2.4 years p-NS). The 23 patients receiving TBI-VP, had 57% GvHD — 9/23 cGvHD and 8/23 cGvHD. Four patients relapsed and four died of TRM (17%). Therefore, after TBI-VP, the EFS was 65% and OS 74%. Compared to Flu-TBI, TBI-VP had a Hazard Ratio (HR) of relapse of 0.77 (95%CI 0.26-2.24), and TRM of 0.96 (95%CI 0.8-4.9), OS of 1.94 (95% CI 0.29-3.18) although with the small numbers none of the outcomes has reached statistical significance.

Conclusions: TBI-VP marrow and TBI-Flu PBSC may have comparable outcomes in Haplo HCT for ALL.

Disclosure: Nothing to declare.

P220

REDUCTION OF TOTAL BODY IRRADIATION DOSE IN THE CONDITIONING OF CHILDREN WITH ALL AND ITS IMPACT ON SURVIVAL AND TOXICITY

Alberto Olaya-Vargas[1], *Gabriela Quinzanos-Gutierrez*[1], *Haydee Salazar-Rosales*[1], *Gerardo López-Hernández*[1], *Nideshda Rámirez-Uribe*[1], *Marcela Caballero- Palacios*[1], *Andrea Iglesias-Amaya*[1], *Lilia Carrizales-Torres*[1], *Alberto Olaya-Nieto*[1], *Yadira Melchor-Vidal*[2], *Monserrat Hernández-Díaz*[2]
[1]*Instituto Nacional de Pediatria, Mexico City, Mexico,* [2]*Centre Médico ABC, Mexico City, Mexico*

Background: Hematopoietic stem cell transplantation (HSCT) remains a curative strategy for children with acute lymphoblastic leukemia (ALL) who present high-risk features at diagnosis or relapse. Total body irradiation (TBI) is a critical component of conditioning regimens, contributing significantly to both treatment efficacy and long-term toxicity. The conventional TBI dose of 1200 cGy has shown strong anti-leukemic efficacy but is associated with substantial adverse effects. This study evaluates whether reduced TBI doses maintain comparable overall survival (OS) and event-free survival (EFS) while reducing toxicity

Methods: To determine whether reduced TBI doses (600 cGy and 200 cGy) preserve OS and EFS comparable to the standard 1200 cGy regimen and to assess whether lower TBI doses correlate with reduced late toxicities.
A retrospective, longitudinal, observational analytical study was conducted in pediatric ALL patients who underwent HSCT between 2013 and 2023 and received TBI-based conditioning. Patients were stratified into three dose groups: 1200 cGy, 600 cGy, and 200 cGy. OS and EFS were analyzed using Kaplan–Meier methods. Toxicity was evaluated in patients with at least 24 months of follow-up.

Results: Seventy-six patients were included: 81.6% received 600 cGy, 10 received 200 cGy, and 4 received 1200 cGy. OS in the 600 cGy group was 74% at 1 year and 72% at 5 years. In the 200 cGy group, OS was 88% at 1 year and 64% at 5 years. The 1200 cGy group showed 50% OS at 1 year. Differences showed a trend toward significance (p = 0.086). EFS in the 600 cGy group was 83% at 1 year and 71% at 5 years. The 200 cGy group showed 75% for both time points, and the 1200 cGy group showed 66% at 1 year (p = 0.8). Among 46 patients evaluable for toxicity, endocrine dysfunction occurred in 56.5%, pulmonary toxicity in 19.6%, and secondary neoplasms in 3 patients (all thyroid cancer). No statistically significant association was found between TBI dose and toxicity.

Conclusions: Patients receiving 600 cGy achieved OS and EFS comparable to historical outcomes with 1200 cGy, with similar or slightly lower toxicity rates. Although limited by sample size and group heterogeneity, findings suggest that 600 cGy may offer adequate disease control with a potentially more favorable toxicity profile. Larger studies are required to confirm these observations.

Disclosure: The authors declare no conflict of interest.

CLINICAL EFFICACY OF HEMATOPOIETIC STEM CELL TRANSPLANTATION IN 20 JMML CASES: A SINGLE-CENTER STUDY

*Mingnan Zhang[1], Yue Lu[1], Deyan Liu[1], YanLi Zhao[1], Zhijie Wei[1], Min Xiong[1], Jianping Zhang[1], **Xingyu Cao**[1], Peihua Lu[1], Ruijuan Sun[1]*
[1]Hebei Yanda Lu Daopei Hospital, Langfang, China

Background: JMML is a rare clonal hematopoietic neoplasm occurring predominantly in infants and young children, with an incidence of 1.2 per million and constituting 2% to 3% of childhood leukemias. Based on the 2016 World Health Organization (WHO) classification of myeloid neoplasms, JMML is categorized as a myelodysplastic/myeloproliferative neoplasm. HSCT currently remains the only potentially curative therapy for JMML. Although transplant strategies are continuously evolving and improving, the OS rate post-HSCT is only 50% to 73%, with high relapse rates due to frequent disease recurrence and severe treatment-related complications. Therefore, this study retrospectively analyzed 20 pediatric JMML patients who underwent HSCT at our institution. Univariate analysis was conducted on factors including whether the patients received intensive chemotherapy(IC) prior to

transplantation, conditioning regimen, transplant type, and occurrence of aGVHD, to identify determinants of prognosis in pediatric patients.

Methods: A retrospective analysis was conducted on 20 pediatric patients diagnosed with JMML who received treatment at Hebei Yanda Lu Daopei Hospital between February 2013 and February 2025. All patients underwent comprehensive diagnostic evaluations, including complete blood count (CBC) with peripheral blood smear review, bone marrow morphology examination, immunophenotyping, molecular biological testing, and cytogenetic analysis. The diagnosis of JMML was confirmed for all patients according to the 2016 WHO diagnostic criteria.
Treatment response was evaluated using the six clinical characteristics and three genetic features outlined in the 2015 consensus as criteria for efficacy assessment. Additionally, minimal residual disease and molecular-cytogenetic monitoring were performed on patient bone marrow samples.
As of December 2025, the primary endpoints were 3-year OS, LFS, and CIR. Secondary endpoints included acute and chronic GVHD,as well as other transplantation-related complications.

Results: Among the 20 patients who underwent HSCT, the 3-year OS, LFS and CIR were 85% ± 7.98%, 84.4% ± 8.32%, and 10.6%. For the 15 Haplo-HSCT, the corresponding 3-year OS, LFS, and CIR were 86.7% ± 8.78%, 86.7% ± 8.78%, and 6.7%(Fig.1).

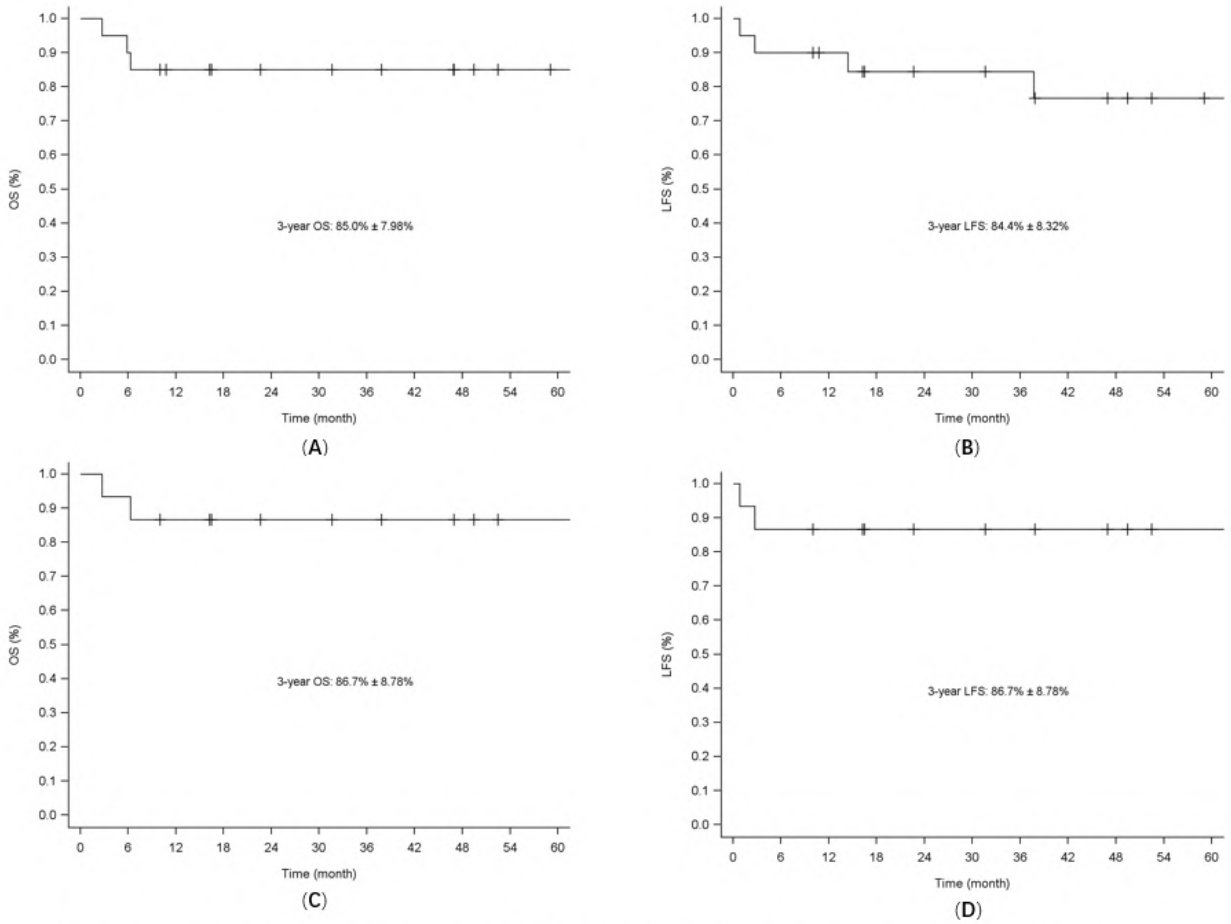

Fig.1 Outcomes of 20 JMML Patients Undergoing HSCT:(**A**) overall survival (OS), (**B**) leukemia-free survival (LFS) Outcomes of 15 JMML Patients Undergoing Haplo-HSCT:(**C**) overall survival (OS), (**D**) leukemia-free survival (LFS)

Factors associated with OS, LFS, and CIR were analyzed using the log-rank test. The results showed no significant correlation with patient age, platelet count at diagnosis, hemoglobin level at diagnosis, genetic subtype, pre-transplant chromosomal karyotype, or conditioning chemotherapy agents. However, OS and CIR were significantly associated with the occurrence of aGVHD after transplantation (Table 1).

Table1 Analysis of factors influencing OS, LFS, and CIR based on log-rank test

Items	**N**	**3-year-OS (95% CI)**	**P**	**3-year-LFS (95% CI)**	**P**	**3-year-CIR (95% CI)**	**P**
Received IC			0.188		0.525	0.199	

Yes	7	0.714 (0.258 - 0.920)		0.686 (0.213 - 0.912)		0.286 (0.031 - 0.636)	
No	13	0.923 (0.566 - 0.989)		0.923 (0.566 - 0.989)		0.077 (0.004 - 0.303)	
Transplant type			0.886		0.643		0.886
Total	20	0.850 (0.604 - 0.949)		0.844 (0.589 - 0.947)		0.150 (0.036 - 0.340)	
Haplo-HSCT	15	0.867 (0.564 - 0.965)		0.867 (0.564 - 0.965)		0.133 (0.020 - 0.354)	
aGVHD			0.023		0.151		0.025
Yes	8	0.625 (0.229 - 0.861)		0.625 (0.229 - 0.861)		0.375 (0.072 - 0.694)	
No	12	1.000		1.000		0	

Transplantation-related complications:The incidence of grade II or higher aGVHD was 35% (n=7), with 6 cases being severe, two of which occurred following donor lymphocyte infusion administered after relapse. cGVHD was 40% (N=8). Three patients died: two due to relapse and one due to severe GVHD. One patient progressed to acute myeloid leukemia.

Conclusions: Whether JMML patients received intensive chemotherapy before transplantation showed no significant difference in OS, LFS, or CIR. Patients with JMML undergoing Haplo-HSCT achieved higher OS and reduced CIR, thereby improving clinical outcomes. This study is limited by its small sample size, and further validation with larger cohorts is required.

THRASSA, A MULTICENTER, OPEN-LABEL STUDY EVALUATING THE SAFETY, TOLERABILITY AND EFFICACY OF MAAT013 IN RUXOLITINIB-REFRACTORY OR INTOLERANT PAEDIATRIC/ADOLESCENT PARTICIPANTS WITH GASTROINTESTINAL ACUTE GRAFT-VERSUS-HOST DISEASE

Marion Bruelle[1], *Laura Alonso*[2], *Virginie Gandemer*[3], *Marta Gonzalez Vicent*[4], *Caroline Lindemans*[5], *Riccardo Masetti*[6], *Pietro Merli*[7], *Luisa Sisinni*[8], *Francesco Paolo Tambaro*[9], *Marco Zecca*[10], *Juliette Jouve*[1], *Behzad Kharabi Masouleh*[1], *Emilie Plantamura*[1], *Karima Yakouben*[11]
[1]*MaaT Pharma, Lyon, France,* [2]*Hospital Universitari Vall d'Hebron, Barcelona, Spain,* [3]*Centre Hospitalier Universitaire, Rennes, France,* [4]*Hospital Niño Jesus, Madrid, Spain,* [5]*Princess Maxima Center, Utrecht, Netherlands (the),* [6]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [7]*Ospedale Pediatrico Bambino Gesù, Roma, Italy,* [8]*La Paz University Hospital, Madrid, Spain,* [9]*Azienda Ospedaliera di Rilievo Nazionale Santobono Pausilipon, Napoli, Italy,* [10]*Fondazione IRCCS Policlinico San Matteo, Pavia, Italy,* [11]*Robert-Debré Hospital, Paris, France*

Background: Acute graft-versus-host disease (aGvHD) is a serious complication following allogeneic haematopoietic stem cell transplantation (allo-HSCT). aGvHD impacts many children (Vincent et al. 2025). The incidence of Grade II–IV aGvHD in children receiving allo-HSCT from unrelated donors varies from 40 to 85% (Andolina et al. 2022; MacMillan et al. 2020). Standard first-line therapy involves corticosteroids (CS), however fewer than half of paediatric patients have durable complete responses and require second-line therapy (Gottardi et al. 2023; MacMillan et al. 2020). In Europe, ruxolitinib was granted approval for the treatment of Steroid-refractory (SR) aGvHD patients aged 28 days and older based on the REACH 2&4 (NCT02913261, NCT03491215) studies. Despite a high response rates for paediatric patients, ORR at any time varies from 45% to 100% (Baccelli et al. 2024), 27% of REACH 4 participants discontinued treatment due to lack of efficacy and 22% due to AEs resulting in almost half of the participants with limited therapeutic options (Locatelli et al. 2024), poor clinical outcomes and a heightened risk of morbidity and mortality.
MaaT013 is an allogeneic, full-ecosystem pooled biotherapeutic intestinal microbiota, drug candidate tested in a completed phase III in adult patients with Gastrointestinal (GI)-aGVHD (NCT04769895) and available on a compassionate use program for patients with aGvHD. MaaT013's promising efficacy and acceptable safety profile suggest a favorable benefit–risk profile as a third-line therapy, warranting evaluation in children. THRASSA is a phase II study designed to evaluate the safety, tolerability and efficacy of MaaT013 as a 3rd line therapy after systemic corticosteroids and ruxolitinib failure in paediatric and adolescent participants with GI-aGvHD (EU-CT#: 2025-524302-15-00).

Methods: It is an open-label, single arm, two-cohort (Cohort 1: ≥ 6 - < 12 years; Cohort 2: ≥ 12 - < 18 years) study involving up to 18 participants (up to 9 per cohort) followed-up for 12-mo. Allo-HSCT recipients diagnosed with Grade II to IV (MAGIC criteria) GI-aGvHD and identified as refractory to steroids and either refractory or intolerant to ruxolitinib, with a Karnofsky/Lansky performance status ≥ 40, and a minimum weight of 15 kg are eligible.

Main exclusion criteria include: previous lines of systemic aGvHD treatment other than CS and ruxolitinib, presence of uncontrolled infection or requiring antibiotics, any other diseases that in the opinion of the investigator would contraindicate study treatment, cGvHD, active cytomegalovirus colitis, relapsed/persistent malignancy requiring rapid immune suppression withdrawal, severe organ dysfunction or other uncontrolled complication. After a 2-day oral vancomycin pre-treatment, patients will receive 3 doses of MaaT013 over 10 days.
The primary endpoint, safety and tolerability, includes incidence of (Serious) adverse events (AEs), assessment of all safety parameters (clinical, laboratory) until M6 and, from M6 to M12 incidence of SAEs and AE of special interest. Main secondary endpoints include: feasibility of MaaT013 administration in paediatric population, GI and all-organ overall response rate, duration of response, overall survival, progression-free survival of the underlying disease and time to progression.

Results: The study is expected to start in May 2026 in France, Italy, Netherlands and Spain.

Conclusions: THRASSA

ONE SIZE DOESN'T FIT ALL: MODIFICATION OF CONDITIONING REGIMEN IN METABOLIC DISEASE HSCT IN PEDIATRIC TRANSPLANTS

Ranjit Kumar Chatada Srivaishnava[1], *Chaitanya G B*[1], *Aribandi Anil*[1], *Kavya Reddy Kambham*[1]
[1]*Sindhu Hospitals, Hyderabad, India*

Background: Conditioning regimen in Allogenic stem cell transplantation is a crucial determining factor for long-term outcome in benign conditions. Modification of conditioning regimen, based on underlying pathophysiology consideration will have great impact for smooth and successful transplant outcomes. Mevalonate kinase deficiency (MKD) is a rare

auto inflammatory syndrome, Allogenic stem cell transplantation has promising results however during the transplantation in view of hyper inflammatory nature of background condition, higher risk of severe cytokine release syndrome and graft rejections and higher Graft versus host disease is a potential threat. Here we are reporting two cases of severe MKD refractory to conventional therapies, undergone haploidentical stem cell transplantation with successful outcome.

Methods: This is a retrospective case study of two MKD with hyper immunoglobulin D phenotype, both were refractory to conventional therapies like steroids, TNF inhibitors and presented with significant crippling joint pains and swelling along with recurrent fever. Both children undergone haploidentical stem cell transplantation, with very high pre-transplantation IL-6 levels, Conditioning regimen was Fluderabine, Treosulfan, Thiotepa and Rabbit ATG as serotherapy [FTTA] ;conditioning regimen was supplemented with addition of Tocilizumab 2weeks prior to conditioning and IL-1 inhibitor Anakinra weekly twice from the conditioning regimen to until the engraftment was continued. Descriptive Data were retrieved from the EMR and tabulated.

Results:

	Case-1	Case-2
Age /Sex	4yrs2month /Male	5yr 8monts/Female
Phenotype	Hyper IgD phenotype	Hyper IgD phenotype
NGS	MVK gene mutation+	MVK gene Mutation+
Prior therapies	NSAIDs, Steroids, Methotrexate	NSAIDs, Steroids, Methotrexate , TNF inhibitors
Type of Transplant	Haploidentical - Father 6/12	Haploidentical – Mother 8/12
Pre-transplant IL-6 level [<7pg/ml]	560pg/ml	316.30pg/ml
Conditioning	FTTA Tocilizumab 2weeks prior at 8mg/kg single dose	FTTA Tocilizumab 2weeks prior at 8mg/kg single dose Inj. Anakinra 100mg S/c weekly twice from conditioning regimen to engraftment.
Stem cell source CD 34 dose	PBSC $7x10^6$/kg	BM + PBSC $4.8x10^8$ MNC + $4x10^6$/kg
Date of HSCT	May-2023	August-2025
GVHD prophylaxis	Pt/CY 40mg/kg Day +3 and +4 Tac + MMF from Day +5	Pt/CY 40mg/kg Day +3 and +4 Tac + MMF from Day +5

Post Transplant events	1. Severe CRS on day +1, 3inotropes / Ventilator support. 2. Mucositis grade 3 3. Delayed engraftment [N-Day+28;P-Day+56 4. CMV reactivation	1. Serum sickness [rATG] 2. CRS-grade -1 3. Mucositis-grade-2 4. Pseudomonas CLABSI
Outcome	Alive	Alive

Conclusions: MVK deficiency related auto-inflammatory condition is difficult to treat, stem sell transplantation though a curative treatment option,we need to modify our conditioning protocol to reduces the hyper-inflammatory response and related complications. Ours is probably first presentation in literature about usage of Anakinra and Tocilizumab even before conditioning chemotherapy to reduces the inflammatory response,CRS,GVHD and Graft rejection in this condition.

Clinical Trial Registry: No.

Disclosure: No conflict of interst.

P224

NON HAEMATOLOGICAL AUTOIMMUNE MANIFESTATIONS FOLLOWING PAEDIATRIC HAEMATOPOIETIC STEM CELL TRANSPLANT

Hilary Cahill[1], *Ramya Hanasoge-Nataraj*[1], *Oana Mirci-Danicar*[1], *Omima Mustafa*[1], *Robert Wynn*[1], *Srividhya Senthil*[1]
[1]*Manchester University NHS Foundation Trust, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

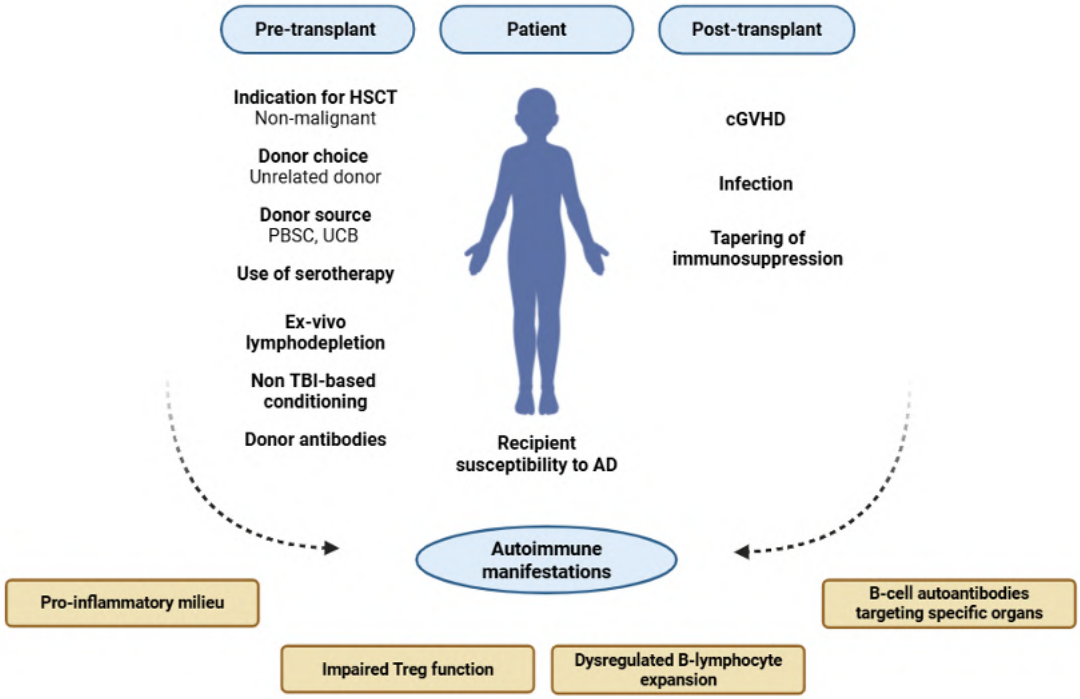
Background: Autoimmune manifestations following haematopoietic stem cell transplant (HSCT) are increasingly recognised as a contributor to morbidity and mortality in paediatric HSCT recipients, and are under-recognised. Most reported autoimmune manifestations are haematological, with autoimmune cytopenias accounting for 22% of all paediatric HSCT complications(1). However, less commonly, single organ or multi-system involvement may manifest, distinct from the more widely recognised immune-mediated graft-vs-host disease (GVHD). The literature is sparse and limited to case reports in paediatric patients. The pathophysiology is poorly understood and is thought to be due to the interaction between the dysregulation of a recovering immune system, and inflammatory factors (see Figure 1). Non-haematological autoimmune manifestations are presumed to be driver by donor immunity against host organs and tissues(2).
We describe three interesting cases from a single UK paediatric transplant centre, who developed non-haematological autoimmune manifestations post HSCT.

Methods: We conducted a retrospective analysis of three patients with non-haematologic autoimmune manifestations post HSCT in a single UK centre, and subsequently analysed

known risk factors and pathophysiology associated with the development of such autoimmune manifestations.

Results: Patient 1 underwent a fully matched unrelated (MUD) donor bone marrow transplant (BMT) with total body irradiation (TBI) and etoposide conditioning with alemtuzumab serotherapy for refractory acute lymphoblastic leukaemia (ALL). She developed grade 1 gut GVHD and HHV6 infection in her post HSCT course, and asymptomatic SARS-Cov-2 infection. Three months post HSCT she developed a rapidly ascending sensorimotor neuropathy consistent with Guillain-Barre syndrome (GBS) treated with IVIG and pulse steroids.
Patient 2 had refractory acute myeloid leukaemia (AML) and underwent a mismatched unrelated umbilical cord blood transplant with busulfan and fludarabine conditioning. Two months post HSCT he developed acute onset hypoalbuminaemia with secondary peripheral oedema. Kidney biopsy was consistent with membranous nephropathy, which responded to increased immunosuppression.
Patient 3 underwent a MUD transplant with busulfan and cyclophosphamide conditioning with anti-thymocyte globulin serotherapy for AML in 2nd remission. He experienced asymptomatic primary Epstein Barr virus reactivation 1 month post HSCT, and went on to develop significant haematological and non-haematological autoimmune manifestations including refractory autoimmune cytopenias, GBS and autoimmune hepatitis. His complications were refractory to a number of lines of therapy. He required a second reduced intensity HSCT for life threatening multi-system autoimmunity however died on day +5 due to severe veno-occlusive disease.

Conclusions: Whilst rare, non-haematologic autoimmune manifestations following transplant are clinically significant and often refractory to treatment. Diagnosis can be challenging due to similar clinical features seen in other more common HSCT complications. Further understanding of the pathophysiology of such conditions is essential to identify patient-specific risk factors and allow for early diagnosis and initiation of targeted therapies to improve patient outcomes. Our reported experience adds to the range of systemic autoimmunity documented in literature, giving insightful consideration for early recognition and treatment.



Disclosure: Nothing to declare

CHALLENGES AND ACHIEVEMENTS OF BUILDING PEDIATRIC BONE MARROW TRANSPLANT PROGRAM IN A DEVELOPING COUNTRY; SINGLE CENTER EXPERIENCE IN IRAQ

Hanafy Hafez[1,2], *Entisar Al Shammary*[1], *Mohamed Abdel Waged*[1], *Fares Hamdy*[1], *Ahmed Saeed*[1], *Inas Al Saadi*[1], *Abdallah Moustafa*[1], *Muayad Aljanabi*[1], *Haydar Alabedi*[1,3]
[1]*AlMojtaba BMTC, Karbala, Iraq,* [2]*National Cancer Institute, Cairo University, Cairo, Egypt,* [3]*Baghdad University/ Medical College, Baghdad, Iraq*

Background: Hematopoietic stem cell transplantation (HSCT)) is now one of the integral treatment modalities for many malignant and non-malignant conditions in pediatric population and considered the only curative option for many diseases. Establishment of a HSCT program in developing countries can face significant challenges, due to lack of infrastructure and resources, lack of well-trained health professionals and expertise, and lack of knowledge about the safety and costs of procedures. The study objective was to assess the feasibility and challenges of building pediatric BMT program in Iraq and to highlight the strategies and interventions that were associated with the successful outcome.

Methods: Initiation of the program started in March 2024 through infrastructure modification to fit for the standard requirement, infection control precautions, cell separation, processing and cryopreservation policies and guidelines, stem cell lab preparations and continuous training and awareness for all the included staff. G-CSF mobilized peripheral blood as 1st line therapy and pre-emptive plerixafor were used for stem cell collection. All Allogenic HCT patients received peripheral blood grafts from fully matched related donors and were given Pt Cy in addition to Cy CSA/ MTX as GVHD prophylaxis

Parameter	**Total (n=36)**	**Autologous NB (n=25)**	**Autologous HL (n=4)**	**Allogeneic (n=**
Age at transplant (years)	Median (range) 6.9 (2.5-16)	5.8 (3-12)	10.75 (5-16)	7.5 (2.5 -14)
Conditioning regimen		BuMel	BeEAM	BU/CY- TBI/CY
CD34⁺ cell dose (×10⁶/kg)	Median (range)	4.03 x 10^6 /kg	3.6 x 10^6 /kg	5.4 x 10^6 /kg
Median ANC engraftment (day)		13.28 (12-19)	13 (12-14)	21.6 (14-31)
Median platelet engraftment (day)		19.4 (12-26)	21.5(20-23)	16.4(14-19)
Patient status Survival in CR Relapse and alive Relapse and death		 21(84%) 2 (8%) 2 (8%)	 4(100%) 0 0	 6(85.7%) 1(14.3%) 0

Results: A total of 36 patients ≤ 15 years were transplanted from March 2024 till November 2025 and included 29 auto transplants (25 cases with high risk neuroblastoma and 4 cases with relapsed Hodgkin lymphoma), and 7 allogenic transplants (5 cases with AML, one with CML blastic crises and one with relapsed Ph positive ALL). Of the neuroblastoma patients, 4/25 (16%) relapsed and 0% non-relapse mortality (NRM) at d+100 with one-year disease free survival and overall survival probabilities of 78% and 88% respectively, while no reported relapses or NRM among the 4 cases of HL. Regarding the allotransplant patients, all of them showed complete chimera and negative MRD post HSC, while one patient with HR AML in CR1 relapsed at d+160. Also, NRM at d+100 was 0% and one patient developed grade I (stage 1 skin) acute GvHD.

Conclusions: Despite the challenges, building a successful pediatric bone marrow program in limited resources countries is feasible through following well planned systematic steps. Following standardized approaches, efficient pre operation staff training and effective infection control precautions and supportive care guidelines are key component for transplant success. Autologous HCT was associated with survival advantages in high-risk neuroblastoma patients in our center.

Disclosure: Nothing to declare.

TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY DRIVES MORTALITY IN PEDIATRIC HSCT: INSIGHTS FROM A SINGLE-CENTER COHORT

Simone Schrauth[1], *Christina Pfann*[1], *Lara Müller-Scholden*[1], *Matthias Eyrich*[1], *Paul-Gerhardt Schlegel*[1], *Matthias Wölfl*[1]
[1]*University Children's Hospital Würzburg, Würzburg, Germany*

Background: Transplant-associated thrombotic microangiopathy (TA-TMA) is a severe and under-recognized complication of hematopoietic stem cell transplantation (HSCT).

Methods: We retrospectively analyzed 205 HSCT from 191 pediatric allogenic HSCT recipients from our center for the accomplishment of diagnostic criteria according to the recently published EBMT-TA-TMA consensus criteria.

Results: Eleven patients met criteria for severe TA-TMA (overall incidence 5.4%) although routine sC5b-9 measurement was frequently unavailable. Nine cases occured after first HSCT (4.8%) and two after second HSCT (12.5%). Nine patients were diagnosed during the clinical course and treated with eculizumab. 5 out of 9 treated patients (56 %) survived. Two patients were diagnosed retrospectively as probable TA-TMA, both had fulminant disease with acute respiratory distress syndrome (ARDS), were not treated with a complement inhibitor and subsequently died. Overall transplant-related mortality (TRM) in our cohort was 15/191 (7.9%), 6 out of these 15 patients (40%) succumbed to TA-TMA, identifying TA-TMA as a major contributor to TRM.
IN TA-TMA patients we observed three clinical manifestation patterns:

1. Six patients (55%) showed prolonged renal involvement in the context of graft-versus-host disease (GvHD) and/or poor graft function.
2. Three patients (27 %) presented with early, fulminant deterioration characterized by a rapidly progressive ARDS.
3. Two patients (18 %) had neurological involvement presenting initially with seizures due to posterior reversible encephalopathy syndrome (PRES).

Out of 6 TA-TMA associated deaths, two presented with ARDS and four with renal involvement. Patients with bone marrow failure syndromes were disproportionately represented in the TA-TMA group (6/11, 55%).

Conclusions: TA-TMA significantly contributes to TRM in pediatric HSCT recipients. Its heterogeneous and sometimes fulminant presentations highlight the need for heightened clinical awareness. In response, we implemented a structured screening protocol for TA-TMA. Development of more precise treatment algorithms is essential to improve outcomes in this otherwise dismal condition.

Disclosure: Nothing to declare

P228

LINEAGE SWITCH FROM B-CELL ACUTE LYMPHOBLASTIC LEUKAEMIA TO T-CELL ACUTE LYMPHOBLASTIC LEUKAEMIA IN A PAEDIATRIC PATIENT WITH *HOX11* EXPRESSION AFTER 11 YEARS：A CASE REPORT

Xinni Bian[1,2], Qingwei Wang[1,2], Senlin Zhang[1], Jun Lu[1,2], Jie Li[1,2], Peifang Xiao[1,2], ***Shaoyan Hu***[1,2]
[1]Children's Hospital of Soochow University, Suzhou, China, [2]Jiangsu Provincial Center for Pediatric Hematology and Oncology, Suzhou, China

Background: Lineage switch, defined as the phenomenon where leukaemia cells of the same clonal origin transform from one lineage to another at relapse, is a rare and challenging event in haematological oncology.We report a unique case of a paediatric patient initially diagnosed with *HOX11*-positive B-cell acute lymphoblastic leukaemia (B-ALL) who, after 11 years of remission, relapsed with T-cell acute lymphoblastic leukaemia (T-ALL). This represents the first reported instance of such a late lineage switch. Furthermore, we identified the rare *KMT2A::BCL9L* fusion gene and a complex mutational landscape potentially driving this transformation.

Methods: In October 2013, a 2-year-old boy presented with fatigue and petechiae. Laboratory tests revealed leucocytosis, anaemia, and thrombocytopenia. Bone marrow (BM) examination confirmed ALL(Figure 1A), with immunophenotyping showing B-lineage markers (Table 1) and positivity for HOX11 by multiplex PCR. Chromosomal analysis showed no dividing cells after two rounds of banding; all FISH tests were negative. The patient was enrolled in the CCCG-2008 intermediate-risk protocol, achieving remission and completing therapy in July 2016.
In January 2025, the patient presented with fever.BM examination revealed relapse(Figure 1B). Strikingly, immunophenotyping now demonstrated a T-lineage phenotype (Table 1). The results of multiplex PCR and karyotyping were consistent with those at initial diagnosis, and FISH demonstrated trisomy of cen4 and cen10. However, transcriptome sequencing identified a rare III-type fusion gene,KMT2A::BCL9L (Figure 1C), along with class I (NRAS p.G13D), class II (WT1 p.R374fs,WT1 p.V268fs,BCL11B p.E34fs,CTCF p.L98*,NOTCH1 p.R1598P), and metabolic (CPT2 p.F383Y) and motility (CCDC40 p.R301*) mutations. T-cell receptor (TCR) clonality assays were positive.
Following the lineage switch diagnosis, the patient received re-induction regimens, achieving morphological remission with negative flow cytometry minimal residual disease (FC-MRD). However, the KMT2A::BCL9L fusion transcript and TCR clonality remained positive. After consolidation, the patient underwent allogeneic haematopoietic stem cell transplantation (HSCT) in May 2025, using a dual graft (umbilical cord blood and peripheral blood stem cells from a haploidentical father).The time to neutrophil and platelet engraftment was achieved on day +14 and +15.

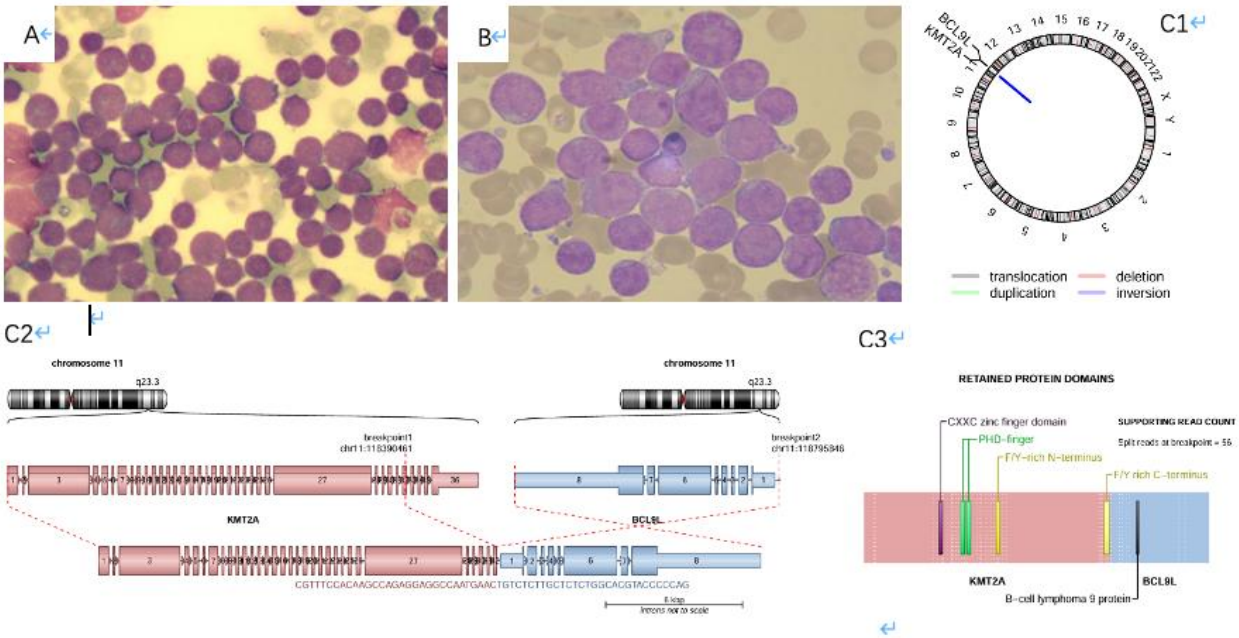

Figure1: Morphological and molecular characteristics of the patient.(A) Bone marrow smear at initial diagnosis (Oil immersion, 100×).(B) Bone marrow smear at relapse (Oil immersion, 100×).(C1-C3) Genomic breakpoint and domain structure of the KMT2A::BCL9L fusion gene.

Results: The patient remained in remission until August 2025, when BM examination revealed a second relapse (blasts: 65%, FC-MRD: 37.1%,KMT2A::BCL9L: 5.02%). Salvage therapies, including the Menin inhibitor Revumenib combined with Venetoclax and Azacitidine, Daratumumab, and the HDAC inhibitor Chidamide, failed to induce remission. Palliative care has been continued for the patient to date.

Conclusions: This case underscores the aggressive nature of lineage-switched leukaemia.Achieving molecular-level MRD negativity prior to HSCT may reduce relapse risk. Administering palliative targeted agents, particularly menin inhibitors, pre-transplant to achieve molecular remission could potentially be superior to post-transplant palliative therapy.

Disclosure: Nothing to declare.

P229

BEYOND NUMBERS: SUPERIOR PEDIATRIC BONE MARROW TRANSPLANT OUTCOMES THROUGH STANDARDIZED, RISK-ADAPTIVE CARE AND PROACTIVE COMPLICATION MANAGEMENT

Ibrahim Eker[1], *Özge Vural*[2], *Nilgün Eroğlu*[3], *Çiğdem Özdemir*[1], *Ahsen Başaran*[1]
[1]*Afyonkarahisar Health Sciences University, Afyonkarahisar, Turkey,* [2]*Gazi University, Ankara, Turkey,* [3]*Etlik City Hospital, Ankara, Turkey*

Background: Pediatric hematopoietic stem cell transplantation (HSCT) is a complex, high-risk intervention with significant morbidity and mortality. Our center aimed to evaluate survival and quality-of-life outcomes in all pediatric patients transplanted since inception, emphasizing that superior outcomes can be achieved through strict adherence to standardized, risk-adaptive protocols and proactive complication management, even in limited cohorts.

Methods: We retrospectively analyzed all pediatric HSCT procedures performed between January 2020 and January 2025. Thirty patients underwent 31 HSCT procedures. Patient demographics, underlying diagnoses, donor type, stem cell source, and transplant characteristics were collected. Survival was estimated using Kaplan-Meier analysis. Quality of life was assessed using Lansky/Karnofsky and ECOG performance scores. All procedures followed a standardized, risk-adaptive transplant protocol, implemented consistently by the multidisciplinary team. Proactive complication management included daily risk assessments, early intervention protocols, and structured team communication.

Results: Thirty patients underwent 31 transplants. Median age at HSCT was 104 months (range, 8–233); 65.3% were male. Diagnoses included acute lymphoblastic leukemia (ALL, 42.3%), acute myeloid leukemia (AML, 15.4%), Wilms tumor (7.7%), thalassemia major (7.7%), juvenile myelomonocytic leukemia (JMML), Hodgkin and non-Hodgkin lymphoma, Fanconi aplastic anemia, acquired severe aplastic anemia, MHC class II deficiency, and Wiskott-Aldrich syndrome (each 3.85%).
Allogeneic HSCT was performed in 27 cases (87.1%), autologous in 4 (12.9%). Related donors accounted for 66.3% (all 10/10 HLA-matched); unrelated donors 33.7% (50% 10/10, 50% 9/10). Stem cell sources included peripheral blood (48.2%), bone marrow (25.9%), and combined sources (25.9%). Median follow-up was 20 months (range 1–51).
Overall survival was 92.3%, with 100-day survival of 100%. Disease-free survival reached 95% for malignant and 83.3% for non-malignant cases. One JMML patient relapsed after the first transplant but remains in remission four years post-second transplant. Complications were minimal: only one patient developed bronchiolitis obliterans; all others (88.4%) maintained Lansky/Karnofsky ≥90 and ECOG ≤1. Two patients (7.7%) died >100 days post-transplant due to thrombotic microangiopathy and adenovirus-related complications.

Conclusions: Our outcomes exceed published benchmarks (ALL: 91% vs 85–90%; AML: 100% vs 65–75%; JMML post-second transplant: 100% vs 50–60%). These results highlight the effectiveness of standardized, risk-adaptive protocols implemented consistently across the multidisciplinary team, combined with proactive complication management. Early recognition and intervention for complications, structured nursing and physician

collaboration, and evidence-based decision-making were pivotal.
This study demonstrates that exceptional pediatric HSCT outcomes can be achieved "beyond numbers," even in a small cohort, offering a model for centers aiming to maximize survival and quality of life through meticulous protocol adherence and proactive clinical management.

P230

PEDIATRIC ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHRONIC GRANULOMATOUS DISEASE: A CASE SERIES OF SINGLE CENTER EXPERIENCE

Ilgen Sasmaz[1,2], *Bulent Antmen*[1], *Nurgul Yonyul*[1], *Moslem Eshghi*[1]
[1]*Acibadem Adana Hospital, Adana, Turkey,* [2]*Cukurova University, Adana, Turkey*

Background: Chronic granulomatous disease (CGD) is a rare primary immunodeficiency, and is associated with phagocyte dysfunction resulting from genetic defects in some of the different subunits of the NADPH oxidase complex. Depending on the protein subunit affected, the pattern of inheritance is autosomal recessive (AR) or X-linked. Hematopoietic stem cell transplantation (HSCT) can cure CGD. We aimed to present our transplant experiences in pediatric patients with CGD at Acibadem Adana Hospital, Pediatric Bone Marrow Transplantation Unit.

Methods: A total of 650 allogeneic hematopoietic stem cell transplantations were performed at Acıbadem Adana Hospital Pediatric Bone Marrow Transplantation Unit in Turkey from 2013 to 2025. 7 of 650 pediatric patients were CGD. In this retrospective analysis of medical records and treatment modalities were evaluated.

Results: In this retrospective analyses, 7 patients were evaluated, age ranging from 2 to 17 years with an average of 10.5 years. Five patients were males, two were female. Five patients had HSCT from an unrelated donor. We included all patients except one patient conditioning with ATG, fludarabine and treosulfan. One patients experienced secondary graft failure and this patients underwent a second transplant. Four CMV reactivation developed in our patients. Acute GVHD ≥ Grade III was observed in only one patient. Chronic GVHD was seen in three patients. Two patients died. One of them died on day 25 due to sepsis. Another patient, who underwent second transplant due to primary graft failure, died on the 277th post-transplant day due to COVİD19 pneumonia. One patient developed VOD despite receiving defibrotide prophylaxis. No serious toxicity was observed in other patients. 5 patients are alive and still following up GVHD free.

Conclusions: HSCT is the only potentially curative treatment option in patients with CGD with significant morbidity and mortality, especially in patients who receive grafts from unrelated donors. These factors need to be considered in the decision-making process and when discussing conditioning and GVHD prophylaxis. In this retrospective study, we showed the results of our reduced toxicity myeloablative conditioning regimen is excellent overall

survival, negligible GVHD, and low toxicity among in pediatric patients with CGD even in those with high-risk pre-HSCT clinical features or those with no HLA-identical family donor who transplanted match unrelated donor.

Disclosure: No disclosure.

P231

CONCENTRATION OF TOTAL NUCLEATED CELLS IN HARVESTED BONE MARROW FROM PEDIATRIC DONORS

Cristian Manuel Sotomayor Fahrenkrog[1], *María Angélica Wietstruck*[1], *Paula Catalán*[2], *Lucia Salas*[2]
[1]*Pontificia Universidad Católica de Chile, Santiago, Chile,* [2]*Hospital Dr Luis Calvo Mackenna, Santiago, Chile*

Background: Bone marrow (BM) has traditionally been the preferred source of hematopoietic stem cells (HSC) in matched sibling donors for pediatric patients. However, data on expected total nucleated cell (TNC) and CD34⁺ cell yields from healthy pediatric donors remain limited.

Methods: We conducted a retrospective analysis of TNC and CD34⁺ cell counts obtained from BM harvests performed in donors aged ≤18 years between January 2015 and October 2025 at two pediatric HSC transplant and collection centers. Demographic characteristics of donors and recipients were recorded. Kendall's tau-b coefficient was used to assess the association between donor age and TNC and CD34⁺ cell concentrations.

Results: During the study period, 81 BM harvests were performed. Fifteen were excluded due to donor age >18 years (n = 4) or insufficient data (n = 11). A total of 66 harvests were included. The median donor age was 11 years (range: 2–17). Median harvested concentrations were 22.06 × 10^6 TNC/mL (range: 8.34–52.12) and 0.39 × 10^6 CD34⁺ cells/mL (range: 0.04–9.48), both measured with additives. No significant correlation was observed between donor age and TNC concentration ($\tau = -0.078$; $p = 0.37$) or CD34⁺ cell concentration ($\tau = -0.026$; $p = 0.76$). The median recipient age and weight were 6 years (range: 0.1–22) and 27 kg (range: 5–97), respectively. The median infused cell dose was 2.00 × 10^9 TNC/kg (range: 1.02–13.20) and 4.8 × 10^6 CD34⁺ cells/kg (range: 0.43–26.75).

Conclusions: Concentrations of TNC and CD34⁺ cells harvested from BM were within the expected numbers and similar to those of high activity adult registries. BM allows the achievement of satisfactory cell doses from pediatric donors to pediatric receptors.

P232

TRANSFUSION PRACTICES AND COMPLICATIONS IN PEDIATRIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A CUBAN EXPERIENCE

Juan Carlos Jaime Fagundo[1], *Carsten Heilmann*[2]
[1]*Institute of Hematology and Immunologu, Havana, Cuba,* [2]*Rigshospitalet, København, Denmark*

Background: Hematopoietic stem cell transplantation in pediatric patients requires intensive transfusion support, which can be challenging in resource-limited settings. Understanding transfusion patterns and associated complications is essential to optimize care.

Methods: A retrospective analysis was conducted on pediatric hematopoietic stem cell transplantation recipients treated between March 2000 to December 2023 at Institute of Hematology and Immunology, Cuba. Transfusion data were collected for red blood cells, platelets, and plasma, along with clinical variables including graft source (bone marrow vs. peripheral blood), ABO compatibility, and transfusion reactions.

Results: The mean age was 10.2 ± 4.9 years old and 66 % were male. Acute non-lymphoid leukemia was the most common transplanted disease. In peripheral blood transplants the mean number of units of blood cells and platelets transfused was 3.9±2.13 and 23.2±18.74 and with the use of bone marrow it was 4.8±2.44 and 41.8±39.8, respectively. ABO incompatibility was present in 35% of cases, associated with delayed engraftment and increased transfusion needs. Transfusion reactions occurred in 12% of patients, predominantly febrile non-hemolytic events.

Conclusions: Peripheral blood grafts were associated with lower transfusion requirements and fewer complications, suggesting a potential advantage in pediatric hematopoietic stem cell transplantation settings. These findings support tailored transfusion strategies and highlight the importance of ABO compatibility in transplant planning.

P233

HAPLOIDENTICAL HEMATOPOEITIC STEM CELL TRANSPLANT (HSCT) – MY EXPERIENCE OVER 2 YEARS FOR VARIED HEMATOLOGICAL ONCOLOGICAL CONDITIONS

Priti Mehta[1]
[1]*NH SRCC Childrens Hospital, Mumbai, India*

Background: The problem faced in our Country is lack of awareness and lack of willingness to register as donors.Not having a matched donor in the family or the registry compels us to use a family member as a haploidentical donor.
Aim: To evaluate the outcome of Haploidentical HSCT in children aged 0-18 years of age

across different hematological conditions.The evaluation incudes the cell dose, engraftment, chimerism, immune reconstitution as well as complications encountered such as Graft vs host disease, viral reactivations, duration of follow up and costs incurred.

Methods: A retrospective analysis of Haploidentical transplants done by me over a 2 year period from October 2023 to December 2025 at a tertiary Pediatric hospital in Mumbai.12 children had undergone a haploidentical transplant,3T cell deplete and 9T replete.

Results: 12 children underwent Haploidentical HSCT, 3 each with Acute myeloid leukemia(AML) and Acute lymphoblastic leukemia(ALL) ,2 with thalassemia major and 1 each with severe aplastic anemia, CML with AML blast crisis in remission,homozygous sickler and with Primary hemophagocytic lymphohistiocyosis. Out of these 12,3 underwent T deplete HSCT, the child with AML blast crisis in CML, one child with Thalassemia major and one child with primary HLH. The median CD34 stem cell dose was 8 x10^6/kg and the median CD3 dose was 3.5x10^8/kg in the T replete cohort and median CD34 of 20x10^6/kg in the T deplete cohort.The median time to neutrophil engraftment was14 days and the median time to platelet engraftment was 18 days of the entire cohort.2 children succumbed to complications of transplant, child with B ALL heavily pretreated prior to transplant with chemotherapy and immunotherapy developed septicemia and venoocclusive disease and succumbed on DAY +43 post transplant to enterococcus septicemia.The child with Thalassemia major developed secondary graft failure secondary to HHV6, cytokine storm and could not be revived. One more child with ALL having undergone nonTBI based conditioning relapsed 4 months post transplant.The rest all are alive at a median follow up of 265 days(range day+29 to +561).Chimerism was 100% at day +30 in 11/12 children except one child with ALL who succumbed to complications.The chimerism persisted to be 100% in those who have completed 365 days post HSCT. Apart from CMV viremia and grade I–II gut GVHD none of the 10/12 children faced any major complications like chronic GVHD.The immune reconstitution was robust with all children having a CD4 of more than 50 cells/ul at day +100.The cost of transplant on average was 16,500-17,000 pounds for T replete and around 33,000-35,000 pounds for T deplete HSCT.

Conclusions: Haploidentical HSCT is a boon for the resource limited countries with meagre donor registries,good outcomes with very few complications post HSCT and not very expensive even in a private tertiary care hospital.Adequate CD34 dose ensures robust engraftment. The maximum CD3 dose in the T replete cohort was 7.8x10^8/kg, range being 1.88 to 7.8x10^8/kg, not inciting severe GVHD in any child.

Disclosure: Nothing to declare

P234

BUSULFAN ASSOCIATED PULMONARY TOXICITY AND INFECTIOUS COMPLICATIONS FOLLOWING AUTOLOGOUS SCT IN A 3-YEAR-OLD CHILD WITH NEUROBLASTOMA

Ines Goppelt[1], *Maria Polacik*[1], *Heike Schützle*[1], *Sebastian Brenner*[1], *Christian Vogelberg*[1], *Kristina Stamos*[1], *Christoph Meißner*[1], *Reinhard Berner*[1], *Denis Martin Schewe*[1]
[1]*University Hospital Carl Gustav Carus at the Technische Universität Dresden, Dresden, Germany*

Background: High-dose busulfan/melphalan (Bu/Mel) remains a standard conditioning regimen for autologous stem cell transplantation in high-risk neuroblastoma but is associated with significant organ toxicity, particularly hepatic and pulmonary injury. Pulmonary toxicities present with nonspecific clinical symptoms and radiological features and have been linked to the development of pulmonary hypertension and acute respiratory distress syndrome (ARDS).

Methods: Here, we report the case of a 3-year-old girl with stage IV neuroblastoma who developed severe, multifactorial pulmonary complications after Bu/Mel conditioning and autologous stem cell transplantation (SCT).

Results:

Early post-transplant complications included a left-sided diaphragmatic hernia on d +9 after previous surgical intervention (abdominal neuroblastoma surgery), hepatic veno-occlusive

disease (VOD) d +26 and respiratory deterioration with need for mechanical ventilation due to concomitant CMV infection and Legionella pneumoniae infection on d +27. A treatment with Defibrotide, Ganciclovir and Azithromycin was initiated. Extubation to High-Flow was possible by d +37; however, a persistently high oxygen requirement and progressive right-sided pulmonary opacification was noted. On d +61, the patient experienced acute deterioration with a cardiopulmonary resuscitation event in the setting of ARDS and methicillin-resistant staphylococcus aureus (MRSA) sepsis, confirmed by MRSA in blood cultures and bronchial secretions. CT imaging demonstrated bilateral pneumonia with necrotizing changes in the right lower lobe and diffuse ground-glass opacities. Management included broad-spectrum antibiotics, inhaled nitric oxide (iNO) and mechanical ventilation with high pressure levels (PEEP and peak pressure). We saw a clinical response with iNO, while echocardiography showed only moderate pulmonary hypertension. We started a treatment with Sildenafil, Macitentan, Epoprostenol in addition to Methylprednisolone pulse therapy and antifibrotic treatment with Nintedanib, Hydroxychloroquin and Azithromycin. While infectious complications and hepatic VOD completely resolved, the patient's respiratory function remained critically impaired. CT scans showed progressive interstitial lung disease with coarse-cystic fibrosis in the right lower lobe, subpleural honeycombing and diffuse ground-glass opacities.In response to recurrent pulmonary bleeding and pneumothorax, a therapeutic attempt was made to functionally exclude the most damaged lung segment, using an occluder device. The procedure was technically successful. However, despite maximal intensive care support the patient's course was ultimately fatal due to persistent severe hypoxemia and refractory ventilation failure.

Conclusions: This case illustrates the complex interplay between infectious complications, post-transplant inflammation and busulfan-induced pulmonary toxicity in a young neuroblastoma patient undergoing Bu/Mel conditioning and autologous SCT. Consideration of busulfan toxicities, especially when presenting with nonspecific early symptoms is important even when alternative explanations such as severe infection may appear equally plausible after autologous SCT. Early recognition, close monitoring of busulfan exposure, and multidisciplinary management are critical to mitigating the risk of life-threatening pulmonary toxicity in children undergoing Busulfan conditioning.

Disclosure: Nothing to declare.

ENDOTHELIAL BIOMARKER DYNAMICS IN SINUSOIDAL OBSTRUCTION SYNDROME FOLLOWING PEDIATRIC ALLOGENEIC HSCT

*Denise Elbæk[1,2], **Katrine Kielsen**[1,3], Michele Rossi[3], Ulrika Boulund[2], Maria Ebbesen Sørum[1], Hilde Hylland Uhlving[1], Claus H. Niesen[1], Jens-Christian Holm[3,4], Jakob Stokholm[2,3], Pär Ingemar Johansson[1,3], Morten Arendt Rasmussen[2,3], Klaus Müller[1,3]*
[1]Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark, [2]Herlev and Gentofte Hospital, University of Copenhagen, Gentofte, Denmark, [3]University of Copenhagen, Copenhagen, Denmark, [4]Copenhagen University Hospital Holbæk, Holbæk, Denmark

Background: Allogeneic HSCT is limited by toxicities related to endothelial dysfunction, including sinusoidal obstruction syndrome (SOS), which can be life-threatening. Early diagnosis of SOS is difficult due to non-specific symptoms and insufficient diagnostic tools, highlighting the need for a biomarker-guided approach. This study investigates longitudinal patterns of endothelial activation and damage biomarkers before conditioning and during the first 2 months after pediatric HSCT.

Methods: We prospectively included 113 children (median age: 8.8 years) undergoing standard HSCT at Rigshospitalet in Denmark from 2010-2019 (Table 1). Two hundred children aged 6-19 years served as controls.
Endothelial biomarkers (ICAM-1, VCAM-1, P-selectin, E-selectin, sVEGF-R1, PECAM-1, sTM, vWF, PAI-1, syndecan-1, and angiopoietin-2) were measured by Luminex and ELISA before conditioning and on days 0, +7, +14, +21, +30, and +60 post-HSCT. Severe SOS was diagnosed retrospectively according to the pediatric EBMT criteria based on medical records. Statistical analyses included principal component analysis (PCA) to identify biomarker patterns and random forest machine-learning models with cross-validated ROC-AUCs to evaluate predictive performance of SOS from biomarkers and demographic baseline information.

TABLE 1 Patient and transplant characteristics		HSCT patients (n=113)		Controls (n=200)	
Sex, male, n (%)		66	(58.4%)	97	(48.5%)
Age (years), median (range)		8.8	(1.1-17.6)	11.7	(6-18.8)
Malignant disease at transplantation, n (%)		68	(60.2)		
Donor type, n (%)					
	Matched sibling donor (10/10)	33	(29.2%)		
	Matched unrelated donor (≥9/10)	80	(70.8%)		

Stem cell source, n (%)					
	Bone marrow	108	(95.6%)		
	Peripheral blood stem cells	5	(4.4%)		
Conditioning regime, n (%)					
	BU-based	49	(43.4%)		
	TBI-based	27	(23.9%)		
	Other chemotherapy-based regimens	37	(32.7%)		
ATG as part of conditioning, n (%)		85	(75.2%)		
GvHD-prophylaxis, n (%)					
	CyA	19	(18.8%)		
	CyA/TA + MTX	94	(83.2%)		
Prophylactic defibrotide, n (%)		7	(6.2%)		

Results: Fifty-one patients developed SOS, including 32 with severe SOS. Median diagnosis was day +5 (range +2-+58).
All selected biomarkers were detectable and included in a PCA analysis to identify patterns associated with severe SOS. The leading principal component (PC1) was mainly characterized by PECAM-1, P-selectin and PAI-1 (figure 1A) with a similar temporal trajectory for patients with mild/no SOS (n=81) and severe SOS (n=32), reflecting general post-transplant changes. PC2 (driven by VCAM-1, ICAM-1, vWF, and syndecan-1, 1figure A) distinguished severe SOS (from mild/no SOS) with the largest differences observed from day +7 to +30 (all $p<0.05$, 1figure B). This indicates that PC2 patterns may identify high-risk patients around the time of severe SOS diagnosis.
Among controls (n=200), PCA revealed distinct differences in biomarkers variability compared with HSCT-patients. PC1 showed greater variability compared to HSCT-patients across day 0, +7, +14, and +21 (all $p<0.001$), while PC2 demonstrated tighter clustering at all time points (all $p<0.00001$). These patterns could indicate that HCST induces a characteristic shift in biomarker patterns, while both controls and HSCT patients show variation within their own groups.
Machine-learning models combining biomarker patterns with baseline characteristics (age, malignant diagnosis, and busulfan-based conditioning) showed high diagnostic accuracy for predicting severe SOS (AUC: 0.75 pre-conditioning, 0.74 day 0, and 0.79 day +7). These combined models outperformed both biomarker-only models (AUC: 0.67, 0.67, and 0.78, respectively) and baseline characteristics-only models (AUC: 0.70), demonstrating that integrating clinical and biological information enables earlier risk identification. Overall, sensitivity was modest while specificity was high for predicting/diagnosing severe SOS in the combined models (16.2% and 92.8% before conditioning, 28.5% and 93.8% on day 0, and 36.5% and 90.1% on day +7, respectively).

Conclusions: Pediatric HSCT patients show significant and early biomarker changes compared to controls. Patterns involving VCAM-1, ICAM-1, vWF, and syndecan-1 may distinguish severe SOS around the time of diagnosis. Combining biomarkers with baseline characteristics may lead to a restriction of the SOS criteria for prediction of high-risk pediatric SOS, supporting targeted monitoring and risk-stratified care.

PRE-TRANSPLANT RESISTOME DISRUPTION PREDICTS ESBL GENE ACCUMULATION IN PEDIATRIC TRANSPLANT RECIPIENTS: A PROSPECTIVE MULTI-CENTER STUDY

*Marygrace Duggar[1], Yilun Sun[1], Davide Leardini[2], Qidong Jia[1], **Edoardo Muratore**[2], Ronald Dallas[1], Jose Ferrolino[1], Anju Cherian[1], Simone Cesaro[3], Maura Faraci[4], Jowita Fraczkiewicz[5], Marek Ussowicz[5], Janet Englund[6], Hana Hakim[1], Randall Hayden[1], Eileen Klein[6], Joshua Wolf[1], Gabriela Maron[1], Li Tang[7], Riccardo Masetti[2], Elisa Margolis[1,8]*
[1]St. Jude Children's Research Hospital, Memphis, United States of America (the), [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy, [3]Azienda Ospedaliera Universitaria Integrata, Verona, Italy, [4]IRCSS Istituto Giannina Gaslini, Genoa, Italy, [5]Wroclaw Medical University, Wroclaw, Poland, [6]Seattle Children's Hospital, Seattle, United States of America (the), [7]Cleveland Clinic, Cleveland, United States of America (the), [8]University of Tennessee Health Sciences Center, Memphis, United States of America (the)

Background: Extended-spectrum β-lactamase (ESBL)–producing organisms are an important cause of post-transplant infections in children undergoing allogeneic hematopoietic cell transplantation (HCT). Whether ESBL gene accumulation during early transplant is primarily driven by peri-transplant antibiotic exposure or by pre-existing resistome disruption remains unclear.

Methods: We conducted a prospective multi-center study including pediatric patients (<18 years) receiving HCT from 4 European centers (Bologna, Genova, Verona, Wroclaw) and one American center (St. Jude Children's Research Hospital, Memphis). Stool samples were collected before HCT, at neutrophil engraftment, and on day +30 after HCT. Metagenomic sequencing was used to quantify antibiotic resistance genes (ARGs), with ESBL genes annotated via MEGARes 3.0. Associations between antibiotic exposure and ESBL gene accumulation before engraftment were assessed using linear regression models weighted by covariate balancing propensity scores. To account for differences in transplant practices between countries, analyses were performed comparing European and American centers.

Results: A total of 133 pediatric HCT recipients were included, 39 from European centers and 94 from St. Jude. Full patients' characteristics are reported in the Table. The cohorts presented some significant differences. As transplant indications, acute myeloid leukemia predominated in the St. Jude cohort (54.3% vs 17.9%), and nonmalignant diseases occurred exclusively in European patients (35.9% vs 0%) ($p<0.001$). Myeloablative regimens used in

79.5% of European patients compared with 34.0% at St. Jude (p<0.001). T-cell depletion strategies, as ATG was used routinely in Europe (71.8%) and not at all at St. Jude (p<0.001). Analysis of ESBL gene dynamics revealed distinct temporal patterns between cohorts. European patients showed a pronounced rise in ESBL gene abundance between HCT and engraftment that persisted through day +30, whereas St. Jude patients demonstrated increases primarily after engraftment. When antibiotic classes were examined, only aminoglycoside exposure before engraftment was associated with ESBL gene accumulation, and this was limited to the European cohort (est: 0.93; 95% CI 0.66–1.20; p=0.002). No associations were observed for exposure to total β-lactams (Europe p=0.685; St. Jude p=0.353), ESBL-cleavable β-lactams (St. Jude p=0.933), antibiotics with anaerobic activity (Europe p=0.893; St. Jude p=0.073), or total daily antibiotic exposure (Europe p=0.643; St. Jude p=0.815). In contrast, pre-HCT resistome disruption emerged as a strong predictor of subsequent ESBL expansion. A higher Bray–Curtis distance from the healthy resistome centroid at baseline was associated with increased ESBL gene abundance both before engraftment (Europe est: 7.48, SE 3.65, p=0.052; St. Jude est: 15.85, SE 6.19, p=0.024) and during the first 30 days post-HCT (Europe est: 15.12, SE 5.51, p=0.013; St. Jude est: 9.58, SE 4.99, p=0.079). Notably, only minimal additional resistome perturbation occurred during neutropenia, despite intensive antibiotic exposure.

Characteristic	European (N = 39)	St. Jude (N = 94)	P-value
Age at Transplant	8.1	8.4	0.865
Gender- Female	17 (43.6%)	42 (44.7%)	0.908
Diagnosis			<0.001
Acute myeloid leukemia	7 (17.9%)	51 (54.3%)	
Acute lymphoblastic leukemia	12 (30.8%)	33 (35.1%)	
Other malignancy	6 (15.4%)	10 (10.7%)	
Nonmalignant disease	14 (35.9%)	0 (0.0%)	
Donor			<0.001
Haploidentical	7 (17.9%)	54 (57.4%)	
Related	5 (12.8%)	14 (14.9%)	
Unrelated	27 (69.2%)	26 (27.7%)	
Graft Source			0.417
Bone Marrow	15 (38.5%)	37 (39.4%)	
Peripheral Blood Mononuclear Cells	23 (59.0%)	57 (60.6%)	

T Cell Depletion			0.006
Yes	28 (71.8%)	43 (45.7%)	
Type of T Cell Depletion			<0.001
Antithymocyte Globulin	28 (71.8%)	0 (0.0%)	
CD3 Depletion and/or CD34 Enrichment	0 (0.0%)	42 (44.7%)	

Conclusions: In pediatric HCT recipients, ESBL gene accumulation is more strongly driven by pre-existing resistome disruption than by early post-transplant antibiotic exposure. Aminoglycosides may contribute to ESBL gene expansion, whereas β-lactam exposure alone does not appear to be a major driver. These findings highlight the importance of pre-HCT microbiome and resistome preservation strategies as potential avenues to reduce ESBL colonization and infection risk in vulnerable transplant populations.

REGULATORY T CELL RECONSTITUTION IS ASSOCIATED WITH ONSET AND SEVERITY OF ACUTE GRAFT-VERSUS-HOST DISEASE IN PEDIATRIC AND YOUNG ADULT HCT RECIPIENTS

*Friederike Kogel[1], Kinga Hosszu[1], Devin McAvoy[1], Charlie White[1], Moises Garcia-Rosa[2], Matthew Thomsen[1], Evangelos Ntrivalas[1], Elizabeth Klein[1], Audrey Mauguen[1], Kevin J. Curran[1], Maria Cancio[1], Andrew C. Harris[1], Andromachi Scaradavou[1], Andrew Kung[1], Miguel-Angel Perales[1], **Jaap Jan Boelens**[1]*
[1]Memorial Sloan Kettering Cancer Center, New York, United States of America (the), [2]Universidad de Puerto Rico RCM / Hospital Pediátrico Universitario, San Juan, Puerto Rico

Background: Regulatory T cells (Tregs), a small subset of circulating $CD4^+$ T cells, play a crucial role in immune tolerance by suppressing auto- and alloreactive immune responses and are essential for establishing and maintaining immune tolerance after allogeneic hematopoietic cell transplantation (alloHCT). A reduction in Treg frequency or numbers has been associated with the onset of acute Graft-versus-Host Disease (aGvHD), a potentially life-threatening complication following alloHCT. The dynamics of Treg reconstitution and differentiation after alloHCT may modulate development of aGVHD. Here, we examined the potential association between Treg frequencies (% Tregs of $CD4^+$ T-cells) and the 90-day onset of aGvHD in pediatric and young adult HCT recipients.

Methods: Patients transplanted between 2020-2025, who had provided consent for ancillary immune reconstitution studies within our TCT program were included. We used our CLIA-approved Treg panel which includes CD4+ regulatory T-cell (CD3+CD4+CD25+CD127low), naïve (CD45RO-HLA-DR-), activated (HLA-DR+) and memory (CD45RO+) Treg subsets. Primary outcome of interest was studying the association between Treg reconstitution and

the development of aGvHD in the first 90 days after alloHCT. We also examined post-HCT Treg patterns in relation to GvHD severity. Uni- and multivariate logistic regression analyses were performed.

Results: 117 patients were enrolled with median age of 12 years, range 0-26. Early Treg data before the onset of aGvHD were available for 79 out of 117 patients; 24 (30%) received cord blood, 14 (18%) T-cell deplete peripheral blood stem cells and 41 (52%) unmodified grafts. 38 (48%) patients developed aGvHD (grade 2-4).
Higher Treg frequencies (>3% of $CD4^+$ T-cells) before day 90 or onset of aGVHD were associated with decreased odds of developing aGVHD (p=0.027). Also age (<12 yrs; p=0.038) and cord blood; p=0.027) were found to be predictors for aGvHD 2-4. Treg frequencies rapidly declined after HCT in patients who went on to develop aGvHD (Figure 1). This decrease was not observed in patient who did not develop aGvHD or in patients treated for aGvHD. The Treg differentiation trajectory indicated that memory and activated Treg subsets, but not naïve Tregs, declined prior to GvHD onset. After development of aGvHD Tregs remained decreased (about 20%) in Grade 3-4 GvHD compared to Grade 0-2 GvHD untill 12-18 months after HCT (n=117; Figure 2).

Figure 1 I Treg frequencies decline prior to aGvHD onset.

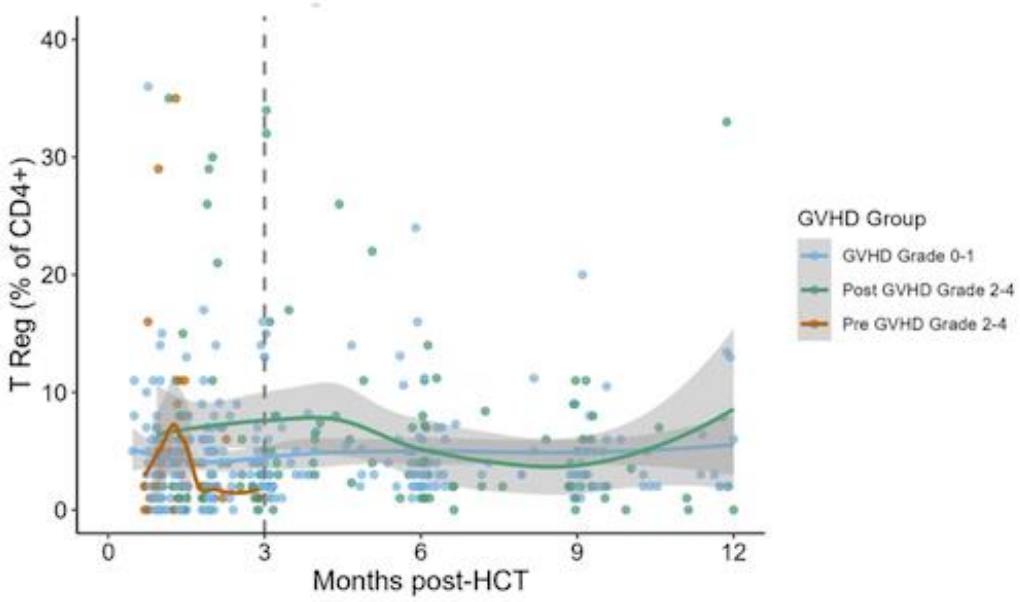

Figure 2 I Activated Tregs decrease with GvHD severity.

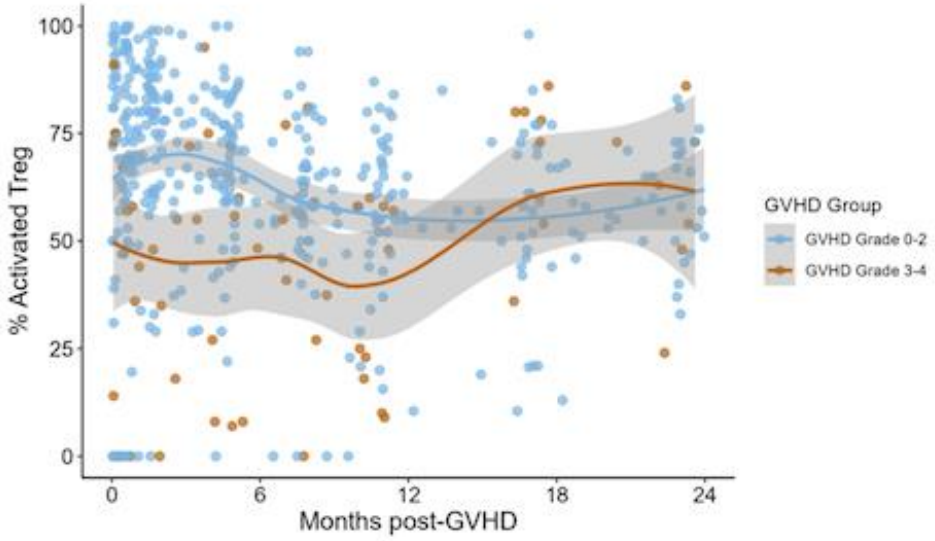

Conclusions: In this large pediatric and young adult cohort, early robust Treg reconstitution (>3% of CD4+ T-cells) was associated with a lower risk of aGvHD. The observed decline in Treg frequencies prior to aGvHD onset appeared to reflect a shift toward a less active Treg profile, with decreasing activated Tregs correlating with GvHD severity. The association between early loss of Treg subsets and aGvHD onset and severity must be confirmed in a larger, multicenter cohort but could be implemented for risk stratification and clinical decision-making.

Background: Methotrexate (MTX) is commonly used as acute graft versus host disease (aGvHD) prophylaxis in combination with cyclosporine A (CsA) following hematopoietic stem cell transplantation (HSCT) in pediatric acute lymphoblastic leukemia (ALL) patients. It inhibits folate metabolism, thus blocking T-cell proliferation and decreasing inflammation. While the pharmacogenetic (PGx) of MTX has already been broadly investigated in the context of high-dose administration for cancer treatment, less is known about its role in GvHD prevention. Here, we investigated whether some of the previously identified polymorphisms impacting MTX pharmacodynamics or pharmacokinetics are playing a role in its anti-aGvHD efficacy.

Methods: The genetic association analysis was performed using data collected from 370 MTX-treated children among 485 participants in the PGx add-on (NCT02670564) of the ALL SCTped 2012 FORUM (NCT01949129) study. We included patients who received bone marrow (BM) or peripheral blood (PB) stem cell transplantation from an HLA-identical sibling (MSD) or a 9-10/10 HLA-matched related or unrelated donor (MD). According to protocol, all analyzed patients received additional CsA prophylaxis and, for non-sibling donors ATG. As most patients who underwent MSD-BM transplantation received CsA prophylaxis alone, this group is underrepresented in the current subset. Patients with cord-blood and missmatched donors HSCT were excluded.
We tested the association between single genetic determinants and grade II-IV aGvHD using Fine-Gray regression models adjusting for donor type, stem cell source, conditioning regimen, disease phenotype, and sex as covariates. Death and relapse were considered competing events for aGvHD and p-values <0.05 after adjustment for multiple testing using Benjamini-Hochberg FDR, were statistically significant.
We selected 24 genetic variants involved in MTX transport or the folate pathway with previous interactions described in the literature.

Results: Of 370 patients aged 0.5-20 years (median=9.4 years), 108 (29.2%) developed grade II-IV aGvHD. In this FORUM subset, PB grafts (N=107, 5 MSD, 102 MD) were associated with a higher risk of aGvHD than BM grafts (N=263, 30 MSD, 233 MD; HR 1.9, 95% CI 1.3-2.8, p=0.001). Acute, but not chronic, GvHD correlated with a lower cumulative incidence of relapse (aGvHD grade II-IV: HR 0.61, 95% CI 0.37-0.98, p=0.042, grade III-IV: HR 0.23, 95% CI 0.06-0.95, p=0.021).
From the 24 selected variants, we identified one significant association between ***MTHFR* rs1801131** (MAF = 0.31) and the cumulative incidence of aGvHD (HR 0.60, 95% CI 0.44-0.82, adjusted p-value=0.024). This single nucleotide polymorphism, also known as **A1298C**, encodes a non-synonymous **E429A** mutation in methylenetetrahydrofolate reductase protein catalyzing a rate limiting step in the one-carbon cycle.

Conclusions: Our candidate gene approach validated the recipient ***MTHFR* A1298C** variant as a significant determinant of MTX prophylaxis efficacy against aGvHD in a homogenous cohort of children with ALL undergoing HSCT from HLA 9-10/10 matched donors. Elucidating the regulatory mechanism of the folate pathway may help personalize MTX administration for post HSCT GvHD prophylaxis.

POTENTIAL FOR PHARMACOGENOMICS TO IMPROVE MEDICATION SAFETY AND EFFICACY IN AUSTRALIAN HAEMATOPOIETIC STEM CELL TRANSPLANT PATIENTS

*Claire Moore[1,2,3], Andreas Halman[1,2], Tayla Stenta[1,2,3], Elizabeth Williams[1,2,3], Roxanne Dyas[1,2,3], Dhrita Khatri[1,2,3], David A. Elliott[1,2,4], **Hannah Walker**[1,3,2], Rachel Conyers[1,2,3]*
[1]Murdoch Children's Research Institute, Melbourne, Australia, [2]University of Melbourne, Melbourne, Australia, [3]Royal Children's Hospital, Melbourne, Australia, [4]The Novo Nordisk Foundation Centre for Stem Cell Medicine, Melbourne, Australia

Background: Children undergoing a haematopoietic stem cell transplant (HSCT) often receive intensive conditioning regimens prior to receiving stem cells. In addition, HSCT patients are prescribed multiple supportive care medications including anti-emetics and anti-infectives, increasing their risk of adverse drug reactions (ADRs). Treatment toxicities can be severe and even life-threatening for these patients. Using pharmacogenomic (PGx) guided prescribing could result in safer and more effective therapy, with established guidelines for many commonly prescribed supportive care medications. Here we describe the frequency of high-risk PGx phenotypes identified in a diverse Australian paediatric oncology cohort, and estimate the prevalence of PGx medications prescribed in paediatric HSCT patients.

Methods: 14 pharmacogenes affecting medications commonly prescribed in paediatric oncology were selected for analysis from the Clinical Pharmacogenetics Implementation Consortium (CPIC) and Dutch Pharmacogenetics Working Group (DPWG) databases. Whole Genome Sequencing (WGS) data was obtained from 180 patients, and a custom PGx bioinformatic pipeline used to genotype and call consensus diplotypes. CPIC diplotype-to-phenotype tables were used to infer predicted phenotypes for the 14 pharmacogenes, including CYP2C19, CYP2D6, CYP3A5, G6PD, HLA-A, HLA-B, MT-RNR1, ABCG2, NUDT15 and TPMT. Paired supportive care medications included allopurinol, sertraline, omeprazole, pantoprazole, voriconazole, ondansetron, tramadol, tacrolimus, flucloxacillin, carbamazepine and amikacin. Electronic medical records were accessed to estimate prescribing rates of PGx medications in a paediatric oncology cohort, and specifically in paediatric HSCT patients.

Results: More than 90% of patients had at least one high-risk PGx phenotype, 58% for CYP2C19 phenotype and 49% for CYP2D6. 30% had high-risk phenotypes for both CYP2C19 and CYP2D6. Most patients (89%) were prescribed ondansetron and a significant number prescribed omeprazole (38%), pantoprazole (19%) and voriconazole (15%). PGx actionability rates were highest amongst patients taking omeprazole, voriconazole and sertraline when analysed as a proportion of patients prescribed the medication. In a cohort of

44 paediatric HSCT patients, ondansetron was prescribed in 71%, voriconazole in 39%, pantoprazole in 41%, omeprazole in 14%, tacrolimus in 9% and tramadol in 9%.

Conclusions: We have demonstrated the prevalence of clinically relevant high-risk PGx phenotypes in a diverse paediatric oncology cohort. Many supportive care medications prescribed for paediatric HSCT patients are likely to be affected, with high prescribing rates observed for some medications with available PGx prescribing guidelines. These results highlight the potential for PGx guided prescribing to improve medication efficacy and reduce toxicity in a paediatric HSCT setting.

Disclosure: Nothing to declare.

HEMATOPOIETIC STEM CELL TRANSPLANTATION AND GUT MICROBIOME DIVERSITY IN CHILDREN

Gustav Ørting Jørgensen[1], *Maria Ebbesen Sørum*[1], *Trine Zachariasen*[2], *Katrine Kielsen*[1], *Marianne Ifversen*[1], *Jakob Stokholm*[2,3], *Urvish Trivedi*[2,3], *Klaus Müller*[1]
[1]*Rigshospitalet, Copenhagen, Denmark,* [2]*University of Copenhagen, Copenhagen, Denmark,* [3]*Copenhagen University Hospital, Herlev-Gentofte, Copenhagen, Denmark*

Background: The gut microbiome (GM) is increasingly recognized as a key modulator of immune homeostasis and post-HSCT recovery. In adult HSCT recipients reduced microbial diversity – driven by conditioning, antimicrobial treatment, and mucosal injury – has been linked to infection risk, delayed immune reconstitution, aGvHD, and overall survival (OS). In children GM diversity pre-conditioning has been associated with aGvHD and OS. Because the pediatric gut microbiome is still developing, longitudinal responses to HSCT may differ substantially from adults, underlining the importance for high-resolution studies of GM in larger pediatric cohorts.

Methods: We prospectively enrolled children aged 1-18 years undergoing allo-HSCT at the national pediatric HSCT center in Copenhagen, Denmark (2015-2024). Patient characteristics are summarized in Table 1. Participants provided stool samples at up to 11 predefined timepoints from pre-conditioning through 52 weeks post-HSCT, yielding 825 samples from 134 patients. Shotgun metagenomic sequencing was performed and species-level community profiles were generated using MetaPhlAn.
Alpha diversity (within-sample diversity) was quantified using Shannon Index.
Longitudinal changes in alpha diversity were evaluated using linear mixed-effects models with fixed effects for time, age, sex, malignant disease, TBI ≥12 Gy, and GVHD grade.
Beta diversity (between-sample diversity) was assessed using Bray–Curtis dissimilarities, visualized by principal coordinates analysis (PCoA), and tested by PERMANOVA (999 permutations).

Results: GM alpha diversity declined markedly from pre-conditioning through Day 0 and weeks 1 to 3, followed by steady increase beginning at week 4. Diversity returned to pre-transplant levels by week 9 and remained stable through week 52 (Figure 1A).

In a multivariate linear mixed-effects model accounting for repeated measurements and clinical variables, mean alpha diversity decreased significantly immediately after conditioning and remained low post stem cell infusion (day 0: $\beta = -0.45$, $p < 0.001$; week 1: $\beta = -0.68$, $p < 0.001$) but increased above the pre-conditioning baseline by 52 weeks ($\beta = 0.23$, $p = 0.029$). Older age was associated with higher diversity ($\beta = 0.021$ per year, $p = 0.006$), whereas sex, malignancy status, TBI ≥12 Gy, and aGvHD grade were not significantly associated with alpha diversity.
Beta diversity analyses showed strong temporal restructuring of the GM, with sampling timepoint explaining 11.9% of community variation ($p = 0.001$). Samples taken the first few weeks after graft infusion (day 0 to week 4) formed a distinct cluster, separate from both pre-conditioning and late timepoint samples, and showed greater within group dispersion, indicating high inter-individual variability during the early transplant phase. In contrast, late timepoints (week 9 – 52) had lower dispersion than early timepoint (Day 0 to week 4) (Tukey's HSD test, $p < 0.001$) and clustered closely with pre-conditioning samples indicating greater compositional similarity between late post-HSCT and pre-conditioning GM (Figure 1B).

Conclusions: This study provides the first large-scale, year-long cohort study with high-resolution characterization of GM dynamics in pediatric HSCT. GM diversity follows a collapse-and-recovery trajectory with GM diversity restored by late follow-up. These findings lay essential groundwork for future studies linking GM dynamics to clinical outcomes and immune reconstitution.

Background: Haematopoietic cell transplantation (HSCT) is often the only curative option for patients with malignant and non-malignant disorders. Advances in transplant care have improved survival, resulting in an expanding cohort of long-term HSCT survivors in whom cardiovascular sequelae are increasingly recognised. However, comprehensive population-level data on these risks remain limited. We evaluated cardiovascular event incidence in HSCT survivors and identified key risk factors in the UK Biobank.

Methods: UK Biobank is a population-based cohort of 500,000 adults recruited between 2006 and 2010, with detailed baseline profiling and prospective follow-up. We identified participants who underwent their first HSCT after recruitment and matched each to up to four non-transplanted controls using propensity-score nearest-neighbour matching. The

model included baseline sociodemographic factors (age, sex, ethnicity, education level, and deprivation index), lifestyle behaviours (smoking status, alcohol intake, and physical activity), and pre-existing comorbidities (hypertension, diabetes, and hyperlipidaemia). The HSCT date was defined as the index date, with matched controls assigned the same index date as their corresponding case. We identified seven incident cardiovascular diseases using linked hospital and mortality records. Cause-specific Cox proportional hazards models (stratified by matched set) were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs). In secondary analyses restricted to HSCT recipients, we fitted multivariable Cox proportional hazards models to evaluate how pre-transplant patient factors influence risk of adverse outcomes. We additionally assessed effect modification by age through interaction terms with transplant type. The HCT-specific comorbidity index (HCT-CI) was replicated using linked hospital records, based on published definitions and used for descriptive purposes.

Results: The study cohort included 757 HSCT recipients (59% men; mean age at transplant, 63.1 years) and 3,028 matched controls (60% men; mean age at recruitment, 56 years) (**Table 1**). The cohort was predominantly White (≥94%). Among HSCT recipients, 72.1% underwent autologous transplants, with peripheral blood stem cells being the predominant graft source (93.3%, n = 706). Common transplant indications included multiple myeloma/plasma cell dyscrasia (49.5%), lymphoma (19.0%), and leukaemia (18.9%). In HSCT recipients, the median HCT-CI was 1 (IQR 0–3). Over a median follow-up of 4.25 years, HSCT survivors had more than a threefold increased risk of cardiovascular disease (HR 3.13; 95% CI 2.56–3.84), with the greatest excess risks observed for pericardial disease (HR 4.64; 95% CI 2.23-9.66), venous thromboembolism (HR 4.27; 95% CI 2.71-6.71), and heart failure (HR 3.87; 95% CI 2.58-5.82) (**Figure 1, panel A**). Within the HSCT cohort, older age at transplant, allogeneic grafts, male sex, pre-transplant smoking, and diabetes were associated with higher post-transplant cardiovascular risk (**Figure 1, panel B**). In interaction analyses, age significantly modified the effect of transplant type, with older allogeneic recipients showing the highest excess cardiovascular risk.

Characteristic	HSCT	General population
N	757	3,028
Age at transplant, years	63.1 (± 7.1)	-
Male	446 (58.9%)	1,808 (59.7%)
White ethnicity	715 (94.5%)	2,893 (95.5%)
Townsend Deprivation Index	-2.4 (-3.8, -0.1)	-2.4 (-3.8, 0.1)
Post-secondary education	410 (54.1%)	1,534 (50.7%)
Alcohol intake daily	143 (18.9%)	592 (19.6%)

Smoking	335 (44.3%)	1,342 (44.3%)
Body mass index, kg/m2	27.5 ± 4.6	27.5 ± 4.7
Hypertension	209 (27.6%)	812 (26.8%)
High cholesterol	147 (19.4%)	535 (17.7%)
Diabetes	43 (5.7%)	170 (5.6%)
Autologous transplant	548 (72.4%)	-

Conclusions: HSCT survivors experience a substantially elevated cardiovascular morbidity compared to matched controls. These findings highlight the importance of evaluating cardiovascular risk before transplant and the need for ongoing monitoring for cardiovascular complications in the long term post-transplant, especially given the shifting demographics toward an older eligible transplant population with greater age-related comorbidities.

SOCIAL IMPACT AND PATIENT–CAREGIVER EXPERIENCE IN CHRONIC GVHD: RESULTS FROM A NATIONAL SURVEY IN SPAIN

Marta Fernandez[1], *Alexandra Carpentier*[1], *Laura Torrebadell*[2], *Aitor Vargas*[2], *Ramon Jordana*[2], *Alejandra Martínez Trillos*[1], *Sergi Querol*[1]
[1]*Fundacion Josep Carreras, Barcelona, Spain,* [2]*Punto De Fuga, Barcelona, Spain*

Background: Chronic Graft-versus-Host Disease (cGVHD) is a complex, multisystemic complication following allogeneic hematopoietic cell transplantation, with profound and lasting effects on patients and caregivers. Despite advances in donor selection, prophylaxis, and treatment, many patients still develop cGVHD remaining a major cause of long-term morbidity, reduced quality of life, and significant social and emotional burden. the objetive of the estudy was to evaluate the social, emotional, physical, and functional impact of cGVHD on patients and caregivers in Spain, identifying unmet needs and areas for improvement in care and support.

Methods: A mixed-methods design combined qualitative data from focus groups with young patients, minors, and caregivers, and quantitative results from an anonymous survey conducted between May and July 2025. The study assessed clinical manifestations, daily life, family, work and studies, economic impact, social and emotional well-being, psychological support, and access to information. The survey was reviewed by a medical board and distributed via the Josep Carreras Foundation. All participants gave informed consent. The study was approval by the CEIM HCB/2025/0626.

Results: A total of 278 participants (207 patients, 71 caregivers) Most patients were women aged 36–60 (55%), living in Catalonia or Madrid, and transplanted for leukaemia more than five years ago (49%). Caregivers were predominantly women (82%), aged 26–45 (70%), and close relatives in 40% of cases.
Symptoms of cGVHD emerged within the first six months post-transplant in **66%** of patients, with **44%** reporting diagnostic delays. Almost all participants (**96%**) required immunosuppressive therapy: **33%** received one line, **33%** received two lines, and **20%** required more than three lines. In **14%**, the number of treatment lines could not be recalled.
Skin (72%), eyes (64%), joints (47%), and oral mucosa (46%) were the most affected areas, with many patients reporting multiple symptoms. Multidisciplinary care was lacking in

almost 40% of cases, and communication between specialists was considered poor.
Family dynamics were notably impacted, with 70% reporting consequences for mental health.
Employment was severely affected: before transplantation, 88% of patients were working, but only 22% remained employed at the time of the survey. 92% of those who have been able to continue working report limitations in their work activity. The care of a patient with cGVHD has a work-related impact on most caregivers (82%).
Social relationships changed for 82% of patients, mainly due to misunderstanding and lack of awareness in their environment. Sexual life was affected for 82%, particularly among women, who also reported a lack of information and support.
Psychological support is considered necessary by 96% of patients; however, only 59% of patients and 46% of caregivers had accessed it. Peer support groups were valued by 88% of respondents.
Information about cGVHD was often perceived as insufficient or overwhelming, with 56% of participants feeling they lacked adequate information, especially regarding symptoms (77%), severity (73%), and treatment (70%).

Conclusions: cGVHD is a transformative and invisible disease that disrupts every aspect of life for patients and families. Greater recognition, multidisciplinary care, and improved information and support systems are urgently needed to address the complex challenges posed by cGVHD.

Disclosure: no conflict of interest. Nothing to declare.

Background: CAR T-cell therapy has become a highly effective treatment for haematological malignancies, and emerging evidence indicates promising benefits for non oncohematological conditions. As its clinical use broadens, understanding long-term outcomes and late complications is increasingly crucial. One critical yet understudied area is fertility, for which current evidence remains limited and no formal guidelines provide direction for patients undergoing CAR T-cell therapy.

Methods: To address this gap, we conducted a cross-sectional survey on behalf of the Cellular Therapy and Immunobiology Working Party (CTIWP) of the EBMT, distributed from January to April 2025 to 341 centers, assessing current fertility-related practices around CAR T-cell therapy. A second, complementary questionnaire was then circulated to gather detailed information on reported pregnancies following CAR T treatment.

Results: In total, 93 centers (27%) answered and were included in the analysis. While most centers reported offering fertility counselling before CAR T-cell infusion, 11 centers (17%) indicated that they do not routinely inform patients of the potential reproductive risks; Indeed, the majority of centers (79%) offered fertility preservation procedures to male and female patients. Additionally, 41 % of the reporting centers do not routinely provide psychological support during CAR T-cell therapy. The most common barriers to fertility preservation referral were the urgency of initiating CAR T-cell therapy in aggressive disease (38%) and extensive prior chemotherapy exposure, defined as more than three previous treatment lines (36%). Among male patients, semen collection and cryopreservation were the most frequently used methods (63%). For female patients, the predominant approaches were oocyte cryopreservation (43%) and ovarian tissue cryopreservation (40%). Endocrinologic follow-up practices after CAR T-cell therapy varied substantially across centers.
A total of 22 pregnancies were reported in 20 patients, resulting in 17 live births, 1 ongoing pregnancy, and 4 miscarriages at the time of data censoring. Fourteen pregnancies occurred in female CAR T-cell recipients, and seven were reported by male recipients through their partners. Notably, pregnancies occurred naturally in 70% of cases. Among 8 patients with

available information, the median time between CAR T-cell infusion and delivery or miscarriage was 2.8 years, (range 2 months to 6 years). Although both low- and high-grade Cytokine Release Syndrome (CRS) and Immune Effector Cell–Associated Neurotoxicity Syndrome (ICANS) were reported among these patients, these events did not appear to influence pregnancy outcomes, acknowledging the small sample size (Table 1).

Center	Female Patient Reporting Pregnancy	Male Patient Reporting Pregnancy With The Partner	Natural or assisted	Live Births	Miscarriages	Time from CAR-T	CRS	ICANS
#1	1	-	Natural	1	-	6 years	G4	G3
#2	1(1 Patient Twice)	-	Natural (Twice)	1	1	1 year 2 months (miscarriage); 2 years 9 months (delivery)	G0	G0
#3	1	-	Assisted	Currently Pregnant	-	1 year	G1	G1
#4	1	1	Natural (Both patients)	2	-	Female: 15 months; Male: 36 months	Female: G1 Male: G0	Female: G2 Male: G0
#5	-	1	Natural	1	-	NA	NA	NA
#6	-	1	Assisted	1	-	3 years	NA	NA
#7	-	1	Natural	1	-	1 year 4 months	NA	NA
#8	-	3	2 Assisted, 1	3	-	NA	NA	NA

			donor semen					
#9	3	-	2 Natural, 1 Assisted	2	1	na	P1: G1 P2: G2 P3 (Miscarriage + Live birth): G1	P1: G1 P2: G4 P3 (Miscarriage + Live birth): G0
#10	3(1 Patient Twice)	-	3 Natural, 1 Assisted	3	1	NA	NA	NA
#11	1	-	Natural	1	-	3 years	G2	G4
#12	1	-	Natural	-	1	2 months	G0	G0
#13	1	-	Natural	1	0	NA	NA	NA

Conclusions: These findings underscore significant heterogeneity in fertility related practices worldwide. As CAR T-cell therapy is increasingly administered earlier in the treatment algorithms and to younger populations, integrating standardized fertility counselling and preservation strategies into routine care will be essential. The pregnancies and live births reported here represent some of the earliest evidence of post–CAR T reproductive success and highlight the urgent need for robust research and formalized guidelines in this evolving field.

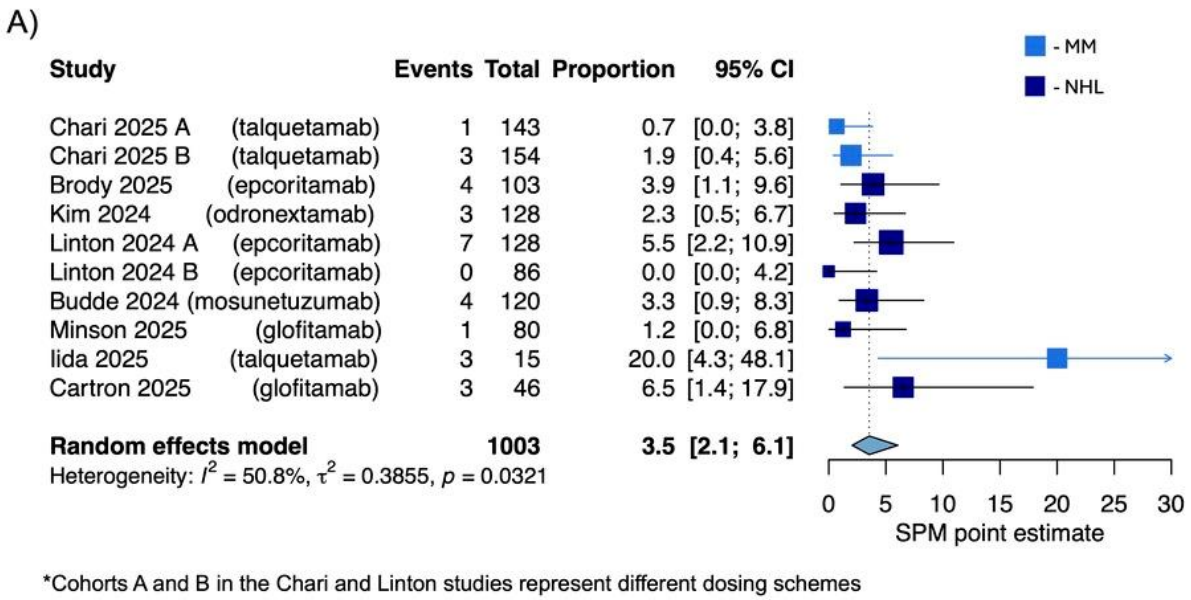
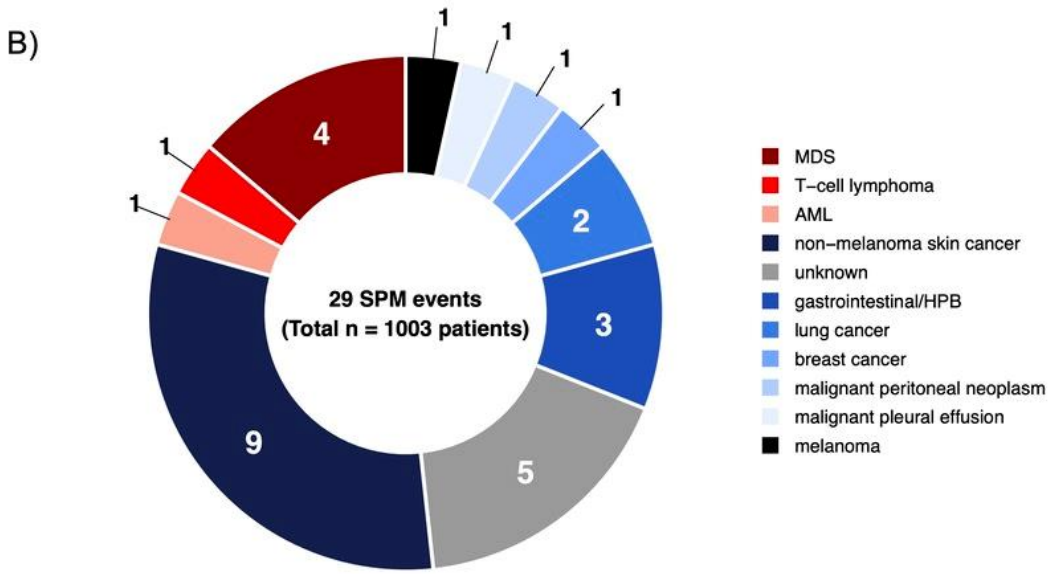
Background: T-cell–redirecting therapies, including CAR T-cell therapy and bispecific antibodies (BsAbs), have transformed the treatment landscape of B-cell lymphoma and multiple myeloma. While second primary malignancies (SPMs) have been reported after CAR-T therapy, it remains unclear whether similar long-term risks accompany T-cell engaging (TCE) bispecific antibody treatment. To address this gap, we conducted a systematic review and meta-analysis to quantify SPM occurrence following TCE BsAb therapy.

Methods: We performed a systematic review and meta-analysis following PRISMA guidelines and a prespecified PROSPERO-registered protocol (CRD420251039203). PubMed/MEDLINE and Embase were searched through October 1, 2025. Clinical trials and real-world studies reporting SPM outcomes in adults treated with TCE BsAbs targeting CD20 for B-cell lymphoma or BCMA/GPRC5D for multiple myeloma were included. Pooled SPM point estimates were calculated using random-effects meta-analysis of single proportions. Meta-regression analyses examined associations between observed SPM rates and study-level features, including follow-up duration, disease type, number of prior therapy lines, prior CAR-T exposure, and completeness of SPM reporting.

Results: Twenty studies met the inclusion criteria. Eight studies (10 cohorts; 1,003 patients) reported all SPMs observed during follow-up and were included in the primary analysis. With a median follow-up of 15.3 months, the pooled SPM point estimate was 3.5% (95% CI, 2.1–6.1) (Figure 1.A). Across these cohorts, 29 SPMs were reported, most commonly non-melanoma skin cancers (n=9), followed by hematologic malignancies (n=6); no single solid tumor subtype predominated (Figure 1.B). Among the hematologic malignancies, myelodysplastic neoplasms were the most common (n=4), while one case of each acute myeloid leukemia and T-cell lymphoma were reported. The SPM point estimate for hematologic malignancies was 1.1% % (95% CI, 0.6–2.1). No study-level clinical or treatment characteristics were significantly associated with SPM occurrence among cohorts with complete reporting.
For sixteen additional cohorts (1548 patients) only SPMs were reported that led to treatment discontinuation or death and demonstrated a lower pooled SPM estimate of 2.1% (95% CI, 1.5 to 3.0). Two MDS cases were identified in this subgroup; for five cohorts (768 patients) no differentiation of SPM was reported.
In a multivariable meta-regression spanning all cohorts, complete SPM reporting was independently associated with higher observed SPM incidence compared with selective

reporting (p=0.02), indicating that reporting practices significantly influence risk estimates.





Conclusions: This study delivers the first quantitative benchmark of SPM risk following TCE BsAb therapy, identifying a point estimate of approximately 3.5% after a median follow-up of 15.3 months, including 1.1% specifically for hematologic malignancies. The strong dependence of observed risk on reporting practices indicates that SPMs are systematically underrecognized, highlighting an urgent need for standardized long-term safety surveillance as TCE BsAbs move earlier in treatment.

QUALITY OF LIFE RECOVERY FOLLOWING CHRONIC GRAFT-VERSUS-HOST DISEASE RESOLUTION IN LONG-TERM ALLOGENEIC TRANSPLANT SURVIVORS

Genevieve Douglas[1,2], *Eric Wong*[1,2], *David Ritchie*[1,3,4], *Teresa Garcia*[1], *Yvonne Panek-Hudson*[1]
[1]*Department of Clinical Haematology and Bone Marrow Transplant Service, Peter MacCallum Cancer Centre and the Royal Melbourne Hospital, Melbourne, Australia,* [2]*Clinical Haematology, Austin Health, Heidelberg, Australia,* [3]*Sir Peter MacCallum Department of Oncology, University of Melbourne, Melbourne, Australia,* [4]*Department of Medicine, University of Melbourne, Melbourne, Australia*

Background: Chronic graft-versus-host disease (cGVHD) is a major cause of impaired quality-of-life (QoL) following allogeneic haematopoietic stem cell transplantation (alloHSCT). Whilst cGVHD can resolve in long-term survivors, it remains unclear whether QoL deficits persist after systemic immunosuppression (SI) is no longer required. We aimed to determine whether QoL improves in long-term survivors who have discontinued SI for cGVHD.

Methods: We conducted a single-centre retrospective analysis of QoL in alloHSCT recipients ≥16 years with haematologic malignancies transplanted at the Royal Melbourne Hospital (2009-2020), Melbourne, Australia. Patients evaluated 2-5 years post-transplant completed QoL surveys including the FACT-BMT, EORTC-QLQ-C30, FACIT-F, and the Hospital Anxiety and Depression Scale(HADS). Significant active cGVHD was defined as requiring SI at assessment. Patients were categorized as either never requiring SI for cGVHD(cohort A), having discontinued SI for cGVHD(cohort B), or having active cGVHD on SI(cohort C). HRQoL scores were compared using the Kruskal-Wallis test (significance $p<0.05$), with post-hoc Dunn's comparisons. K-means cluster analysis evaluated whether cGVHD status could predict QoL cluster membership. Statistics were performed using SPSS v29 (IBM Corp, 2024).

Results: Among 511 participants (median 3 years post-transplant), cohort A comprised 210(41%), cohort B 179(35%), and cohort C 122(24%) participants. Mean total FACT-BMT scores were similar for cohorts A and B (117, SD±20.0 vs 114, SD±21.0; $p=0.92$) but significantly improved compared to cohort C (106, SD±22.0; $p=0.001$) (Table 1). Differences were driven by worse physical ($p<0.001$) and functional wellbeing ($p=0.007$), and the bone marrow transplant-specific subscale($p<0.001$) among cohort C patients.
Fatigue, measured by FACIT-F, was similar in cohort A and B (mean 41, SD±10 vs 39, SD±10.5; $p=0.212$), but worse for cohort C (mean 35, SD±11.9, $p<0.001$). Global EORTC-QLQ-C30 was similar between cohort A and B (mean 74, SD±18.0 vs 75, SD±18.9; $p=1.0$), but significantly worse for cohort C (mean 63, SD±20.4, $p<0.001$). EORTC-QLQ-C30 functioning subscales were similar for cohorts A and B but significantly worse for cohort C in physical ($p<0.001$), role ($p<0.001$), emotional ($p<0.001$), cognitive ($p=0.006$), and social functioning ($p<0.001$). Whilst cohort B reported similar symptom burden to cohort A, worse fatigue ($p<0.001$), pain ($p=0.031$), and dyspnoea ($p<0.001$) were reported for cohort C. Financial difficulty showed a different pattern – similar between cohort B and C ($p=0.496$), but both significantly worse than cohort A ($p=0.047$). No differences in HADS anxiety

(p=0.699) or depression symptoms (p=0.083) were observed.
Cluster analysis (Figure 1) identified two statistically distinct QoL clusters: C1(more adverse) and C2(better). Patients with resolved cGVHD were distributed between clusters, comprising 32% of C1 and 34% of C2. In contrast, active cGVHD patients comprised 35% of those in C1 compared to 19% in C2(p<0.001).

Table 1: Mean quality of life survey scores with comparison for Cohorts A, B and C

Quality of life survey	Cohort A mean score (range)	Cohort B mean score (range)	Cohort C mean score (range)	p-value

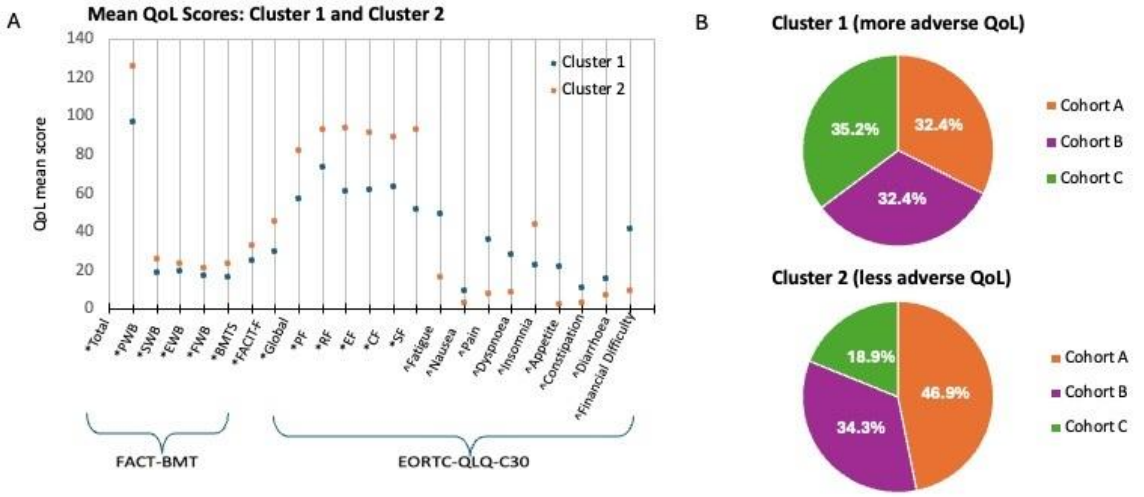
Diarrhoea^	6.0 (0-67)	13.7 (0-100)	12.2 (0-100)	**0.023**
Financial difficulty^	19.6 (0-100)	22.0 (0-100)	23.0 (0-100)	**0.047**

PWB=physical wellbeing, SWB=social wellbeing, EWB=emotional wellbeing, FWB=functional wellbeing, BMTS=bone marrow transplant subscale, HADS=Hospital anxiety and depression score, PF=physical functioning, RF=role functioning, EF=Emotional functioning, CF=Cognitive functioning, SF=social functioning
*The higher the score, the better the QoL
^ The higher the score, the worse the symptom is rated

Figure 1: Quality-of-life cluster analysis
A: Mean QoL survey scores for clusters 1 (more adverse) and 2 (less adverse)
B: Pie-chart demonstrating proportion of patients within cohorts A, B and C, for each QoL cluster



PWB=physical wellbeing, SWB=social wellbeing, EWB=emotional wellbeing, FWB=functional wellbeing, BMTS=bone marrow transplant subscale, HADS=Hospital anxiety and depression score, PF=physical functioning, RF=role functioning, EF=Emotional functioning, CF=Cognitive functioning, SF=social functioning *The higher the score, the better the QoL ^ The higher the score, the worse the symptom is rated

Conclusions: Long-term survivors with resolved cGVHD can achieve QoL comparable to those without prior significant cGVHD, while those with active cGVHD show persistent impairment across multiple domains. Financial difficulty appears problematic for those who experience significant cGVHD, regardless of resolution. These findings demonstrate that QoL recovery is possible following cGVHD resolution and underscore the limitations of single-timepoint assessments for evaluating long-term outcomes after alloHSCT.

A419

LONGITUDINAL ASSESSMENT OF FRAILTY AND FUNCTIONAL RECOVERY AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE PROPHYLAXIS

Adriana Cuartas[1], *Laia Guardia*[1], *Berta Sole*[1], *Cristina Moreno*[1], *María Suárez-Lledó*[1], *Raquel Salinas*[1], *María Cancio-Solé*[1], *Paola Charry*[1], *Joan Cid*[1], *Miquel Lozano*[1], *Enric Carreras*[1], *María Teresa Antonio*[1], *Pedro Castro*[1], *Laura Rosiñol*[1], *Carmen Martínez*[1], *Concepcion Closa*[1], *Montserrat Rovira*[1], *Francesc Fernández-Avilés*[1], *María Queralt Salas*[1]
[1]*Hospital Clinic de Barcelona, Barcelona, Spain*

Background: Post-transplant cyclophosphamide (PTCy) is widely used for GVHD prophylaxis, but its early post-transplant course is associated with increased toxicity, delayed engraftment, and higher infectious burden, factors that may hinder functional recovery. Frailty is an established predictor of survival in allo-HCT, but its evolution after transplantation remains insufficiently characterized. In 2021, our institution implemented a structured multidisciplinary frailty assessment program to determine the incidence and trajectory of frailty before and after PTCy-based allo-HCT.

Methods: From 2021 to 2025, all consecutive adults undergoing PTCy-based allo-HCT were systematically assessed for frailty and prospectively enrolled after informed consent. Patients were evaluated by trained nursing staff in 10–15 minutes without additional resources and categorized as fit, pre-frail, or frail. Assessments were performed at admission, day +100, 6 months, and 1 year, limited to patients in remission. Quality of life (QoL) was monitored at admission, day +100, and 1 year using the EQ-5D-3L.

Results: A total of 166 patients were evaluated at baseline: 21.3% were fit, 61.3% pre-frail, and 17.8% frail. Frail patients had a higher comorbidity burden (HCT-CI >3: 29% vs. 11% in fit; P=0.023), lower performance status (KPS <90%: 43% vs. 14%; P=0.048), higher prevalence of mobility impairment, self-care limitations, and greater symptom burden (Table 1). Frailty at admission did not predict specific complications but was associated with longer hospitalization (median 32 vs. 26 days; P<0.001). Frail patients had lower 1-year OS (42.9% vs. 82.1% and 80.0%; P<0.001), mainly due to increased NRM (21.4% vs. 8.2% and 5.9%; P=0.127) compared with fit and pre-frail individuals (Figure 1A).
At day +100 (n=119), frailty prevalence was unchanged (fit 21.8%, pre-frail 59.1%, frail 19.1%) and was more frequent in patients experiencing early toxicities such as sinusoidal obstruction syndrome, invasive fungal infections, or grade II–IV acute GVHD requiring corticosteroids (Table 1). Frailty at day +100 landmark was associated with inferior outcomes (1-year OS: 63.6% vs. 87.5% and 91.3%; P=0.003; 1-year NRM: 19.5% vs. 0 and 2.5%; P=0.017) (Figure 1A) and poorer QoL.
Among 6-month survivors (n=84), frailty prevalence declined (fit 24.4%, pre-frail 68.6%, frail 4.7%), suggesting progressive functional recovery (Figure 1B). Persistent frailty was mainly associated with prolonged complications, especially steroid-dependent chronic GVHD. At 1 year (n=67 evaluated), recovery was more pronounced: 41.3% were fit, 52.3% pre-frail, and only 6.4% frail (Figure 1B). With a median follow-up of 15 months, only 6

additional deaths occurred after 6 months, all due to relapse. Among survivors, QoL improved over the first year, with fit patients increasing to 41% and reporting better mobility, self-care, activities of daily living, and higher EQ-VAS scores.

Table. Characteristics according to frailty assessment and post–trasplantation complications.

Figure 1A. OS and NRM according to frailty categories

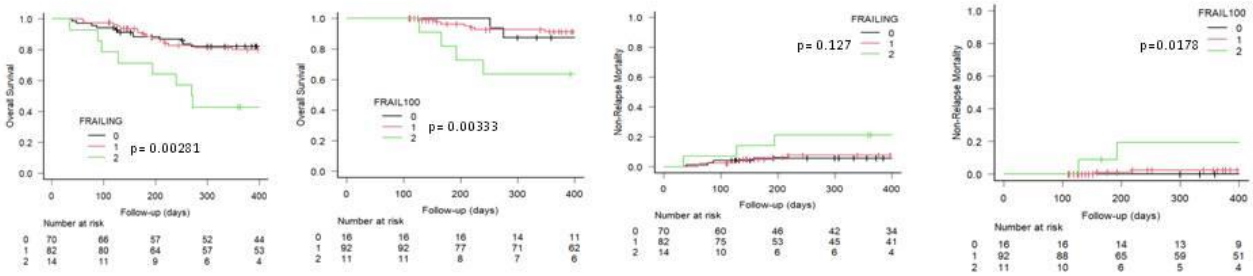

Figure 1B. Frailty dynamics towards post-transplant evolution

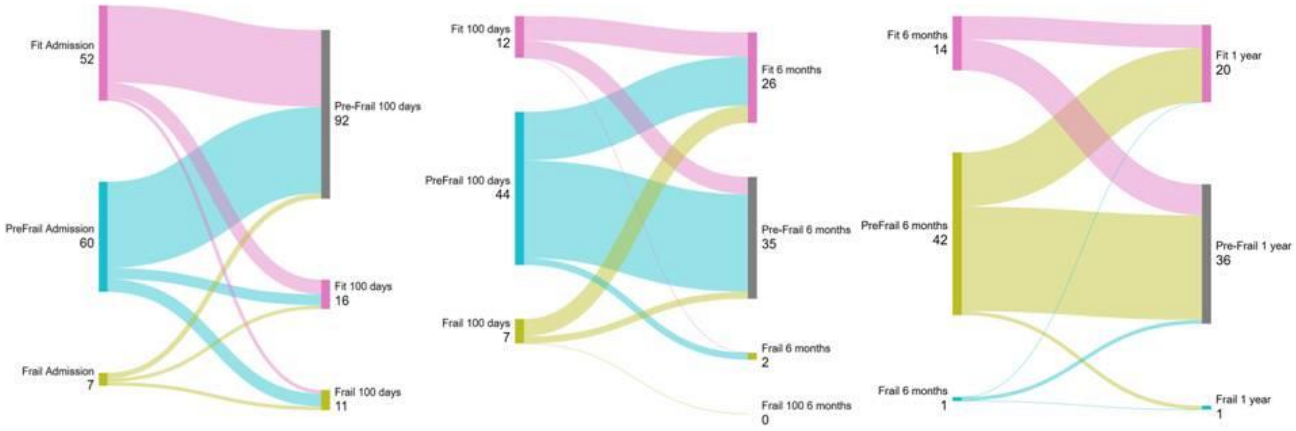

Conclusions: Frailty in the context of PTCy-based allo-HCT is dynamic, with clear functional improvement over the first post-transplant year among survivors. Nonetheless, when present, frailty is associated with inferior survival and poorer QoL. Early complications—particularly prolonged hospitalization, GVHD, and infections—appear to limit functional recovery and contribute to persistent frailty. Routine frailty monitoring may help identify patients who could benefit from multidisciplinary interventions aimed at enhancing recovery and QoL.

EXTENSIVE OR SEVERE CHRONIC GVHD IS ASSOCIATED WITH SUSTAINED AND WORSENING IMPAIRMENTS IN SYMPTOMS AND WELL-BEING UP TO 5 YEARS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

Pleun Schonewille[1], *Zoë Kamperman*[2], *Tineke Nagtegaal-de Wit*[1], *Lian Schoonhoven-Bos*[1], *Frances Verheij*[1], *Jürgen Kuball*[1], *Simone Oerlemans*[2], *Moniek de Witte*[1]
[1]*University Medical Center Utrecht, Utrecht, Netherlands (the),* [2]*Netherlands Comprehensive Cancer Organization (IKNL), Utrecht, Netherlands (the)*

Background: While allogeneic haematopoietic stem cell transplantation (allo-HSCT) can be curative, chronic GVHD (cGVHD) remains a debilitating complication, despite novel transplantation techniques. We investigated how cGVHD affects health-related quality of life (HRQOL) long-term after allo-HSCT.

Methods: Adult patients undergoing an allo-HSCT at UMCU were invited from 2013 to complete HRQOL questionnaires from pre-transplant (2017) through 10 years post-transplant. Analyses included first allo-HSCTs with follow-up up to five years. HRQOL data were collected through PROFILES, a registry for collecting data on impact of cancer developed by the Netherlands Comprehensive Cancer Organization(IKNL) and Tilburg University. HRQOL was assessed using the Functional Assessment of Cancer Therapy-General(FACT-G), with items scored on a 5-point Likert scale. Clinical data were extracted from EBMT and UMCU databases.
To assess symptom prevalence, single HRQOL item outcomes were grouped into unfavourable, intermediate, and favourable responses. For being bothered by side effects of treatment, unfavourable comprised "Quite a bit"/"Very much"; for being able to work, "Not at all"/"A little bit". cGVHD groups were compared cross-sectionally using Kruskal-Wallis and post-hoc Wilcoxon tests. HRQOL-subscales (scores for physical, social, emotional, and functional well-being) were analysed longitudinally using mixed-effects models with random intercepts and cGVHD-time interactions. Models adjusted for sex, age, indication, HCT-CI, graft engineering, donor type/match, donor age, and sex match.

Results: This study included 525 patients. Median age at transplant was 58 years (IQR 45-65), 60% were female, and 73% of patients received an αβT cell-depleted allograft. Up to five years post-transplant, 406 patients (77%) did not develop cGVHD, 74 (14%) developed mild/moderate, and 45 (9%) developed extensive/severe cGVHD. Median cGVHD onset was 259 days (IQR 170-457) post-transplant. The Table shows numbers of individuals at each time point.
Three months to five years post-transplant, patients without cGVHD showed significant improvements in physical (21.3-24.1), functional (17.3-22.4), and emotional well-being (19.2-20.6; all $p<0.001$) (Figure). In contrast, patients with extensive/severe cGVHD showed different trajectories: physical (19.6-19.8) and functional well-being (17.9-18.0) remained stable, while emotional well-being declined slightly (19.2-18.6, all $p\leq0.002$). Patients with mild/moderate cGVHD had similar trajectories to those without cGVHD. Social well-being remained stable over time.

At one year post-transplant, 32% of extensive/severe cGVHD patients reported being bothered by side effects "Quite a bit"/"Very much", compared to 17% (mild/moderate) and 9% (no cGVHD, $p<0.001$) (Figure). At five years, these were 43%, 12% and 5% respectively ($p<0.001$). Similarly, at one year, 43% of extensive/severe cGVHD patients reported to be able to work "Not at all"/"A little bit", compared to 37% (mild/moderate) and 29% (no cGVHD, $p=0.041$). At five years, these were 48%, 19% and 19% ($p=0.011$).

Favourable QOL

Number of individuals with available QOL data by cGVHD status at each time point after allo-HSCT											
Time point (months after allo-HSCT)	0	3	8	12	16	20	24	30	36	48	60
No cGVHD	324	256	204	255	175	141	175	129	148	118	93
Mild/moderate cGVHD	0	46	40	60	41	37	56	34	45	35	26
Extensive/severe cGVHD	0	20	17	32	20	11	24	16	26	22	21

Conclusions: We present one of the largest HRQOL datasets in allo-HSCT to our knowledge and demonstrate that cGVHD, particularly extensive/severe forms, associates with persistent symptom burden and impairments in physical, functional, and emotional well-being. Almost half of extensive/severe cGVHD patients are unable or barely able to work five years post-transplant. Instead, patients without cGVHD show sustained recovery. These findings highlight the long-term impact of cGVHD and the need for improved prevention.

Disclosure: We have no conflicts of interest to disclose.

A421

SIGNIFICANT IMPROVEMENT OF SURVIVAL AND GVHD- AND RELAPSE-FREE SURVIVAL AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA OVER TIME

*Julia Cserna[1], Lina Rüsing[1], **Hanna Knaus**[1], Philipp Wohlfarth[2], Axel Schulenburg[1], Armin Bumberger[1], Wolfgang R. Sperr[1], Margit Mitterbauer[1], Werner Rabitsch[1], Nina Worel[1], Alexandra Kaider[1], Hildegard Greinix[1]*
[1]Medical University of Vienna, Vienna, Austria, [2]University Hospital Wiener Neustadt, Wiener Neustadt, Austria

Background: Currently, AML is one of the main indications for allogeneic HSCT. Although survival after allogeneic HSCT has improved, relapse of the underlying disease and transplant-associated complications have remained to be a challenge negatively impacting outcome.

Methods: We conducted a retrospective single-center cohort analysis of all patients undergoing allogeneic HSCT for AML at our institution between 01/2010 and 12/2024. This analysis aims to show changes in patient characteristics and outcome after allogeneic HSCT for AML over the last 15 years. Patients were grouped into two cohorts based on transplant year.

Results: A total of 546 patients (median age: 53 [IQR: 43-61] years, 47% female) received an allogeneic HSCT, 248 (45%) in group 1 (2010-2017) and 298 (55%) in group 2 (2018-2024). Patients in group 2 were older (median 51 [IQR: 39-59] vs. 55 [IQR: 45-62] years, p<0.001), had more frequently ELN 2022 adverse risk AML (44% vs. 25%, p<0.001) and were more often in first complete remission at HSCT (74% vs. 65%, p<0.001). Also, more patients received reduced intensity or reduced toxicity conditioning in group 2 (73% vs. 52%, p<0.001). Haploidentical donors (19%) and posttransplant cyclophosphamide (25%) were used exclusively after 2018. For better comparability between the two groups patients who received haploidentical HSCT or cord blood were excluded, leaving 469 patients for further analyses. At 2 years after HSCT a lower cumulative incidence of acute GvHD (21% vs. 32%, p=0.0018), chronic GvHD (16% vs. 27%, p=0.0019) and CMV reactivation (26% vs. 38%, p=0.0019), was observed in group 2. Relapse rates were comparable between both groups (cumulative incidence at 2 years of 22% vs. 27%, p=0.5262), but 2-year cumulative incidence of NRM was lower in group 2 (13% vs. 18%, p=0.0582). Survival was significantly improved in group 2 compared to group 1 with a 5-year overall survival (OS) of 63% vs. 48% (p=0.0113) and a 5-year GvHD- and relapse-free survival (GRFS) of 56% vs. 42% (p<0.001), with a median follow-up of 34 and 102 months, respectively. In the univariate Cox regression model, ELN 2022 risk (HR 2.914 for intermediate risk AML and HR 3.716 for adverse risk AML, p<0.001), disease status at HSCT (HR 2.293 for patients with active disease, p<0.001) and transplant year showed a significant impact on survival, with a mortality risk reduction of 4.3% per year (HR 0.957, p=0.0261). A time-dependent mortality risk could be identified for patients with active disease at transplant (HR 4.072 2 months after HSCT, HR 1.633 1 year and HR 0.720 5 years after HSCT). These results were confirmed in the multivariable model with an even greater mortality risk reduction of 6.5% per year.

Conclusions: We observed an improvement in OS and GRFS, and a reduction of acute and chronic GvHD in AML patients given HSCT in more recent years even though patients' pretransplant risks including age were increasing. These promising findings can be explained by the use of lower intensity conditioning regimens, improved GvHD prophylaxis and treatment and expanded infectious prophylaxis. Unfortunately, relapse risk remains an area for improvement.

Background: Employment after hematopoietic cell transplantation (HCT) is an important indicator of social reintegration and long-term survivorship. However, data on younger HCT recipients who had no work experience before diagnosis remain limited. This study aimed to clarify post-HCT employment outcomes and identify associated factors.

Methods: Eligible participants were survivors aged ≤39 years at the time of allogeneic or autologous HCT, aged ≥20 years at the time of the survey, relapse-free for at least two years after transplantation, and without continuous employment experience before diagnosis. A nationwide anonymous web-based questionnaire was conducted from November 2023 to October 2024. Participants were recruited from 135 HCT centers (94 adult and 41 pediatric). The questionnaire assessed employment outcomes (employment status, timing of first employment, employment type, leave of absence, and resignation) and potential associated factors (age, sex, educational background, donor source, disease disclosure, availability of an occupational physician, and use of employment support systems). Multivariate analyses were performed to identify independent factors associated with employment and job stability.

Results: Among 694 survivors recruited from 135 centers, 275 responded (40%). After excluding two non-consenting and 33 previously employed respondents, 240 responses were analyzed. Median ages at diagnosis, transplantation, and survey were 16 (range, 0–39), 17 (0–39), and 26 (20–54) years, respectively. Transplant types included unrelated bone marrow (29%), related bone marrow (21%), cord blood (19%), related/unrelated peripheral blood stem cell (15%), and autologous transplantation (13%). The median post-transplant duration was 11 (3–36) years. Overall, 78% (n = 186) had work experience after HCT, with a median time to first employment of 5 years post-HCT (range, 0–21 years). At their first employment, 39% held regular positions, 26% had fixed-term or part-time contracts, and

12% were self-employed or in temporary positions. Among employed survivors, 16% had taken leave, and 37% had resigned. In a multivariate analysis of pre-transplant factors (sex, age, underlying disease, donor type, number of transplants, education, and post-HCT duration), only educational attainment was independently associated with post-HCT employment (reference: junior high/high school; vocational/junior college: HR 1.7, 95% CI 1.1–2.6; university/graduate school: HR 1.0, 95% CI 0.7–1.5). In analyses limited to employed survivors (n = 186), female sex was associated with a higher risk of taking leave (HR 2.3, 95% CI 1.0–5.2). The availability of an occupational physician was independently associated with higher leave rates (HR 3.4, 95% CI 1.4–8.1) and lower resignation rates (HR 0.5, 95% CI 0.2–0.9), suggesting that their involvement may help facilitate leave rather than resignation.

Conclusions: Many CAYA survivors without prior work experience eventually achieved employment after HCT. Clinical factors had minimal impact on post-HCT employment, whereas educational attainment was the only independent pre-transplant predictor. The presence of an occupational physician was associated with higher leave but lower resignation rates, suggesting that good communication between workplaces and healthcare providers—for example, sharing information on health status and feasible working conditions—may promote sustainable employment among CAYA HCT survivors.

A423

GONADAL FUNCTION OF CHILDREN AND ADOLESCENTS AFTER ALLOGENEIC HSCT WITH TREOSULFAN- AND TBI-BASED CONDITIONING

*Elvira Sultanova[1], Elena Ilyina[1], Darya Shasheleva[1], Elizaveta Rumyantseva[1], **Susanna Arakelyan**[1], Anastasia Protsvetkina[1], Larisa Shelikhova[1], Dmitry Balashov[1], Michael Maschan[1], Alexei Maschan[1], Wassily Delyagin[1], Yulia Skvortsova[1]*
[1]Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation (the)

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is the only curative treatment for many orphan diseases. HSCT significantly improves prognosis and survival. Conditioning regimens include gonadotoxic alkylating agents and/or body irradiation. Here we present the function of gonads in children after HSCT with treosulfan- and total body irradiation (TBI)-based conditioning.

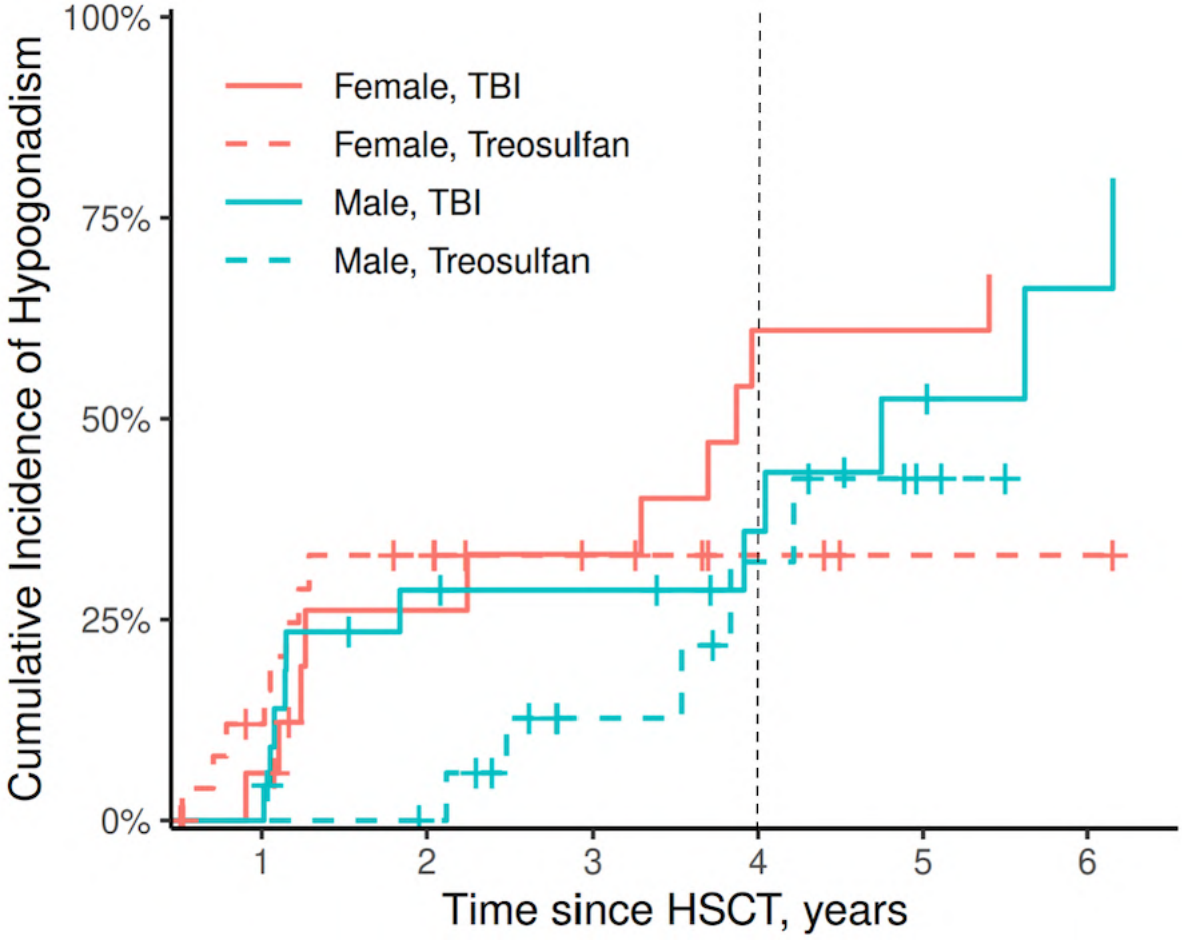
Methods:

Diagnosis	Overall, N=185	Treosulfan, N=88	TBI, N=97
B-/T- acute lymphoblastic	108 (58.4%)	16 (18.2%)	92 (94.8%)

leukemia, acute bilineal leukemia, lymphoma			
Acute myeloid leukemia, myelodysplastic syndrome	50 (27%)	45 (51.1%)	5 (5.2%)
Non-malignant disorders (aplasia, thalassemia, primary immunodeficiencies)	27 (14.6%)	27 (30.7%)	0

From September 2018 to December 2023, 747 paediatric patients with various diagnoses underwent allogeneic HSCT at our centre (Table). The study included 73 girls (=>8 years) and 112 boys (=>10 years at HSCT), aged >13 and >14 years, respectively, on the day of data analysis. First group received treosulfan 36-42mg/m^2 (N=88, f/m=40/48), second - TBI 12Gr (N=97, f/m=33/64) as part of conditioning regimen.
Levels of gonadotropins, sex hormones, menstrual cycle and pubertal development were assessed dynamically. Total gonadotoxicity of alkylating agents was calculated using Cyclophosphamide Equivalent Dose (CED) (threshold - 4000mg/m^2).
Median age at HSCT was 13.5 years (range, 8.2-18.3). Additional conditioning agents were fludarabine 150mg/m^2 (in all), thiotepa 10mg/kg(51.9%)/ melphalan 80-140mg/m^2(7.6%)/ etoposide 40-60mg/kg(32.4%), cyclophosphamide 50-100mg/kg(8.1%). 15.1% patients received post-transplant cyclophosphamide as GVHD prophylaxis, 73.5% got transplants with TCRab depletion. Incidence of acute and chronic GVHD did not differ between the groups.

Results:



Median follow-up was 31.4 months (0–76.9 months). The rates of graft rejection (5.7/6.2%) and relapses (26.1/29.9%) were similar in both groups. In boys of group1, level of gonadotropins was slightly lower than in group2; median follicle-stimulating hormone (FSH) levels returned to normal after 3 years of follow-up. In girls, median FSH level after treosulfan and TBI was similar and higher than in boys and did not decrease throughout the follow-up period. Median testosterone levels in boys remained within the normal range and median estradiol levels in girls were decreased in both groups over the follow-up.
Overall hypogonadism (HG) cumulative incidence (CI) in boys by 3 years after HSCT was 21%, by 4 years – 34%, while in girls the rates were higher – 34 and 54%, respectively. Differences depending on conditioning regimen are presented on figure: the 4-year HG CI in boys in group1 – 36% vs 32% in group2 while in girls the 3-year HG CI was the same in both groups (33%), but the 4-year HG CI doubled after TBI (61%), while in treosulfan group the figures did not change.
HG CI in boys at 4 years after HSCT with low CED ranged from 0% in group1 to 24% in group2, in girls - 14% and 75%, respectively. In girls receiving treosulfan the difference between low and high CED was 14% versus 39% (p=0.4). There were no cases of HG in

boys receiving treosulfan in combination with CED<4000mg/m², the addition of alkylators with high CED led to toxicity comparable to the effect of TBI (p=0.2).

Conclusions: The effect of treosulfan on gonadal function in children was less significant than TBI, but the final gonadotoxicity depends on the combination of treosulfan with other alkylating agents and is directly proportional to the increase in their CED. Further monitoring and analysis is needed to fully understand the fertility prognosis of patients.

Background: Allogeneic stem cell transplantation (alloSCT) can be considered as consolidation therapy for Acute lymphoblastic leukemia (ALL) patients over 40 years old in first complete remission (CR1). A Dutch cohort study from 2001-2015 indicated a 5-year survival for this group of 39-54%, depending on the conditioning intensity used (Sijs-Szabo et al. 2023). Modern transplant strategies incorporating fractionated total body irradiation and post-transplant cyclophosphamide potentially lead to better outcomes. Impact of alloSCT on the long-term quality of life (QoL) in this vulnerable patient group is unknown.

Methods: In July 2025, a nationwide study started, including all patients ≥ 40 years with ALL in CR1 who underwent an alloSCT between January 1 2018, and June 30 2023. The study consists of two parts. First, we investigated overall survival (OS), non-relapse mortality (NRM) and relapse rate in this cohort. Second, we evaluated prospectively changes in QoL of surviving patients. OS was estimated using Kaplan–Meier methods. NRM and relapse rate were analyzed using competing-risks methods, with NRM and relapse rate treated as mutually competing events. Point estimates at the cohort's median follow-up were reported with 95% confidence intervals. QoL is evaluated using two validated questionnaires: PROMIS Global Health (PROMIS-GH) and Functional Assessment of Cancer Therapy - Bone Marrow Transplantation (FACT-BMT). The PROMIS-GH is a general health questionnaire providing mental and physical health scores, classifying into 5 categories: poor, fair, good, very good,

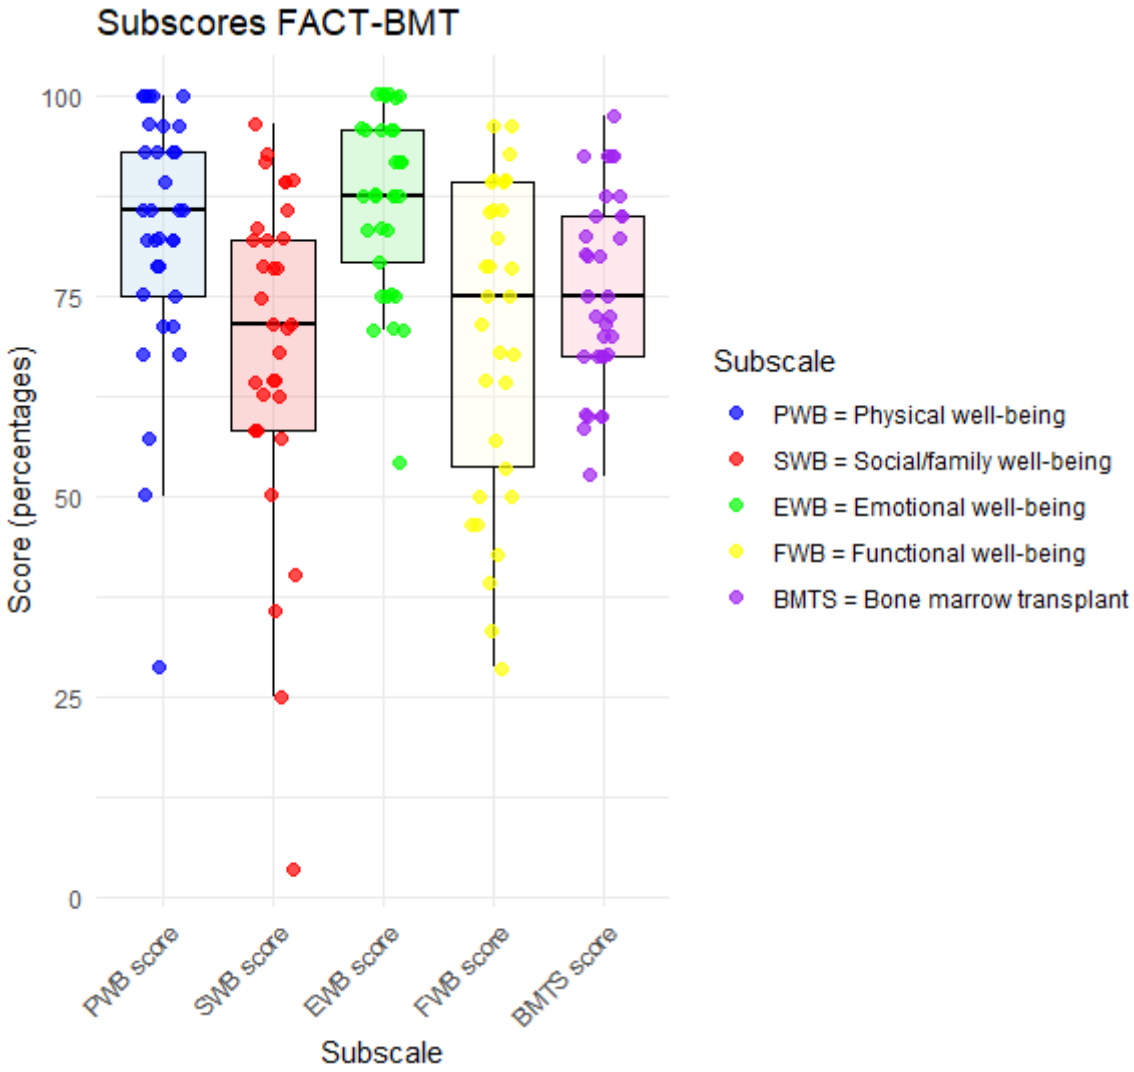
and excellent. The FACT-BMT is a cancer- and transplant-specific questionnaire with 5 subscales: Physical, Social/Family, Emotional and Functional Well-Being and a transplant subscale. QoL data are collected at start of the study and 1, 3, and 5 years thereafter. This abstract presents the first analysis assessing the feasibility of the study and results from 5 of the 7 participating centers.

Results: To date, the cohort consists of 99 patients. The 76 surviving patients were invited to participate in the QoL assessment; 45 provided consent, 11 declined and 20 have not yet responded. Baseline characteristics for both the total group and QoL group are shown in Table 1.
Median follow-up time of surviving patients was 4 years. The 4-years OS was 77% (95% confidence interval 69%-86%), NRM 14% (95% CI 8%-22%) and relapse rate 13% (95% CI 7%-21%).
In the PROMIS-GH questionnaire, Physical Health scores were distributed as follows: 6% poor, 27% fair, 27% good, 18% very good, and 21% excellent. For Mental Health: 24% poor, 15% fair, 18% good, 24% very good, and 18% excellent. FACT-BMT scores are shown in Figure 1, indicating relatively high scores for Emotional and Physical Well-Being, while Social/Family and Functional Well-Being have lower scores.

Baseline characteristics	**Total cohort (n=99)**	**QoL cohort (n=45)**
Gender		
Male	55 (56%)	28 (62%)
Female	44 (44%)	17 (38%)
Age (median, range)	56 (41 - 73)	58 (41-72)
Type of ALL		
B-ALL	83 (84%)	37 (82%)
B-ALL with BCR::ABL1 fusion	*27 (31%)*	*11 (30%)*
T-ALL	16 (16%)	8 (18%)

Baseline characteristics	Total cohort (n=99)	QoL cohort (n=45)
Donor		
MSD 10/10	25 (25%)	9 (20%)
MUD 10/10	67 (68%)	32 (71%)
MUD 9/10 (GvH)	7 (7%)	4 (9%)
HCT-CI score		
0	17 (17%)	6 (13%)
1-2	40 (40%)	19 (42%)
3+	36 (36%)	19 (42%)
Unknown	6 (6%)	1 (2%)
Median follow-up time of patients alive (years)	4.1	3.9

Tabel 1. Baseline characteristics. MSD: matched sibling donor, MUD: matched unrelated donor, GvH: graft versus host, HCT-CI-score: Hematopoietic Cell Transplantation-specific Comorbidity Index



Conclusions: This analysis of the first data from a nationwide study showed a promising 4-year OS of 77% compared to earlier cohorts. With a median follow-up of 4 years, patients reported generally good physical QoL, whereas mental health outcomes are still insufficient. In the future, this study will show how QoL evolves over time, aiming to identify factors associated with QoL with the goal of developing interventions that may improve (mental) QoL in this patient group.

GONADAL TOXICITY AND PREMATURE OVARIAN INSUFFICIENCY AFTER HEMATOPOIETIC STEM CELL GENE-THERAPY IN FEMALE PATIENTS WITH METACHROMATIC LEUKODYSTROPHY

Salvatore Recupero[1,2], *Vera Gallo*[1], *Marianna Rita Stancampiano*[1], *Silvia Laura Carla Meroni*[1], *Mara Sangalli*[1], *Gianni Russo*[1], *Alessandro Aiuti*[1,3], *Francesca Fumagalli*[1], *Valeria Calbi*[1]
[1]*IRCCS San Raffaele Scientific Institute, Milan, Italy,* [2]*University of Rome Tor Vergata, Rome, Italy,* [3]*Vita-Salute San Raffaele University, Milan, Italy*

Background: Metachromatic leukodystrophy (MLD) is a severe demyelinating lysosomal storage disorder caused by arylsulfatase A (ARSA) deficiency. Atidarsagene autotemcel (arsa-cel) is an ex vivo autologous hematopoietic stem-cell gene therapy and it is infused intravenously following single agent busulfan conditioning. Arsa-cel is currently the only disease-modifying treatment for pre-symptomatic late-infantile (LI) or early-juvenile (EJ) MLD, or early-symptomatic EJ MLD. Premature ovarian insufficiency (POI) is one of the most relevant long-term sequelae after chemotherapy because of its gonadotoxicity. We investigated the incidence, determinants and characteristics of POI in pediatric females with MLD treated with arsa-cel.

Methods: To identify cases of POI we retrospectively reviewed endocrine clinical, hormonal and instrumental assessments after arsa-cel treatment, performed according to local standard of care.

Results: As of October 2025 at our institution 51 early-onset pediatric patients with MLD (M 32, F 19) received arsa-cel across several clinical trials and in the commercial setting. In 13 (7 LI, 6 EJ) of 19 female patients, baseline and post-treatment endocrine data were consistently available and they were included in this analysis. Median follow up post arsa-cel was 8.8 years (range 3-12.6). Five (38.5%) of 13 patients received sub-myeloablative busulfan conditioning (median total predicted area-under-the-curve [AUC] 68 µg*h/mL), and the remaining 8 (61.5%) received myeloablative regimen (median total predicted AUC 82.5 µg*h/mL).
In the sub-myeloablative group, median age at last follow-up was 12 years (range 9.4–14.6). Four patients reached pubertal age. Among these, 3 patients showed POI (hypergonadotropic hypogonadism, absence of menarche) and started hormone replacement therapy (HRT) at median age of 13 years (range 10.5–15.4), with median menarche at 15.4 years (range 13.3–17.5). One patient experienced normal puberty, with menarche at 11.8 years. One patient (8.2 years of age at last follow-up) remained prepubertal without hormonal alterations.
In the myeloablative group, median age at last follow-up was 8.1 years (range 3.7–16.6). Three patients reached pubertal age. Among these, POI was identified in 2, who started HRT at 13 and 14.6 years, and menarche occurred at 15.5 and 17.9 years respectively. One patient exhibited spontaneous puberty with menarche at 12.8 years despite initial hypergonadotropic hypogonadism (FSH peak 169 IU/mL; undetectable estradiol), which normalized without treatment. Among the 5 pre-pubertal patients (median age 5.8 years, range 3.7–10.2), 3 showed severe persistent biochemical hypergonadotropic hypogonadism. Anti-Müllerian hormone (AMH), a biomarker of ovarian reserve, was undetectable in 84.6%

(11/13) of patients during follow-up.
Overall, most patients in both groups showed evidence of severe gonadal dysfunction. However, longer follow-up is needed to correlate this aspect with other clinical parameters, such as bone mineralization.

Conclusions: In our analysis POI is a frequent adverse effect associated with busulfan, consistent with previous reports. Sub-myeloablative exposure does not appear reducing the incidence of gonadal dysfunction compared with myeloablative regimen. Longitudinal hormonal assessments demonstrate early impairment of ovarian reserve, and the need to offer fertility preservation before arsa-cel and to initiate HRT when indicated. Finally, further long-term analyses are also needed to assess the unclear potential contribution of sulfatide accumulation in the gonadal tissue of patients with MLD.

Palo Alto, United States of America (the), [10]Massachusetts General Hospital, Boston, United States of America (the), [11]MD Anderson Cancer Center, Houston, United States of America (the)

Background: Allogeneic hematopoietic cell transplantation (HCT) is curative for hematologic malignancies, yet access remains inequitable. To address these challenges, the NMDP-sponsored, CIBMTR-led ACCESS trial (NCT04904588) evaluated safety and efficacy of peripheral blood stem cells (PBSC) from mismatched unrelated donors (MMUD) in adults with high-risk hematologic malignancies receiving myeloablative (MAC) or reduced-intensity/non-myeloablative conditioning (RIC/NMA) and PTCy as GVHD prophylaxis. Primary results demonstrated excellent one-year overall survival and acceptable rates of GVHD and other complications, irrespective of conditioning intensity and HLA mismatch. This study examines 1-year post-treatment quality of life (QOL) trajectories, particularly by age.

Methods: Patients who completed at least a baseline and 1-year patient-reported outcome (PRO) surveys were included. QOL surveys were collected at baseline, day (D)100, D180, and 1-year post-HCT using the Lee Symptom Scale (LSS) and PROMIS domains (physical, cognitive, social, sexual function, anxiety, depression, fatigue, sleep disturbance, and pain interference). Mixed models for repeated measures (MMRM) assessed QOL trajectories over time for each PRO measure, adjusting for baseline clinical characteristics and QOL. ANCOVA models assessed adjusted mean differences at 1-year between patients who developed moderate/severe chronic GVHD (cGVHD) versus no/mild cGVHD. Clinically meaningful differences were defined as >5 points for LSS and PROMIS; published norms interpreted symptom burden.

Results: Among 268 ACCESS participants, 113 (42%) patients submitted baseline and 1-year PRO surveys; 18 (15.9%) developed moderate/severe cGVHD. 66 (58%) of patients were <65; 47 (42%) were 65+.
Impact of cGVHD at 1-year. Patients with moderate/severe cGVHD at 1-year had significantly higher LSS scores (Figure 1) and lower PROMIS physical function (PF) compared to those with no/mild cGVHD. LSS scores were 5.21 points higher for moderate/severe cGVHD, a clinically and statistically significant difference. Higher HCT-CI (≥3) was the only other factor tested associated with higher 1-year LSS (4.07 vs. HCT-CI 0). PF was 4.82 points lower for patients with moderate/severe cGVHD; age and educational level were also significantly different. No other QOL domains differed by cGVHD status, however several factors were significantly associated with differences in other QOL domains at 1-year (Table 1).
Trajectory Analyses. Sex and KPS significantly impacted LSS scores over time. Female patients reported an average of 3.5 points lower LSS scores at 1 year than male patients (9.0 vs. 12.5, p<.05). Patients with KPS 90–100 reported 12.4 versus 9.0 for <90 KPS. Age significantly impacted PROMIS cognitive function trajectories, with the largest difference at D100 (patients ≥65 scored 3.1 points lower than <65), though 1-year cognitive was not different by age. PROMIS fatigue trajectories were also age-affected (older patients reported

less fatigue after D100).

Figure 1. Lee Symptom Scale Scores at each timepoint, by cGVHD status

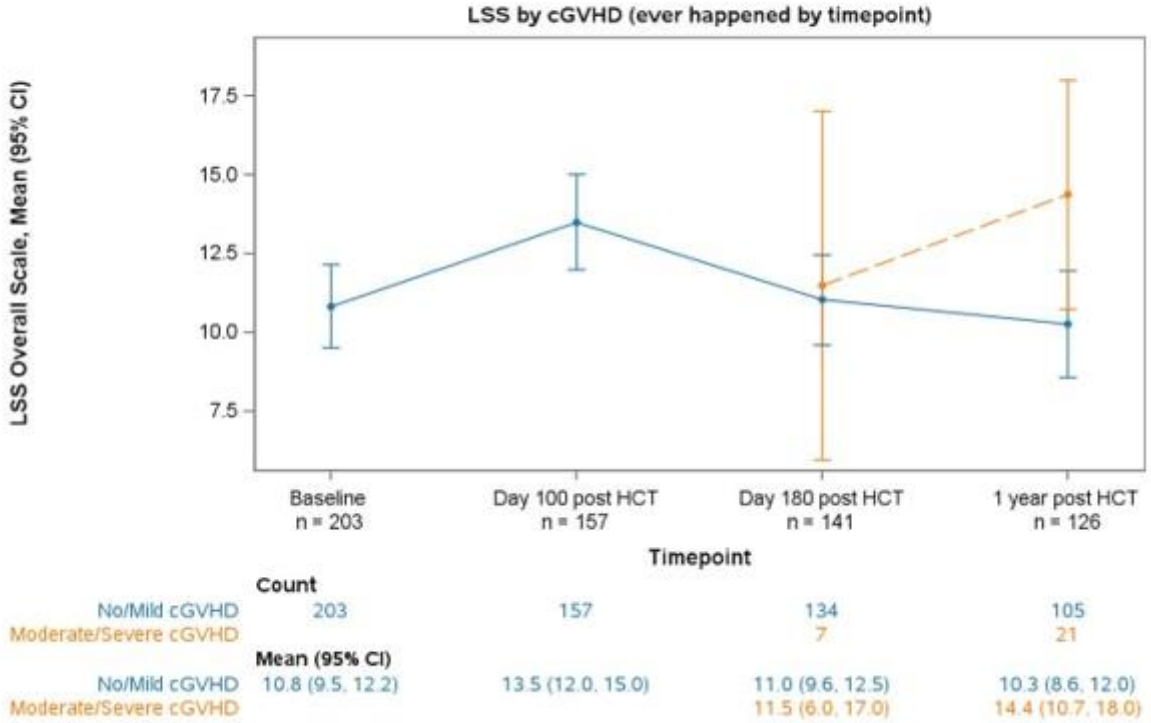

Table 1. ANCOVA Results for each Quality of Live (QOL) domain, significant cGVHD or other covariates		
QOL Outcome	**1-year score differe by cGVHD (95% CI)**	**Other Significant Covariates associated with <u>better</u> QOL scores**
LSS	5.21 (1.43, 8.99)**	Lower HCT-CI
PROMIS Cognitive Function	--	--
PROMIS Physical Function	-4.88 (-8.67, -.96)*	Younger Age Higher Education

PROMIS Social Function	--	--
PROMIS Anxiety	--	Female Job status: Currently employed (vs. Retired or Unable to work due to illness or disability)
PROMIS Depression	--	--
PROMIS Fatigue	--	--
PROMIS Sleep Disturbance	--	Higher Education
PROMIS Pain Interference	--	--
PROMIS SexFS Interest	--	Male
PROMIS SexFS Satisfaction	--	Job status: Currently employed (vs. all other job statuses)
Note: *=p<.05; **=p<.01		

Conclusions: The incidence of moderate/severe cGVHD in this study was relatively low. We found the overall LSS and PF were worse at 1-year for patients with moderate/severe cGVHD, but no other QOL domains were impacted. Older patients typically had less fatigue after D100 and higher cognitive scores over the first-year post HCT, but had significantly worse PF at 1-year. Similar QOL data are being collected in current accruing trials to allow further validation of these findings.

EVALUATING THE POTENTIAL OF E-HEALTH TO IMPROVE POST-TRANSPLANT CARE: PRELIMINARY RESULTS OF THE MY-MEDULA RANDOMIZED TRIAL

Sara Redondo[1], Anna De Dios[2], Marina Vallvé[1], Jordi Real[3], Mercè Triquell[4], Olga Aso[4], Albert Esquirol[1], Estela Moreno[5], Mireia Riba[5], Alex Blasco[6], Eva Tobajas[7], Eva Iranzo[1], Rodrigo Martino[1], Javier Briones[1], Mar Gomis[2], ***Irene García-Cadenas***[1]
[1]Hematology Department, Hospital de la Sant Creu i Sant Pau. IR-Sant Pau and José Carreras Leukemia Research Institutes. Universitat Autonoma of Barcelona, Barcelona, Spain, [2]Pharmacy Department and Digital Health Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [3]Digital Health Department, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [4]Hematology Nursing Department, Hospital de la Sant Creu i Sant Pau, Barcelona, Spain, [5]Pharmacy Department, Hospital de la Sant Creu i Sant Pau, Barcelona, Spain, [6]Dietetics Department, Hospital de la Sant Creu i Sant Pau, Barcelona, Spain, [7]Psycho-Oncology Department, Hospital de la Sant Creu i Sant Pau, Barcelona, Spain

Background: eHealth-based integrated care models have shown benefits in the management of chronic diseases; however, evidence supporting their implementation in the allogeneic hematopoietic cell transplantation (alloHCT) setting remains limited. "MyMedula" is a mobile application and web platform developed by a multidisciplinary HCT team to provide individualized, behavior-based support aimed at mitigating post-HCT complications. A prior pilot study confirmed the tool's feasibility and high patient acceptance (Redondo et al., TCT 2021). The present analysis reports preliminary findings from a randomized clinical trial evaluating whether complementing standard care with "MyMedula" can enhance patient experience and clinical outcomes following alloHCT.

Methods: Single-center randomized-controlled trial (IIBSP-EME-2019-44) conducted at a tertiary university hospital by an interdisciplinary team. Adult alloHCT recipients were randomized 1:1 to standard care (control group, CG) or to the "MyMedula" strategy (intervention group, IG). The intervention comprised multifaceted, patient-tailored actions triggered by patient-reported data captured through the mobile application. Primary endpoints were major post-HCT complications and healthcare resource utilization during the first-year post-transplant.

Results: Between August 2022 and August 2024, 105 alloHCT recipients were invited to participate within one month after discharge; 6 (5.7%) declined due to technological barriers. A total of 99 patients were finally enrolled: 54 (54.5%) in the CG and 45 (45.4%) in the IG. Median follow-up was 19.6 months (95% CI: 17.5–23.5) in the CG and 20.2 months (95% CI: 15.6–23.9) in the IG. Baseline demographic and clinical characteristics were comparable between groups (Table 1), and no differences in baseline technological proficiency were observed according to the CAMBADOS questionnaire.
At last follow-up, no significant differences were observed between groups in the incidence of major post-HCT complications, including infections and graft-versus-host disease. Rates of unplanned visits to the day care clinic or emergency department, hospital readmissions, and other healthcare utilization indicators were also comparable between the CG and IG.

However, when all visit types were aggregated, the IG presented a higher total number of visits than the CG (median [IQR]: 8 [5–12] vs. 6 [3–11]; p = 0.04974).
Survival outcomes—including relapse incidence, transplant-related mortality, and overall survival—also showed no meaningful differences between groups (Table 2). Analyses of patient satisfaction, app usability, and quality-of-life measures are ongoing.

Variable	Control group (n=54)	Intervention group (n=45)	p-value
Age, Median [IQR]	54 [41–62]	55 [45–62]	0.459

Viral respiratory tract infection	31 (57.4%)	29 (64.4%)	0.612
Invasive fungal infection	2 (3.7%)	0 (0%)	0.499
Relapse	9 (16.7%)	8 (17.8%)	1.000
Causes of death:			1.000
- Relapse	6 (11.1%)	3 (6.7%)	
- Infection	1 (1.9%)	0 (0%)	
Healthcare utilization			
Total number of day-care clinic visits *median [IQR]*	2 [1-4]	1 [0-3]	0.457
Total number of hospital admissions *median [IQR]*	0 [0-1]	1 [0-2]	0.272
Total number of primary care visits *median [IQR]*	2 [0-5]	4 [2-7]	0.064
Total number of emergency department visits *median [IQR]*	1 [0-2]	1 [0-3]	0.173

Conclusions: Integrating a mobile health tool into post-alloHCT follow-up is feasible and well accepted for most patients across age groups. In this preliminary analysis, the "MyMedula" strategy did not reduce post-transplant complications and was associated—perhaps paradoxically—with a modest increase in healthcare interactions compared with standard care. Ongoing analyses will further clarify its impact on patient-reported outcomes and help identify strategies to optimize its clinical utility.

Disclosure: Nothing to declare

IMPACT OF REDUCED-INTENSITY CONDITIONING REGIMENS ON FEMALE GONADAL FUNCTION IN SICKLE CELL DISEASE

Tamara Diesch-Furlanetto[1], *Ilhem Rahal*[2], *Laure Joseph*[3], *Jeremy Sroussi*[4], *Virginie Barraud-Lange*[5], *Mathilde Bourdon*[6], *Nathalie Dhedin*[7], *Catherine Poirot*[8]
[1]*Schweiz (+41), Basel, Switzerland,* [2]*Hematology Unit, AP-HP, Hôpital Necker Enfants-Malades, Paris, France,* [3]*Department of Biotherapy, French National Sickle Cell Disease Referral Center, Hôpital Necker, Assistance-Publique Hôpitaux, Paris, France,* [4]*Department of Obstetrics Gynecology, APHP, Lariboisière Hospital, University Paris Cité, Paris, France,* [5]*Department of Reproductive Biology, APHP Center, Cochin Hospital, University Paris Cité, Paris, France,* [6]*Department of Gynecology Obstetrics II and Reproductive Medicine, Assistance Publique-Hôpitaux de Paris, Hôpital Universitaire Paris Centre, Centre Hospitalier Universitaire Cochin, Paris, France,* [7]*Department of Hematology, AYA Unit, Saint Louis Hospital, Paris, France,* [8]*Department of Hematology, AYA Unit, Saint Louis Hospita, Paris, France*

Background: Reduced-intensity conditioning (RIC) regimens are increasingly employed in allogeneic hematopoietic stem cell transplantation (HSCT) for young adults with sickle cell disease (SCD). These strategies aim to reduce treatment-related toxicity while maintaining curative potential. Among the potential toxicities of HSCT, impairment of ovarian function is a major concern for young women, given the impact on fertility and long-term quality of life.
Objective: This study evaluated the impact of three RIC regimens on ovarian function and fertility outcomes among female SCD patients undergoing HSCT, with the goal of improving fertility preservation counselling.

Methods: We conducted a retrospective analysis of 30 consecutive women with severe SS genotype SCD who underwent HSCT between November 2013 and March 2022 for cerebral vasculopathy, recurrent vaso-occlusive crises, or refractory acute chest syndrome. Patients received one of three transplant modalities

- **R1 (n=11):** RIC haploidentical HSCT (Antithymoglobulin (ATG), thiotepa, fludarabine, cyclophosphamide, 2Gray TBI followed by post cyclophosphamide).
- **R2 (n=4):** RIC matched related HSCT (ATG, fludarabine, cyclophosphamide, 2 Gy Total Body irradiation (TBI)).
- **R3 (n=15):** Non myeloablative matched related HSCT: Alemtuzumab, 3Gy TBI.

All patients attended fertility preservation (FP) consultations prior to HSCT. Logistic regression analysis was performed to identify potential risk factors for premature ovarian insufficiency (POI). POI was defined as cessation of menstruations more than 4 months before the age of 40 and FSH levels >25IU/L.

Results: The median age at HSCT was 21.4 years (range 15.8–37.9), highest in R2 group (31.3 years). FP was undertaken in 66.7% overall, most frequently in R1 (90.9%) and R2 (100%) compared with 40% in R3. Pre-HSCT median Anti-Müllerian Hormone (AMH) levels were highest in R2 group (3.5 ng/mL). The medium cumulative Cyclophosphamide exposure was greater in R1 (6.9 g; 129 mg/kg) than R2 (2.9 g; 50 mg/kg). Median follow-up was longest in R2 (6.8 years vs. 4.0 in R1 and 3.0 in R3). Menstrual recovery occurred in 67.9% overall, with rates of 100% (R2), 78.6 % (R3) and 45.5% (R1). Despite clinical recovery of ovarian function, post-HSCT AMH levels remained low in all three groups (median 0.1 ng/mL, range 0.01 – 0.87). Four natural pregnancies (13.3%) occurred post-transplant: two in R1 and two in R2. The highest incidence of POI (21.4%) occurred in the R3 group. Logistic regression did not identify significant predictors of POI.

Table 1. Patients characteristics

Patients characteristics	**Overall** N = 30	**R1** N = 11	**R2** N = 4	**R3** N = 15
Age at HSCT (years)

(Min, Max)	(0.01, 0.87)	(0.01, 0.30)	(0.07, 0.07)	(0.01, 0.87)
Natural pregnancies, n (%)			4 (13.3)	2 (18.2)

NA: non adapted; HSCT: hematopoietic stem cell transplantation; AMH: Anti-Müllerian Hormone

Conclusions: RIC regimens can preserve ovarian function in some women with SCD undergoing HSCT. Nonetheless, persistently low AMH levels indicate diminished ovarian reserve and highlight the risk of future POI. These findings emphasize the importance of early fertility counseling, pre-transplant preservation strategies, and long-term reproductive monitoring to optimize fertility outcomes in this population.

NOT JUST SURVIVING BUT THRIVING – A PEDSQL-MEASURED QUALITY OF LIFE IN LONG TERM SURVIVORS WHO UNDERWENT HSCT FOR IBMFS

Krithika Krishnakumar[1], *Minakshi Balwani*[1], *Nithya Sheshadri*[1], *Vijayshree Muthukumar*[1], *Kavitha Ganesan*[1], *Indira Jayakumar*[1], *Ramya Uppuluri*[1], *Revathi Raj*[1]
[1]*Apollo Specialty Hospital, Chennai, India*

Background: Inherited bone marrow failure syndromes (IBMFS) constitute a diverse group of genetic disorders requiring hematopoietic stem cell transplantation (HSCT) for cure. We report a twenty-year experience with emphasis on graft outcomes, transplant-related complications, survival, and long-term health-related quality of life (HRQoL) using the PedsQL 4.0 system in survivors over two years post-HSCT.

Methods: This retrospective analysis included all children ≤18 years undergoing HSCT for genetically or clinically confirmed IBMFS between January 2005 and December 2023. Conditioning was diagnosis-adapted, with reduced-intensity conditioning (RIC) used for Fanconi anemia (FA) and myeloablative conditioning (MAC) applied in non-FA disorders. HRQoL was assessed in children surviving over two years post-HSCT using the PedsQL 4.0 Generic Core Scales. Total Transform scoring categorized QoL as good (score=1), moderate

(score=2), or poor (score=3). Statistical comparisons between FA and non-FA survivors used Fisher Exact testing, Mann-Whitney U test, and ordinal logistic regression.

Results: A total of 96 HSCTs were performed for 91 children (median age 8 years; male: female ratio 1.5:1). FA constituted the largest subgroup (n=72, followed by pure red cell aplasia (n=8), congenital amegakaryocytic thrombocytopenia (n=5), congenital neutropenia (n=2), Shwachman–Diamond syndrome (n=2), and other IBMFS (n=5). The overall survival at last follow-up was 53.8% (49/91)**.**
We performed the long-term follow-up HRQoL in 48 survivors as one child's family refused participation in the survey due to a language barrier. As graft versus host disease had an impact on the quality of life, we documented the impact of chronic GVHD. 19.7 % children had chronic GVHD and 3/48(6.2%) had extensive chronic GVHD impacting on all domains of quality of life.
The majority demonstrated reassuring functional recovery: 39 children (81.2%) achieved a "good" quality-of-life score, while 14 (18.8%) fell within the moderate-to-poor range and there was no difference was observed in outcome distribution using either dichotomized or ordinal scoring methods (Fisher exact p=0.74; Mann–Whitney U p=0.68; ordinal logistic regression p=0.67), indicating that underlying diagnosis did not independently predict quality-of-life status among survivors.
Domain-specific analysis revealed variability in recovery patterns. Emotional functioning demonstrated the highest mean score (86.46%), followed by physical health (84.88%), while Social (83.13%) and School Functioning (82.71%) were the lowest scoring domains. School functioning was identified as the most affected area, suggesting sustained challenges with academic reintegration, fatigue, absenteeism, and psychosocial impact following prolonged treatment and immune isolation. Despite these limitations, the majority of surviving children reported relatively high HRQoL scores, indicating meaningful functional recovery following transplant.

Conclusions: The majority of long-term pediatric IBMFS survivors demonstrated encouraging post-HSCT HRQoL outcomes, with emotional well-being and physical functioning largely preserved.

Clinical Trial Registry: None

INCIDENCE, RISK FACTORS AND OUTCOMES OF AVASCULAR NECROSIS IN ALLOGENEIC STEM CELL TRANSPLANT RECIPIENTS DEVELOPING GRAFT-VERSUS-HOST DISEASE

Rohan Jacob Verghese[1,2], *Sachin Punatar*[1,2], *Anant Gokarn*[1,2], *Akanksha Chichra*[1,2], *Sumeet Mirgh*[1,2], *Gourav Bain*[1,2], *Lingaraj Nayak*[1,2], *Bhausaheb Bagal*[1,2], *Amit Janu*[1,2], *Libin Mathew*[1], *Navin Khattry*[1,2,2]
[1]*Advanced Centre for Treatment, Research and Education in Cancer (ACTREC), Tata*

Memorial Centre, Navi Mumbai, India, [2]Homi Bhabha National Institute (HBNI), Mumbai, India

Background: Avascular necrosis(AVN) is an important late complication of allogeneic stem cell transplant(ASCT), impacting mobility in survivors. Prior studies report AVN post-ASCT at rates of 3.7% to 24%, with up to 80% of patients needing joint replacement within five years. However, data on risk factors beyond graft-versus-host disease (GVHD) remains inconsistent, and there is no published data from India.

Methods: This single-centre retrospective analysis included ASCT recipients between January 2008 and December 2022 who survived at least 180 days post-transplant and developed either acute or chronic GVHD. AVN was assessed in symptomatic patients; diagnosis was based on MRI, and the ARCO (Association Research Circulation Osseous) stage was recorded for involved hip joints. Serum vitamin D levels were assessed pretransplant and at the diagnosis of AVN and supplemented if deficient(<20ng/ml). Use of steroids pre- and post-transplant was recorded, and steroid doses were standardized to prednisolone equivalents for analysis. Data on demographics, transplant parameters, and other risk factors were compared between AVN and non-AVN patients using the Mann-Whitney U test.

Results: Of 411 transplanted patients, 192 were excluded for early mortality(n=92), pre-existing AVN(n=5), or absence of GVHD(n=95), leaving 219 eligible patients(median age 28 years, 72% male). Primary indications for ASCT in the eligible cohort were AML(n=62), ALL(n=68), MPAL(n=6), CML(n=46), Hodgkin lymphoma(n=9), MDS(n=13), and other(n=15). Transplants in thse patients were MRD(n=176,81%), MUD(n=11,5%), and haploidentical(n=32,15%) with median post-ASCT follow-up of 60 months.
Fourteen of 219 patients(6.4%) developed AVN symptoms at a median of 641 days post-ASCT(range: 21-1299), confirmed by MRI at a median of 644 days(range: 40-1330). All patients had hip involvement with median ARCO stage II; 4 had shoulder and 1 had wrist involvement(median number of joints involved: 2,range:1-4).
Twelve AVN patients required vitamin D supplementation at diagnosis of AVN, and 13 received bisphosphonates(alendronate:11, zoledronate:2). Five were managed conservatively; surgery was advised in 9 of whom 8(57.1%) underwent at least one procedure(hip decompression:2, joint replacement:7, both:1). Median time to first surgery was 1,046 days(range: 576-1,547).
No significant differences were noted in age, anthropometric measurements, ASCT type, conditioning intensity, TBI use, comorbidities, or CD34+ cell dose between both groups. AVN patients received higher median CD3+ cell dose (184.6 vs 135.5 ×10^6 cells/kg, p=0.048) and had higher rates of pre-ASCT vitamin D deficiency(12/14, 85.7% vs 117/205, 57.1%; p=0.036). Pre-ASCT steroid exposure was more common(13/14, 92.8% vs 133/205, 65.2%; p=0.035), and median pre-ASCT steroid dose was higher in the AVN group(2,643 vs 202.7 mg/m^2, p=0.006). AVN cases received higher starting dose of systemic steroids for acute GVHD(median:2.19 vs 1.19 mg/kg prednisolone equivalents, p=0.016), but there were no differences in steroid therapy duration, steroid-refractoriness, or use of maintenance prednisolone and oral budesonide. Chronic GVHD occurred in 11/14(78.5%) AVN patients and 127/205(61.9%) non-AVN patients, with a higher proportion of AVN patients requiring systemic steroids(7/11, 63.6% vs 42/127, 33.1%; p=0.043).

Conclusions: Symptomatic AVN incidence among ASCT recipients who developed GVHD was 6.4%, with 57% requiring surgery. Higher pre-ASCT steroid exposure, higher initial steroid dose for acute GVHD, higher CD3+ cell dose, and pre-ASCT vitamin D deficiency were potentially modifiable risk factors for AVN.

SECOND PRIMARY MALIGNANCY AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION – LONG-TERM FOLLOW-UP AT A SINGLE INSTITUTE EXPERIENCE

*Tran-Der Tan[1], **Lun-Wei Chiou**[1], An-Chen Feng[1], Yi-Hsuan Lin[1], Yi-Mei Hsiao[1], Hua-Mei Yen[1], Mei-Ling Kuo[1], Wan-Hwa Chou[1], Yi-Wen Tsai[1], Hsiao-Ping Chen[1]*
[1]Koo Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan (Province of China)

Background: Hematopoietic stem cell transplantation is a curative treatment for various hematologic malignancies and some benign hematologic diseases. Besides chronic GVHD, the second primary malignancy is also a long-term adverse effect.

Methods: We retrospectively searched our post-transplant patients' long-term follow-up data between 2001 and 2021, and analyzed the incidence, types, and outcomes of second malignancies and excluded EBV-related post-transplant lymphoproliferative disorders at a single institution over 20 years.

Results: Twelve patients of second primary malignancy, including 5 of head and neck squamous cell carcinoma, 3 of MDS/AML, 1 of ALL, 1 of esophageal squamous cell carcinoma, 1 of breast cancer, and 1 of papillary thyroid cancer in 380 patients of our cohort (autologous in 184 and allogeneic in 196 patients). Eight patients who underwent allogeneic hematopoietic stem cell transplants had five head and neck, one esophageal, one breast, and one papillary thyroid cancer. Four who underwent autologous transplants were three MDS/AML and one ALL. All six patients with five head and neck cancers and one esophageal cancer had extensive chronic GVHD. Of these six squamous cell carcinoma patients, four were disease-free after surgery, but one died after the vaccination for COVID-19. The other two died of a second cancer in progression. In four of the MDS/AML and ALL patients, two were persistent leukemia-free after intensive chemotherapy and salvage allogeneic hematopoietic stem cell transplantation, one low-risk MDS on watchful observation without treatment, and one AML patient died of leukemia relapse even after allogeneic transplant. The other two patients with breast cancer and papillary thyroid cancer were disease-free after surgery and adjuvant therapy. Nine of our patients were disease- or progression-free; three died of second cancers (hypopharyngeal, esophageal, and AML).
The cumulative incidence was 6% at 10 years and 16% at 19 years, including 5% versus 7% at 10 years and 15% versus 17% at 19 years after autologous and allogeneic HCT, respectively, which is higher than reported in a previous large-scale study of the CIBMTR database, the cumulative incidence of new solid cancers was 1% at 10 years, 2.2% at 15

years, and 3.3% at 20 years after transplantation. A single-institution review of 4905 survivors of allogeneic hematopoietic cell transplant from Seattle reported 581 secondary cancers in 499 individuals after a median follow-up of over 12 years. The cumulativeincidence of secondary malignant neoplasms at 30 years after HCT for the entire cohort was 22.0%. At 20 years post-HCT, the cumulative incidence rates were 8.1%, 13.5%, and 23.6% for patients younger than 20 years of age, 20–50 years, and older than 50 years, respectively, which is similar to our cohort.

Conclusions: The cumulative incidence of second malignancy was 6% in 10 years and 16% in 19 years, and post-autologous and post-allogeneic transplants were 5% vs. 7% and 15% vs. 17% in 10 years and 19 years, respectively. Extensive chronic GVHD is a risk factor for upper aerodigestive tract squamous cell carcinoma. Most patients can be salvaged after local or systemic treatment.

Clinical Trial Registry: KFSYSCC-IRB No./Protocol No.: 20221110A (Interim report 3).

NON-INFECTIOUS COMPLICATIONS AFTER CAR-T CELL THERAPY

Juan Manuel Cerezo Martín[1,2], *Miriam Sanchez Escamilla*[1,2], *Lucía España Herreros*[1], *Leddy Patricia Vega Suarez*[1], *Héctor Cruz Barquín*[1], *Vicente González Quintanilla*[3], *Guillermo Martín Sánchez*[1], *Cristina Alburquerque Prieto*[1], *María Puente Pomposo*[1], *Mercedes Colorado Araujo*[1], *Carmen Montes Gaisán*[1], *Sonia González de Villambrosia*[1], *Javier Núñez Céspedes*[1], *José Íñigo Romón Alonso*[1,4], *Enrique M. Ocio San Miguel*[1,4], *Maria Aranzazu Bermúdez Rodríguez*[1,4]
[1]*Hematology Department, University Hosptial Marqués de Valdecilla-IDIVAL, Santander, Spain,* [2]*Both Authors Collaborated Equal to the Work, Santander, Spain,* [3]*Neurology Department, University Hospital Marqués de Valdecilla-IDIVAL, Santander, Spain,* [4]*Cantabria University, Santander, Spain*

Background: CAR-T has demonstrated remarkable efficacy in treating R/R B-cell neoplasms, such as diffuse large B-cell lymphoma (DLBCL) and multiple myeloma (MM). Despite its success, long-term effects and sequelae of CAR-T on the immune system remain underestimated.

Methods: In the present retrospective study, we aim to analyze non-infectious complications after CAR-T cell therapy.

Results: Sixty patients were infused between august-2022 and November-2025. 50% were males, 32% had an auto previous and 12% had tandem auto. Median lines of therapy were 1.9 (range 1-5) and median age was 64-yo (range 37-79). Twenty-three patients (38%) had DLBCL, 5 (8%) other B cell lymphomas and 32 (53%) had MM. Previous to CAR-T, 6 patients (10%) were in CR, 19 patients (32%) in PR, 7 (12%) in VGPR, 4 (7%) with stable disease and 23 (38%) with RR.Forty-six patients had CRS grade 1 or 2 (27 [39%] and 20 [29]). Twenty-one patients had ICANS grade 1 (7 [10%]), grade 2 (3 [4%]), grade 3 (7 [10%]),

grade 4 2 (3%) or grade 5 (1 [1%]). In our series, 13 patients (22%) needed to be admitted in the ICU after CAR-T infusion, the causes of ICU admission were: severe CRS (2), severe ICANS (9) and other (1). At 28 days post-infusion, 37 patients (54%) had ICAHT requiring treatment in 22 (59%). G-CSF, Eritropoyetin or Eltrombopag were used in 20 (29%), 16 (23%) and 14 (20%) of the patients.

In terms of non-infectious complications (NIC), we observed late onset neurotoxicity in 6 patients, cardiovascular in 4 , immunomediated fenomena in 4 , pulmonary complications in 3 and secondary malignancies y other 3. See Table1. Cumulative incidence (CI) of (NIC) at 1y for the whole series was 22% (CI 95% 11-38) and for lymphoma and MM was 31% (CI 95% 16-54) and 11% (CI 95% 3-40).

With a median follow up of 5 months, at last follow up 50 patients were alive. Ten patients died after the infusion, in 5 cases due to relapse and in the other 5 cases due to non-relapse mortality (NRM) (1 ICANS, 4 infections). For the whole population, 1-year overall survival (OS), relapse free survival (RFS) and NRM was 83% (CI 95%: 68-91), 76% (CI 95%: 60-86) and 10% (CI 95%: 4-21), for lymphoma patients was 73% (CI 95% 51-86), 62% (95% CI 40-77) and 15% (CI 95% 5-31) respectively and for MM patients was 96% (CI 95% 75-99), 96% (CI 95% 75-99) and 4% (CI 95% 1-17), respectively.

Univariable analysis showed that a diagnosis of MM vs lymphoma (p=0.03) and 1 vs >1 treatment lines prior to CAR-T (p=0.02) were associated with an inferior CI of NIC. Multivariable analysis showed that only lines of therapy pre-CAR-T was associate with an inferior CI of NIC (HR 0.1: CI 95% 0.02-0.9; p-value=0.02).

Patient	Non-infectious complication	Age	Sex	Disease	Lines of therapy	CAR-T product	Response pre/post	CRS	ICANS	D10 lymphocytosis	Last status	Cause of death
1	- Fronto-subcortical cognitive impairment - Warthin's tumor/Oncocytoma	63	Male	Lymphpoma	3	Tisacel	RR/CR	Grade2	No	Yes ALC7400/uL	Alive	
2	- Mild cognitive impairment - Pneumonitis on CT scan - Transaminitis	58	Female	MM	1	Ciltacel	PR/CR	Grade1	No	Yes ALC3500/uL	Alive	
3	- Trigeminism	76	Male	Lymphoma	2	Tisacel	RR/CR	Grade2	Grade1	Yes ALC3600/uL	Alive	
4	- Unclassified Interstitial Lung Disease (ILD)	69	Female	MM	1	Ciltacel	CR/CR	Grade1	No	No	Alive	
5	- Movement and neurocognitive treatment-emergent adverse event (MNTs)	73	Male	Lymphoma	2	Tisacel	PR/CR	Grade1	Grade2	Yes ALC4800/uL	Alive	
6	- Pulmonary hypertension and hypertensive arteriopathy	76	Female	Lymphoma	2	Axicel	RR/RR	Grade1	No	No	Death	Disease
7	- Self-limiting ICANS, no treatment	48	Female	Lymphoma	2	Axicel	RR/CR	Grade1	Grade3	No	Alive	
8	- Hypovolemic shock	71	Female	Lymphoma	2	Axicel	CR/CR	Grade2	Grade2	No	Alive	
9	- Septapical dyssynchrony with LVEF 45%	66	Male	Lymphoma	2	Axicel	RR/CR	Grade2	Grade3	No	Alive	
10	- Pituitary macroadenoma	77	Male	Lymphoma	1	Axicel	RR/CR	Grade1	Grade1	No	Alive	
11	- Late onset ICANS - IEC-HS	71	Female	Lymphomoa	2	Axicel	CR/CR	Grade2	Grade3	No	Death	Infection
12	- Enteritis	72	Male	MM	4	Ciltacel	VGPR/CR	Grade1	No	Yes ALC3000/uL Prophylactic dexametasone	Alive	
13	- AML	72	Male	Lymphoma	3	Tisacel	RR/CR	Grade1	No	No	Alive	
14	- IEC-HS	58	Female	Lymphoma	2	Axicel	RR/PR	No	Grade4	No	Death	Infection
15	- Cranial nerve palsy	67	Female	MM	1	Tisacel	PR/Pending	Grade2	No	No but later needed prophylactic dexametasone for ALC>3000/uL	Alive	

ILD: Interstitial Lung Disease, MNTs: Movement and neurocognitive treatment-emergent adverse event, ICANS: Immune-effector-cell associated neurotoxicity syndrome, LVEF: Left ventricular ejection fraction, IEC-HS: Immune Effector Cell-associated Hemophagocytic Lymphohistiocytosis-like Syndrome, AML: Acute myeloid leukemia, RR: Relapse/refractory, CR: Complete remission, PR: Partial remission, VGPR: Very good partial remission, ALC: Absolute lymphocyte count

Conclusions: Non-infectious complications after CAR-T are underestimated in many of the guidelines. In our study more than 1 line of therapy was associated with higher NIC development. In terms of mortality, NRM was 10% and mostly due to infectious complications.

Disclosure: No COI.

A434

FROM CHILDHOOD TO ADOLESCENCE: LONG-TERM RISKS AND RECOVERY MORE THAN FIVE YEARS AFTER NON-TBI HSCT

*Atieh Karimzadeh[1], **Amir Ali Hamidieh**[1], Maryam Behfar[1], Behnaz Nikoubin[1], Atoosa Eftekhar[1], Amirreza Kamyabi[1], Soheil Pourheidar[1], Hamid Farajifard[1], Mohammad Jahanpanah[1]*
[1]Pediatric Cell and Gene Therapy Research Center, Gene, Cell & Tissue Research Institute, Tehran University of Medical Sciences, Tehran, Iran (Islamic Republic of)

Background: Hematopoietic stem cell transplantation (HSCT) remains a cornerstone of curative therapy for children with life-threatening hematologic, oncologic, immunologic disorders and inborn errors of metabolism. Conventional conditioning regimens incorporating total body irradiation (TBI) are associated with substantial long-term toxicities, including endocrine dysfunction, infertility, and increased risk of secondary malignancies. Consequently, non-TBI conditioning approaches have gained wider adoption in pediatric HSCT. However, data on the late effects associated with these regimens remain limited. As survival improves, understanding long-term complications and quality-of-life outcomes in survivors is increasingly important. This study aimed to evaluate late effects among pediatric patients who underwent non-TBI HSCT.

Methods: We conducted a cross-sectional analysis of patients who underwent HSCT at <18 years of age, had at least 5 years of post-transplant survival, and were attending routine follow-up visits at the HSCT clinic of Children's Medical Center, the country's leading pediatric HSCT center. Transplant indications included both malignant and non-malignant disorders. All patients received non-TBI conditioning regimens, categorized as myeloablative (MAC), non-myeloablative (non-MAC), or reduced-intensity conditioning (RIC), according to disease-specific protocols.

Results: A total of 67 patients were enrolled. The mean follow-up duration was 8.62 ±2.64 years , with 30% of patients having undergone HSCT more than 10 years prior. The most common indications for transplantation were malignant hematologic disorders (29.9%) and primary immunodeficiencies (22.4%). Most patients received fully matched donor grafts (80.6%), and 59.7% were transplanted from sibling donors; all grafts were peripheral blood stem cells. Only one patient required a second transplant. At last follow-up, 9 patients (13.4%) demonstrated mixed chimerism and had received donor lymphocyte infusion. 27 (40.3%) patient had a bone mineral density Z-score < −2 indicating below the expected range for age.Cardiac function remained normal (EF >55%) in all but one patient. Endocrine complications included hypoparathyroidism in 4 patients (6%) and hypothyroidism in 11 patients (16.4%). Metabolic abnormalities were observed in 10 patients (14.9%) with dyslipidemia, 8 patients (11.9%) with pre-diabetes, and 1 patient with diabetes mellitus. Gonadal dysfunction was present in 36 patients (40.7%); among 10 male patients who underwent semen analysis, 6 (60%) showed evidence of infertility.No cases of disease recurrence or secondary malignancy were identified.

Conclusions: In this cohort of long-term survivors of pediatric HSCT conditioned without TBI, late effects remained common but were largely manageable, with a notably low burden

of cardiotoxicity, secondary malignancies, and disease recurrence. Endocrine, metabolic, and gonadal complications represented the predominant long-term morbidities, underscoring that non-TBI regimen, while mitigating many classic radiation-associated toxicities, do not fully eliminate the risk of late organ dysfunction. The high prevalence of reduced bone mineral density and gonadal impairment highlights the need for structured survivorship care, proactive screening, and early intervention. As non-TBI conditioning strategies continue to expand in pediatric transplantation, comprehensive long-term follow-up is essential to refine risk-adapted conditioning, optimize supportive care, and ultimately improve the quality of survival for this growing population of HSCT survivors.

BRONCHIOLITIS OBLITERANS SYNDROME AFTER PAEDIATRIC ALLOGENEIC HSCT: A SYSTEMATIC REVIEW OF THERAPEUTIC STRATEGIES

Kristene Rimbaldo[1], Diane Hanna[1,2,3], Shivanthan Shanthikumar[1,3,2], ***Hannah Walker****[1,2,3]*
[1]Royal Children's Hospital, Melbourne, Australia, [2]Murdoch Children's Research Institute, Melbourne, Australia, [3]University of Melbourne, Melbourne, Australia

Background: Bronchiolitis obliterans syndrome (BOS) is a rare but severe complication following allogeneic haematopoietic stem cell transplantation (HCT). Management strategies for paediatric BOS are largely extrapolated from adult data, and no prior systematic review has synthesised the evidence base specific to the paediatric population. This review aimed to evaluate all available data on therapeutic interventions for paediatric BOS and to assess the quality of the available evidence.

Methods: A systematic search of MEDLINE, EMBASE, PubMed, and the Cochrane Library was performed. The search strategy was adapted, with permission, from the strategy used in the European Respiratory Society (ERS)/European Society for Blood and Marrow Transplantation (EBMT) clinical practice guidelines on the treatment of pulmonary cGvHD in adults. Eight PICO questions were explored. Eligible studies reported therapeutic interventions for BOS or lung cGvHD in patients <18 years, including mixed-age cohorts where paediatric data were extractable. Screening, data extraction and risk-of-bias assessment were performed independently by two reviewers. Observational studies were assessed using a modified Newcastle–Ottawa Scale, prospective interventional studies using ROBINS-I-V2, and the included systematic review using ROBIS. A complementary search of major clinical trial registries identified ongoing or unpublished trials relevant to paediatric BOS.

Results: Only sixteen studies met inclusion criteria, encompassing fewer than 205 children worldwide. The majority of studies were single-centre, retrospective case series with heterogeneous diagnostic and response criteria. Evidence for treatment effectiveness

remained limited. Ruxolitinib demonstrated the most consistent therapeutic benefit, with clinical and functional improvements and notable steroid sparing effects. Risk of bias was high or critical in most studies due to small sample sizes, retrospective design and inconsistent outcome measurement.

Conclusions: The current evidence base for the management of paediatric BOS following HCT is sparse, heterogeneous and of generally of low methodological quality. Although ruxolitinib showed some promise, the evidence remains low and no therapy has been validated in a prospective paediatric clinical trial. There is an urgent need for paediatric specific diagnostic and response criteria and for prospective, multicentre studies to define optimal treatment strategies and improve outcomes for children affected by this rare but devastating complication.

LATE MORTALITY IN PEDIATRIC HEMATOPOIETIC STEM CELL TRANSPLANTATION SURVIVORS

Yun-Jung Huang[1], *Hsin-Yun Hsieh*[1], *Ming-Hsin Hou*[1], *Cheng-Ying Ho*[2], *Ting-Yen Yu*[3], *Chih-Ying Lee*[1], *Giun-Yi Hung*[1], *Tzeon-Jye Chiou*[4], *Chia-Jen Liu*[1], *Sheng-Hsuan Chien*[1], *Wen-Chun Chen*[1], *Yi-Wei Chen*[1], *Cheng-Ying Shiau*[1], *Hsiu-Ju Yen*[1]
[1]*Taipei Veterans General Hospital, Taipei, Taiwan (Province of China),* [2]*Shin Kong Wu Ho-Su Memorial Hospital, Taipei, Taiwan (Province of China),* [3]*Far Eastern Memorial Hospital, Taipei, Taiwan (Province of China),* [4]*Taipei Municipal Wanfang Hospital, Taipei, Taiwan (Province of China)*

Background: Hematopoietic stem cell transplantation (HSCT) is curative for various pediatric malignant and nonmalignant disorders. As post-transplant survival improves, late mortality, defining as death occurring more than 2 years after HSCT, has become an important health issue in survivorship care. However, data on Asian pediatric populations remain limited.

Methods: We conducted a single-center, retrospective cohort study of pediatric patients who underwent HSCT between 2005 and 2022 at Taipei Veterans General Hospital, and survived more than 2 years post-transplant. Clinical records were reviewed.

Results: Eighty-four long-term survivors (85 HSCTs) were analyzed, with a median follow-up of 8.5 years. Hematologic malignancies were the most common underlying diseases (38.8%), followed by brain tumors (23.5%), solid tumors (23.5%), and benign diseases (14.1%). The 10-year overall survival and relapse-free survival were 83.5% and 70.7%, respectively. Fifteen patients (17.6%) died within a median of 6.2 years post-HSCT; relapse accounted for 54% of deaths, followed by secondary malignancies (20%), chronic graft-versus-host disease (13%), and pulmonary fibrosis (13%). In multivariate analyses, disease type was the only independent predictor of late mortality, with higher risk in brain and solid tumors compared with hematologic malignancies or benign diseases (HR = 0.208, p =

0.009). Relapse related mortality (RRM) plateaued at 12 years, while non-relapse related mortality (NRM) continued to rise and exceeded RRM after 18 years after HSCT. Secondary malignancies occurred in 9.5% of patients, mostly diagnosed within 5–10 years post-transplant.

Conclusions: In this Asian pediatric HSCT cohort, late mortality is strongly related to the underlying disease, with poorer outcomes in patients of brain and solid tumors. While relapse was the leading cause of late death, NRM, particularly secondary malignancies and pulmonary fibrosis, became more prominent over time. Transplant strategies to maintain treatment efficacy while avoiding unnecessary long-term NRM are urgently required. In addition, long-term risk-adapted surveillance is essential for early identification and prompt intervention for transplant survivors.

P235

SEXUAL ACTIVITY DURING NEUTROPENIA AND IMMUNOSUPPRESSION: WHAT DO YOU TELL YOUR PATIENT?

Sigrun Einarsdottir Anna Nordlander[1], *Cecilia Olofsson, Sinja Kristiansen, Cecilia Karrberg, Cornelia Liebau, Eva Smith Knutsson, Petra Tunback, Anna Nordlander*
[1]*Karolinska University Hospital, Stockholm, Sweden*

Background: Patients undergoing intensive chemotherapy or hematopoietic stem cell transplantation frequently develop neutropenia and immunosuppression, increasing vulnerability to infections. Sexual health guidance is traditionally highly restrictive, with some sources recommending abstinence or consistent condom use even within long-term monogamous relationships. However, these recommendations are based largely on theoretical risks rather than clinical evidence. The situation parallels the historical "neutropenic diet," which persisted for decades without proven benefit and negatively affected quality of life. Given the importance of sexual well-being and intimacy during cancer treatment, there is a critical need to reassess current practices.

Methods: We performed a narrative synthesis of published transplant and infection-prevention guidelines, patient education materials, psychosocial studies, and clinical evidence related to infection risks during neutropenia. Risk factors were categorized according to partner type, mucosal integrity, sexual practices, and exposure routes. Hygiene recommendations, contraceptive considerations, and chemotherapy-related excretion risks were reviewed to distinguish infection-related advice from other valid indications for barrier protection.

Results: Direct evidence linking sexual activity to increased infection rates during neutropenia is limited. Infection risk varies substantially depending on context:
• **Lower-risk situations:** monogamous, stable partnerships where partners share household flora; routine condom use adds minimal infection-prevention benefit if the partner is healthy.

• **Higher-risk situations:** sexual practices involving fecal exposure, significant mucositis or genital ulceration, or involvement of new or multiple partners.
• **Hygiene:** gentle routine hygiene is sufficient; excessive washing may disrupt mucosal barriers and microbiome integrity.
• **Other indications for condoms:** prevention of drug exposure after chemotherapy and contraception should not be conflated with infection prevention.
Restrictive, non-evidence-based advice may reduce intimacy and worsen psychological distress.

Conclusions: Current sexual activity recommendations for neutropenic and immunosuppressed patients often exceed available evidence and may negatively impact quality of life. Counseling should be individualized, balancing genuine infection risks with patient values and relationship context. Further research—including behavioral-infection correlation studies, qualitative partner-focused research, and trials comparing counseling strategies—is needed to inform evidence-based guidelines.

P236

LONG-TERM RESULTS OF AUTOLOGOUS AND ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION (AUTO-HCT AND ALLO-HCT) – REAL-LIFE DATA FROM A SINGLE CENTER ANALYSIS OF 15- AND 20-YEAR SURVIVALS

Kajetan Karaszewski[1,2], *Jakub Góra*[1], *Agnieszka Tomaszewska*[1], *Wiesław Wiktor Jędrzejczak*[1]
[1]*Central Clinical Hospital, Medical University of Warsaw, Warsaw, Poland,* [2]*Doctoral School, Medical University of Warsaw, Warsaw, Poland*

Background: Despite the well-documented efficacy of both auto-HCT and allo-HCT in treating malignancies of the hematopoietic system, survival analyses in the literature are mostly limited to 5-year or 10-year survival following transplantation. Further observations are lacking, despite the potential occurrence of relapses even 10 years following HCT. The study aimed to evaluate 15- and 20-year overall and progression-free survival (OS and PFS) rates of auto-HCT and allo-HCT, and discuss these results in the context of available data on 5-year and 10-year survival rates.

Methods: We identified 468 auto-HCT recipients and 272 allo-HCT recipients treated in a single center from 1999 to 2014. If available, survival analyses were performed using Kaplan-Meier curves, the Cox proportional hazards model, and the log-rank test. Survival analyses were valid for auto-HCT recipients with multiple myeloma (MM), Hodgkin lymphoma (HL), non-Hodgkin lymphomas (NHLs), AL amyloidosis, acute myeloid leukemia (AML), and

immunodeficiencies, and for allo-HCT recipients with AML, acute lymphoblastic leukemia (ALL), chronic myeloid leukemia (CML), myelodysplastic neoplasms (MDS), NHLs, and severe aplastic anemia (SAA).

Results: In most cases, both 15-year and 20-year OS and PFS rates were obtained. Crucial findings for selected diseases were summarized in the attached Table.

OS rates	**5-year**	**10-year**	**15-year**	**20-year**	**median OS**	**last death**
auto-HCT in MM	50.5%	27.3%	17.1%	8.9%	62 months	month 236
auto-HCT in HL	74.2%	65.9%	62.3%	62.3%	N/A	month 154
auto-HCT in NHL	58.7%	54.3%	45.2%	45.2%	125 months	month 157
PFS rates	**5-year**	**10-year**	**15-year**	**20-year**	**median PFS**	**last relapse**
auto-HCT in MM	43.0%	22.7%	19.2%	19.2%	45 months	month 179
auto-HCT in HL	65.4%	58.1%	54.8%	54.8%	N/A	month 108
auto-HCT in NHL	54.7%	52.7%	43.8%	43.8%	125 months	month 59
OS rates	**5-year**	**10-year**	**15-year**	**20-year**	**median OS**	**last death**
allo-HCT in AML	45.2%	42.6%	39.3%	39.3%	31 months	month 176
allo-HCT in ALL	63.6%	60.6%	60.6%	60.6%	N/A	month 102
allo-HCT in CML	42.1%	42.1%	42.1%	31.6%	41 months	month 202
PFS rates	**5-year**	**10-year**	**15-year**	**20-year**	**median PFS**	**last relapse**
allo-HCT in AML	42.7%	38.6%	36.6%	36.6%	24 months	month 128
allo-HCT in ALL	59.5%	56.7%	56.7%	56.7%	N/A	month 12
allo-HCT in CML	38.9%	34.0%	34.0%	25.5%	22 months	month 67

In auto-HCT recipients with MM, both 5-year and 10-year survival rates were consistent with other studies performed in similar years. Plateau effect was obtained in PFS after 10 years of analysis. In patients with HL, 5-year survival rates were consistent with other studies, while 10-year survival rates were ~15% higher than in another study performed in the 1990's. It implies that these findings were reasonable for our inclusion period. Plateau effects in both OS and PFS were obtained after 12 years of analysis. In patients with NHLs, our results were consistent with other studies, with the exception of 10-year PFS, which was ~15% higher in our analysis. However, the reference study included only patients with relapsed/refractory NHLs, while our study included all auto-HCT recipients with NHLs.
In allo-HCT recipients with AML, both 5-year and 10-year survival rates were consistent with other studies. Plateau effects for both OS and PFS were obtained after 5 years of analysis.

While in patients with ALL, 5-year survival rates were ~15% higher than in other studies, 10-year survival rates were consistent with other studies. Notably, ALL is a disease with heterogeneous clinical manifestations and genetic background, and complex indications of transplantation, which frequently cause discrepancies in survival analyses. Plateau effects for both OS and PFS were obtained after 8 years of analysis. In patients with CML, our findings were consistent with another study from the 1980s up to 20 years of follow-up, implying a similar prognosis in individuals who cannot be treated with alternative therapies throughout the years.

Conclusions: HCT is a group of therapeutic methods with unprecedented efficacy in treating malignancies of the hematopoietic system. Its therapeutic effect is often maintained for over 15, or 20 years following transplantation. It implies the possibility to cure patients with these diseases, or, in other words, achieve a prognosis comparable to the general population.

Disclosure: Nothing to declare.

MORBIDITY BURDEN, SOCIAL REHABILITATION AND QUALITY OF LIFE IN LONG-TERM SURVIVORS OF HAEMATOPOIETIC CELL TRANSPLANTATION: A SINGLE-CENTRE EXPERIENCE FROM INDIA

Bishal Sharma[1,2], Akanksha Chichra[3,2], Nishant Jindal[3,2], Chaitali Nashikkar[3,2], Libin Mathew[3,2], Shubham Naikwadi[3,2], Gourav Bain[3,2], Sumeet Mirgh[3,2], Lingaraj Nayak[1,2], Anant Gokarn[3,2], ***Sachin Punatar***[3,2]*, Bhausaheb Bagal[1,2], Navin Khattry[3,2]*
[1]Tata Memorial Centre, Mumbai, India, [2]Homi Bhabha National Institute, Mumbai, India, [3]ACTREC, Navi Mumbai, India

Background: The combined impact of conditioning regimens and transplant-related complications can lead to chronic health conditions (CHCs) and quality of life (QoL) impairment post hematopoietic cell transplant (HCT). To our knowledge there is no data from India. We conducted this study to assess the burden of morbidity, functional status, fertility and QoL in long-term survivors post-HCT from a tertiary cancer centre in India.

Methods: Patients who underwent autologous or allogeneic HCT between 1st July 2007 and 30th June 2013 and had completed at least 10 years of follow-up were eligible. Autologous HCT for multiple myeloma was excluded. Data were collected between 1st January 2024 and 4th June 2025. CHCs were captured using a structured interview and record review against a pre-specified list of 36 cardiovascular, neurological, respiratory, renal, musculoskeletal, mucocutaneous, hematological, ocular, gastrointestinal, endocrine, ear, psychiatric and malignant disorders. Patients with pre-transplant comorbidities were excluded. Functional status, social rehabilitation and fertility outcomes were assessed using investigator-developed questionnaires, while QoL was measured using the validated FACT-BMT instrument, which includes physical, social, emotional, functional and BMT-specific subscales, with higher scores reflecting better QoL.

Results: Sixty patients consented and were included, 43 allogeneic and 17 autologous recipients. The median age at transplant was 24 years (range 4–51), and 78% were male. Indications of allogeneic transplant were acute leukemia (n=26; 43 %), CML(n=5; 8 %), aplastic anemia (n=7; 11 %), MDS/MPN (n=3, 5 %), thalassemia (n=1, 2 %),lymphoma (n=1, 2 %) and for autologous transplant were HL (n=12, 20 %), NHL (n=4,7%) and neuroblastoma(n=1,2%). Forty-five patients (75%) developed at least one CHC (median 2, range 1-5). The most frequent CHCs were diabetes mellitus (30%), hypertension (20%), dyslipidemia (13%), obesity (12%) and cataract (10%). Incidence of CHCs was higher post-allogeneic HCT in comparison to autologous HCT (diabetes in 14/43 (32%) vs 4/17 (23%); p=0.55) and hypertension in 10/43 (23%) vs 2/17 (12%);p=0.47). All 23 patients employed pre-HCT returned to work, and 26 of 28 (93%) who were pursuing education at transplant completed their education post-HCT. Regular menstrual cycles resumed in 9/22 (40%) female patients. Of 15 patients or partners desiring conception, 9 (60%) achieved pregnancy, indicating partial preservation of fertility. Median Composite FACT-BMT score was 127 (score range 0-148) suggesting good QoL in majority of the patients. Importantly, there was no difference in QoL between autologous and allogeneic HCT survivors.

Conclusions: In patients who have survived a decade after their HSCT; three-fourth of our long-term survivors have at-least one CHC. The commonest chronic health conditions in our cohort were diabetes mellitus, hypertension, dyslipidemia and obesity. Most patients were able to have gainful employment and those pursuing education were able to complete their education post-HCT. Fertility was preserved in at least half of the patients who desired conception. Majority of patients had good QoL post-HCT. This is the first study to our knowledge from India that highlights comprehensively the chronic health conditions including fertility and QoL of patients who are long term survivors and emphasizes the importance of long-term monitoring and follow up of patients post-HCT.

DE NOVO DONOR-DERIVED PDGFRA-REARRANGED EOSINOPHILIA AFTER HAPLOIDENTICAL HSCT IN A PATIENT WITH PRIOR AML AND T-LBL: A CASE OF SEQUENTIAL MULTILINEAGE MALIGNANCIES

Angelica Cabbuag[1], *Francisco Vicente Lopez*[1]
[1]*St Luke's Medical Center-Global City, Taguig City, Philippines (the)*

Background: Donor-derived hematologic neoplasms are rare complications after allogeneic hematopoietic stem cell transplantation (HSCT) and are distinct from recipient relapse. While myeloid/lymphoid neoplasms with eosinophilia (MLN-Eo) associated with PDGFRA rearrangements are well described, donor-derived PDGFRA-positive disease is uncommon. We report a unique case of sequential hematologic malignancies—AML followed by T-cell lymphoblastic lymphoma (T-LBL)—in a patient who subsequently developed de novo donor-derived PDGFRA-rearranged eosinophilia more than 600 days after haploidentical HSCT.

Methods: Clinical data, histopathology, cytogenetics, fluorescence in situ hybridization (FISH), and short tandem repeat (STR) chimerism analyses were reviewed in a patient presenting with late post-transplant hypereosinophilia. The timeline of engraftment and onset of eosinophilia was assessed to distinguish between relapse, secondary recipient neoplasm, and donor-derived disease.

Results: A 58-year-old male was diagnosed with FLT3-negative AML in 2014 and achieved complete remission following 7+3 induction and HiDAC consolidation. Nine years later, in 2023, he developed T-LBL presenting as large bilateral mediastinal masses, confirmed by biopsy with expression of CD3, TdT, CD5, CD7, CD99, and Ki-67 >95%. After two cycles of hyper-CVAD with marked radiographic response, he underwent haploidentical HSCT from his son in January 2024. Pre-transplant CBCs from both donor and recipient showed no eosinophilia. Post-transplant recovery was uneventful, and routine CBC monitoring through 2024–2025 demonstrated stable engraftment and no eosinophilia (eosinophils 0–7%).
The patient remained in remission until September 2025, when new-onset hypereosinophilia was observed with eosinophils rising to 40% and 23% (absolute eosinophil count ~4.1 × 10^9/L) despite stable hemoglobin, platelets, and no clinical signs of leukemic relapse. FISH for HES-associated abnormalities demonstrated a PDGFRA rearrangement in 32.67% of cells. STR chimerism at day +634 showed 100% donor alleles across all informative loci, establishing complete donor chimerism and indicating a donor-derived myeloid neoplasm rather than recurrence of the patient's previous AML or a lineage switch from T-LBL.
The donor remains hematologically normal, supporting a de novo acquisition of the mutation in the recipient. Imatinib therapy was initiated, with clinical stabilization and declining eosinophil counts.

Conclusions: This case highlights a rare instance of de novo donor-derived *PDGFRA*-rearranged eosinophilia arising more than 1.5 years post–haploidentical HSCT. It demonstrated the sequential occurrence of three distinct clonal hematologic disorders—AML, T-LBL, and donor-derived eosinophilia—representing a unique pattern of multilineage malignancies spanning both recipient and donor hematopoiesis. The absence of hematologic abnormalities in the donor strongly supports a de novo origin of the PDGFRA clone within the recipient's post-transplant milieu. This case emphasizes the need for early molecular workup and chimerism studies in post-transplant eosinophilia, as PDGFRA-positive disease is highly responsive to imatinib.

KIDNEY TRANSPLANTATION FOLLOWING HSCT, COMPLICATED BY TA-TMA WITH PROGRESSION TO END-STAGE RENAL DISEASE

Evelina Lyudovskikh[1], *Arina Trofimova*[2], *Sergey Arzumanov*[2], *Alexandra Shutova*[1], *Svetlana Kozlovskaya*[1], *Anna Vasilieva*[1], *Alexander Bazaev*[1], *Elvira Sultanova*[1], *Viktoria Vedmedskaya*[1], *Dmitry Pershin*[1], *Larisa Shelikhova*[1], *Michael Maschan*[1], *Dmitry Balashov*[1], *Yulia Skvortsova*[1]

[1]Dmitry Rogachev National Medical Research Center Of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation (the), [2]Federal State Autonomous Institution National Medical Research Center for Children`s Health of the Ministry of Health of the Russian Federation, Moscow, Russian Federation (the)

Background: Chronic kidney disease (CKD) is a significant long-term complication affecting survivors of allogeneic hematopoietic stem cell transplantation (HSCT), with 5-20% progressing to end-stage renal disease (ESRD). The principal etiologies include nephrotoxic drug exposure, Graft-Versus-Host Disease (GVHD), recurrent viral infections (notably BK virus and cytomegalovirus), and Transplant-Associated Thrombotic Microangiopathy (TA-TMA). Kidney transplantation following related-donor hematopoietic stem cell transplantation (HSCT) raises the question of using the same individual as the kidney donor. This consideration is important due to the potential for reducing immune-mediated risks and fostering immune tolerance.

Methods: We report the case of a 7-year-old girl with severe combined immunodeficiency due to adenosine deaminase deficiency (ADA-SCID) who developed ESRD following haploidentical HSCT. Four years prior, she received a TCRab-depleted graft from a haploidentical donor (mother). Engraftment was achieved by day +18, with sustained full donor chimerism. Post-transplant complications included late acute GVHD grade 3 progressed to chronic GVHD of the skin and lungs, persistent viral infections with organ involvement (HHV6, CMV, BK-viruses), invasive pulmonary aspergillosis. Graft failure led to the introduction of CD34-selected boost and combined with freshly isolated donor-derived regulatory T-cell (Treg) infusion to control GVHD and improve immune reconstitution. Finally progressive CKD attributed to BK virus-associated nephritis, nephrotoxic therapy and secondary TA-TMA developed. Following last 2-year period she required renal replacement therapy and was maintained on peritoneal dialysis for 12 months.

Results: One year after the initiation of peritoneal dialysis, a kidney transplant (KT) from the same related donor (mother) was successfully performed. A personalized regimen for induction and maintenance immunosuppression was tailored based on the patient's complex history: high-dose methylprednisolone and eculizumab. Eculizumab was selected for dual rationale: 1) prophylaxis against TA-TMA recurrence, taking into account the patient's history and pro-thrombotic risk of KT; and 2) immunomodulation without inducing profound lymphodepletion. On post-operative day +4, the same donor-derived Treg cells were infused to promote tolerance and prevent immune complications. Current therapy consisted of abatacept and continued eculizumab.
Pathological examination of the removed kidney revealed diffuse global glomerulosclerosis, severe interstitial fibrosis, and C3d deposition in the glomeruli, consistent with advanced CKD caused by a combination of TA-TMA and viral nephritis.
At the two-month follow-up, the patient remains off systemic immunosuppressive therapy with excellent kidney graft function.

Conclusions: Kidney transplantation from a hematopoietic stem cell donor became a necessary step in the therapy of a patient with ESRD following HSCT. The presence of full donor chimerism prior to kidney transplantation allowed to minimize the volume of induction therapy before the solid organ transplant. The use of regulatory T-cells was considered as an additional option, aimed both at controlling GVHD and preventing kidney allograft rejection

while promoting immune tolerance. Thus, the potential to forego prolonged immunosuppression emerges as a major advantage of this approach, directly contributing to an improved long-term quality of life.

P240

COST EFFECTIVENESS EVALUATION OF THE IMPLEMENTATION OF AN ON-LINE EXTRACORPOREAL PHOTOCHEMOTHERAPY TECHNOLOGY FOR POST BMT C-GVHD PREVIOUSLY TREATED WITH AN OFF-LINE TECHNOLOGY IN ANOTHER HOSPITAL

Paola Maria Manzini[1], *Ilaria Avonto*[1], *Laura Maddalena*[1], *Lorenzo Comba*[1], *Barbara Mandrile*[1], *Antonella Peyrachia*[1], *Carmine Dell'Aglio*[1], *Francesca Rumbolo*[1], *Giorgio Giuliano*[1]
[1]*Azienda Ospedaliera Santa Croce e Carle Cuneo, Cuneo, Italy*

Background: Extracorporeal photopheresis (ECP) is an immunomodulatory therapy to treat patients with graft-versus-host disease (GVHD), solid organ transplant rejection, cutaneous T-cell lymphoma and various autoimmune disease. ECP can be performed using two technologies: Off-line ECP with leukapheresis and photoactivation performed on separate devices and On-line ECP with all phases of the procedure collection, photosensitization, irradiation, and reinfusion performed within a single closed and automated system. Until July 2025 haematological patients with c-GVHD followed in our hospital were treated with an off-line ECP technology in the nearest ECP center 150 Km far from our area because our department was not equipped with a device for ECP treatments.

Methods: In July 2025 our center in Cuneo implemented a new technology (*Amicus Blue, Fresenius Kabi AG*) to perform on-line ECP in house. Four patients, affected by c-GVHD, previously treated in the other center started treatments in our center. In this paper we retrospectively evaluate our experience comparing procedures data, timing, cost and the patient perception of effectiveness and quality of life through individual Patient questionnaire.

Results: 40 ECP procedures were performed on four patients from July 2025 to December 2025 using the on-line system with a single procedure average time of ~ 120 minute using single needle procedures because of patient's choice; all ECP products were compliant with our quality controls (MNC harvest efficiency, T-cell apoptosis, microbiological evaluation). All products were reinfused to patients with no side effect. Response was comparable to previous treatments. Time related to the single procedure was reduced in all cases from 8 to 2-3 hours with a time saving of 65-75%. Cost analysis of the two different procedures showed a higher cost of 26% for the on-line one that was completely covered by patient's transportation cost for the off-line one. Evaluation of time saving cost of the on-line procedure was -390€ so that the real cost for the on-line ECP was 870€ compared to 1280 of the off-line performed in the other hospital with a cost saving of 32% (Table 1). Patient's perception of effectiveness was only slightly higher with the on-line procedure while quality

of life was clearly globally improved (mean +65%) mainly due the opportunity to perform ECP in their city with a mean time saving of ~5 hours for each "ECP procedure day".

Off-line ECP external hospital	Time (h)	Cost (€)	On-line ECP internal hospital	Time (h)	Cost (€)
Patient transportation time/cost*	~ 4 h	~ 280 €	Patient transportation time/cost*	-	-
ECP Off-line time/cost**	~ 4 h	~ 1.000 €	ECP On-line time/cost**	2 h	~ 1.260 €
Total ECP external Time/Cost	~ 8 h	~ 1.280 €	Total ECP internal Time/Cost	3 h	~ 1.260 €
			Time/cost saving On-line Procedure***	2	- 390€
			Real ECP on-Line cost		870€

*cost for patient transportation to external Hospital (RT); no transportation needed for internal on-line ECP
**calculation of all disposable and timing (converted in €) for each methodology
***calculation of time saving (converted in €) generated by the on-line technology

Table 1. Cost analysis comparison of the off-line and on-line ECP procedures in our context.

Conclusions: Our experience showed that our strategy to implement a local on-line ECP service, clearly increased the patient quality of life maintaining a high standard of ECP treatment quality with no impact on financial hospital resources.

Disclosure: Nothing to declare.

P241

ERYTHROCYTOSIS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: A SINGLE-CENTRE EXPERIENCE

Ajda Gunes[1], *Ufuk Demirci*[2], *Fatma Keklik Karadağ*[1], *Nur Soyer*[1], *Mahmut Töbü*[1], *Fahri Şahin*[1], *Güray Saydam*[1], *Filiz Vural*[1]
[1]*Ege University, İzmir, Turkey,* [2]*Celal Bayar University, Manisa, Turkey*

Background: Post-transplant erythrocytosis is a rare complication following allogeneic hematopoietic stem cell transplantation (allo-HSCT). Its underlying mechanisms and clinical course remain poorly understood. In the literature, most reported cases involve young male

patients, frequently with aplastic anemia (AA). Here, we present our single-centre experience with post-transplant erythrocytosis in long-term survivors of allo-HSCT.

Methods: We conducted a retrospective analysis of our institutional database, including a total of 315 adult allogeneic HSCTs performed at the Ege University Adult Bone Marrow Transplantation Unit between January 2014 and November 2025. All patients were aged ≥18 years.Erythrocytosis was defined as: (a) hemoglobin/hematocrit (Hb/Hct) levels exceeding 16.5 g/dL/49% in men and 16 g/dL/48% in women, extrapolated from the WHO fifth edition polycythemia vera criteria, and (b) persistent elevation confirmed by at least two measurements obtained ≥3 months apart. Patients with conditions commonly associated with secondary erythrocytosis were excluded.

Results: A total of 11 patients who developed erythrocytosis after allo-HSCT were included. With a median follow-up of 6.1 years (range, 0.4–12.3 years), long-term outcomes could be adequately assessed. The cohort was predominantly male (10/11, 91%), with a median age of 32 years (range, 23–52 years).Underlying diagnoses included aplastic anemia (AA, n=4), acute myeloid leukemia (AML, n=3), primary myelofibrosis (PMF, n=1), pure red cell aplasia (PRCA, n=1), myelodysplastic syndrome (MDS, n=1), and paroxysmal nocturnal hemoglobinuria (PNH, n=1). Five patients (45%) received grafts from matched sibling donors and six (55%) from matched unrelated donors; 10 patients (91%) had fully matched (10/10) donors. Two patients required immunosuppressive therapy for chronic GVHD. Erythrocytosis developed at a median of 32 months (range, 23–52 months) following allo-HSCT. The median duration after the onset of erythrocytosis was 14.3 months (range, 2.7–56.9 months). At the time of erythrocytosis, the median LDH level was 222 U/L (range, 171–311 U/L), with mild LDH elevation observed in 5 patients (45%). Median leukocyte and platelet counts were within normal ranges, and no patient had splenomegaly. Among evaluable patients, serum erythropoietin levels were within normal limits, and no patient demonstrated elevated EPO levels. JAK2 V617F mutation analysis, performed in 5 patients, was negative in all cases. All patients received low-dose aspirin as antithrombotic prophylaxis. Therapeutic phlebotomy was required in 3 patients (27%), while the remaining patients were managed conservatively without additional cytoreductive interventions. A single thrombotic event occurred, with one patient experiencing myocardial infarction requiring coronary stent implantation during the sixth year of follow-up. All patients were alive at the last follow-up. Patient characteristics are summarized in Table 1.

Table 1. Patient Characteristics

Patients, n	11
Male sex, n (%)	10 (91)
Age, years	32 (23–52)
Underlying diagnosis, n Aplastic anemia AML Other*	 4 3 4

Follow-up duration, years	6.1 (0.4–12.3)
Time from HSCT to erythrocytosis, months	32 (23–52)
Normal EPO, n / tested	4/4
JAK2 mutation detected, n / tested	5/0
Low-dose aspirin, n (%)	11 (100)
Therapeutic phlebotomy, n (%)	3 (27)

* MDS, PRCA, PMF, PNH

Conclusions: Post-transplant erythrocytosis is an uncommon complication. In our single-centre cohort, predominantly affecting young male long-term survivors, it followed a generally benign clinical course and was not associated with clonal myeloproliferative disease, as evidenced by normal erythropoietin levels and the absence of JAK2 mutations among evaluable patients. Patients were successfully managed with low-dose aspirin, with or without therapeutic phlebotomy. However, long-term surveillance remains warranted to monitor potential vascular complications.

Disclosure: Nothing to declare.

P242

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH SEVERE CARDIOVASCULAR COMORBIDITY

Nadezhda Shnalieva[1], Yuriy Osipov[1], Macsim Axenov[1], Natalia Stepanova[1], Julia Podmankova[1], Anastasia Admakina[1], Irina Budaeva[1], Elza Lomaia[1], Galina Salogub[1], ***Ilya Potapov***[1]
[1]*Almazov National Medical Research Centre, Saint-Petersburg, Russian Federation (the)*

Background: Allogeneic hematopoietic stem cell transplantation (alloHSCT) is a key therapeutic option for patients with hematologic malignancies. However, the prevalence of cardiovascular disease (CVD) among alloHSCT recipients is higher than in general population. Prior exposure to cardiotoxic antineoplastic therapy, advanced age, and a history of coronary interventions further increase cardiovascular risk. Patients with ischemic heart disease, previous myocardial infarction, or myocardial revascularization are frequently considered at very high CVD risk, and evidence regarding the safety of alloHSCT in this population remains limited. Real-world data addressing post-transplant cardiovascular outcomes in such patients are particularly scarce.

Methods: Seven patients with hematologic malignancies and confirmed cardiovascular disease who underwent alloHSCT were included to the analysis. Median age was 63 years

(range 48–67); four patients were male and three female. The median duration of hematologic disease prior to transplantation was 17 months, and the median overall duration of hematologic disease follow-up was 50 months. All patients had documented CVD, including ischemic heart disease, prior atherothrombotic myocardial infarction or myocardial infarction with non-obstructive coronary arteries (MINOCA), coronary stenting, coronary artery bypass grafting, cerebrovascular disease, valvular heart disease. Due to CVD anamnesis, all patients were stratified to the very high cardiovascular risk category according to European Society of Cardiology stratification.
Pre-transplant assessment included cardiovascular history, electrocardiography, echocardiography, and laboratory markers of myocardial dysfunction and atherosclerosis. Data on prior antineoplastic therapy, conditioning regimens, graft-versus-host disease (GVHD) prophylaxis, cardioprotective treatment, and cardiovascular events in early (<100 days) and late post-transplant period were collected.
Cardiovascular risk of new or worsening pre-existing CVD at 1 and 5 years was estimated using the CARE-BMT Risk Score.

Results: Patients' characteristic and the details of alloHCT are presented in Table. All patients successfully proceeded to alloHSCT. Median follow-up after alloHSCT in all 7 patients was 14 months, while in survivors after alloHST it was 40,5 months. No acute or chronic GVHD ³ grade 2 was observed.
Four patients remain alive after alloHSCT, and no deterioration of CVD was observed in the post-transplant period. Of these, two patients (with diffuse large B-cell lymphoma and chronic myeloid leukemia, respectively) had a history of unstable angina and prior coronary artery bypass grafting; one patient with acute myeloid leukemia had stable coronary artery disease, a history of cerebrovascular accident, and arterial thrombosis; and one patient with peripheral T-cell lymphoma had a history of MINOCA).
Three patients with a history of myocardial infarction and coronary artery stenting (underlying hematologic malignancies: hepatosplenic T-cell lymphoma, blast transformation of essential thrombocythemia, and acute myeloid leukemia) had a stable cardiovascular status; however, they died in the post-transplant period due to relapse of the underlying disease.

Patient	Hematologic Malignancy	Cardiovascular History	Time from CV Event to HSCT (mon)	CARE-BMT Score	Cardioprotective therapy	Conditioning Regimen / GVHD Prophylaxis	Date of allo-HSCT	Follow-up after HSCT (mon)	Outcome
F / 53y	Essential thrombocythemia, blast transformation	MI with RCA stenting	11	5	Antiplatelet, β-blocker, statin	FluBu8 / PtCy + Rux	09 Apr 2024	8	Relapse, death

		(June 2024)							(Dec 2024)
M / 67y	Hepatosplenic T-cell lymphoma	MI, LAD stenting (June 2023); aortic and mitral valve stenosis; AH	12	7	Antiplatelet, β-blocker, statin	FluBend / PtCy + Rux + abatacept	19 June 2024	14	Relapse, death (Aug 2025)
M / 48y	Hodgkin lymphoma → DLBCL in 13 years	IHD, unstable angina; LCx stenting (Feb 2018)	60	4	Antiplatelet, β-blocker, Ca-channel blocker, statin	FluBu8 / PtCy	20 Feb 2023	33	Alive, no CV events
M / 52y	Chronic myeloid leukemia	Stable IHD; CABG (Nov 2017)	48	6	Antiplatelet, β-blocker, statin	FluBu8 / PtCy + tacrolimus + MMF	02 Nov 2021	48	Alive, no CV events
F / 65y	Peripheral T-cell lymphoma	MINOCA (2008)	192	5	Not required	FluBu8 / PtCy + tacrolimus + MMF	11 Sep 2024	14	Alive, no CV events
M / 64y	Acute myeloid leukemia	Stable angina; CHF; AH; stroke (2010)	84	11	Antiplatelet, β-blocker, ACE inhibitor, statin	FluBu8 / PtCy + tacrolimus + MMF	30 Mar 2017	104	Alive, no CV events
F / 63y	Acute myeloid leukemia	IHD; MI (2016); multiple coronary stents (2016–2024)	91	5	Antiplatelet, statin, diuretic	FluBu8 / PtCy + tacrolimus + MMF	20 June 2024	7	Relapse, death (Feb 2025)

Abbbeviations and acronyms: M – male, F – female, CV – cardiovascular; HSCT – hematopoetic stem cell transplantation; CARE-BMT – Cardiovascular Registry in Bone Marrow Transplantation; GVHD – graft-versus-host-disease; MI – myocardial infarction;

RCA – right coronary artery; left anterior descending artery; IHD – ischemic heart disease; LCx – circumflex artery; AH – arterial hypertension; CABG – coronary artery bypass grafting; MINOCA – myocardial infarction with non-obstructive coronary arteries; CHF – congestive heart failure; ACE-inhibitor – angiotensin-converting enzyme inhibitor; FluBu8 – fludarabine150 mg/m2 + busulfan 8 mg/kg; PtCy – posttransplant cyclophosphamide; Rux – ruxolitinib; FluBend – fludarabine 90 mg/m2 + bendamustine 130 mg/m2; Tx – tacrolimus; MMF – mycophenolate mofetil.

Conclusions: The presence of severe cardiovascular comorbidity, including prior myocardial infarction and coronary revascularization, should not be considered as an absolute contraindication to alloHSCT. In patients with stable cardiovascular disease, careful pre-transplant cardiovascular assessment and continuation of cardioprotective therapy allow alloHSCT to be performed safely without cardiovascular comorbidity exacerbation.

SUCCESSFUL TREATMENT OF SECONDARY HISTIOCYTIC SARCOMA AFTER B-ALL TRANSPLANTATION WITH TARGETED THERAPY COMBINED WITH RADIOTHERAPY: A CASE REPORT

Changwei Dong[1], Nannan Li[1], Wei Su[1], Bohan Li[1], Jianping Zhang[1], ***Jing Long***[2]
[1]Hebei Yanda Ludaopei Hospital, Langfang, China, [2]Beijing Lu Daopei Institute of Hematology, Beijing, China

Background: This article reports a case of secondary histiocytic sarcoma (HS) following transplantation for B-cell acute lymphoblastic leukemia (B-ALL), in which the patient achieved long-term survival after receiving targeted therapy with a MEK1/2 inhibitor combined with a bispecific antibody (BsAb) and radiotherapy.

Methods: A patient, 17-year-old male, was diagnosed B-ALL in August 2020.
Bone marrow morphology evaluation confirmed the second completed remission (CR), the patient subsequently underwent unrelated allogeneic hematopoietic stem cell transplantation on 26th Aug 2021. Consecutive bone marrow morphology revealed maintained CR and chimerism analysis demonstrated persistent mixed chimerism after transplantation. The decitabine and a single reinfusion of the donor's cryopreserved peripheral blood stem cells were administered.
In June 2022, the patient presented fever without responding to anti-infective treatment. CT-scan revealed rib bone destruction. Whole-body PET-CT showed multiple focal areas of increased metabolic activity throughout the skeletal system. Bone marrow morphology revealed CR. On 28th July 2022, Ultrasound-guided biopsy of a lower rib lesion confirmed histiocytic sarcoma on pathological examination, and genetic testing identified FANCC, BRCA2, ARAF and NF1 mutations.
The patient initiated MEK1/2 inhibitor Trametinib on 19th August 2022. The osteolytic destruction was improved. In May 2024, multiple abnormal changes observed in the liver and

pancreatic tail by abdominal ultrasound. CT-guided liver biopsy indicated involvement by histiocytic sarcoma. Genetic testing identified new PTPN11, SH2B3, LUC7L2, SF3A1 mutation. Consideration of Disease progression, trametinib was discontinued due to presumed drug resistance.
On 21st June 2024, the patient started on oral MEK1/2 inhibitor tunlametinib at a dose of 12 mg twice daily which induced severe Skin and soft tissue infection after 4 weeks, necessitating a dose reduction to 6 mg twice daily without interruption of therapy. The Skin and soft tissue infection occurred intermittently with symptomatic treatment. After 6th August 2025, the dose of trametinib was reduced to 9 mg once daily which has been continued to the present. The Skin and soft tissue infection was completely recovery. After six months, PET/CT indicated nodular metabolic activity in the pancreatic tail, suspected to represent residual HS and slightly increased metabolic activity in liver segment 7 (S7). Tunlametinib was combined with one dose of ipilimumab. After ten months, proton therapy was administered targeting the lesions in the pancreatic tail (GTV60GyE/30F, CTV54GyE/30F) and liver S7 (57GyE/19F). Ipilimumab was given twice during radiotherapy and followed by an additional once after radiotherapy.

Results: Bone destruction showed a significant reduction in pre and post trametinib (Image 1-A). The nodules in the pancreatic tail and liver S7 decreased in size before and after tunlametinib (Image 1-B).
The patient is recovering well at home and able to perform activities of living independently by follow-up visit.

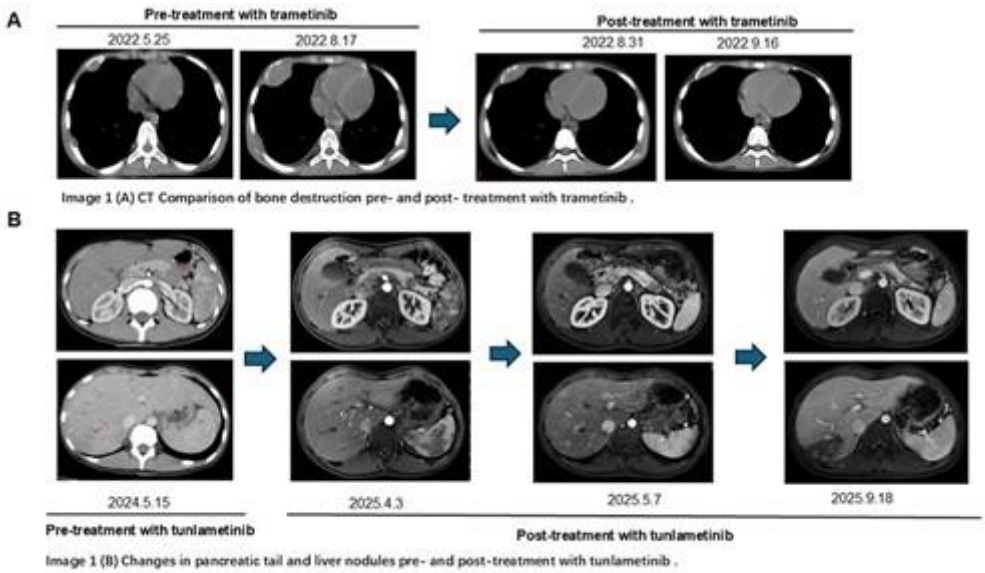

Image 1 (A) CT Comparison of bone destruction pre- and post- treatment with trametinib .
Image 1 (B) Changes in pancreatic tail and liver nodules pre- and post-treatment with tunlametinib .

Conclusions: This patient presents with a rare secondary HS following B-ALL transplant. There is no standardized or consistently effective treatments. Patients who are gene test positive, targeted therapies can be considered. However, genetic evolution may occur during treatment and frequently lead to resistance. The combination of MEK1/2 inhibition with BsAb and radiotherapy may offer potential survival benefits for patients with HS.

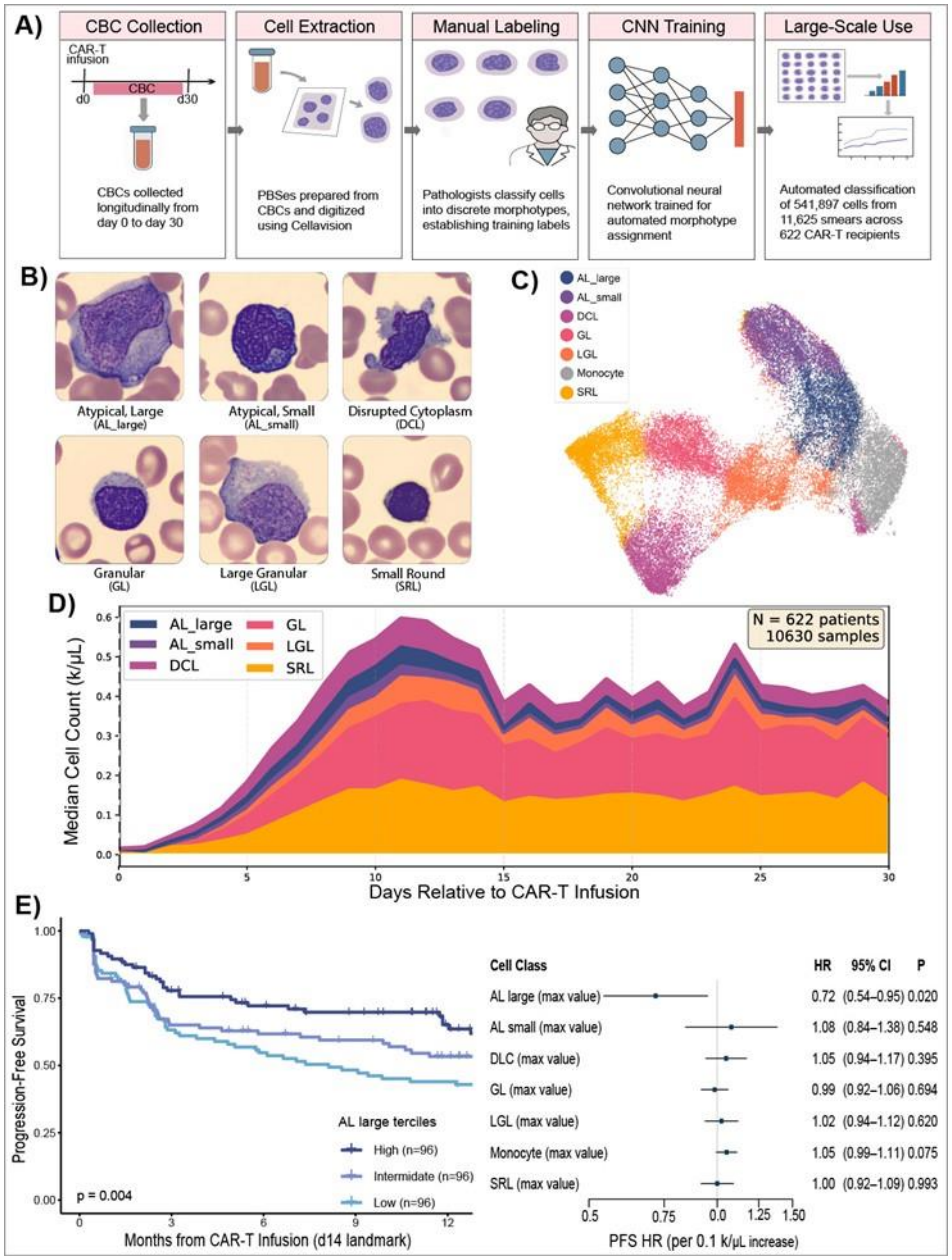
Background: Real-time assessment of CAR T-cell activity remains challenging in routine clinical practice, as available assays are resource-intensive and poorly suited for longitudinal monitoring at scale. Peripheral blood smears (PBS) are inexpensive, ubiquitous, and serially collected, yet remain largely unexplored as an immune-monitoring modality. We developed a deep learning–based framework to transform standard PBS into scalable and quantitative markers of post–CAR-T immune dynamics.

Methods: We assembled a large repository of digitized PBS obtained between days 0–30 after infusion from patients treated with commercial CAR-T products for non-Hodgkin lymphoma, B-cell acute lymphoblastic leukemia, and multiple myeloma (2018–2025). Expert hematopathologists reviewed early post-infusion smears and defined recurrent lymphocyte morphologies ("morphotypes"). A convolutional neural network was trained to classify single-cell images into these morphotypes (**Fig. 1A**). Longitudinal morphotype distributions were quantified and associated with clinical outcomes. Correlations between morphotype abundance and CAR-T transgene levels measured by digital droplet PCR (ddPCR) were assessed using Spearman's coefficient.

Results: Hematopathologist curation of 1,600 lymphocyte-like cells from days 0–14 post-infusion defined six reproducible lymphocyte morphotypes based on cell size, nuclear contour, cytoplasmic texture, and granularity, with monocytes add as a distinct class (**Fig. 1B).** Using this framework, we trained MorphoCAR, a convolutional neural network that

achieved strong performance on patient-separated test data (macro-accuracy 83%, AUROC 0.98).
MorphoCAR was applied to 541,897 single-cell images derived from 11,625 peripheral blood smears obtained between days 0 and 30 following CAR-T infusion in a cohort of 622 patients. UMAP projection of learned embeddings revealed a coherent morphologic landscape with clear clustering by morphotype (**Fig. 1C**). Longitudinal analyses demonstrated dynamic morphotype trajectories (**Fig. 1D**), with variations by CAR-T product. For instance, large and small atypical lymphocytes (ALs) expanded early post-infusion, typically peaking on days 6–14 before contracting, whereas small round lymphocytes (SRLs) showed early expansion followed by stabilization. Large AL expansion was highest with liso-cel and cilta-cel and lowest with tisa-cel.
Among patients with large B-cell lymphoma (n=322) treated with axi-cel, liso-cel, or tisa-cel, higher peak abundance of large AL morphotypes during the early expansion window was independently associated with improved progression-free survival in multivariable Cox models landmarked at day 14 (**Fig. 1E**). No prognostic association was observed for other morphotypes or for absolute lymphocyte count, underscoring the added value of morphology-resolved immune profiling.
In a subset of patients with paired PBS and ddPCR measurements, CAR transgene levels correlated positively with both large AL ($\rho = 0.534$, $p = 0.023$) and small AL ($\rho = 0.479$, $p = 0.044$) morphotypes. Finally, CAR-T cells expressing activation marker CD69 sorted from infusion products consistently exhibited morphologic features closely resembling the large AL phenotype.



Conclusions: Artificial intelligence applied to routine peripheral blood smears reveals quantitative and qualitative immune signals that enhance assessment of CAR-T activity and treatment risk. This study delivers the first scalable morphology-based monitoring tool for CAR-T therapy and create the basis for real-time immune analytics grounded in routine clinical data.

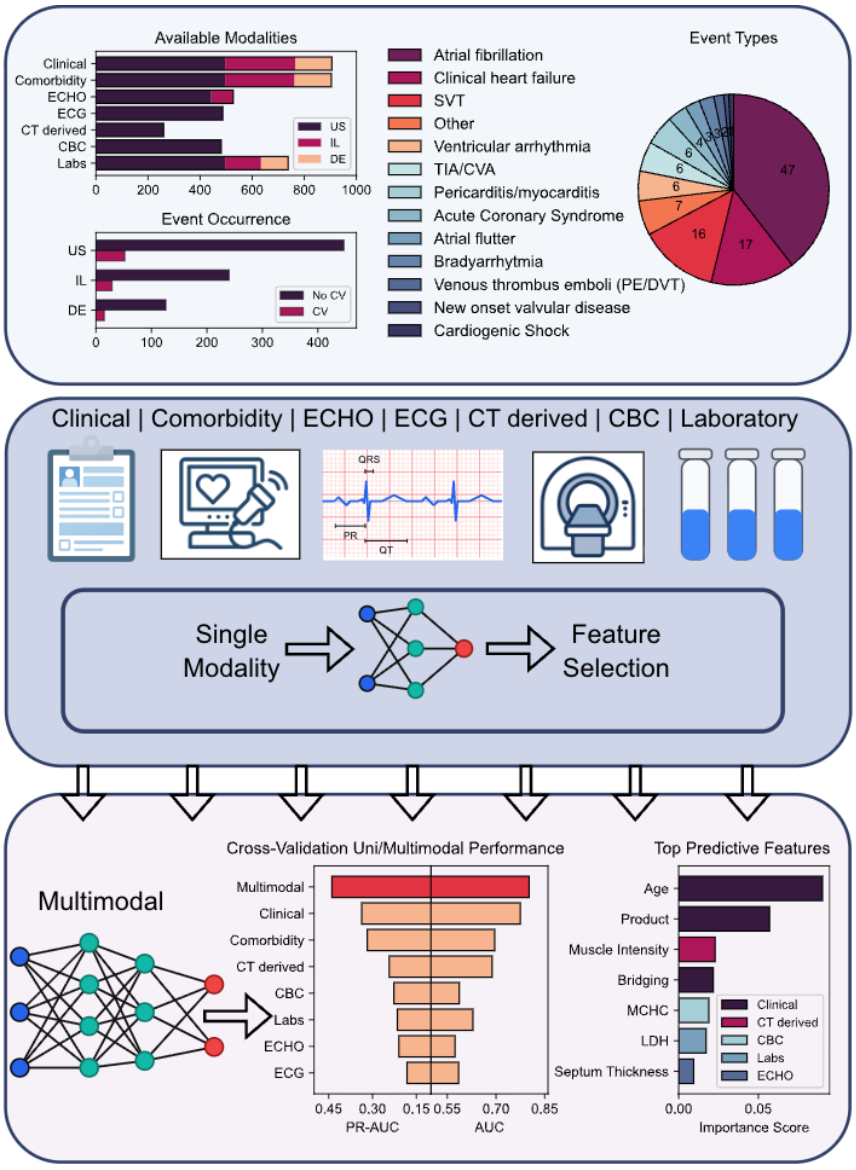
Background: Cardiovascular toxicity is an increasingly recognized complication of chimeric antigen receptor T-cell (CAR-T) therapy, yet remains difficult to anticipate at the individual patient level. Although comprehensive cardiovascular assessments are routinely performed prior to CAR-T, these heterogeneous data are not systematically integrated for risk stratification. We developed a multimodal machine-learning framework that integrates clinical, laboratory, imaging, and electrophysiologic data to predict early cardiovascular toxicity after CAR-T therapy.

Methods: We conducted a multicenter international study of adult patients treated with commercial CAR-T therapy for large B-cell lymphoma, mantle cell lymphoma, or indolent B-cell lymphoma across tertiary centers in the United States (US), Germany (DE), and Israel (IL). The primary endpoint was composite cardiovascular toxicity within 30 days of CAR-T infusion, including clinically significant arrhythmias, heart failure, ischemic and cerebrovascular events, and other major cardiovascular complications.
Pre-treatment data included clinical characteristics (demographics-, disease-, and treatment-

related factors) and comorbidities, laboratory testing and complete blood counts, electrocardiography (ECG), echocardiography, and CT-derived body composition features, with variable availability across centers (**Fig. 1**). Data were analyzed using a multimodal machine-learning framework with modality-specific encoders that integrate heterogeneous inputs and accommodate missing modalities. Model performance was assessed using internal cross-validation in the US development cohort and external validation across international cohorts, using area under the receiver operating characteristic curve (AUC) and precision–recall area under the curve (PR-AUC).



Results: The study included 906 patients across five centers (development cohort n=496; validation cohort n=410). Most patients had large B-cell lymphoma (development 83%, validation 86%), followed by mantle cell lymphoma (11%, 9%) and indolent B-cell

lymphoma (6%, 5%). CAR-T products included axi-cel (41%, 62%), tisa-cel (16%, 25%), liso-cel (37%, 4%), and brexu-cel (6%, 9%).
Approximately 10% of patients in the development cohort experienced cardiovascular toxicity within 30 days, most commonly arrhythmias. Event rates in external validation cohorts ranged from 7% to 15%.
In unimodal analyses, clinical characteristics, comorbidity profiles, and CT-derived body composition measures demonstrated the strongest predictive contribution, while laboratory parameters, complete blood counts, ECG, and echocardiography provided complementary information. Given the low event rate, PR-AUC was particularly informative (higher value corresponds with better performance). The multimodal model outperformed all unimodal approaches, achieving an AUC of 0.81 and PR-AUC of 0.43 in internal cross-validation (Fig. 1).
Feature-importance analyses (Fig. 1) for prediction of 30-day cardiovascular toxicity identified established clinical determinants, including age, CAR-T product, and bridging therapy, alongside modality-specific predictors such as CT-derived skeletal muscle radiodensity and CBC-derived hematologic indices, including mean corpuscular hemoglobin concentration.
External validation of the multimodal model demonstrated comparable discrimination despite heterogeneous data availability. In Israeli cohorts, performance was AUC 0.70; PR-AUC 0.26, and in the German cohort AUC 0.69; PR-AUC 0.30, indicating stable performance across independent healthcare settings.

Conclusions: This international multicenter study establishes an artificial intelligence–based multimodal framework for predicting early cardiovascular toxicity after CAR-T therapy. By integrating routinely collected pre-treatment data across clinical, imaging, and laboratory domains, this approach enables robust, generalizable risk stratification and supports a shift toward AI-informed, risk-adapted cardiovascular assessment and management in CAR-T recipients.

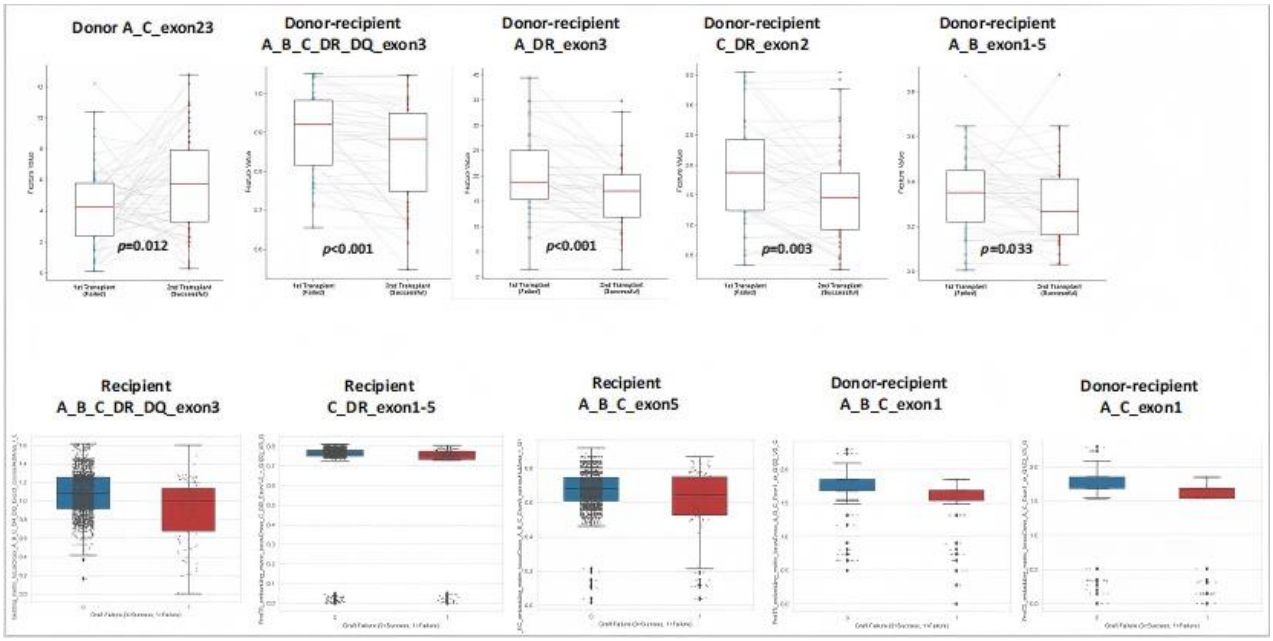
Background: Graft failure (GF) remains a fatal complication after haploidentical stem cell transplantation (haplo-SCT). While our previous multicenter, retrospective study suggested that changing donors improves outcomes in second transplantation (*Haematologica, 2025*), the underlying immunological mechanisms, particularly those involving donor-specific or donor–recipient paired factors remain unclear. In haplo-SCT, conventional HLA matching based on allelic identity often fails to capture subtle physicochemical and structural incompatibilities that drive immunogenicity. With recent advances in protein language models (PLMs), we employed a machine learning approach to explore the association between HLA structural features in donors or donor–recipient pairs and GF, aiming to identify HLA structural biomarkers for GF prediction.

Methods: 127 patients who experienced GF after haplo-SCT and subsequently underwent a second transplantation from the same (n=53) or a different donor (n=74) were analyzed. Using protein embedding models (ESM, ProtT5, and protV), functional embedding vectors from the amino acid sequences encoded by HLA alleles were extracted. Specifically, a novel PLM-based HLA functional diversity metric (the joint convex hull area) representing the total breadth of the HLA physicochemical landscape was defined. Metrics were calculated for donors and donor-recipient pairs in the GF cohort. Successful second donors from the same patients, as well as donors from a historical haplo-SCT cohort without GF (n=1,699), were used as control groups for comparative analysis.

Results: From an initial pool of 8,718 features, five structural features were identified to be significantly associated with GF ($p < 0.05$). Spatial mapping demonstrated that all five features involved cross-class interactions between HLA class I and class II loci, rather than single-locus effects, highlighting the importance of overall structural topology. Feature importance analysis revealed that one of the five features was donor-intrinsic, while the other four reflected interactions between donors and recipients. Compared with the successful second donors, the failed first donors exhibited a smaller hull area spanning HLA-A to HLA-C loci (A_C_exon23, p=0.012, HR=0.4987). Failed first donor–recipient pairs displayed larger hull areas across several multi-locus regions (A_B_C_DR_DQ_exon3, p<0.001; A_DR_exon3, p<0.001; C_DR_exon2, p=0.003; A_B_exon1-5, p=0.033;) relative to successful second-transplant pairs (Figure 1, top panels). Compared with the non-GF control cohort (n=1699), five structural features were established, including three recipient-intrinsic features (A_B_C_DR_DQ_exon3, C_DR_exon1-5, A_B_C_exon5) and two donor-recipient interaction features (A_B_C_exon1, A_C_exon1) (Figure 1, bottom panels). A composite risk score based on these five features showed robust predictive performance (AUC=0.656).



Conclusions: To our knowledge, this is the first study to interrogate GF mechanisms in haplo-SCT through an HLA immunogenicity lens using protein language models. Our findings suggest that, beyond conventional HLA matching, structural and spatial features of HLA molecules may identify “bad donors” or “bad pairs” that are at high risk for GF. This approach could refine donor selection and risk stratification regarding GF for haploidentical transplantation.

Background: GvHD remains a major cause of morbidity and mortality after allogeneic hematopoietic cell transplantation (alloHCT). Beyond HLA mismatch, GvHD occurrence in HLA-identical transplants suggests the relevance of minor histocompatibility antigens (mHAg), donor-recipient (D/R) differing peptides arising from genetic variation and expected to be highly immunogenic due to lack of donor tolerance. Recent collaborative studies in which a computational framework for exome-wide mHAg discovery was developed associated mHAg load with increased risk of acute GvHD (aGvHD) in AML/MDS patients treated with HLA-identical sibling-donor alloHCT (Cieri *et al.*, Nat Biotechnol. 2025). Since mHAgs as GvHD biomarkers beyond HLA-identical sibling-donor HCT remain unexplored, we herein aimed to assess such mHAg-GvHD association in the HLA-identical unrelated-donor HCT setting.

Methods: We recruited 52 AML/MDS patients receiving their first HLA-matched unrelated-donor HCT between 2013-2021 and analyzed D/R pairs through whole-exome sequencing and an adaptation of our previous pipeline. For mHAg load quantification, we filtered D/R identified variants to retain non-synonymous polymorphisms absent in the donor and occurring on genes expressed on GvHD target organs. We retrieved organ-specific expression profiles from single-cell RNAseq datasets (liver, lung, skin, vaginal wall, eye, gastrointestinal tract, oral mucosa and hematopoietic tissue), selecting all genes with pseudobulk expression above 20 counts per million in at least one cell cluster. Finally, we computed all variant-encompassing 8-11-mer peptides and kept those which could not arise from any other loci (blasting them against D/R exome-inferred proteomes) and which would be presented on patient-specific HLA-I molecules, relying on NetMHCpan-4.2 for binding assessment (predicted rank below 0.5%). We compared GvHD cumulative incidence (CI) between groups using Gray's test and Fine-Gray model for hazard ratio (HR) calculation, considering non-GvHD death and relapse as competing events.

Results: Median mHAg load was 1208 peptides, which we used to stratify patients into low or high mHAg groups. Although we did not find differences regarding chronic GvHD, our results showed greater grades II-IV aGvHD CI in patients with high mHAg load, *P*=0.049 (Gray's test) and HR [95% confidence interval] = 2.99 [0.98–9.15], *P*=0.055 (univariable Fine-Gray model) (Figure 1). Subsequent multivariable Fine-Gray analysis adjusting for D/R ages, female-to-male transplant, graft source, conditioning regimen and GvHD prophylaxis suggested mHAg load as independent predictor of grades II–IV aGvHD (Table 1).

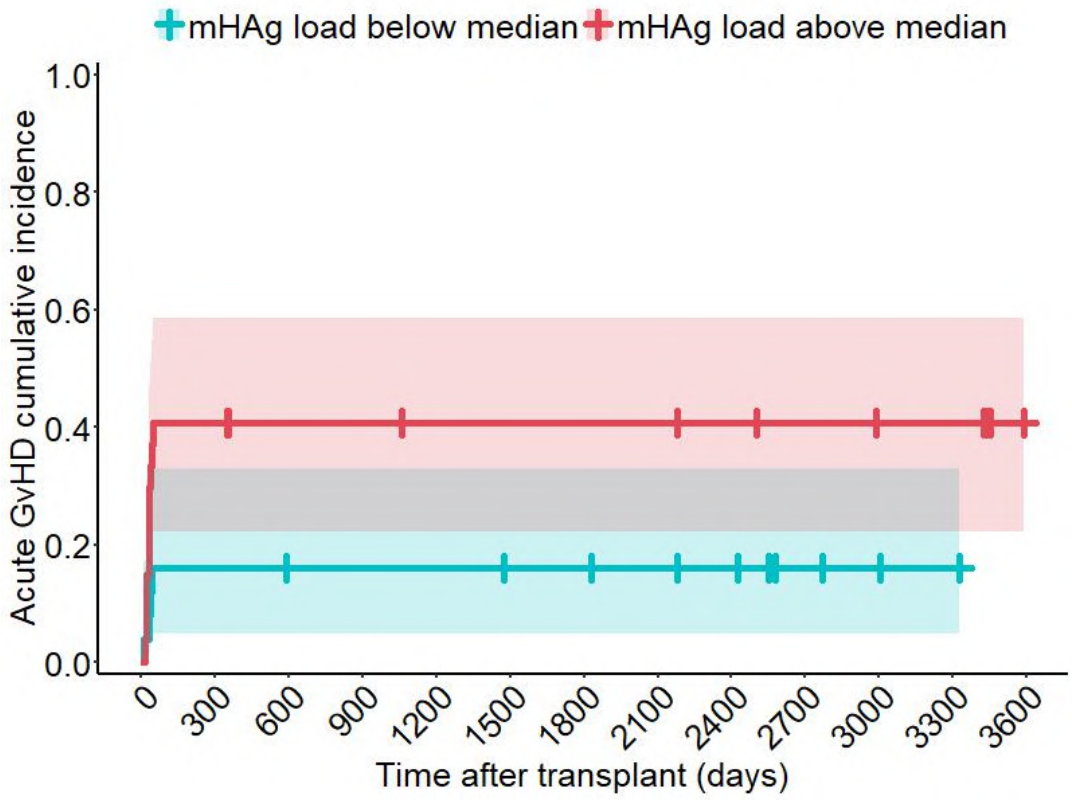

Figure 1: High mHAg load patients display greater aGvHD incidence after unrelated-donor HCT. Grades II-IV aGvHD CI of patients below (blue) or above (red) median mHAg number of 1208. One-year aGvHD CI [95% confidence interval] was 16% [4.9%–33%] and 41% [22%–59%] for low and high groups, respectively. Two-sided *P*=0.04919 (Gray's test); HR = 2.99 [0.98–9.15], *P*=0.055 (Fine-Gray model); n=52.

Variable	n (%) / median (IQR)	HR	95% confidence interval	P
mHAg load

Table 1: Multivariable Fine-Gray model for aGvHD risk assessment. mHAg: minor histocompatibility antigens; CNI: calcineurin inhibitor; PTCy: post-transplant cyclophosphamide; ATG: anti-thymocyte globulin; IQR: interquartile range; HR: hazard ratio.

Conclusions: Our results suggest mHAg as useful aGvHD biomarkers in HLA-identical unrelated-donor transplants. This supports the potential of mHAg-based donor selection and post-transplant risk stratification and therapeutic intervention to reduce aGvHD incidence and thus decrease healthcare costs and improve patients' quality of life.

Background: Allogeneic hematopoietic cell transplantation (allo-HCT) is the only potentially curative option for patients with myelodysplastic syndromes (MDS). However, only 10-15% access to this procedure, post-transplant outcomes remain highly heterogeneous, and widely used scores such as IPSS-R, developed outside the transplant setting, show only modest discrimination. Using the EBMT registry, we aimed to develop and validate a stacked machine-learning (ML) survival model for MDS patients undergoing allo-HCT and to benchmark it against other clinical scores (IPSS-R, HCT-CI) to assess its incremental prognostic value.

Methods: We analyzed 10,129 patients with MDS undergoing allo-HCT, partitioning the EBMT dataset by country into a ~70% training and ~30% test cohort. Missing baseline data were handled using Multiple Imputation by Chained Equations, incorporating 34 available pre-transplant variables into the models. Four survival analysis algorithms (L2-penalized Cox, elastic-net Cox, Random Survival Forest, and Gradient Boosting) were trained via cross-validation, and risk estimates were used to train a stacked survival model with penalized Cox and Random Survival Forest metalearners. Performance was evaluated in the geographically

independent test cohort using the concordance index and benchmarked against IPSS-R and HCT-CI.

Results: Thirty-four baseline variables were used for model development, including demographic characteristics (patient and donor age, sex), disease-related factors at diagnosis (blast percentage, cytogenetic risk, MDS subtype), performance status, donor–recipient compatibility measures (HLA matching, specific locus mismatches, donor relationship), transplant-related features (conditioning regimen, stem-cell source, type of GvHD prophylaxis), and established clinical indices (HCT-CI and IPSS-R). Four types of survival models were trained. In the training set, their performance was broadly comparable (CoxNet: 0.618, CoxPen: 0.620, RSF: 0.624, Gradient Boosting: 0.625). In the external test cohort, performance remained stable (CoxNet: 0.620, RSF: 0.616, Gradient Boosting: 0.620, CoxPen: 0.622). To improve predictive accuracy, out-of-fold risk estimates from all four models were combined into a stacked survival model. Among the two metalearners evaluated, the Random Survival Forest metalearner achieved the best internal performance (C-index 0.629 vs 0.628 for penalized Cox). In the external test cohort, the stacked model showed a C-index of 0.625, very similar to the penalized Cox metalearner (0.623). Compared with the stacked model, conventional clinical scores showed markedly weaker prognostic performance in patients with complete data (IPSS-R: n=2,489; HCT-CI: n=8,991). For IPSS-R, the C-index was 0.523 in train and 0.578 in test, while the stacked model reached 0.650 and 0.647, respectively. HCT-CI achieved 0.535 in train and 0.547 in test, compared with 0.642 and 0.629 for the stacked model.

Conclusions: We present a stacked ML survival model that outperforms established clinical risk scores, including IPSS-R and HCT-CI, while maintaining discrimination in an external, geographically independent test cohort. This integrative ML approach captures prognostic information beyond traditional scoring systems and substantially improves risk stratification for patients with MDS undergoing allo-HCT.

PROTEIN LANGUAGE MODEL-DERIVED FUNCTIONAL DIVERSITY METRIC OF HLA ALLELES BETWEEN DONOR AND RECIPIENT PREDICTS GRAFT FAILURE IN SALVAGE SECOND HAPLO-HSCT USING THE SAME DONORS

Rui Ma[1], *Xiao-Jun Huang*[1], *Yu-Qian Sun*[1], *Yijie Wang*[2], *Xiaobo Li*[2], *Xiangjun Liu*[2]
[1]*Peking University People's Hospital, Beijing, China,* [2]*Beijing BFR Gene Diagnostics Co., Ltd., Beijing, China*

Background: Graft failure (GF) is a severe and life-threatening complication of haploidentical hematopoietic stem cell transplantation (haplo-HSCT), and salvage second transplantation serves as a critical therapeutic strategy for patients with primary GF. Notably, from our previous study, recurrent GF remains highly prevalent in second transplantations when using the same donor (*Haematologica, 2025*), while the underlying immunogenetic mechanisms remain poorly elucidated. We hypothesized that functional diversity of HLA alleles between donor and recipient, extracted via protein language models (PLMs), might serve as a computational tool to dissect HLA-associated contributors to recurrent GF in salvage haplo-HSCT with the original donor.

Methods: We analyzed a cohort of 39 patients undergoing salvage haplo-HSCT with the original donor following primary GF. We utilized ProtV, a published PLM fine-tuned on Gene Ontology-Biological Process (GO-BP) annotations; this fine-tuning specifically aligns high-dimensional embeddings with immune regulation-related biological objectives (Fig.1a), thereby enhancing the capture of HLA molecules' functional relevance to immune recognition and antigen presentation. Principal Component Analysis (PCA) was applied to project HLA allele embedding vectors into a 2D functional space (Fig.1c), on which we introduced a novel PLM-based HLA functional diversity metric (defined by the joint convex hull area, Fig.1b) representing the total breadth of the HLA physicochemical landscape. Associations of this metric with GF post second transplantation were assessed using the Mann-Whitney U test, with false discovery rate (FDR) correction applied to adjust for multiple testing errors. The critical threshold of the convex hull area (0.2) was determined via receiver operating characteristic (ROC) curve analysis to maximize diagnostic accuracy for engraftment outcome.

Results: Among the 39 cases of original-donor retransplantation, 15 developed recurrent GF while 24 achieved successful engraftment, corresponding to an overall engraftment success

rate of 61.5%. Despite identical donor-recipient pairings across the two transplantations, biologically aware embeddings from the ProtV-GO-BP model revealed distinct functional profiles between the engraftment success and recurrent failure groups. Specifically, the functional convex hull area formed by donor-recipient HLA-A and HLA-B alleles differed significantly between groups (Fig.1d): the median area was substantially higher in the successful engraftment group (0.19; interquantile range [IQR]: 0.12–0.37) than in the recurrent failure group (0.06; IQR: 0.04–0.15) (p=0.0069). For cases with a convex hull area > 0.2, the engraftment success rate reached 91.7% (11/12), whereas the rate dropped to 48.1% (13/27) for cases with an area ≤ 0.2. This finding indicates that broader functional diversity of donor-recipient HLA-A and HLA-B alleles is associated with a higher likelihood of successful salvage engraftment.

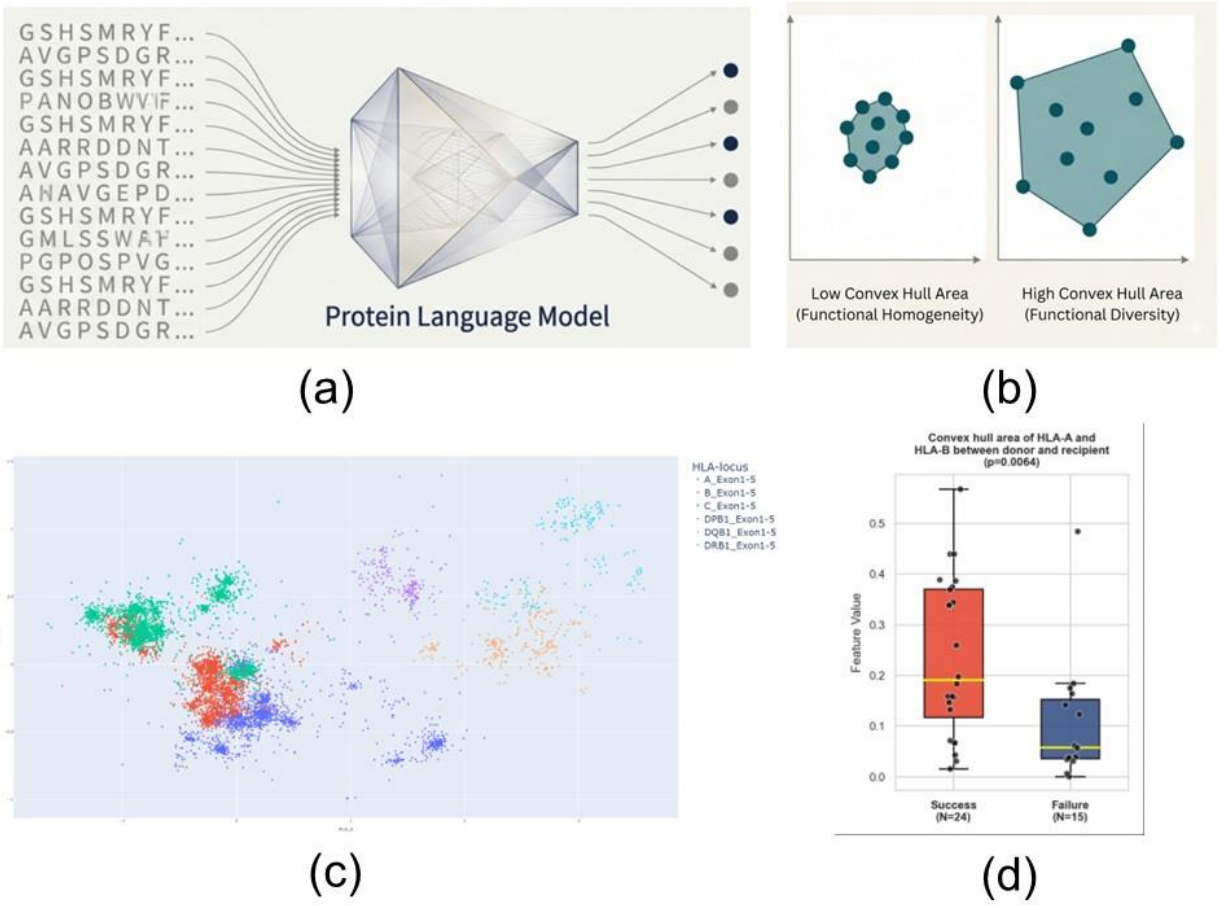

Figure 1. PLM-based HLA functional analysis workflow and clinical validation. (a) Schematic of transforming HLA amino acid sequences into high-dimensional functional embeddings using the **ProtV** protein language model. **(b)** Definition of the **Joint Convex Hull Area**, quantifying the physicochemical breadth of the combined donor-patient allele repertoire projected in 2D space. **(c)** Dimensionality reduction strategy using **ProtV fine-tuned on GO-BP** annotations to capture biologically relevant immune features via PCA. **(d)** Comparison of the **Joint HLA-A/B Convex Hull Area** in the second haplo-HSCT cohort (unchanged donors). The metric is significantly higher in the successful engraftment group (**n=24**) compared to the recurrent failure group (**n=15**) (**P=0.0069**, Mann-Whitney U test).

Conclusions: This study introduces a PLM-integrated geometric convex hull analysis as a novel approach to evaluating donor suitability in salvage haplo-HSCT using the original donor. While our findings are limited by the small sample size, this metric holds promise as a potential biomarker to aid clinical decision in donor selection for salvage second transplantations. Further validation in multicenter, large-scale cohorts is warranted to confirm its clinical utility.

AUTOMATED EXTRACTION AND VISUALIZATION OF PEDIATRIC BMT CLINICAL NOTES USING A COST-EFFICIENT GPT-4.1-MINI PIPELINE

Dua'a Zandaki[1], *Arwa Kiswani*[1], *Tasneem Guzu*[1], *Mayada Abu Shanab*[1], *Eman Khattab*[1], *Hasan Hashem*[1], *Rawad Rihani*[1], *Iyad Sultan*[1]
[1]*King Hussein Cancer Center, Amman, Jordan*

Background: Physician documentation in patient records is the ultimate source for data extraction for research purposes. Hematopoietic Stem Cell Transplant (HSCT) clinical notes carry a large load of information that need to be accurately detailed and organized, given the complicated variables and prolonged hospitalizations. However, free-text notes bring a major challenge in this realm, since they have a high rate of human errors and are add labor to the data extraction process.

Methods: We included 100 discharge summaries from records of patients admitted to receive HSCT. We used pydantic_ai (GPT-4.1-mini; mean 37 s/note, <$0.01) for data extraction, to fill 23 predefined fields relating to patient and transplant details and inpatient early post-transplant course. Three blinded human evaluators reviewed the discharge summaries and data extraction to score each extracted field. A two-review design produced 4,363 field-level decisions and 1,297 evaluator pairs. A 10% error threshold was set for non-approval of data extraction.

Results: Global approval of data extraction reached 96.8 % (4,223/4,363 fields). Fifteen fields achieved ≥99 % approval; a further six exceeded 90 %. Only two fields breached the 10 % non-approval threshold over 139 instances: pre-transplant morbidity (38.1 %) and engraftment kinetics (11.3 %). The non-approved instances spanned 97 notes and were dominated by "section extracted" (22 %) and missing conditioning-intensity keywords (10 %). Inter-observer raw agreement was 95.5 % across 1,297 pairs ($\kappa = 0.10$, reflecting class imbalance). Field-specific agreement ranged 78–100 %; conditioning intensity showed the most discordance ($\kappa \approx 0.42$). Independent evaluator-level approval rates were 95.2 %, 97.2 % and 97.6 %, respectively. The resulting dashboard successfully aggregated 723 pediatric HSCT episodes, allowing interactive queries on clinical data such as engraftment timing, GvHD prophylaxis and post-HSCT complications in under 2 seconds.

Conclusions: GPT-4.1-mini provided near-real-time, high-fidelity extraction of complex HSCT notes at negligible cost. Error clustering in pre-transplant morbidity and engraftment data fields prompts future engineering refinements for the platform. This interactive pipeline offers an opportunity for rapid and accurate data extraction of free-text clinical notes, tailored to BMT-related variables. Our future plan is to further enhance its performance so it serves in research data extraction and building quality dashboards for the department.

CREATING A POOL OF READY-TO-USE CORD BLOOD UNITS BY SELECTING DONORS USING HLA-INFORMED ALGORITHMS

Maude Dumont-Lagacé[1], *Gabrielle Thauvette*[2], *Albert Feghaly*[3], *Sandra Cohen*[4], *Guy Sauvageau*[3,2], *Diane Fournier*[1]
[1]*Héma-Québec, Montréal, Canada,* [2]*ExCellThera Inc, Montreal, Canada,* [3]*Institut de recherche en immunologie et cancérologie, Université de Montréal, Montréal, Canada,* [4]*Cellular Therapy & Transplantation Program, Maisonneuve-Rosemont Hospital and Université de Montréal, Montréal, Canada*

Background: Cord blood (CB) represents a readily available source of stem cell for hematopoietic stem cell transplantation, associated with a shorter time required for search and procurement compared to an adult donor. However, most CB units still require final release testing once they are reserved, a process which usually takes at least two weeks. CB units could be pre-qualified in advance to shorten this time, although at a non-negligible cost if applied to the entire CB bank.
In this study, we compared three different strategies for the selection of CB units with the objective to maximise the proportion of patients having access to a suitable graft in a small pool of selected CB units.

Methods: Two different HLA-informed selection algorithms were compared: (1) ECTmatch which optimizes donor selection based on HLA-typing data only, and (2) HQmatch which optimizes donor selection based on HLA-typing data and CD34 cell content and which selects a portion of donors specifically for ethnic minorities. These two algorithms are then compared to the selection of the same number of CB units based on their CD34 cell content (largest CB units). CB selection was done within the Hema-Quebec CB bank for CB units that contained a minimum of $7x10^6$ CD34 cells (n=2260).
Population coverage was assessed using two datasets: (1) donors registered in the Hema-Quebec registry (n=39 828), and (2) patients for whom a donor search has been performed at Hema-Quebec between January 2013 and October 2025 (n=6463). For the second dataset, patients were also analyzed in sub-groups according to age, ethnicity, country of residence and type of donor search. Patient weight was also used to assess whether the selected CB units contained enough total nucleated cells (TNC) and CD34 cells for a single CB transplant.

Results: ECTmatch and HQmatch significantly increased population coverage compared to the largest units. When only considering HLA-match, a small pool of 100 CB units selected using HLA-informed algorithms achieved a 55-60% population coverage for a 5/8 HLA match, compared to 30% with the 100 largest CB units.
When considering TNC, CD34 cell contents and HLA-matching, HQmatch outperformed ECTmatch for adult patients, who require larger CB units to achieve the targeted TNC and CD34 cell dose. When considering both cell dose and HLA-match, a small pool of 100 CB units selected using HQmatch achieved a 31% population coverage for a 5/8 HLA match, compared to 26% coverage with ECTmatch or 24% with the largest CB units.

In contrast, ECTmatch achieved slightly higher population coverage for pediatric patients (47%) compared to HQmatch (44%) and the largest units (23%), suggesting that ECTmatch selects a pool of donor with a slightly broader genetic diversity than HQmatch. When evaluating the algorithms performance for different ethnic groups, HQmatch achieved a higher population coverage than other selection strategies, especially for adult patients of Asian and Hispanics descents.

Conclusions: Using HLA-informed selection algorithm allows the selection of a small number of donors that significantly increases the percentage of patients having access to an adequately HLA-matched CB donor.

Disclosure: MDL and DF are employed at Hema-Quebec. GT is employed by ExCellThera Inc. SC is a consultant for the clinical program of ExCellThera and will receive royalties from the sales of UM171. GS is the founding scientist and major shareholder of ExCellThera which owns an exclusive license to use UM171 for stem cell expansion.

DEVELOPMENT OF A MACHINE LEARNING MODEL TO PREDICT PROGRESSION FREE SURVIVAL IN PATIENTS WITH MULTIPLE MYELOMA AFTER CAR-T CELL THERAPY

Anushri Soni[1], *Kimberly Seymour*[2], *Emma Cordover*[3], *Santiago Beltran*[4], *Chandan Das*[4], *R. Alejandro Sica*[2], *David Levitz*[2], *Ridhi Gupta*[2]
[1]*Jacobi Medical Center/ Albert Einstein College of Medicine, New York, United States of America (the),* [2]*Montefiore Einstein Comprehensive Cancer Center, New York, United States of America (the),* [3]*Albert Einstein College of Medicine, New York, United States of America (the),* [4]*Montefiore Medical Center, New York, United States of America (the)*

Background: In multiple myeloma (MM), accurate post–CAR-T progression-free survival (PFS) estimation is challenging in contemporary real-world cohorts because outcomes are evolving and follow-up is immature. Post–CAR-T PFS is important for patient selection and post–CAR-T maintenance and disease management. Machine-learning (ML) survival models may integrate high-dimensional clinical and biological data to support individualized risk estimation. Leveraging institutional experience with ML in hematologic malignancies, we developed an ML model for PFS prediction using patient-related, clinical, and laboratory data collected before and after CAR-T therapy in a real-world cohort.

Methods:

We identified 49 patients with MM treated with ciltacabtagene autoleucel (anti-BCMA CAR-T) at our institution between 9/2023 and 3/2025; data were obtained by manual chart review and modeled in Python. PFS was defined as time from CAR-T infusion to progression or death, censored at last follow-up.

Two approaches were evaluated: a Random Survival Forest and a ridge-penalized Cox model as a benchmark, each using demographic, disease, and treatment variables. Model

performance was assessed on a 20% held-out validation set using 6- and 12-month concordance indices, Brier scores, and comparison with a Kaplan–Meier model, with diagnostics examining follow-up maturity, censoring, event sparsity, and stability of risk rankings.

Results:

Forty-nine patients with relapsed triple-class-refractory MM were included, with median follow-up of ~13 months. The cohort had immature follow-up (76% censoring) with sparse events (12 PFS events). In the validation cohort, only two progression events occurred, and all samples had follow-up exceeding 314 days.

Global concordance for the RSF model was low (C-index = 0.23), reflecting metric instability with sparse events. Directional concordance was higher when risk rankings were inverted (C-index = 0.77), suggesting meaningful prognostic structure despite heavy censoring. Horizon-specific concordance at 6 months could not be estimated due to the absence of early progression events, indicating that early relapse risk cannot yet be reliably determined in this cohort. 12-month concordance estimates were less stable and highly sensitive to individual events because of limited event accrual within that time window.

Brier score analysis showed comparable calibration between the RSF and Kaplan–Meier models. The penalized Cox model yielded similar results, with no improvement in 12-month prediction error. Across both modeling approaches, diagnostic and resampling analyses consistently suggested underlying prognostic signal, with predictive performance constrained primarily by limited event accrual rather than model specification.

Conclusions:

In small, heavily censored real-world myeloma CAR-T cohorts, ML-based and penalized survival models identified biologically meaningful risk patterns, but individualized prediction was constrained by rare events. Calibration-based metrics and horizon-specific evaluation were more appropriate at this stage. Evaluation of 18-month concordance is planned as follow-up matures and additional progression events accrue. This study represents a methodological proof of concept for post–CAR-T PFS modeling. As follow-up matures, these models may support population-level risk stratification and inform post–CAR-T management strategies. Ongoing multi-institutional validation is planned.

Disclosure: Nothing to declare.

AN EXPLORATORY STUDY EVALUATING *T*UMOUR *R*ADIOMICS *A*S A *M*OLECULAR *A*DJUNCT IN *D*IFFUSE *L*ARGE *B*-CELL *L*YMPHOMA (TRAMADOL STUDY)

Amrita Guha[1], *Jayant S. Goda*[1]
[1]*Advanced Centre for Treatment, Research and Education in Cancer (ACTREC), Homi Bhaba National Institute, Navi Mumbai, India*

Background: Diffuse large B-cell lymphoma (DLBL) has been classified into two distinct molecular subtypes based on their cell of origin- namely germinal center B-cell-like (GCB) and activated B-cell-subtype (non-GCB) based on Han's algorithm. These two entities are also prognostically distinct. We assessed CT based tumour radiomic features using machine learning classifiers to distinguish the two molecular subtypes.

Methods: One hundred one patients of DLBL were accrued in the study after institutional ethics committee approval. GCB subtype was diagnosed in 59 while 42 patients were non-GCB subtype. Lesion with maximum SUV was delineated using a semi-automated segmentation method (3D slicer) and radiomic features were extracted using Pyradiomics. A total of 1030 features were extracted including Shape features, first, second, third, higher order and wavelet-based features. Recursive feature elimination was used for feature selection and optimal 10 features were selected. Five machine learning (ML) tools were used to build a model to sub- classify the two molecular subtypes. Model performance was assessed using Accuracy, Precision, Recall, F1 score and Area under curve of receiver operating characteristic curve. The models were constructed by two methods.1) using a 10-fold internal cross validations strategy and 2) by splitting the data set into training set (70%) and a validation set (30%).

Results: Recursive feature elimination using a random forest algorithm method was used to select 10 radiomic features. These features were then used to build the model using the 5 ML classifiers. Of the five classifiers, Random Forest Classifier (RFC) using a 70:30 training: test strategy was the best performer among all the ML models, with the highest accuracy of 80%, AUC of 0.87, recall(sensitivity), f1score(specificity) & precision (Positive Predictive value; PPV) or precision of 82% respectively. When an internal 5-fold cross validation strategy was used, RFC again performed better than other ML classifiers with an accuracy of 75%, AUC of 0.80, recall of 79%, PPV of 77% and specificity of 79%.

	Validation	Model	Accuracy	Classification report			AUC
				Precision	Recall	f1-score	
Random Forest Classifier (RFC)	10-folds cross-validation	RFC	0.75±0.10	0.79±0.12	0.79±0.14	0.77±0.12	0.80±0.1
	Train-Test(7:3)	RFC	0.80	0.82	0.82	0.82	0.87
Support vector classifier (SVC)	10-folds cross-validation	SVC	0.61±0.15	0.63±0.12	0.76±0.16	0.69±0.13	0.70±0.1
	Train-Test(7:3)	SVC	0.73	0.75	0.78	.81	0.75
Gradient Boosting Classifier (GBC)	10-folds cross-validation	GBC	0.65±0.12	0.72±0.14	0.68±0.13	0.69±0.10	0.70±0.1
	Train-Test(7:3)	GBC	0.63	0.65	0.76	0.70	0.81
Naive Bayes Classifier	10-folds cross-validation	NBC	0.64±0.16	0.67±0.13	0.77±0.13	0.71±0.12	0.63±0.2
	Train-Test(7:3)	NBC	0.67	0.83	0.87	0.85	0.68
AdaBoost Classifier (ABC)	10-folds cross-validation	ABC	0.73±0.13	0.76±0.14	0.79±0.13	0.77±0.11	0.76±0.1
	Train-Test(7:3)	ABC	0.68	0.75	0.78	0.75	0.74

Conclusions: Models using machine-learning based radiomics features extracted from pre-treatment CT images can provide a simple and non-invasive method for the prediction of DLBL molecular subtypes with favourable predictive accuracy. The Random Forest Classifier was the most accurate in distinguishing GCB subtype from the ABC subtype.

NANOBODY-DERIVED CD19/CD22 TANDEM CAR-T THERAPY AS SALVAGE TREATMENT FOR IMMUNOTHERAPY-REFRACTORY B-ALL AFTER BLINATUMOMAB, INOTUZUMAB, OR PRIOR SINGLE-TARGET CAR-T: PHASE 1A DOSE FINDING AND RP2D EVALUATION

Yi-Han Yang[1,2,3], *Ting Zhao*[1], *Ying Wu*[1], *Yao Chen*[1], *Ting-Ting Han*[1], *Jing Liu*[1], *Hai-Xia Fu*[1], *Xu-Ying Pei*[1], *Yu-Qian Sun*[1], *Xiao-Dong Mo*[1], *Yu Wang*[1], *Lan-Ping Xu*[1], *Xiao-Hui Zhang*[1], *Xiang-Yu Zhao*[1], *Meng Lv*[1,2,3], *Xiao-Jun Huang*[1,2,3]
[1]*Peking University People's Hospital, Beijing, China,* [2]*Peking University Institute of Hematology, Beijing, China,* [3]*National Clinical Research Center for Hematologic Disease, Beijing, China*

Background: Emerging data from single-target CAR-T trials (e.g., ZUMA-3) indicate that prior exposure to immune-based therapies significantly compromises CAR-T efficacy in R/R B-ALL. As immunotherapies such as Blinatumomab, inotuzumab, and prior CAR-T are increasingly used, effective salvage strategies for immunotherapy-refractory disease remain an unmet clinical need. Nanobody-derived CD19/CD22 tandem CAR-T therapy represents a promising high-activity salvage approach for this population.

Methods: Unique alpaca-derived nanobodies (VHHs) targeting CD19 and CD22 were screened and engineered into a tandem dual-target CAR construct (SL0217). In the phase I study (NCT06880913), a standard 3+3 dose-escalation design is being used to evaluate the safety and tolerability of autologous nanobody-based CD19/CD22 CAR-T cells and to determine the recommended phase 2 dose (RP2D). Three dose levels are tested: 0.3×10^6, 1.0×10^6, and 2.0×10^6 CAR-T cells/kg. Following dose escalation, a single-dose expansion cohort at the RP2D is conducted to further evaluate efficacy.

Results: As of Dec 2025, 35 patients with R/R B-ALL were enrolled; one patient with high tumor burden (PB blasts >90%) failed CAR-T manufacturing, and one withdrew after achieving remission with bridging therapy. Thirty-three patients received standard FC lymphodepletion followed by CAR-T infusion. During 3+3 dose escalation, one dose-limiting toxicity (DLT, grade 3 CRS resolving after 7 days) occurred at dose level 2, prompting cohort expansion without additional DLTs and allowing escalation to dose level 3, which was selected as the RP2D (2.0×10^6 cells/kg). Overall analyses were performed in 12 patients in dose-escalation and 12 patients in RP2D with completed M1 evaluation.
Bone marrow MRD was monitored by FCM, fusion gene qPCR, and NGS-IgH monthly for the

first 6 months and every 3 months thereafter, while extramedullary disease(EMD) was assessed by PET–CT at baseline, M1, and M3. Among the 24 evaluable patients, the median age was 34.5 years, and 62.5% were male. All patients were heavily pretreated, with **prior exposure to blinatumomab (41.6%), inotuzumab (41.6%), prior CD19 CAR-T (37.5%), or CD22 CAR-T (8.3%); 58.3% had prior allogeneic HSCT.** Dual CD19/CD22 expression was observed in 87.5% of patients. Disease involvement included isolated bone marrow (37.5%), extramedullary diseases (29.1%), or both (33.3%), with a median pre-lymphodepletion marrow blast of 12.0% (Interquartile range 0.5-79.5%).
CAR-T cells reached peak expansion at a median of 14 days after infusion. Grade 1–2 CRS occurred in 58.4% of patients, while CRS ≥3 was observed in two patients (8.3%), including one RP2D patient who died from progressive leukemia with pericardial infiltration. No ICANS was observed; one patient developed tumor inflammation–associated neurotoxicity (TIAN). Grade 3–4 early neutrophil Immune effector cell–associated hematotoxicity(N-ICAHT) occurred in 29.1%. **The ORR (CR/CRi/MLFS) was 83.3% (20/24), including 82.4%(14/17) in bone marrow disease and 93.3%(14/15) in extramedullary disease.** Among patients achieving bone marrow response, **100% attained MRD negativity across all available assessment methods**. Median PFS and OS were not reached, with 6-month PFS and OS of 58.8% (95% CI, 37.6–91.9%) and 89.0% (95% CI, 75–100%), respectively.

Characteristics		**Characteristics**		**Characteristics**		**Safety**

Background: Most adult patients with r/r B-ALL suffer disease progression, indicating a need for more effective therapies. Rapcabtagene autoleucel is an innovative autologous next-generation CD19-directed chimeric antigen receptor (CAR)-T cell therapy, rapidly manufactured using the T-Charge™ platform. Here we present safety and efficacy data for

rapcabtagene autoleucel in adults with r/r B-ALL in a phase 1, multicenter study (EUCT number: 2023-507062-34-00).

Methods: Eligible patients were ≥18 years of age, had CD19-positive r/r B-ALL, morphologic disease in the bone marrow, ECOG 0-1, and ≥1 of the following: prior allogeneic hematopoietic stem-cell transplantation (alloHSCT), ≥2 prior therapeutic lines, primary refractory disease, relapse within 12 mo of first remission, or Philadelphia chromosome-positive B-ALL with failure/intolerance of ≥2 different tyrosine kinase inhibitors. Patients received single-infusion rapcabtagene autoleucel at targeted dose level (DL) DL1 (2.5×10^6 CAR+ cells), DL2 (5×10^6 CAR+ cells), DL3 (7.5×10^6 CAR+ cells), or DL4 (12.5×10^6 CAR+ cells). Primary endpoints characterized safety and dose-limiting toxicities (DLTs) to identify a recommended dose. Secondary endpoints include best overall response (BOR) of complete remission (CR)/CR with incomplete blood count recovery (CRi) by month 3, and duration of response (DOR).

Results: At data cutoff (February 20, 2025; median follow-up from infusion: 27.7 [18.9-49.5] months), 35 (85%) of 41 enrolled adult patients with r/r B-ALL received rapcabtagene autoleucel: DL1 (n=10), DL2 (n=6), DL3 (n=12), DL4 (n=6), and 1 patient, assigned to DL3 received 18.9×10^6 CAR+ cells. Median age was 41 years, 91% received ≥2 prior lines (range 1-10), and 66% had prior alloHSCT. Sixteen (46%) patients were previously treated with blinatumomab and 13 (37%) patients with inotuzumab. Median (range) time from most recent relapse/progression to infusion was 2.3 (1.0-7.6) months. Reported adverse events are summarized in **Table 1**. DLTs were experienced by 2/10 patients at DL1 (1 patient: Grade 5 cytokine release syndrome [CRS]; 1 patient: Grade 4 neurotoxicity, Grade 3 CRS, Grade 4 bone marrow failure), 1/6 patients at DL2 (Grade 4 CRS, Grade 4 ICANS), 1/12 patients at DL3 (Grade 4 neutropenia) and 0/6 patients at DL4. BOR (CR/CRi) by 3-month was achieved in 70% (40% / 30%), 100% (50% / 50%), 92% (50% / 42%), and 83% (67% / 17%) patients at DL1, DL2, DL3 and DL4 respectively. Median DOR was 5.3 months for DL1 and 10.8 months for DL2 and not reached for DL3 or DL4. Cellular expansion was higher at DL2 (139,000 copies/µg DNA), DL3 (55,300 copies/µg), and DL4 (68,300 copies/µg) compared with DL1 (20,900 copies/µg). Median time to last detectable CAR19 transgene concentration was 91, 226, 57, and 181 days for DL1, DL2, DL3, and DL4, respectively.

AE, adverse event; CRS, cytokine release syndrome; DL, dose level; DLT, dose-limiting toxicity; ICANS, immune effector cell-associated neurotoxicity syndrome; NE, not estimable.				

Conclusions: Data from this phase 1 study suggest high cellular expansion, durable efficacy for DL2–DL4, and a manageable safety profile of rapcabtagene autoleucel in adult patients with r/r B-ALL. DL3—at which 92% of patients achieved BOR of CR/CRi by 3 months, with median DOR not reached after 22 months median follow-up— exhibited a favorable risk-benefit based on safety, cellular expansion, and encouraging efficacy.

Background: Allogeneic hematopoietic cell transplantation (allo-HCT) remains a key component in the management of Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph+ ALL), particularly in patients with high-risk genetics and delayed measurable residual disease (MRD) clearance. Multiple TKIs are used in frontline therapy, including imatinib and more potent second- and third-generation TKIs. Early molecular remission is more frequently achieved with newer generation TKIs, and predicts better long-term outcomes. However, the impact of different TKIs used before and after allo-HCT on long-term clinical outcomes in Ph+ ALL remains to be explored.

Methods: This retrospective registry-based analysis used data from the European Society for Blood and Marrow Transplantation. Adult patients (≥18 years) diagnosed with Ph+ ALL, treated with TKI-based induction therapy, and who underwent allo-HCT in CR1 regardless of MRD between 2010 and 2022 were included. The use of a prophylactic TKI was evaluated as a time dependent covariate in an adjusted Cox model.

Results: A total of 958 patients were analyzed (median age: 44 years [range 18–76]; 54% male). The median time from diagnosis to transplant was 5.5 months. At the time of allo-HCT, 61% were MRD-undetectable, assessed by PCR (75%) or flow cytometry (21%). Donors included matched related (37%), haploidentical (21%), and matched unrelated (26%). Peripheral blood stem cells were used in 84% of cases, with 79% receiving myeloablative conditioning, and 51% receiving total body irradiation.
TKI use prior to transplant included imatinib (N=612, 64%), dasatinib (N=210, 22%), nilotinib (N= 96, 10%), and ponatinib (N=40, 4%). Ponatinib was more frequently used in recent years and in older patients. Baseline characteristics, including MRD status at transplantation, were otherwise balanced across TKI groups.
The 3-year post-allo-HCT prophylactic TKI incidence was 31% including imatinib (51%), dasatinib (28%), nilotinib (16%) and ponatinib (3%). After a median follow-up of 5.2 years (95% CI: 4.9-5.7), 3-year overall survival (OS) was 73% (95% CI: 70–76) and leukemia-

free survival (LFS) was 62% (95% CI, 59–65). Three-year OS was 70% with imatinib, 78% with dasatinib, 81% with nilotinib, and 84% with ponatinib. Corresponding 3-year LFS rates were 57%, 69%, 75%, and 70%, respectively. The 3-year cumulative incidence of relapse was 21%, and graft-versus-host disease–free, relapse-free survival was 47%.
Multivariable analysis showed that use of pre-transplant TKIs other than imatinib was independently associated with improved LFS (hazard ratio [HR]: 0.75; 95% CI: 0.58–0.97; p=0.03). Increasing age negatively affected both LFS and OS. Use of a prophylactic post-allo-HCT TKI was associated with significantly improved LFS (HR: 0.62) and OS (HR: 0.50), both p<0.001. Donor type, TBI use, and pre-transplant MRD status were not significant predictors of survival outcomes.

Conclusions: In this large, multicenter cohort of patients with Ph+ ALL undergoing allo-HCT in CR1, the use of second- and third-generation TKIs during induction was associated with superior survival outcomes compared to imatinib. Post-transplant TKI prophylaxis significantly improved survival regardless of pre-transplant MRD status. These findings support the incorporation of newer TKIs and prophylactic strategies in the transplant setting to optimize long-term outcomes in Ph+ ALL.

Clinical Trial Registry: Not applicable.

Background: Obe-cel is an autologous fast off-rate 41BB-ζ CD19-directed chimeric antigen receptor (CAR) T-cell therapy, with demonstrated efficacy and low, single-digit incidence of severe immunotoxicity in adult patients with R/R B-ALL, based on data from the Phase Ib/II FELIX study (NCT04404660). Here, we report long-term clinical outcomes in patients who achieved remission in FELIX, presented by best overall response (BOR). These data provide beneficial information for evaluating treatment efficacy and guiding clinical decision making.

Methods: In FELIX, overall remission was defined as a BOR of complete remission (CR) or CR with incomplete haematological recovery (CRi). CR criteria were <5% blasts in the bone marrow, no extramedullary disease, no circulating lymphoblasts in peripheral blood, absolute neutrophil count (ANC) >1000/μL, platelet count >100,000/μL, no platelet transfusions in the last seven days and no administration of short-acting granulocyte colony-stimulating factor (G-CSF) and long-acting G-CSF in the last three and 14 days, respectively. CRi was defined as CR criteria with recovery of platelets to ≤100,000/μL and/or recovery of ANC to

<1000/µL. Duration of remission, EFS and OS were summarised using Kaplan-Meier methodology.

Results: In FELIX, 78.0% (99/127) of infused patients achieved remission following treatment with obe-cel (responders); 73.7% (73/99) achieved CR (CR group) and 26.3% (26/99) achieved CRi (CRi group) anytime following obe-cel infusion. The CRi group were more likely to have received ≥3 lines of prior therapy (42.3% vs 30.1%; prior blinatumomab or inotuzumab ozogamicin: 65.4% vs 43.8%) and had higher median bone marrow blasts at screening (78.5% vs 30.0%) vs the CR group. The median study follow-up was 32.8 months (range: 19.9–52.8). Long-term outcomes in responders and by BOR are summarised in the **Table**. Of the responders, 38.4% (38/99) were in ongoing remission without receiving other anti-cancer therapy, excluding tyrosine kinase inhibitors: 42.5% (31/73) of the CR group and 26.9% (7/26) of the CRi group. Whilst in remission, 18.2% (18/99) of responders received consolidative stem cell transplant at the investigators' discretion: 16.4% (12/73) of the CR group and 23.1% (6/26) of the CRi group. Median EFS (95% confidence interval [CI]) was 44.6 months (14.3–not estimable [NE]) in responders, 44.6 months (15.1–NE) in the CR group and 6.1 months (2.9–NE) in the CRi group. Median OS (95% CI) was 28.8 months (21.0–NE) in responders, 44.6 months (23.8–NE) in the CR group and 11.9 months (6.7–28.8) in the CRi group.

Conclusions: Most patients with R/R B-ALL who achieved remission following obe-cel achieved CR. Interpretation of long-term outcomes among the CRi group remains limited due to the small number of individuals in this subgroup. A substantial number of patients who responded to obe-cel treatment had a sustained survival benefit, regardless of BOR, with the most pronounced long-term benefit observed in patients who achieved CR.

Table. Long-term outcomes in responders and by best overall response.

Clinical outcome	**Responders (n=99)**	**Patients who achieved CR (n=73)**	**Patients who achieved CRi (n=26)**
Median DoR, months (95% CI)*	42.5 (12.5–NE)	42.5 (14.2–NE)	5.2 (1.4–NE)
12-month rate, % (95% CI)	61.8 (50.1–71.5)	68.3 (54.8–78.5)	40.9 (19.5–61.4)
24-month rate, % (95% CI)	54.1 (42.1–64.6)	58.0 (43.9–69.8)	40.9 (19.5–61.4)
Median EFS, months (95% CI)*	44.6 (14.3–NE)	44.6 (15.1–NE)	6.1 (2.9–NE)
12-month rate, % (95% CI)	63.2 (51.5–72.7)	68.1 (54.6–78.4)	47.4 (24.8–67.1)
24-month rate, % (95% CI)	54.1 (42.1–64.6)	57.9 (43.8–69.7)	41.5 (19.8–62.0)
Median OS, months (95% CI)‡	28.8 (21.0–NE)	44.6 (23.8–NE)	11.9 (6.7–28.8)

12-month rate, % (95% CI)	73.7 (63.9–81.3)	82.2 (71.3–89.2)	50.0 (29.9–67.2)
24-month rate, % (95% CI)	56.0 (45.6–65.2)	62.1 (49.7–72.3)	38.5 (20.4–56.3)

*DoR/EFS censoring for non-protocol anti-cancer therapies, including consolidative SCT.
‡OS without censoring for consolidative SCT.
Disease assessment was completed by an independent response review committee.
CI, confidence interval; CR, complete response, CRi, CR with incomplete haematological recovery; DoR, duration of remission; EFS, event-free survival; NE, not estimable; OS, overall survival;
SCT, stem cell transplant.

Gemelli" IRCCS, Rome, Italy, [13]Ludwig-Maximilian University Munich, Munich, Germany, [14]IRCCS Istituto Clinico Humanitas, Rozzano, Italy, [15]Istituto di Ricovero e Cura a Carattere Scientifico, San Raffaele Scientific Institute, Milano, Italy, [16]Hospital Universitari i Politècnic La Fe, Valencia, Spain, [17]Chaim Sheba Medical Center, Tel Hashomer, Israel

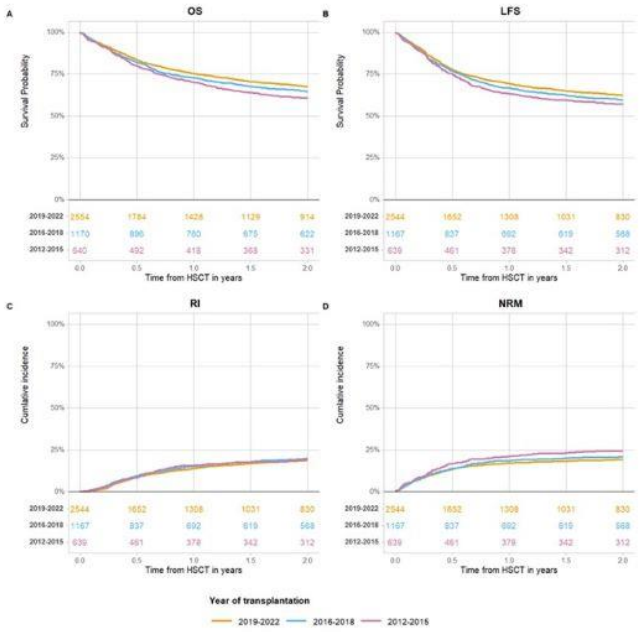
Background: Over the past decade, haploidentical stem cell transplantation (haplo-SCT) has evolved from an experimental approach to a standard option in many centers. This progress has been driven by the introduction of post-transplant cyclophosphamide (PTCy), the use of anti-thymocyte globulin (ATG), advances in HLA typing, and developments in immunology. However, limited data exist on longitudinal changes in haplo-SCT practices and associated outcomes. This study aimed to evaluate trends in graft source, GVHD prophylaxis strategies, and outcomes over time in patients with AML undergoing haplo-SCT.

Methods: Adult patients (≥18 years) receiving a first haplo-SCT for AML between 2012 and 2022 were identified in the EBMT registry. Three time periods were predefined for comparison: 2019–2022, 2016–2018, and 2012–2015. Patient-, disease-, and transplant-related characteristics were compared between groups using the Pearson's Chi-squared test for categorical data and the Kruskal-Wallis rank sum test for continuous data. All outcomes were measured from the time of transplant. NRM was calculated using cumulative incidence curves in a competing risk setting. LFS and OS were evaluated using the Kaplan-Meier

method. Univariate analyses were performed using the log-rank test for LFS and OS. A Cox regression multivariate analysis was used for all endpoints.

Results: A total of 6,818 patients were included: 1,207 (2012–2015), 1,914 (2016–2018), and 3,697 (2019–2022). PBSC became the dominant graft source, rising from 53.4% to 83.4% across the study periods (p<0.001). The proportion of patients transplanted in CR1 increased from 53% to 69.1%, while those with active AML decreased from 26.2% to 18.8% (p<0.001). Median age at transplant rose from 49.6 to 55 years (p<0.001), and the use of RIC increased from 36.2% to 43.3% (p<0.001). Donors were significantly younger in the most recent cohort, and there were also more male donors. GVHD prophylaxis practices evolved markedly: ATG without PTCy decreased from 21.8% to 11.8%, PTCy alone increased from 58.7% to 68.8%, and PTCy+ATG from 4.6% to 7.9% (p<0.001).
Among patients transplanted in CR1, 2-year outcomes improved over time. OS increased from 60.4% to 67.3%; LFS from 56.8% to 62.2%; and NRM decreased from 24.1% to 19.2%, however relapse incidence (RI) remained stable (19.1% vs. 18.6%).
In multivariate analysis using 2019–2022 as the reference, outcomes were significantly worse in earlier periods: OS: HR 1.42 (95% CI 1.17–1.73), p<0.001 ; LFS: HR 1.36 (95% CI 1.13–1.64), p=0.001 ; NRM: HR 1.61 (95% CI 1.25–2.08), p<0.001. No significant changes were observed in RI.

Outcomes in AML patients transplanted in CR1 : overall survival (OS), Leukemia-free survival (LFS), Relapse incidence (RI), Non-relapse mortality (NRM)



Conclusions: Since 2012, haplo-SCT for AML has expanded significantly, accompanied by major shifts in clinical practice: transplantation in older patients, increased use of RIC, greater proportion of transplants performed in CR1, widespread adoption of PBSC as the preferred graft source, and changing patterns of PTCy utilization. These evolutions were associated with significantly improved OS, LFS, and NRM. Relapse remains the main challenge, which underscores the importance of developing new conditioning regimens,

exploring the value of post-transplant maintenance therapy, and above all integrating targeted therapies and immunotherapy in order to improve patient outcomes.

Background: Core binding factor acute myeloid leukemia (CBF-AML), defined by t(8;21)/*RUNX1::RUNX1T1* or inv (16)/*CBFβ::MYH11*, is categorized as favorable-risk. We aimed to delineate the clinical similarities and differences between these two subsets.

Methods: 779 de novo CBF-AML patients (511 *RUNX1::RUNX1T1*, 225 *CBFβ::MYH11*) were enrolled (Figure 1A). Measurable residual disease (MRD) was assessed via multi-parameter flow cytometry (MFC-MRD) and quantitative polymerase chain reaction (Mol-MRD) during/after treatment. Responders are defined as achieving MRD negativity (MFC-MRD 0.01% aberrant cells and Mol-MRD > 3-log reduction) after the second consolidation cycle (C2). Otherwise, it is considered positive. Survival analyses employed Kaplan-Meier and landmark methods (3-month cutoff [corresponding to the median time of C2 completion] for immortal time bias). Treatment response comparisons used time-dependent Cox models, while relapse risks were evaluated via the Prentice, Williams and Peterson (total times) (PWP-TT) modeling.

Results: With a median follow-up of 34.6 months (range: 3.9-106.2), early mortality by C2 was lower in *RUNX1::RUNX1T1* (4.7%, n=25) versus *CBFβ::MYH11* (7.1%, n=18, P = 0.042) patients. The 3-year overall survival (OS) was significantly better in patients with

CBFβ::MYH11 compared to *RUNX1::RUNX1T1* (90.2% vs 80.6%, P = 0.011) .
695 patients were evaluable for C2 assessment, with 42.5% with *RUNX1::RUNX1T1*(n = 206) and 33.2% with *CBFβ::MYH11* fusions (n = 74) as responders (Figure 1A). Landmark analysis showed superior 3-year OS for *RUNX1::RUNX1T1* responders vs. non-responders (86.3% vs. 76.5%, P = 0.008) (Figure 1B), however, responders and non-responders have comparable survival outcomes in patients with *CBFβ::MYH11* (95.1% vs. 88.1%, P = 0.49) (Figure 1C). Multivariable Cox model and the PWP-TT model further identified non-responders at C2 as significant risk factors for *RUNX1::RUNX1T1* survival and relapse, respectively, with no associations in *CBFβ::MYH11*.
For *RUNX1::RUNX1T1* non-responders, Allogeneic hematopoietic stem cell transplantation (allo-HCT) provided a superior 3-year OS than chemotherapy (81.9% vs. 56.4%, P < 0.001) (Figure 1D), which was different from non-responders with *CBFβ::MYH11*(Figure 1E). Responders with *RUNX1::RUNX1T1* or *CBFβ::MYH11* had comparable outcomes when consolidated with allo-HCT or chemotherapy. Transplant in first CR provided better outcomes for *RUNX1::RUNX1T1* (CR1 vs. non-CR1: 3-year OS: 85.8% vs. 71.4%, P < 0.001; relapses: 8.3% vs. 18.9%, P = 0.024) (Figure 1F-G). Consolidation therapies did not show significant impacts on long-term outcomes in *CBFβ::MYH11* patients (Figure 1H-I).
At last, we developed a comprehensive predictive model by Logistics regression models for C2 response incorporating clinical factors: (age < 50y [1 score], initial white blood count [<10 × 109/L: 10 score; 10 -50: 1 score; 50-100: 2 score; ≥ 100: 3 scores]; hemoglobin < 100 g/L [1 score]), mutational profiling (KIT D816/D822 variants [3 scores], other KIT mutations [1 score], FLT3-ITD [1 score]), as well as initial RUNX1::RUNX1T1/ABL value (<500%[4 scores], 500-1000%[3 scores], 1000-1500%[2 scores], ≥1500%[1 score]). A score ≥8 predicted non-response with 78.3% specificity and 57.4% sensitivity, effectively identifying high-risk *RUNX1::RUNX1T1* AML cases needing transplant evaluation (Table 1).

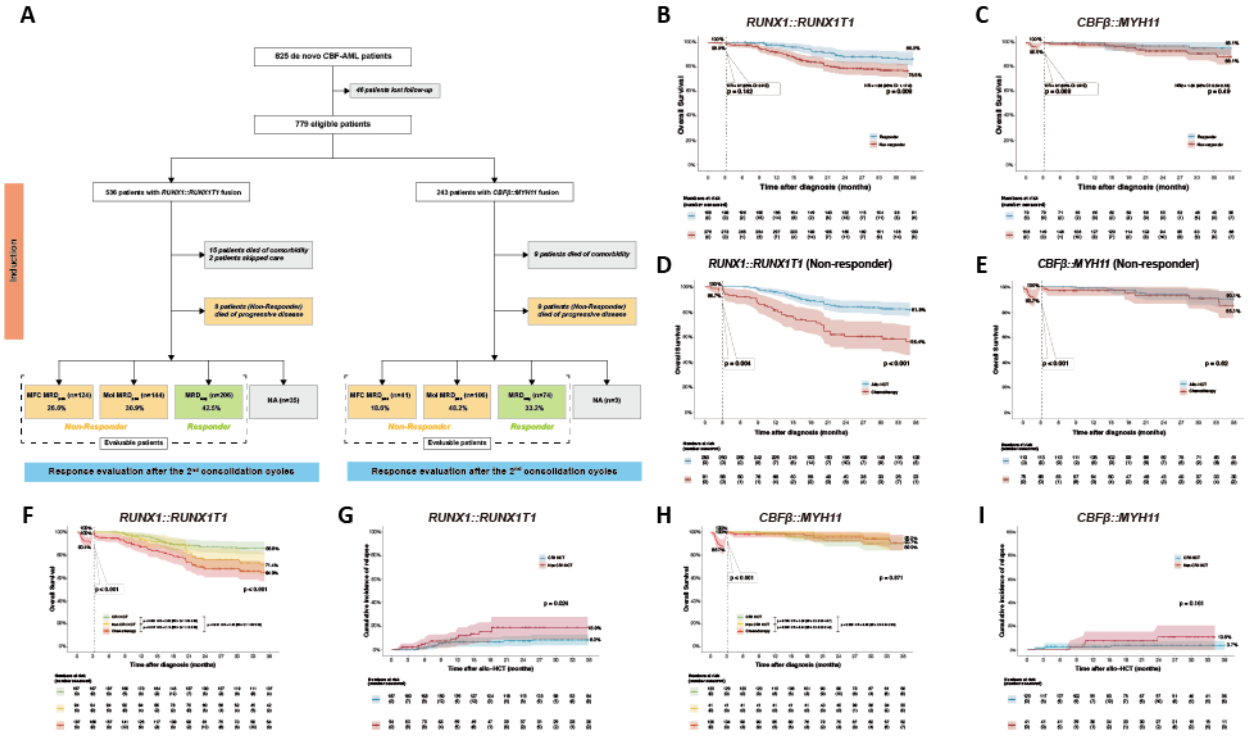

Figure 1. The diversity of CBF-AML. (A). Flow chart. Comparison of 3-year OS according to MRD status at PC2 among patients with RUNX1::RUNX1T1 **(B)**, patients with CBFβ::MYH11 fusions**(C).** Comparison of 3-year OS al between chemotherapy and allo-HCT in MRD non-responders at PC2 among RUNX1::RUNX1T1 **(D)** and CBFβ::MYH11 **(E)** patients. Comparison of 3-year OS or cumulative incidence of relapse (CIR) among patients with RUNX1::RUNX1T1 **(F-G)** or CBFβ::MYH11 **(H-I)** who underwent allo-HCT at different times or chemotherapy alone.

Table 1. Predictive scoring system for treatment response at PC2 in *RUNX1::RUNX1T1* patients.

Predictive variable	0	1	2	3	4
Age	≥50y	<50y	—	—	—
WBC count (× 10^9/L) at diagnosis	<10	10-50	50-100	≥ 100	—
Hemoglobin (g/L) at diagnosis	≥ 100	< 100	—	—	—
FLT3 mutations	WT or other FLT3 mutation	—	*FLT3-ITD*	—	—
KIT mutations	WT	Other KIT mutations	—	KIT D816/D822 mutations	—

Predictive variable	0	1	2	3	4
Initial RUNX1::RUNX1T1/ABL value at diagnosis	—	≥1500%	1000-1500%	500-1000%	<500%

— indicates not applicable.
Abbreviations: WBC, white blood cell; WT, Wild type.

Conclusions: For *CBFβ::MYH11* AML, C2 assessment offers minimal clinical significance, with allo-HCT reserved for CR2. In contrast, *RUNX1::RUNX1T1* patients with post-C2 MRD positivity should receive allo-HCT at CR1.

Disclosure: Nothing to declare.

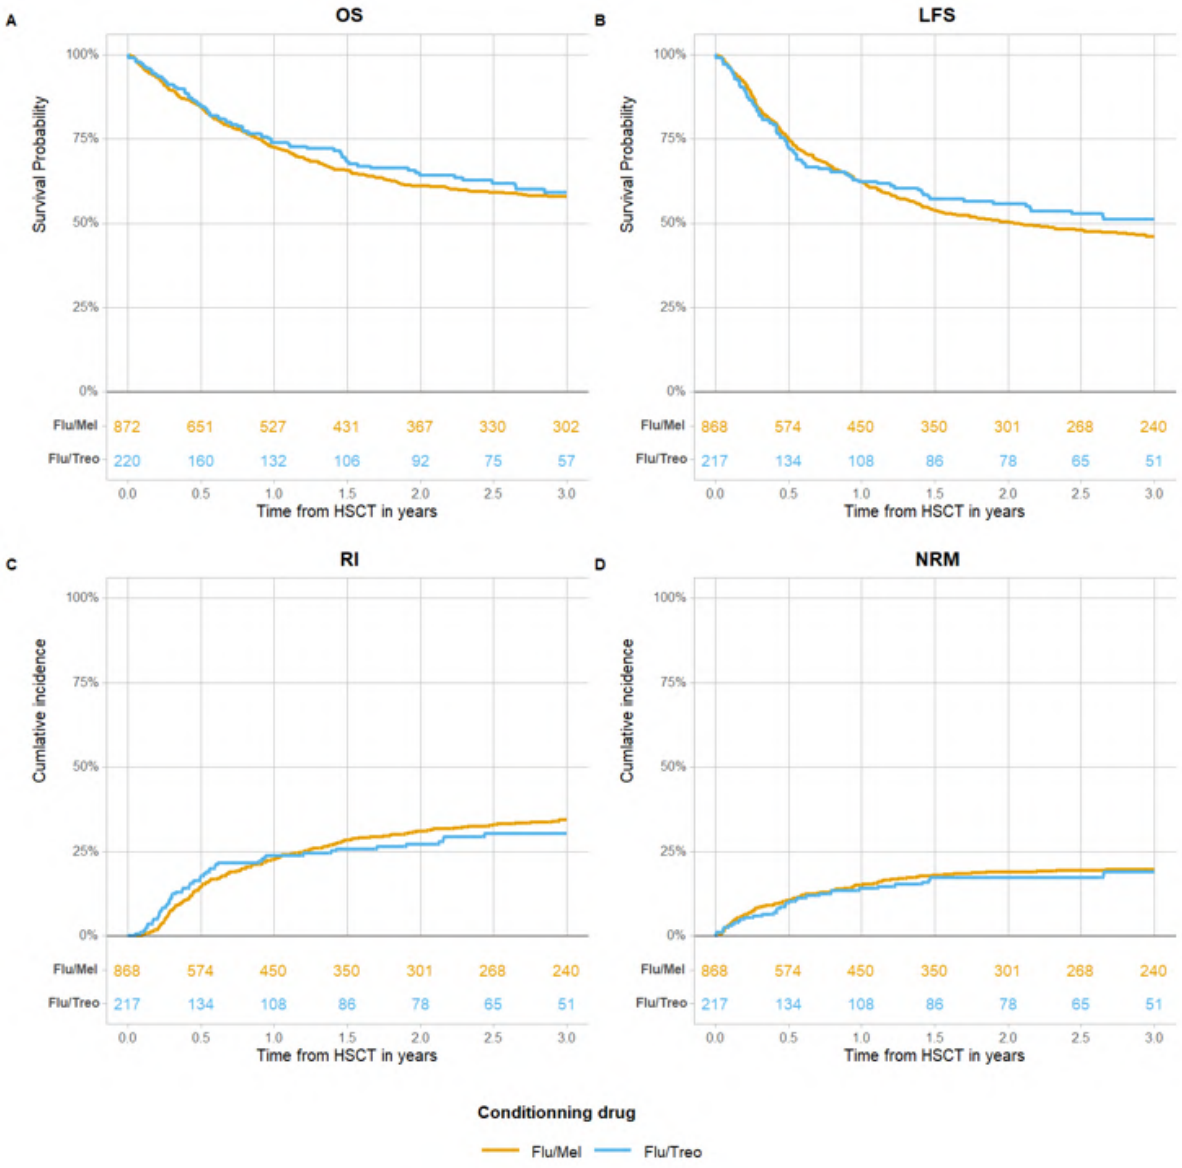
[17]EBMT, Sorbonne University, Hôpital Saint Antoine, Department of Hematology, Paris, France, [18]IRCCS San Raffaele Hospital Scientific Institute, Milan, Italy

Background: Allogeneic haematopoietic stem cell transplantation (allo-HSCT) is a potentially curative option for adult patients with high-risk acute lymphoblastic leukaemia (ALL), but outcomes are influenced by conditioning-related toxicity and disease control. Many patients are older or have comorbidities limiting the use of myeloablative regimens, leading to increased use of reduced- or intermediate-intensity approaches. Treosulfan offers a favourable toxicity profile while preserving myeloablative and anti-leukaemic activity, although evidence in adult ALL remains limited. This study evaluated whether fludarabine–treosulfan (Flu/Treo) provides survival and disease control comparable to fludarabine–melphalan(Flu/Mel) in adult ALL undergoing allo-HSCT.

Methods: This retrospective study included adult patients(≥18 years) with ALL undergoing first allo-HSCT between 2012 and 2024. Patients receiving Flu/Mel or Flu/Treo conditioning were analysed. Patients transplanted in CR1, CR2+ or with active disease were eligible, and all donor types were allowed. GVHD prophylaxis was administered according to centre practice.
The primary endpoint was 2-year leukaemia-free survival(LFS). Secondary endpoints included overall survival (OS), relapse incidence(RI), non-relapse mortality (NRM) and GVHD. Survival was analysed using Kaplan–Meier estimates, while competing risks methodology was applied for RI and NRM. Multivariable Cox models adjusted for relevant covariates. Subgroup analyses were performed in B-lineage and T-lineage ALL, with propensity score matching applied in T-ALL.

Results: A total of 1,097 adult patients were included, of whom 876 received Flu/Mel and 221 Flu/Treo conditioning. Median follow-up was 3.8 years overall and differed between groups, being longer in the Flu/Mel cohort (4.1 years) than in the Flu/Treo cohort (2.9 years), reflecting more recent adoption of treosulfan-based regimens. Patients treated with Flu/Treo were older at transplantation and more frequently received myeloablative-intensity conditioning, whereas Flu/Mel was predominantly administered as reduced-intensity conditioning.
Despite these differences, transplant outcomes were comparable. At 2 years, OS was 64.2% after Flu/Treo and 60.9% after Flu/Mel, while LFS was 55.7% and 50.3%, respectively. The cumulative incidence of relapse was numerically lower in the Flu/Treo group (27.1% vs 30.9%), whereas NRM was similar (17.1% vs 18.8%). In multivariable analysis adjusting for year of transplantation, disease status at transplant, performance status, patient and donor age, CMV serostatus and centre effect, Flu/Treo conditioning was independently associated with improved LFS (HR 0.70, 95% CI 0.52–0.94; p=0.018) and reduced relapse risk (HR 0.62, 95% CI 0.42–0.91; p=0.014), without increasing NRM. No significant difference in OS was observed.
Results were consistent in B-lineage ALL. In T-lineage ALL, a propensity score–matched analysis generated well-balanced cohorts (94 Flu/Mel and 36 Flu/Treo). In the matched population, 2-year OS (72.9% vs 65.7%), LFS (68.8% vs 59.5%), RI (21.9% vs 31.3%) and NRM (9.3% vs 9.1%) were comparable between regimens. Cox regression confirmed no significant association between conditioning type and outcomes.



Conclusions: In adult patients with ALL undergoing first allo-HSCT, Flu/Treo conditioning provides survival and disease control outcomes comparable to Flu/Mel. Flu/Treo was associated with similar overall survival and non-relapse mortality, and with improved leukaemia-free survival and reduced relapse risk in multivariable analysis. These findings, support Flu/Treo as an effective and safe intermediate-intensity conditioning alternative to Flu/Mel in adult ALL.

Background: Acute myeloid leukemia (AML) patients with t(16;21)(p11;q22)/*FUS::ERG* demonstrate poor outcomes even after allogeneic hematopoietic cell transplantation (allo-HCT). Therefore, it is necessary to investigate the clinicopathological features, genomic and transcriptomic landscape, as well as treatment outcomes in a larger cohort to gain an in-depth understanding of this specific subtype.

Methods: We initiated a retrospective study of adult patients in Chinese TROPHY group. Patients with t(16;21)(p11;q22)/*FUS::ERG* were identified by reviewing karyotypes, polymerase chain reaction or RNA sequencing (RNA-seq) results. The survival data were estimated using Kaplan–Meier curves and log-rank test. Prentice, Williams and Peterson total time (PWP-TT) model was used for analysis of recurrent time-to-event data, with results presented as hazard ratios (HR) and corresponding 95% confidence intervals (CI) for risk factors (age, gender, ELN risk stratification, and allo-HCT) regarding disease relapse. Data of 899 patients with transcriptome results were provided as a reference cohort.

Results: A total of 104 adult AML patients with *FUS::ERG* were identified, and RNA-seq were available in 25 patients. The median age was 35 (range: 14-73) years old, 13 patients aged older than 60. Patients showed high WBC (median: 12.9×10^9/L) and BM blast counts (median: 72.0%), M5 (51.0%) was the predominant FAB subtype. Complex karyotypes were found in 41.3% of patients. *PTPN11*, *RUNX1*, and *NRAS* are the most prevalent somatic

mutations. Ninety-two patients were stratified according to 2022 ELN with 56 (60.9%) cases in adverse-risk group. Ninety-one patients were eligible for intensive chemotherapy, 8 patients received low intensity induction. After two courses of induction, 83.8% patients achieved morphology complete remission (CR).

Characteristics	***FUS::ERG* fusion· (N=104)**
Male, *n* (%)	60 (57.7)
Age (median [IQR])	35.0 [22.5, 51.0]
White blood cell count (x10^9/L, median [IQR])	12.9 [4.0, 30.8]
Bone marrow blast% (median [IQR])	72.0 [55.0, 84.0]
Induction treatment, *n* (%) Intensive Lower-intensity Frail	 91 (87.5) 8 (7.7) 5 (4.8)
CR after 1st course, *n* (%)	61/99 (61.6)
MFC-MRD negativity after 1st course, *n* (%)	20/52 (38.5)
CR after 2nd course, *n* (%)	83/99 (83.8)
MFC-MRD negativity after 2nd course, *n* (%)	33/71 (46.5)
Allo-HCT in CR1, *n* (%)	55/83 (66.3)

The estimated 2-year probability of relapse, EFS, and OS of 77.2%, 18.7%, and 38.1%, respectively. Fifty-five patients underwent allo-HCT in CR1, 3 in CR2, and 7 in active disease. In CR1 cohort, both 2-year OS (allo-HCT: 59.1%, 95% *CI*: 46.2-75.5%; chemotherapy: 5.1%, 95% CI: 0.8-33.7%, *P*<0.0001) and EFS (allo-HCT: 34.1%, 95% *CI*: 22.7-51.2%; chemotherapy: 0%, *P*<0.0001) were improved significantly with allo-HCT. The PWP-TT model revealed higher risk of relapse in patients aged ≥60 (HR: 8.1, 95% CI: 2.7–23.7, *P*<0.001), and allo-HCT can significantly reduce recurrence (HR: 6.5; 95% CI, 3.8–11.4, *P*<0.001). Compared to reference cohort, *FUS::ERG* AML demonstrated similar long-term survival to the ELN adverse-risk group.

Transcriptome-based analysis clustered all 25 cases together and classified into the myelodysplasia-related/-like subtype.Differential expression gene (DEG) analysis revealed that insulin-like growth factor-2 mRNA-binding protein 1 (*IGF2BP1*) expression was significantly upregulated in *FUS::ERG* fusion AML comparing to reference cohort. Gene Ontology (GO) analysis indicated that immune function-related pathways were significantly down-regulated, including immune system process, immune response, regulation of immune system, MHC protein complex binding, antigen binding and immune receptor activity.

Elevated levels of *IGF2BP1* correlated with loss of MHC class II expression (HLA-DR, -DQ, -DP, -DM, -DO) alongside suppression of most immune stimulators (CD28, CD80, CD86, KLRK1 and TNFSF/TNFRSF).

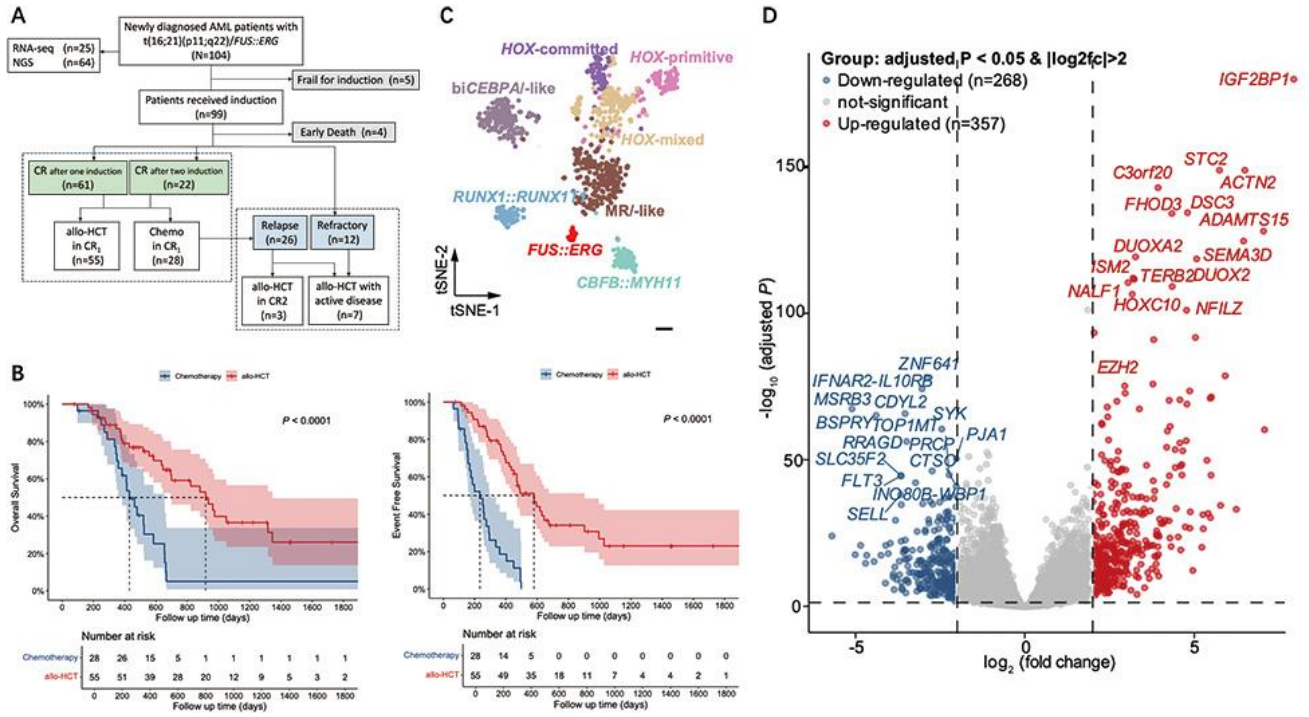

Figure 1. (A) Flow Chart. (B) Long-term survival of *FUS::ERG* AML. OS and EFS between patients treated with allo-HCT or chemotherapy for consolidation in CR1. (C) Transcriptome-based analysis clustered all 25 cases together. (D) Volcano plots show the positive and negative correlation of gene expression patterns.

Conclusions: We presented the largest comprehensive evidence to characterize adult AML with *FUS::ERG* fusion which demonstrate poor outcomes with high relapse even after allo-HCT. Immune-evasion phenotype driven by *IGF2BP1* overexpression may be the key factor contributing to the poor prognosis.

Background: Relapsed acute myeloid leukemia (AML) post allogeneic stem cell transplant (HSCT) remains a major challenge. Hypomethylating agents (HMA) alone or combined with venetoclax (VEN) are effective and well tolerated in newly diagnosed and relapsed AML. While the former have been used as maintenance, preemptive and salvage therapy to enhance graft-versus-leukemia effects; nonetheless, optimal combinations-particularly with VEN remain undefined.

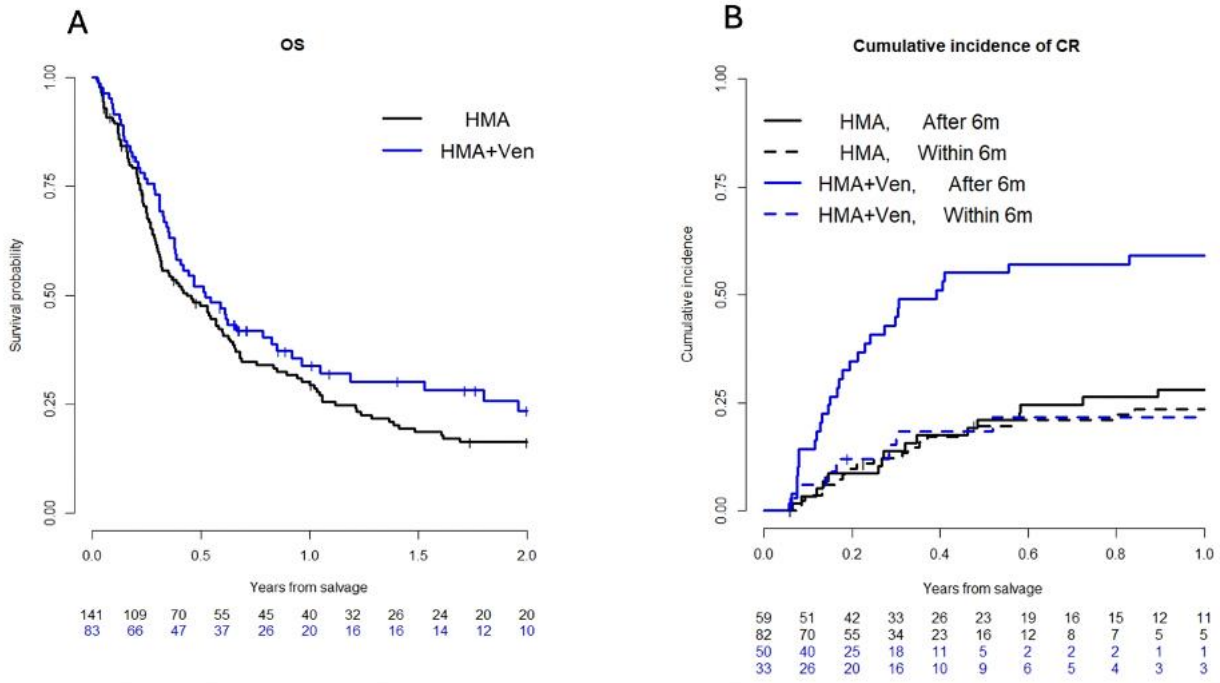
Methods: EBMT registry-based multicenter analysis approved by the ALWP, including adults who underwent first HSCT in first complete remission between 2010-2022 with subsequent relapse comparing outcomes with treatment with HMA alone or with venetoclax (started within 2 months of relapse).

Results: A total of 224 patients (NPM1 mutation in 17% and FLT3-ITD in 18%) with relapse post HSCT. Of the total cohort, 83 received HMA/VEN (75 azacitidine/VEN), while 141 patients received HMA alone (128 azacitidine). Most received peripheral blood stem cells (97%). Table 1 shows baseline characteristics for both groups. Pre-transplant azacitidine (21% vs. 8%; p=0.006) or VEN (11% vs. 2%; p=0.01) were more commonly used in the combination group. There was no significant difference with respect to gender or female donor to male recipient. HMA/VEN resulted in improved 1-year cumulative incidence of complete remission (CR) post salvage [44% (95% CI 33-55) vs. 26% (95% CI 19-33); p=0.003], and higher likelihood of second HSCT [27% (95% CI 17-38) vs. 12% (7-18)], with however no difference in 2-year overall survival (OS) from salvage [24% (IQR 14-35) in the HMA/VEN group vs.16% (IQR 11-23); p=0.18]. Relapse beyond 6 months post HSCT and the absence of adverse risk cytogenetics positively affected the 1-year cumulative incidence of CR post-salvage and 2-year OS, while female gender improved 2-year OS. In multivariable analysis, the absence of adverse cytogenetics (hazard ratio [HR] 0.68, 95% CI 0.5-0.9; p=0.01) and late relapse were predictive of better OS [HR for early relapse 1.64, (95% CI 1.2-2.2); p=0.002]. For those with late relapse, HMA/VEN treatment was associated with improved cumulative incidence of CR (HR 3.52, 95% CI 1.9-6.7; p<0.001), while in the early relapse group there was no difference between the salvage groups (HR 0.49, 95% CI 0.3-1.9; p=0.61). 73 patients achieved CR following post-HSCT relapse (2-year OS from CR was 47%); including 36 who received combination therapy having shorter median time from

salvage to CR compared to those who received HMA alone (62 vs. 115 d; p=0.008), higher likelihood to receive a 2nd HSCT within 2-year from CR (46% vs. 8%), and lower likelihood to receive donor lymphocyte infusion (6% vs. 22%).

Patient Characteristics		HMA N=141	HMA/VEN N=83	P-value
Year of HSCT	Median [IQR]	2016 [2014-2018]	2020 [2019-2021]	<0.001
Age at HSCT	Median [IQR]	57 [47-63]	55 [40-62]	0.25
AML type (%)	De novo Secondary	100 (72) 39 (28)	61 (75) 20 (25)	0.59
Adverse risk cytogenetics (%)	Yes	76 (56)	32 (43)	0.13
Pre-HSCT Treatment (%)	Azacitidine VEN	11 (8) 3 (2)	17 (21) 9 (11)	**0.006** **0.01**
Time to HSCT (months)	Median [IQR]	4.4 [4-6]	4.6 [4-6]	**0.47**
Donor type (%)	Matched sibling Haploidentical Unrelated	42 (30) 15 (11) 82 (57)	20 (24) 14 (17) 47 (57)	NA
Conditioning (%)	Myeloablative	58 (41)	49 (59)	**0.01**
PTCy (%)	Yes	30 (21)	28 (34)	**0.03**
Time to relapse post HSCT (days)	Median [IQR]	157 [97-356]	269 [142-528]	**0.002**
Time relapse to salvage (days)	Median [IQR]	12 [4-19]	13 [6-21]	0.39
Follow up (years)	Median [IQR]	6.8 [4.4-7.5]	2.6 [1-3.3]	NA

Table 1. Baseline Characteristics for patients receiving HMA and those receiving combination HMA/VEN
Abbreviations: AML: acute myeloid leukemia; HMA: hypomethylating agents; PTCY: post-transplant cyclophosphamide; VEN: venetoclax.



Graph 1. A Overall survival (OS) for both groups; B: cumulative incidence of complete remission (CR) with treatment and time to relapse.

Conclusions: HMA±VEN are viable salvage treatment options for AML relapsing post HSCT, with long-term survival in a select group of patients, particularly those with late relapse and no adverse risk cytogenetics. HMA/VEN combination results in increased CR rates and likelihood of a second HSCT.

Disclosure: Nothing to declare.

A NOVEL RISK STRATIFICATION FRAMEWORK FOR CEBPA MUTANT AML BASED ON CEBPA BZIP IN-FRAME INSERTION/DELETION AND NRAS/CSF3R CO-MUTATIONS

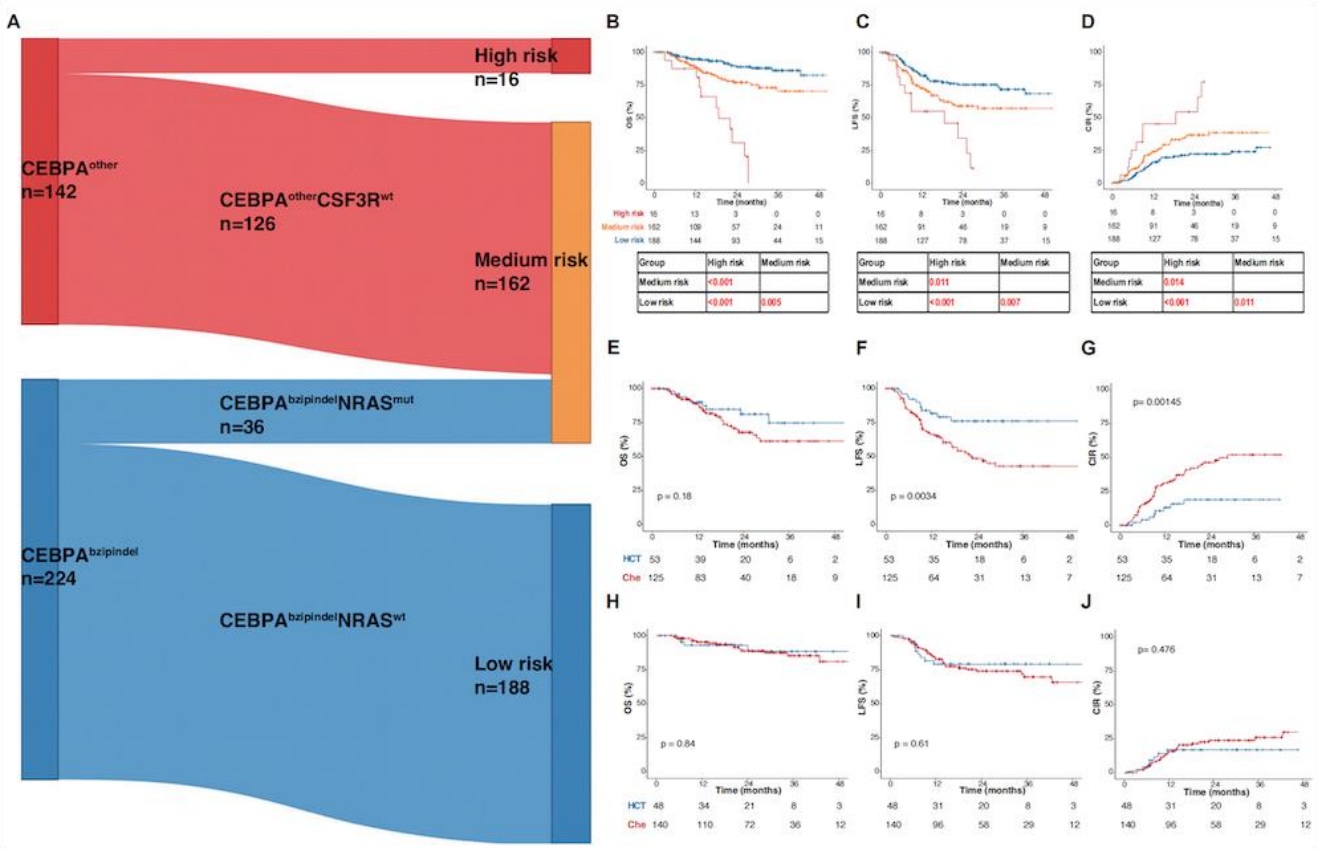
*Yishan Ye[1], Ziqi Ai[2], **Zhile Chen**[1], Ruoxuan Zhang[3], Yi Luo[1], Jimin Shi[1], Jian Yu[1], Lizhen Liu[1], Xiaoyu Lai[1], Huarui Fu[1], Congxiao Zhang[1], Yi Yu[1], Lin Li[1], Xiaoxia Hu[2], He Huang[1], Yang Cao[3], Yunxiang Zhang[2], Yanmin Zhao[1]*

[1]The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China, [2]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, [3]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China

Background: CEBPA mutation occurs in 10% to 15% of AML patients. CEBPA bZIP in-frame insertions/deletions (CEBPA^{bzipindel}) have been identified as a distinct entity associated with favorable outcomes. However, co-occurrence of other mutations significantly impacts prognosis of CEBPA mutant AML. A refined framework for CEBPA-mutant AML is needed for risk stratification and clinical decision-making.

Methods: Data from 366 consecutive de novo CEBPA mutant adult AML patients diagnosed between 2015 and 2024 from three centers across China were analyzed. Based on CEBPA mutation subtype, patients were classified into CEBPA^{bzipindel} (n=224) and CEBPA^{other} (n=142) cohorts. Multivariate survival analyses were conducted using Cox proportional hazards regression models.

Results: The median follow-up were 21.87 months (interquartile range [IQR], 12.47-33.64) for the CEBPA^{bzipindel} cohort and 17.35 months (IQR, 10.24-28.12) for the CEBPA^{other} cohort. Following two cycle of induction chemotherapy, the composite complete remission rate (CRc) rate was 99.5% in the CEBPA^{bzipindel} and 94.5% in the CEBPA^{other} cohort, respectively.
An exploration of the co-mutation landscape identified WT1, TET2, GATA2, NRAS, and CSF3R as the most recurrent mutations in the entire population. The top 5 co-mutations in the The CEBPA^{bzipindel} cohort were WT1, GATA2, NRAS, TET2, and CSF3R, respectively. The top 5 co-mutations in the CEBPA^{other} cohorts was TET2, WT1, NPM1, STAG2 and IDH2, respectively.
In multivariate analysis, CSF3R mutation emerged as an independent factor for poorer overall survival (OS), both in the entire cohort (aHR = 2.02 [95%CI, 1.07-3.81]) and the CEBPA^{other} cohort (aHR = 3.51 [95%CI, 1.68-7.30]). NRAS mutations was independently correlated with poorer leukemia-free survival (LFS) in the entire cohort (aHR = 1.65 [95%CI, 1.01-2.69]) as well as the CEBPA^{bzipindel} cohort (aHR = 1.95 [95%CI, 1.03-3.47]).
Within the *CEBPA*^{bzipindel} cohort, patients harboring concurrent *NRAS* mutations (*CEBPA*^{bzipindel}*NRAS*^{mut}) had significantly inferior 2-year LFS and higher 2-year cumulative incidence of relapse (CIR) than *CEBPA*^{bzipindel}*NRAS*^{wt}. Within the *CEBPA*^{other} cohort, the presence of *CSF3R* mutations (*CEBPA*^{other}*CSF3R*^{mut}) was associated with significantly inferior 2-year OS, LFS and higher 2-year CIR compared with *CEBPA*^{other}*CSF3R*^{wt} cohort.
Furthermore, all major transplant outcomes were comparable between the *CEBPA*^{bzipindel}*NRAS*^{mut} and *CEBPA*^{other}*CSF3R*^{wt} cohorts.
Accordingly, the four cohorts were further re-defined into a three-tier risk model: low risk (*CEBPA*^{bzipindel}*NRAS*^{wt}), intermediate risk (*CEBPA*^{bzipindel}*NRAS*^{mut} and *CEBPA*^{other}*CSF3R*^{wt} combined), and high risk (*CEBPA*^{other}*CSF3R*^{mut})
. This proposed risk model demonstrated robust discriminatory capacity for key survival endpoints, including 2-year OS, LFS, and CIR.To further evaluate the utility of this risk model in guiding allogeneic hematopoietic stem cell transplantation (allo-HCT) decision making, we compared outcomes between patients receiving allo-HCT and those treated with chemotherapy only within each risk category. In the intermediate/high risk cohort, allo-HCT conferred a clear survival advantage over chemotherapy alone (OS: HR = 0.60 [95%CI, 0.29-1.26]; LFS: HR = 0.39 [95%CI, 0.21-0.75]; CIR: HR = 0.33 [95%CI, 0.16-0.71]). In the low risk cohort, allo-HCT was associated with similar outcomes compared with chemotherapy.



Conclusions: Integrating *CEBPA* bZIP insertion/deletion, *NRAS* and *CSF3R* status into the stratification of *CEBPA* mutant AML allow for a more precise risk stratification and assist in clinical decision making especially allo-HCT.

Background: Ph+ is the most common cytogenetic abnormality in adults with ALL. 60%-70% of the Ph+ ALL patients (pts) harbor additional chromosomal abnormalities (ACA) and complex karyotype (CK). The impact of ACA and CK on outcomes of Ph+ ALL pts undergoing allogeneic transplantation (HSCT) while in first complete remission (CR1) in the tyrosine kinase inhibitors (TKIs) era is controversial.

Methods: 514 Ph+ pts that received TKI (Imatinib-62%, Dasatinib-17.7%, Nilotinib-13.3%, other-7%) followed by HSCT while CR1 between 2010-2022 were included.

Results: 345 pts harbor ACA (109 had 1 ACA, 100 had 2-3 ACA, and 136 had $\geq$ 4 ACA) and 169 did not (noACA). 210 pts had at least one monosomy, most frequently monosomy 7 (n=63). 101 pts had at least one trisomy. Twelve pts had 11q23 translocations. IKZF1 mutations were observed in 8.7% and 7.7% of pts with and without ACA, respectively. The presence of ACA was associated with a higher rate of MRD-negativity pre HSCT (56.2% vs. 46.5%, p=0.04). Median follow-up was 4.2 years. Median year of transplant was 2018. Median age was 42.6 years, and 54.5% were male. The groups (ACA vs. noACA) did not differ significantly in terms of age, gender, and interval from diagnosis to HSCT. Donors were matched siblings in 32.5% vs. 28.4%, unrelated in 37.1% vs. 27.2%, or haploidentical in 28.7% vs. 40.2%, respectively. More pts with ACA received PB grafts compared to the noACA group (86.4% vs. 78.1%, p=0.03). CMV seropositivity was higher in the ACA group (70.5% vs. 57.2%, p=0.009). Myeloablative conditioning was used more frequent in the noACA group (87% vs. 75.9%, p=0.003), with TBI-based in 51.9% vs. 40.2%, respectively. Day 30 ANC $\geq 10^9$/L was 97.9 % vs. 98.2 % and day 60 platelet count $\geq 20x10^9$/L was 93.9 % vs. 95.5%, for the ACA and noACA groups. Day 100 acute (a) GVHD grades II-IV was 26.4% vs. 31% and of grades; III-IV was 8.6% vs. 9.7%, respectively. 4-year chronic (c) GVHD was 40.5 % vs. 39.9 % and of extensive cGVHD was 19.3% vs. 20.1 %. 4-year NRM was 13.1 %

vs. 13. 5%, and 4-year RI was 19.2 % vs. 21.1 %, respectively. The 4-year LFS and OS rates were 67.7% vs. 65.4 % and 76.3% vs. 78.5%, respectively. 4-year GRFS was 48.5% vs. 45%, respectively (Figure). In multivariate analysis, having ACA and the number of ACAs did not affect transplant outcomes significantly. Compared to noACA, HR for LFS were 0.93, 0.90, and 1.06 for 1 ACA, 2-3 ACA, and ≥4 ACA, respectively. MRD-positivity pre-HSCT was a poor prognostic factor for LFS, OS, and NRM. A mismatched related donor was associated with lower RI and higher NRM.

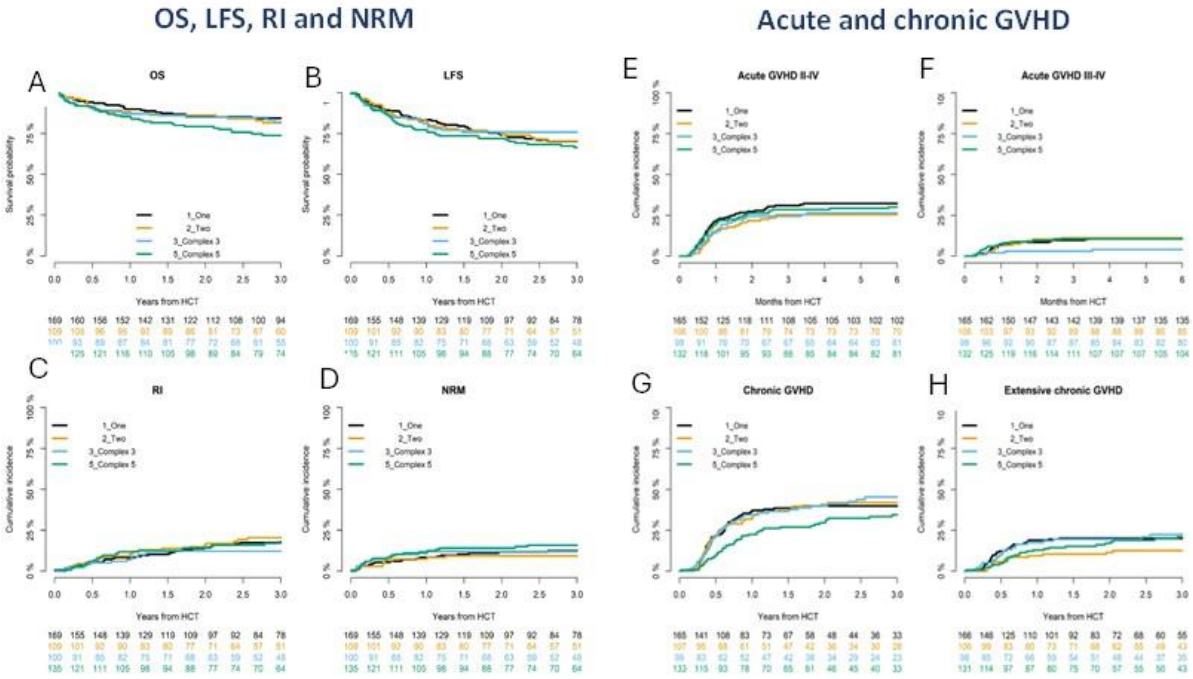

Figure legend: Outcomes of allogeneic HSCT in patients with Ph+ ALL in CR1 with or without additional cytogenetic abnormalities and complex karyotype: A. overall survival (OS); B. leukemia-free survival (LFS); C. relapse incidence (RI); D. non-relapse mortality (NRM); E. acute graft versus host disease (GVHD) II-IV; F. acute GVHD III-IV; G. chronic GVHD; H. extensive chronic GVHD.

Arnon Nagler[1*] and Jordi Esteve[2*] contribute equally to the study

Conclusions: Harboring ACA and CK did not affect outcomes of Ph+ ALL pts receiving a TKI and subsequent HSCT. Notably, achieving MRD-negativity pre HSCT was significantly higher in pts with ACA. These data may indicate that the administration of a TKI upfront, followed by HSCT, may overcome the poor prognosis influence of the ACA, including CK in Ph+ ALL.

Advancing the Art of Patient Care

SURVIVAL BENEFIT OF ALLOGENEIC TRANSPLANT IN TP53-MUTATED AML ACROSS SINGLE- AND DOUBLE-HIT DISEASE

*David Mueller[1,2], Sharon Santhosh[2], Adit Singhal[1,2], Saud Khallaf[2], Kelli Cole[3], Ruthee Bayer[1,3], **Jaime Andres Suarez-Londono**[1,3], David Chitty[1,2], Douglas E. Gladstone[1,3], Stephanie Boisclair[1,3]*
[1]Donald and Barbara Zucker School of Medicine at Hofstra University, Hempstead, United States of America (the), [2]Northwell Health, New Hyde Park, United States of America (the), [3]Northwell Health Cancer Institute, Adult Transplantation and Cellular Therapy Program, New Hyde Park, United States of America (the)

Background: Outcomes in TP53-mutated AML remain poor, while the role of allogeneic hematopoietic stem cell transplant(allo-HSCT) in this group is increasingly debated. TP53 mutations can be categorized as single-hit(SH) or double-hit(DH), however, its impact on transplant outcomes is not well defined. We assessed the use allo-HSCT and outcomes across TP53-mutated AML subgroups.

Methods: We retrospectively reviewed TP53-mutated AML patients, defined by a TP53 mutation (VAF ≥2%), 17p cytogenetic abnormality, or both. Allelic status was classified per Grob et al., 2022: DH was defined as ≥2 TP53 mutations, a TP53 mutation with 17p abnormality, or a single mutation with VAF >55%. Post-transplant outcomes were analyzed from day 0, whereas survival comparisons between transplanted and non-transplanted groups were measured from morphological leukemia-free state (MLFS). To reduce immortal-time bias inherent to the transplant group, comparisons of transplant versus non-transplant were restricted to patients who achieved MLFS with survival ≥4 months, the median time to transplant. Overall survival (OS) and relapse-free survival (RFS) were estimated with Kaplan–Meier methods and estimated cumulative incidences (ECI) with Gray's competing risk model.

Results: Between 2019 and July 2025, 113 TP53-mutated AML patients were identified (median age 71.3years); 26.5% had SH, 61.9% had DH, and 11.5% were unclassifiable due to missing data. Most had de novo AML(56.6%) and received HMA +/- Venetoclax induction regimens(63.7%). Of classifiable patients, 53 achieved MLFS with 23 whom underwent allo-HSCT in first remission(Table 1). In the allo-HSCT cohort, median OS, RFS, and GVHD- and relapse-free survival (GRFS) from transplant were 12.4 mo(6.16–NR), 12 mo(3.4–NR), and 8.3 mo(4–21.4), respectively(Figure 1A). The 1-year ECI of grade II–IV acute GVHD was 27.1%(10.6-46.7%), with no grade III–IV events; the 2-year ECI of moderate/severe chronic GVHD was 9.1%(1.4–26%). Patients who developed GVHD(n=9) had improved 2-year OS (76.2% vs 25.4%; p=0.006) and RFS(76.2% vs 23.4%; p=0.004). One-year ECI of relapse and NRM were 27%(10-46%) and 8.7%(1.4-24.6%). Likely due to a small cohort, conditioning intensity, donor type, and GVHD prophylaxis did not significantly affect OS, RFS, or GRFS.
In the MLFS-eligible group, allo-HSCT was associated with improved mOS (17.7 vs 10.0mo; p=0.0045) and mRFS (19.2 vs 9.2mo; p=0.0005) compared with non-transplanted patients (Figure 1B). This benefit was observed in both SH and DH patients with improved OS and RFS(Figures 1C–1D). Within the allo-HSCT cohort, SH patients had longer OS (81.2 vs 12.3mo; p =0.29) and RFS (81.2 vs 8.3mo, p=0.43) compared to DH patients though did

not reach statistical significance. ECIs of relapse, NRM, and acute or chronic GVHD were similar between SH and DH. Of note, three DH patients with day +60 MRD positivity received HMA maintenance.

Table 1: Baseline Characteristics of TP53-mutated AML cohort		All TP53 mutated (n=113)	No Allo-HSCT (n=90)	Allo-HSCT (n=23)
Sex (%)	Female	50 (44.2)	43 (47.8)	7 (30.4)
AML subtype:	Denovo	64	54	10

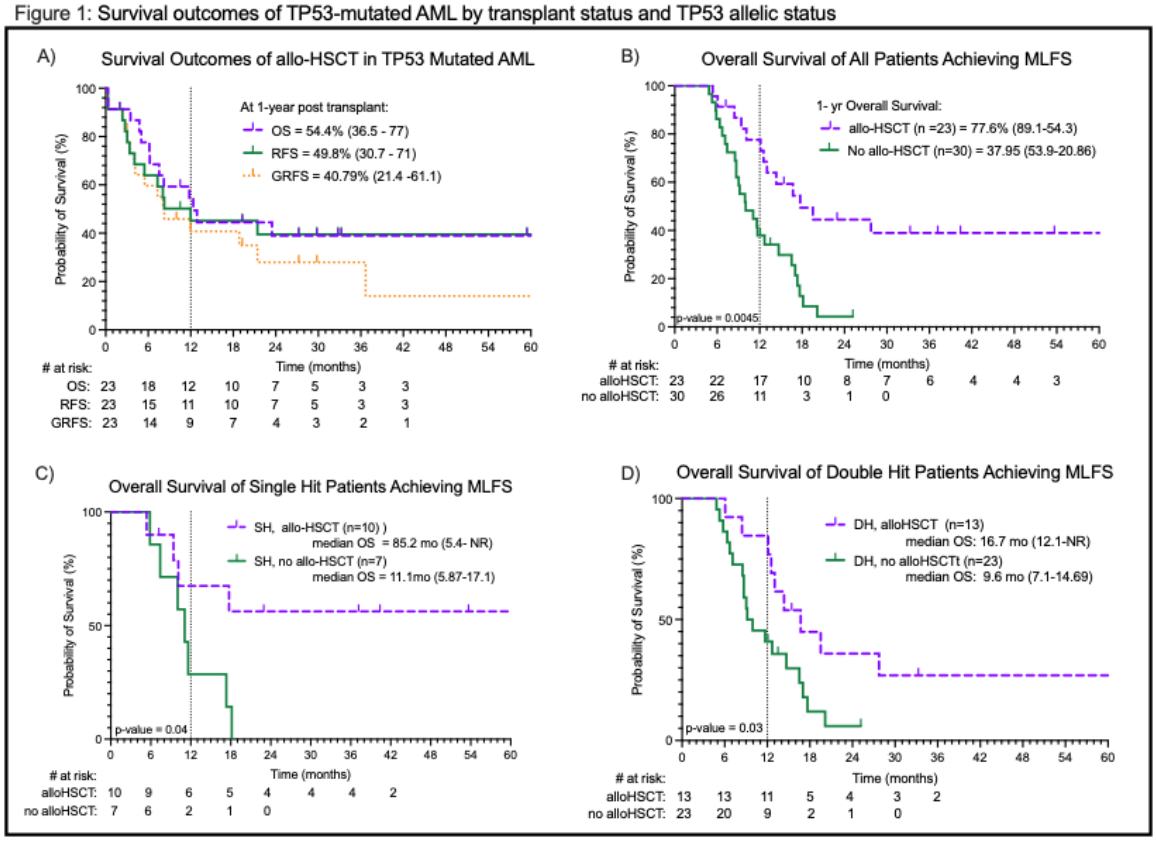
	Clinical trial/Unknown	-	-	2/2

Figure 1: Survival outcomes of TP53-mutated AML by transplant status and TP53 allelic status



Conclusions: Allo-HSCT conferred a significant OS and RFS advantage for TP53-mutated AML patients who achieved MLFS, with benefit observed in both SH and DH disease. As modern transplant strategies continue to reduce toxicity, our findings support offering allo-HSCT to eligible TP53-mutated AML patients, although it remains unlikely to be curative for most. Larger studies are needed to define optimal conditioning and GVHD prevention regimens in this high-risk population.

Background: Inotuzumab ozogamicin (InO) is an anti-CD22 antibody-drug conjugate that achieves high rates of remission and measurable residual disease (MRD) clearance in relapsed or refractory (R/R) B-ALL, and is increasingly used as a bridge to allogeneic hematopoietic cell transplantation (alloHCT). Its use may increase the risk of sinusoidal obstruction syndrome (SOS) and affect transplant outcomes, but real-world data remain limited.

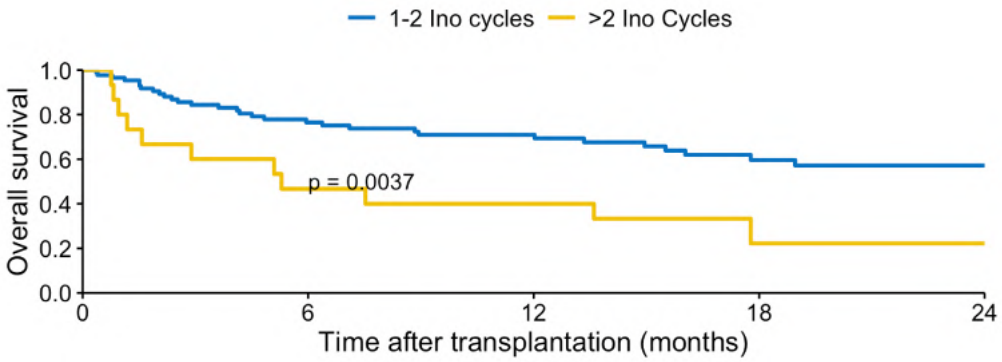
Methods: We conducted a retrospective multicenter analysis of adolescent and adult patients (³15 years old) with R/R B-ALL treated with InO who subsequently underwent alloHCT at 19 Spanish centers to evaluate its impact on transplant outcomes and SOS. Cases refractory to InO were excluded.

Results: A total of 101 patients were analyzed, 53 were male, with a median age of 38 years (range, 15-70). B-ALL NOS was the most frequent subtype (65%). InO was given for relapsed (55%) or refractory (43%) disease, with a median of 2 cycles (range, 1-6) and a median interval of 49 days (range, 16-189) from last InO to alloHCT. CR prior to transplant was 97%, with 71 MRD-negative patients. Donors included MSD (n=31), MUD (n=27), MMUD (n=19) and haploidentical (n=24). Myeloablative conditioning was used in 65 patients; overall, 57 received TBI-based and 31 double-alkylator regimens. PTCY-based GVHD prophylaxis was used in 73 patients.
Main transplant outcomes and risk factors are summarized in Table 1. SOS occurred in 33 patients at a median of 13 days (range, 4-90), mostly early-onset (88%) Cumulative incidence of SOS was 32% at 100 days. According to EBMT severity criteria, 3% were mild, 15% moderate, 41% severe and 41% very severe. Defibrotide was used in all but one patient, with SOS resolution in 22 patients (67%). Eleven patients died (30%) directly due to SOS (n=7) or from other causes with active SOS (n=4). SOS had a negative impact on NRM (HR 3.57, 95% CI: 1.6-8.3, P=0.002). Risk factors for SOS in multivariate analysis were: male gender, 2 or more lines prior to InO, <50 days interval between InO and alloHCT and TBI-based conditioning whereas type of donor and double-alkylator showed no impact.

Median follow-up of survivors was 16 months. Cumulative incidence of grades 2-4 acute GVHD and moderate-severe chronic GVHD were 27% and 16%, respectively.
Twenty-three patients died without prior relapse at a median of 101 days, most commonly due to infections (48%) or SOS (30%). One-year NRM was 21%. Thirty-three patients relapsed a median of 159 days; 1-year relapse incidence was 27%.
OS, LFS and GRFS at one year were 66%, 50% and 41%, respectively. Multivariate analysis showed worse OS and LFS for patients receiving 2 or more lines prior to InO and > 2 cycles of InO (Figure 1) as well as those with positive MRD prior to alloHCT.

Outcomes	Overall, % (95% CI)	Multivariate analysis Variables	HR	95% CI per HR	P value
SOS, at 100 days	32 (24-42)	Male Gender Lines prior InO >1 Interval InO-HCT ≥ 50d TBI-based	3.2 2.22 3.57 2.56	1.45-7.05 1.06-4.65 1.6-7.7 1.2-5.2	0.004 0.034 0.002 0.015
NRM, at 1 year	21 (14-30)	Lines prior InO >1 Interval InO-HCT ≥ 50d InO cycles >2	2.61 2.86 2.84	1.2-6.1 1.06-7.7 1.16-6.96	0.028 0.037 0.022
Relapse, at 1 year	27 (18-37)	Negative MRD	0.45	0.22-0.93	0.031
LFS, at 1 year	50 (41-62)	Negative MRD Lines prior InO >1 InO cycles >2	0.30 2.01 2.47	0.17-0.55 1.15-3.62 1.21-5.05	<0.001 0.015 0.013
OS, at 1 year	66 (57-76)	Negative MRD Lines prior InO >1 InO cycles >2	0.50 2.34 3	0.25-0.99 1.21-4.53 1.4-6.44	0.047 0.011 0.005
GRFS, at 1 year	41 (32-53)	Negative MRD Lines prior InO >1	2.44 2	1.39-4.17 1.17-3.46	0.002 0.012

Figure 1.



Conclusions: InO is an effective bridge to alloHCT for responsive R/R B-ALL patients. However, relapse and SOS remain major challenges, with InO exposure (>2 cycles or <50-day interval), number of prior treatment lines, and MRD status emerging as key risk factors influencing transplant outcomes.

Clinical Trial Registry: No.

"LESS IS MORE"? PTCY+CNI WITH VS WITHOUT MMF IN 10/10 MUD HCT FOR AML IN CR1. FROM THE GLOBAL COMMITTEE AND ALWP OF EBMT

Jia Chen[1], *Yuhua Ru*[1], *Allain-Thibeault Ferhat*[2], *Alexander Kulagin*[3], *Carin Hazenberg*[4], *Jurjen Versluis*[5], *Jan Vydra*[6], *Montserrat Rovira*[7], *Jaime Sanz*[8], *Peter A. von dem Borne*[9], *Depei Wu*[1], *Mohamad Mohty*[2], *Fabio Ciceri*[10], *Norbert-Claude Gorin*[2]
[1]*The First Affiliated Hospital of Soochow University, Suzhou, China,* [2]*EBMT Paris Office, Hôpital Saint Antoine, Paris, France,* [3]*RM Gorbacheva Research Institute, Pavlov University, Petersburg, Russian Federation (the),* [4]*University Medical Center Groningen, Groningen, Netherlands (the),* [5]*Erasmus MC Cancer Institute, Rotterdam, Netherlands (the),* [6]*Institute of Hematology and Blood Transfusion, Prague, Czechia,* [7]*Hospital Clinic, Barcelona, Spain,* [8]*University Hospital La Fe, Valencia, Spain,* [9]*Leiden University Hospital, Leiden, Netherlands (the),* [10]*IRCCS San Raffaele Hospital Scientific Institute, Milano, Italy*

Background: Post-transplant cyclophosphamide (PTCy) is increasingly adopted in matched unrelated donor (MUD) hematopoietic cell transplantation (HCT) to decrease the risk of graft-versus-host disease (GVHD). While its efficacy is recognized, the optimal companion agents

for PTCy in the MUD setting remain debated. Clinical practice currently varies between a two-drug regimen (PTCy plus a calcineurin inhibitor [CNI]) and a three-drug regimen that adds mycophenolate mofetil (MMF). With limited data directly comparing these two approaches, the necessity of including MMF remains unproven. Therefore, a direct comparison is urgently needed to define the optimal GVHD prophylaxis strategy for patients undergoing MUD HCT in the PTCy era.

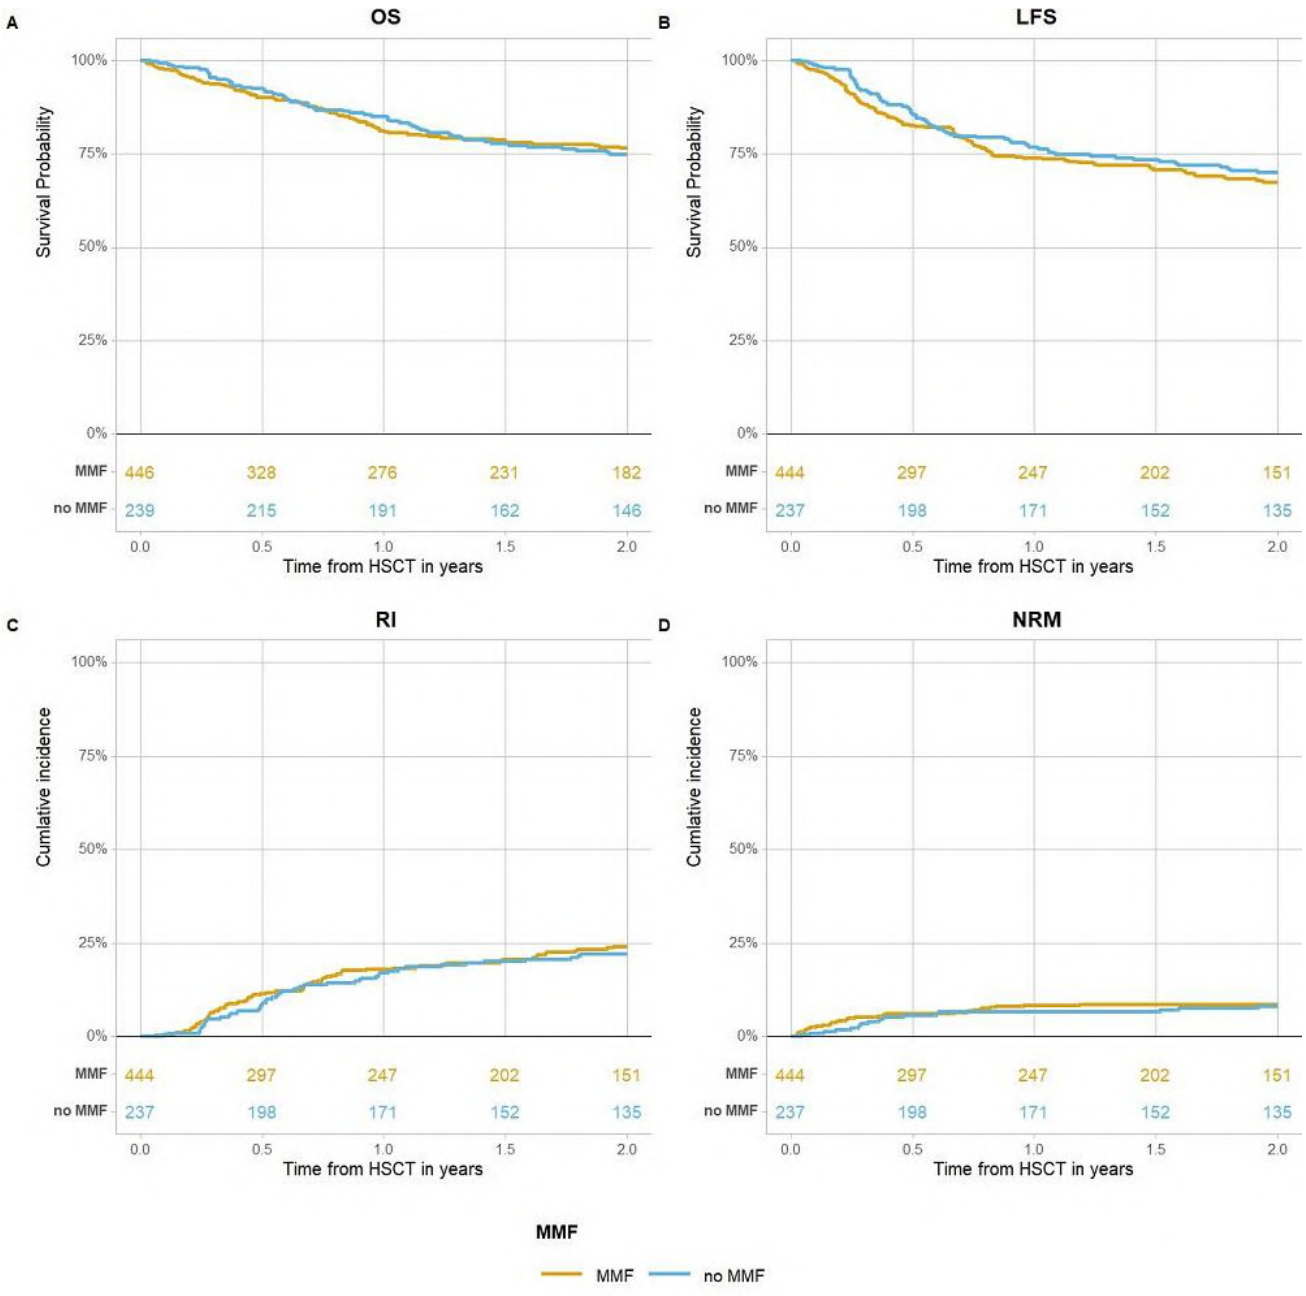
Methods: We retrospectively analyzed adult patients (≥18 years) with acute myeloid leukemia (AML) in first complete remission (CR1) who underwent their first allo-HCT between 2010 and 2022 from a 10/10 MUD using peripheral blood (PB) stem cells. Patients received PTCy+CNI with or without MMF for GVHD prophylaxis. Data were reported to the European Society for Blood and Marrow Transplantation (EBMT).

Results: The analysis included 687 patients: 448 received PTCy+CNI+MMF and 239 received the PTCy+CNI regimen. The median follow-up was 2.1 and 3.2 years, respectively. In the PTCy+CNI+MMF and PTCy+CNI groups, 52.8% and 66.1% of patients were male (P<0.001), respectively. Patients in the PTCy+CNI+MMF group were younger (median age: 52.8 vs. 58.1 years, P<0.001), transplanted more recently (median year: 2020 vs. 2019, P<0.001), and had better Karnofsky Performance Score (KPS ≥90: 84.8% vs. 60.3%, P<0.001). The PTCy+CNI+MMF group had a higher rate of patient Cytomegalovirus (CMV) seropositivity (79.4% vs. 61.2%, P<0.001) and a lower rate of donor-/recipient- CMV seronegative pairs (14.7% vs. 33.9%, P<0.001). More patients in the PTCy+CNI+MMF group received reduced-intensity conditioning (RIC) (39.4% vs. 30.5%, P=0.022). Cyclosporine was used as the associated CNI in 37% and 56.7% of the PTCy+CNI+MMF and PTCy+CNI groups, respectively (P<0.001). Patients in the PTCy+CNI+MMF group received grafts from older donors (median donor age: 29.6 vs. 27.0, P<0.001). The two patient cohorts did not differ regarding European LeukemiaNet (ELN) 2022 risk, donor sex, donor/recipient sex mismatch, and donor CMV status.
Outcomes at 2 years for the PTCy+CNI+MMF vs. PTCy+CNI groups were: overall survival (OS) 76.4% vs. 74.8%; leukemia-free survival (LFS) 67.3% vs. 70%; relapse incidence (RI) 24.1% vs. 22.1%; and non-relapse mortality (NRM) 8.6% vs. 7.9% (Figure 1). In multivariate analysis, no significant differences were observed in OS (HR=0.8, P=0.269), LFS (HR=0.89, P=0.583), or RI (HR=1.11, P=0.681). However, the omission of MMF (PTCy+CNI group) was significantly associated with lower NRM (HR=0.41, P=0.02). Additionally, older patient age (per 10 years) was associated with higher NRM (HR=1.47, P=0.007). Myeloablative conditioning (MAC) was associated with superior OS (HR=0.66, P=0.023) compared to RIC. More recent transplantation (per 5 years) was associated with better OS (HR=0.62, P=0.014) and lower NRM (HR=0.29, P=0.001).

Table 1. Patient characteristics

	Overall N = 687	PTCy+CNI+MMF N = 448	PTCy+CNI N = 239	P-value
Year of transplantation				<0.001

Median (IQR)	2020 (2018, 2022)	2020 (2018, 2022)	2019 (2017, 2021)	
KPS				<0.001
≥90	507 (76.2%)	367 (84.8%)	140 (60.3%)	
< 90	158 (23.8%)	66 (15.2%)	92 (39.7%)	
Missing	22	15	7	
Age of the Patient				<0.001
Median (IQR)	55.4 (41.4, 64.2)	52.8 (38.8, 63.4)	58.1 (47.2, 66.3)	
Sex of the Patient				<0.001
Female	292 (42.6%)	211 (47.2%)	81 (33.9%)	
Male	394 (57.4%)	236 (52.8%)	158 (66.1%)	
Missing	1	1	0	
RIC or MAC regimen				0.022
RIC	249 (36.3%)	176 (39.4%)	73 (30.5%)	
MAC	437 (63.7%)	271 (60.6%)	166 (69.5%)	
Missing	1	1	0	



Conclusions: Addition of MMF to PTCy+CNI resulted in comparable survival and relapse outcomes but significantly higher NRM compared to PTCy+CNI alone. The two-drug regimen (PTCy+CNI) may be a sufficient and potentially safer GVHD prophylaxis strategy for AML patients in CR1 undergoing 10/10 MUD transplantation.

Disclosure: Nothing to declare.

IMPACT OF INDUCTION RESPONSE AND CO-MUTATIONS ON TRANSPLANT OUTCOMES IN AML WITH MYELODYSPLASIA-RELATED GENE MUTATIONS: A MULTICENTER RETROSPECTIVE STUDY

*Xing Chen[1], Ruoxuan Zhang[1], Liang Huang[2], Xiaodong Mo[3], **Xiaoxia Hu**[4,5], Yang Cao[1]*
[1]Department of Hematology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, [2]State Key Laboratory of Experimental Hematology, Institute of Hematology & Blood Diseases Hospital, Department of Stem Cell and Regenerative Medicine, Chinese Academy of Medical Sciences and Peking Union Medical College, Tianjin, China, [3]Peking University People's Hospital & Peking University Institute of Hematology, National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China, [4]State Key Laboratory of Medical Genomics, Shanghai Institute of Hematology, National Research Center for Translational Medicine, Shanghai Rui Jin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, [5]Collaborative Innovation Center of Hematology, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Acute myeloid leukemia (AML) is a genetically heterogeneous hematologic malignancy. According to the International Consensus Classification (ICC) 2022, AML with mutations in ASXL1, BCOR, EZH2, SF3B1, SRSF2, STAG2, U2AF1, ZRSR2, or RUNX1 is defined as AML with myelodysplasia-related gene mutations (AML-MR) and categorized as adverse risk by ELN-2022. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) remains a potentially curative treatment; however, the prognostic impact of AML-MR co-mutations in the transplant setting remains unclear.

Methods: This is a multicenter, retrospective designed study, based on the transplant database of the TROPHY group. AML patients receiving allo-HSCT between February 2016 and December 2023 were screened. Inclusion criteria were AML diagnosis, ELN-2022 adverse-risk classification, and presence of ≥1 AML-MR mutation. Induction therapy followed NCCN guidelines. Complete remission (CR) was defined as <5% bone marrow blasts with hematologic recovery. Patients failing first induction received a second cytarabine-based regimen. Consolidation strategies were determined by MRD status, donor availability, and patient fitness. Endpoints included relapse-free survival (RFS), overall survival (OS), cumulative incidence of relapse (CIR), and non-relapse mortality (NRM).

Results: A total of 341 patients were included. The most frequent AML-MR mutations were ASXL1 (32%), RUNX1 (29%), and BCOR (22%). Common co-mutations included TP53 (7%) and epigenetic regulator genes (IDH1/2, DNMT3A, TET2; each 6%). Overall, 193 patients (56.6%) achieved CR after first induction. Hypomethylating agent- or venetoclax-based regimens resulted in higher CR rates than conventional IA regimens (61.8% vs. 45.0%, p=0.007). Prior to allo-HSCT, 322 patients (94.4%) achieved CR. The 2-year OS and RFS for the entire cohort were 77.4% and 70.0%, respectively.
Patients achieving CR before transplantation had superior RFS (2y-RFS: 71.1% vs. 49.3%,

p=0.026) and a trend toward lower CIR. Achieving CR after first induction was associated with significantly improved RFS (81.8% vs. 55.5%), OS (85.6% vs. 66.3%), lower CIR (9.5% vs. 18.8%), and reduced NRM (all *p*<0.05). Multivariate analysis identified post-remission consolidation as an independent predictor of improved OS (HR=0.56, *p*=0.015). Grade III–IV acute GvHD and TET2 co-mutation were associated with inferior OS, while Grade III–IV acute GvHD and pre-transplant MRD positivity predicted inferior RFS. TP53 and NPM1 co-mutations showed no significant impact on survival. Patients with epigenetic regulator mutations had reduced OS (2y-OS: 73.0% vs. 83.1%, *p*=0.044).

Conclusions: In patients with AML-MR, Induction regimens incorporating hypomethylating agents or Venetoclax were associated with improved CR rates. Achieving CR after first induction significantly improves post-transplant RFS and OS along with reduced CIR and NRM. Co-mutations in TP53 and NPM1 did not significantly impact survival. Notably, epigenetic regulator mutations were linked to reduced OS, highlighting the prognostic relevance of specific co-mutations in AML-MR.

Disclosure: Nothing to declare.

Background: The availability of reduced-toxicity conditioning regimens and modern graft-versus-host disease (GVHD) prophylaxis has expanded access to allogeneic haematopoietic stem cell transplantation (allo-HSCT). Treosulfan-based conditioning reduces transplant-related mortality while preserving antileukaemic efficacy, and post-transplant cyclophosphamide (PTCy) effectively limits acute and chronic GVHD across donor platforms. The combination of reduced toxicity and selective elimination of alloreactive T cells may mitigate the historical impact of donor HLA disparity. This study compared outcomes after 9/10 HLA-mismatched unrelated donor and haploidentical transplantation in adult AML patients in first complete remission (CR1), testing whether reduced toxicity conditioning may outweigh donor HLA matching.

Methods: This retrospective EBMT registry study included adult patients with acute myeloid leukaemia (non-APL) in first complete remission (CR1) undergoing allo-HSCT between 2012 and 2023. All patients received treosulfan-based conditioning and PTCy-based GVHD prophylaxis, and were transplanted from either a 9/10 mismatched unrelated donor or a haploidentical related donor. The primary endpoint was 1-year event free survival. Secondary endpoints included survival outcomes, non-relapse mortality, relapse incidence, GVHD, GVHD-free/relapse-free survival, and engraftment. Survival analyses used Kaplan–Meier estimates, while competing risks and multivariable Cox and Fine–Gray models were applied as appropriate.

Results: Overall, 275 adult AML patients in first complete remission were included, of whom 206 underwent haploidentical transplantation and 69 received a 9/10 HLA-mismatched unrelated donor transplant. Median follow-up was 2.5 years and was comparable between donor groups. Median age at transplantation was similar (62.3 vs 60.3 years, p=0.39), as were performance status and time from diagnosis to transplantation. The primary endpoint, 1-year event-free survival(EFS - 66.3% vs 65.2%, HR 1.12 p =0.66), was comparable between haploidentical and 9/10 MMUD transplants, with overlapping survival curves and no statistically significant difference between donor types. This finding remained consistent despite differences in conditioning intensity and stem cell source. Secondary outcomes supported the primary analysis. At 2 years, overall survival was similar between haploidentical and MMUD transplants(73.1% vs 71.6%, p=0.96). The cumulative incidence of relapse did not differ between donor groups (17.1% vs 18.7%, p=0.84), nor did non-relapse mortality (16.6% vs 16.1%, p=0.86). The cumulative incidence of acute GVHD grade II–IV by day 100 was 28.1% (17.1–40.1) in the MMUD group and 24.7%(18.7–31.2) in the haploidentical group (p=0.70), while acute GVHD grade III–IV occurred in 8.9%(3.2–18.2) and 9.5% (5.8–14.3) of patients, respectively (p=0.99). At 2 years, the cumulative incidence of chronic GVHD was significantly lower after MMUD transplantation compared with haploidentical transplantation (12.7% vs 36.4% HR 2.14 p =0.048). However, the incidence of extensive chronic GVHD remained low and similar between groups (6.0%, 1.5–14.9 vs 5.0%, 2.3–9.1; HR 1.18 p=0.81).

Fig. 1A

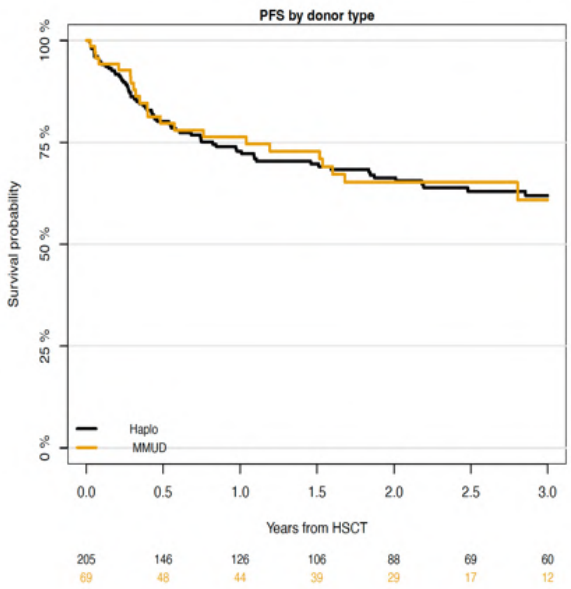

Fig. 1B

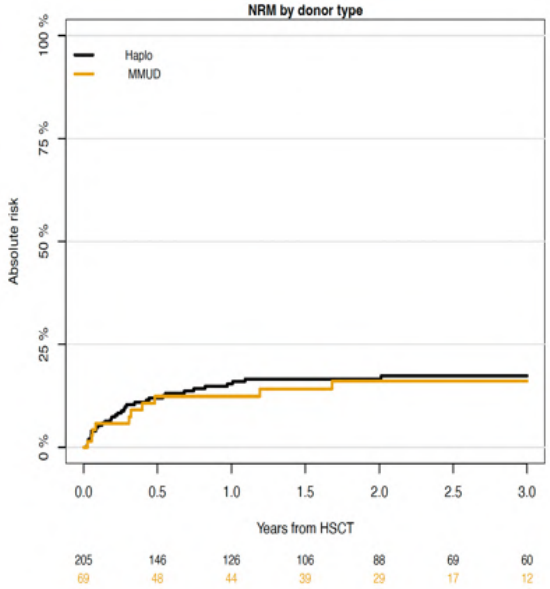

Conclusions: In AML patients in CR1 undergoing allo-HSCT with treosulfan-based conditioning and PTCy, transplant outcomes are comparable between 9/10 mismatched unrelated and haploidentical donors. These data indicate that effective control of toxicity and alloreactivity largely mitigates the historical impact of HLA mismatch, supporting donor availability and rapid access to transplantation as key determinants of outcome within a treosulfan–PTCy platform.

Background: Allogeneic HSCT (alloHSCT) is commonly used as consolidation therapy in children with high-risk (HR) *de novo* AML in first complete remission (CR1). According to AIEOP (Associazione Italiana OncoEmatologia Pediatrica) guidelines, HR patients (defined on the basis of the presence of specific, recurrent genetic lesions and response to induction therapy) have an indication to allogeneic HSCT in CR1.

Methods: HR patients were defined as: i) those carrying high-risk clinical/cytogenetic feature [including monosomal/complex karyotype, most of KMT2A-rearrangments, FLT3-ITD, CBFA2T3-GLIS2, NUP98-rearrangements, FAB M0, M6, M7, and infants without FABM7/t(1;22,)] or ii) showing poor response to induction therapy, defined as no CR at end of first of the 2 induction (EOI1) or measurable residual disease by flow-cytometry (fMRD) >1% at EOI1 or >0.1% at EOI2. The recommended conditioning regimen was busulfan+cyclophosphamide+melphalan in case of transplant from an HLA-matched donor, while for mMUD or PMFD conditioning was chosen by the treating physician. GvHD prophylaxis consisted of short-course methotrexate and cyclosporine-A; serotherapy (Grafalon 5 mg/kg/day for 3 days) was added in patients transplanted from an unrelated donor. For transplant from haploidentical donors, either TCRαβ/CD19-depletion or post-transplant cyclophosphamide (PT/Cy) were applicable, depending on center choice/expertise.

Results: 152 patients (52.6% males) consecutive HR patients were enrolled in 13 AIEOP centers and underwent alloHSCT in CR1 between 2014 and 2021. Median age at diagnosis and HSCT were 7.1 (range 0-18) and 7.7 years (range 0.4-18.6), respectively. The donor was a matched family donor for 36 patients (23.7%), an unrelated donor for 65 (42.7%; 48 fully-matched, MUD, and 27 mismatched, mMUD), and a PMFD for 51 (33.6%); of these haploidentical HSCT 38 were performed after *ex-vivo* TCRαβ/CD19-depletion, while 13 patients were given a PT/Cy HSCT. Stem cell source was bone marrow in 91 cases (59.9%), peripheral blood in 52 (34.2%) and cord blood in 9 (5.9%). Median total nucleated and CD34+ cells infused with the graft (excluding cord transplants) were 5.7 x 10^8/kg (range 0.9-13.7) and 6.9 x 10^6/kg (range 1.9-38.7), respectively. Cumulative incidence of grade II-IV and grade III-IV acute GvHD were 23.7% (95% CI 17.6-31.4) and 8.2% (95% CI 4.7-14.0), while that of chronic GvHD was 9.5% (95% CI 5.4-16.3). Non-relapse mortality and cumulative incidence of relapse were 7.2% (95% CI 3.9-12.2) and 21.7% (95% CI 15.4-28.7); patients transplanted from PMFD experienced the lowest NRM (3.9%,95% CI 0.7-11.9), while those receiving an allograft from a mMUD the highest (14.8%, 95% CI 4.7-30.4). With a median follow-up of 6.6 years for surviving patients, 10-year projected overall survival and event-free survival were 77.4% (95% CI 68.9-83.9) and 71.0% (95% CI 62.9-77.6), respectively.
Seven patients (4.6%) developed a severe VOD at a median of 13 days after HSCT; two of these patients died of transplant-related causes (both because of sepsis). Additional seven

patients developed thrombotic microangiopathy, 2 of them dying later because of this complication.

Conclusions: These data confirm improvement in transplant technique in recent years, as supported by the low incidence of NRM, and indicate that allo-HSCT is an efficacious option for consolidation of pediatric patients with HR AML.

Background: Relapse post allogeneic stem cell transplantation (HSCT) for acute myeloid leukemia (AML) remains a major challenge. Post-HSCT prophylaxis, primarily with FLT3 inhibitors (FLT3i) has shown promising efficacy with acceptable safety, while the role of hypomethylating agents (HMA) remains controversial. Key questions persist regarding patient selection, optimal agent, timing and duration of treatment.

Methods: EBMT registry-based multicenter analysis, approved by the ALWP, including adult AML patients (> 18 years) in first complete remission who underwent first HSCT between 2010-2022, then received FLT3i or HMA prophylaxis within 180 days post-HSCT.

Results: 317 patients identified, 171 received prophylaxis with FLT3i (58% Sorafenib, 30% midostaurin, 11% gilteritinib; 3 patients received sorafenib and midostaurin); while 146 patients received HMA (135 azacitidine/11 decitabine). Table 1 shows the characteristics for each group (not intended to compare the groups due to significant differences). Overall, 63% received myeloablative conditioning, and 97% peripheral blood stem cells. The median time to initiation of post HSCT FLT3i was 74 days [Interquartile range(IQR) 50-111], while the median duration of FLT3i prophylaxis was 364 days(IQR 98-675). At a median follow up of 3 years, the 2-year overall survival (OS) and leukemia free survival (LFS) from time of initiation of prophylaxis were 87% (95% CI 81-91) and 82% (95% CI 75-87) respectively; and were not significantly affected by age, measurable residual disease (MRD) status at HSCT, use of FLT3i before HSCT, prior graft-versus-host-disease (GVHD), or type of FLT3i (2-year OS and LFS: 88% and 81% for sorafenib; 91% and 87% for midostaurin; 70% and 70% for gilteritinib; p=0.13 and 0.28-figure 1). Conversely, the 2-year relapse incidence was higher for those with MRD positivity at transplant (21% versus 8%; p=0.03). For the HMA group, maintenance was initiated at a median of 69 days(IQR 52-97) and given for a median duration of 172 days(IQR 86-343); with 2-year OS and LFS of 77% (95% CI 69-83) and 72% (64-78) respectively. GVHD prior to initiation of maintenance improved OS and LFS [2-year OS 91% (95% CI 78-97) versus (vs) 71% (95% CI 60-79); p=0.03, 2-year LFS 85% (95% CI 72-93) vs 66 (95% CI 55-74); p=0.02], while age, type of AML, cytogenetics and pre-transplant MRD status had no significant impact on these outcomes. Adverse risk cytogenetics was associated with worse 2-year molecular LFS (56% vs 73%; p=0.047) which was conversely improved by presence of GVHD before maintenance (83% vs 61%; p=0.007).

Patient Characteristics		FLT3i (N=171)	HMA (N=146)
Age at HSCT	Median (IQR)	51 (41-61)	55 (38-63)
Year of HSCT	Median (IQR)	2020 (2019-2022)	2018 (2016-2021)
Type of AML (%)	Secondary	28 (17)	57 (39)
Mutations (%)	NPM1 FLT3 ITD FLT3 TKD alone/other FLT3 absent/missing	85 (51) 154 (90) 8 (5)/4 (2) 4 (2)/1 (1)	9 (7) 10 (8) 4 (3)/0 (0) 112 (89)/20 (14)
Cytogenetics (%)	Adverse risk (ELN 2022)	15 (9)	41 (30)
Treatment before HSCT	Sorafenib Midostaurin Giltertinib Azacitidine Decitabine	19 (11) 106 (62) 25 (15) 16 (9) 0 (0)	0 (0) 3 (2) 0 (0) 22 (15) 1 (1)
MRD status at HSCT (%)	Positive	39 (25)	44 (34)

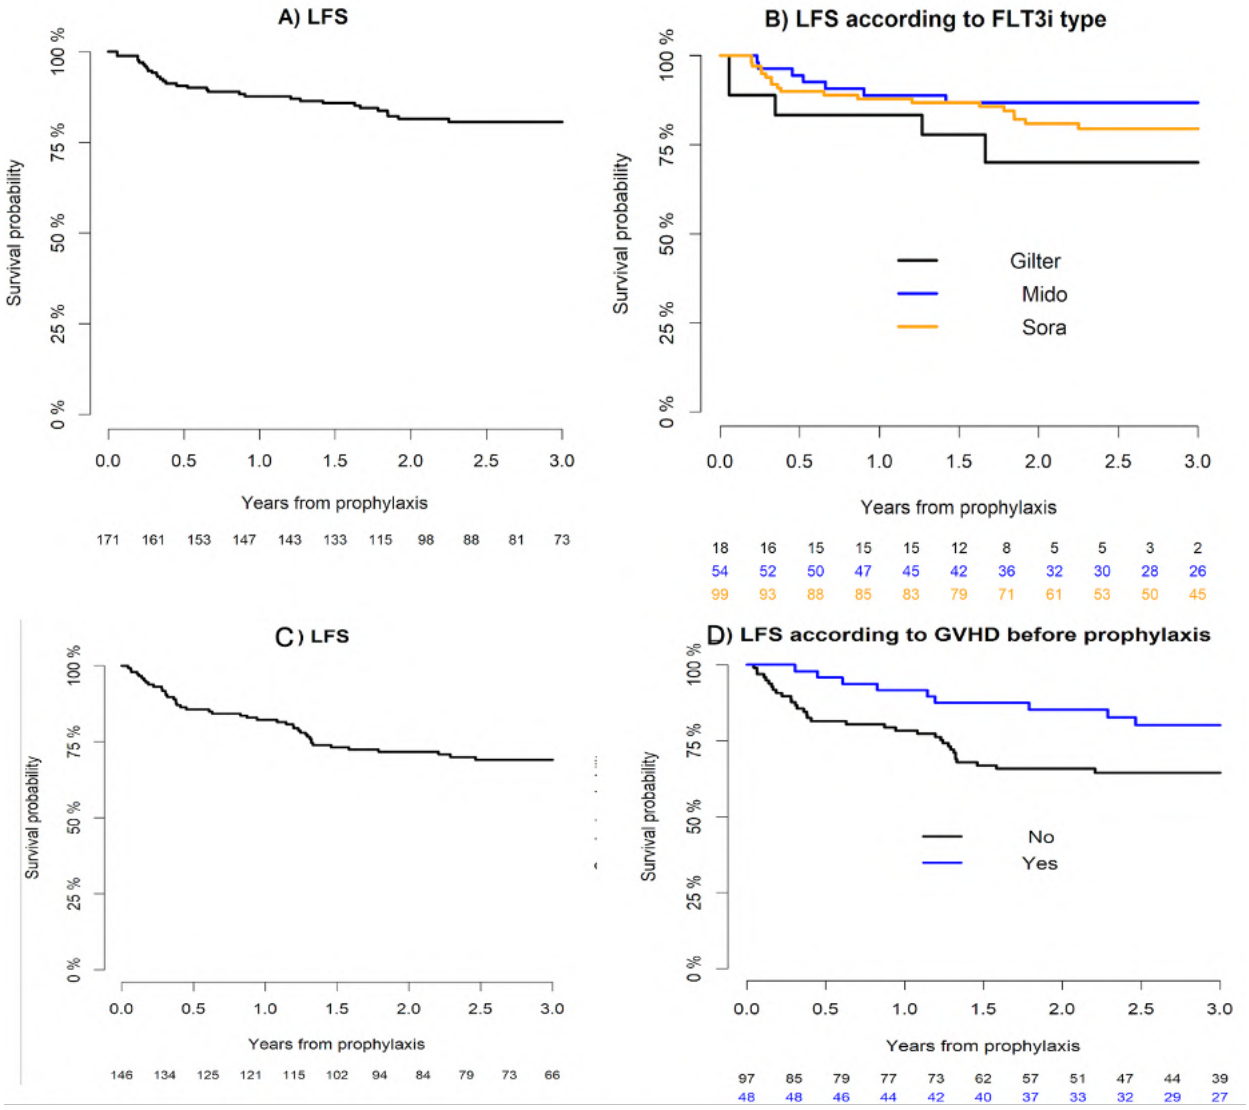
GVHD prior to prophylaxis (%)	Yes	60 (35)	48 (33)
Agent used as prophylaxis (%)	Sorafenib Midostaurin Giltertinib Azacitidine Decitabine	99 (58) 54 (31) 18 (11) NA NA	NA NA NA 135 (92) 11 (8)

Table 1. Patient characteristics for both groups (FLT3i and HMA)
Abbreviations: AML: acute myeloid leukemia; ELN: European LeukemiaNet; GVHD: graft versus host disease; HSCT: allogeneic hematopoietic stem cell transplant; IQR: interquartile range; MRD: minimal residual disease



Graph 1. Leukemia free survival for FLT3 inhibitor group (A: total cohort; and B by FLT3i type) and for patients receiving hypomethylating agents (C: total cohort and D: by prior graft-versus-host disease)

Conclusions: This real-world data reinforces FLT3i, especially sorafenib, as standard post-HSCT maintenance in AML patients, with 2-year LFS exceeding 80% regardless of MRD status or prior FLT3i exposure. Additionally, HMA showed encouraging results with 2-year LFS >70% particularly among those with prior GVHD.

Disclosure: Nothing to declare.

SUCCESSFUL ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR NEWLY DIAGNOSED AND RELAPSED/REFRACTORY ACUTE MYELOBLASTIC LEUKEMIA FOLLOWING A HIGHLY EFFICIENT REGIMEN, FLAG-MITOXANTRONE WITH LOW-DOSE 7 DAYS VENETOCLAX

Ahmad Ibrahim[1], *Kamal Al Zahran*[2], *Ahmad Khalil*[2], *Ali Youssef*[3], *Eliana Kachaamy*[2], *Jad Ibrahim*[4], *Wassim Hamadeh*[5], *Mohamad Abbas*[5], *Tamima Jisr*[3], *Charbel Khalil*[2], *Rima Moghniyeh*[6]

Background: FLAG (G-CSF, Fludarabine, Cytarabine) combined with either Idarubicin (Ida) or Mitoxantrone (Mitox) are effective and well tolerated in newly diagnosed (ND) or relapsed/refractory (R/R) Acute Myeloblastic Leukemia (AML)(Burnett et al. 2018 – Muhlneck et al. 2022). FLAG-Ida with Venetoclax (Ven) induced deep remissions and high rates of transition to allogeneic hematopoietic stem cell transplantation (AHSCT) in patients (pts) with ND or R/R AML (DiNardo 2022). Lowering the Cytarabine dose (to 1.5mg/m2/d for 5d) and shortening the duration of Ven administration in FLAG-Ida+Ven led to lower hematological and infectious toxicities (DiNardo 2025 – Shahswar 2024). We report the outcomes of a pilot study on FLAG-Mitox+Ven (given for 7d) in ND and first R/R AML pts.

Methods: Between 6/2020 and 6/2025, pts from 18 to 60 yo fit for intensive chemotherapy were included. FLAG-Mitox +Ven combined G-CSF (5µg/kg/d) on d1-7, Fludarabine (30mg/m2/d IV), and Cytarabine (1.5g/m2/d IV) on d2-5, Mitox (12mg/m2/d IV) d2,4 and Ven (100mg PO daily) given with voriconazole d2-8. Responding pts planned for AHSCT received 1 to 2 cycles of consolidation, while responding pts non planned for AHSCT received 3 cycles of consolidation. Fludarabine and Cytarabine were given on d2-4 and G- CSF d1-5, while Mitox and Ven were given at the same schedule in consolidation. Anti FLT3 was given to pts with FLT3 mutations. Measurable residual disease (MRD) was assessed by flow cytometry.
Endpoints included rate of composite CR (CRc: CR, CRh, CRi), OS, EFS and toxicity.

Results: Hundred and five pts were included with 55 ND and 50 R/R pts. There were 55 females and 50 males. Median age was 43yo (18–60). Among the ND pts, 11 (20%), 18 (33%), and 26 (47%) were ELN 2022 favorable, intermediate, and adverse, respectively. Sixty percent of the ND pts transitioned to AHSCT in CR1. The CRc rate after the first induction therapy was 91%, with a flow MRD-negativity of 86%. The 3-y OS and 3-y EFS rates were 68% and 64%, respectively. Outcomes were not significantly different across ELN 2022 risk groups. Among the 50 R/R pts, first induction therapy consisted of 7+3 regimen in 32 pts (64%), FLAG-Ida in 15 pts (30%) and 5-Azacytidine+Ven in 3 pts (6%). AHSCT was included in first line therapy of 15 pts. The CRc rate after FLAG-Mito+Ven was 78% with a flow MRD- negativity of 74%. Sixty percent of these R/R pts transitioned to AHSCT. The 3-y OS and 3-y EFS rates were 66% and 62%, respectively, for the pts who underwent AHSCT.

However, non-transplanted pts had a significantly lower 3-y OS (22%, p=0.025) and 3-y EFS (18%, p=0.002), respectively. The most frequent adverse events (grade ≥3) were hematologic, infectious (pneumonia), and gastrointestinal. The mortality rates at 30 and 60 days of FLAG-Mitox+Ven were 0% and 2.8%, respectively.

Conclusions: FLAG–Mitox+Ven (7d) is a highly-effective and well-tolerated for remission induction and MRD negativity in ND and R/R AML pts. High survival outcomes were demonstrated across ELN 2022 risk groups in ND AML pts. This regimen is also an effective bridge to AHSCT.

Disclosure: No

Background: *NRAS*, and/or *KRAS* mutations are identified in 10–15% of patients diagnosed with acute myeloid leukemia (AML). While their prognostic value in non-transplant settings remains inconsistent and treatment-dependent, their impact in the context of allogeneic hematopoietic cell transplantation (allo-HCT) is underexplored.

Methods: This retrospective registry-based study was conducted following approval by the Acute Leukemia Working Party (ALWP) of the EBMT. Adult AML patients who underwent allo-HCT between 2016 and 2021 with known *NRAS* and/or *KRAS* mutation status at diagnosis

were included, regardless of the disease status at transplant. The primary endpoints were overall survival (OS), leukemia-free survival (LFS), cumulative incidence of relapse (CIR), and non-relapse mortality (NRM).

Results: A total of 770 patients were identified, with a median age at allo-HCT of 53 years (range: 18–79); 53% were male. Median time from diagnosis to allo-HCT was 5 months (interquartile range: 4–8) for patients in first complete remission (CR1). Most had *de novo* AML (77%) and intermediate-risk ELN2022 cytogenetics (64%, with normal karyotype in 43%); 25% had adverse-risk cytogenetics. *NPM1* and *FLT3*-ITD mutations were present in 42% and 30% of patients, respectively. Myeloablative conditioning was used in 56% of cases. Donors included matched sibling (19%), haploidentical (25%), and matched unrelated (33%).
At transplant, 537 patients were in CR1, 93 in second or third CR (CR2+), and 140 had active disease. Compared to CR1 and active disease patients, those in CR2+ were more often female (59% vs. 46% vs. 43%, p=0.03), had *de novo* AML (91% vs. 80% vs. 57%), and were enriched for favorable cytogenetics (mainly inversion 16; 26% vs. 10% vs. 5%, p<0.001) and *NPM1* mutations (67% vs. 37% vs. 38%, p<0.001).
After a median follow-up of 2 years (95% confidence interval [CI]: 1.9–2.1), 2-year OS and LFS for the entire cohort were 65% (95% CI: 61-69) and 54% (95% CI: 50-58), respectively; 2-year CIR was 31% (95% CI: 27-35), and NRM 15% (95% CI: 12-18). In CR1 patients, 2-year OS, LFS and CIR were 72%, 61% and 26%, respectively; for CR2+ patients, 2-year OS was 62%, LFS 57%, and CIR 26%; for active disease, 2-year OS was 41%, LFS 28%, and CIR 51%. According to ELN2022 cytogenetic risk, 2-year LFS among CR1 patients was 77%, 61%, and 55% (p=0.04) for favorable, intermediate, and adverse risk, respectively.
Multivariable analysis for CR1 patients showed inferior LFS in secondary AML (hazard ratio [HR]: 1.57; 95% CI: 1.11–2.22; p=0.01), while haplo-identical transplant (HR: 0.54; 95% CI: 0.34–0.86; p=0.009), and recipient cytomegalovirus seropositivity (HR: 0.71; 95% CI: 0.5-0.96; p=0.03) were associated with improved LFS. Increasing age adversely affected OS.

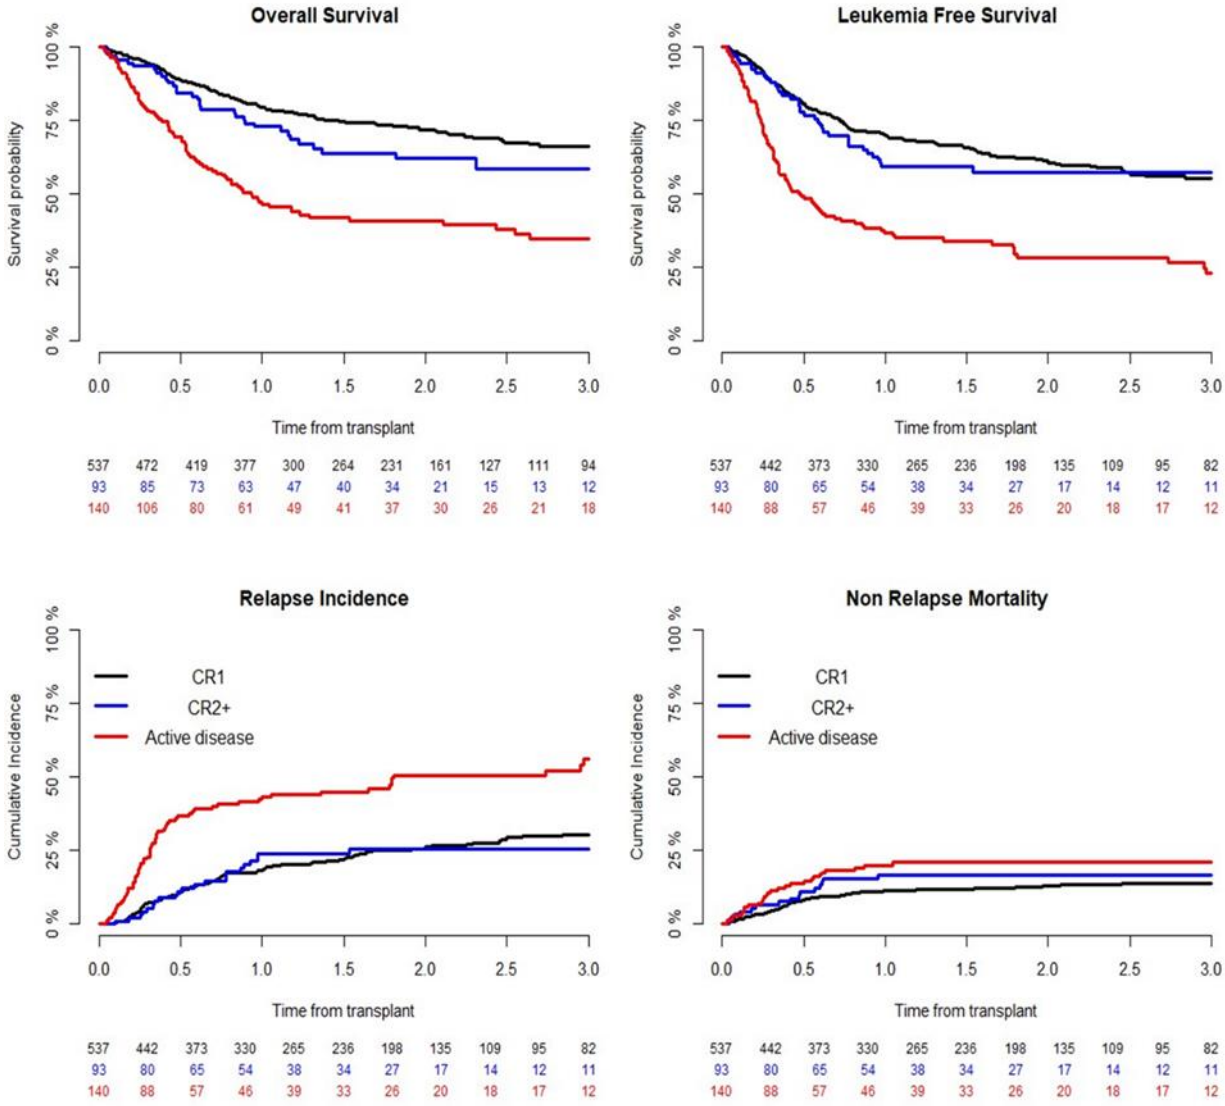
Source of cells	PB BM	635 (82) 43 (6)	434 (81) 26 (5)	77 (83) 4 (4)	124 (89) 13 (9)	Not done
Donor type	Matched related donor Haplo-identical Matched Unrelated Mismatched Unrelated	157 (20) 191 (25) 253 (33) 31 (10)	119 (22) 143 (27) 165 (31) 45 (8)	11 (1) 27 (29) 28 (30) 12 (13)	27 (20) 21 (15) 60 (43) 14 (9)	Not done



Conclusions: In this large EBMT registry analysis, outcomes of AML patients harboring *NRAS* and/or *KRAS* mutations were encouraging, with 2-year LFS exceeding 60%. Notably, patients in CR2+ had predominantly favorable features, and achieved survival outcomes not different to those in CR1. In addition, haploidentical transplant appeared to confer a better LFS in this cohort, suggesting a potential role for graft-versus-leukemia effects.

Clinical Trial Registry: Not applicable.

Background: The thiotepa-busulfan-fludarabine (TBF) protocol has shown promising outcomes in haploidentical and cord blood hematopoietic cell transplantation (HCT), but evidence remains limited for matched sibling donor (MSD) and unrelated donor (URD) transplants in acute myeloid leukemia (AML) patients in first complete remission (CR1) with measurable residual disease positivity (MRD+).

Methods: We retrospectively analyzed adult AML patients in CR1 with MRD+ undergoing first allogeneic HCT (allo-HCT) between 2010–2023 using 10/10 MSD or 10/10 or 9/10 URD. Conditioning was TBF or fludarabine/busulfan (Flu/Bu).

Results: The analysis comprised 1221 patients, with 209 in the TBF group and 1012 in the Flu/Bu group. The median follow-up was 2.2 and 3.8 years, respectively. Compared to the Flu/Bu group, patients in the TBF group were younger (50.4 vs. 55.1 years, P<0.0001), transplanted more recently (2020 vs. 2018, P<0.0001), had longer diagnosis-to-transplant intervals (5.9 vs. 5.3 months, P=0.0036), had higher Karnofsky Performance Scores (KPS ≥90: 88.3% vs. 77.8%, P=0.0007), received more 9/10 URD grafts (28.2% vs. 12.1%, P<0.0001), and received post-transplant cyclophosphamide (PTCy) more frequently (32.5% vs. 10.7%, P<0.0001). Other baseline characteristics were comparable between groups (Table 1).
In univariate analysis, 100-day acute graft-versus-host disease (aGVHD) grades II–IV and III–IV were similar between the TBF and Flu/Bu groups (26.5% vs. 24.6%, P=0.76; 12% vs. 8.9%, P=0.53). However, the TBF group exhibited lower 2-year chronic GVHD (cGVHD; 21.3% vs. 34.8%, P=0.0006) and extensive cGVHD (0.6% vs. 8.3%, P=0.0005). Two-year overall survival (OS; 62.5% vs. 65.4%, P=0.8) and leukemia-free survival (LFS; 55.7% vs. 55.4%, P=0.77) did not differ between groups. Notably, the TBF group experienced higher non-relapse mortality (NRM; 17.9% vs. 10.9%, P=0.04) and potentially lower relapse incidence (RI; 26.4% vs. 33.7%, P=0.06) (Figure 1).
In multivariate analysis, the incidence of aGVHD grade II–IV and grade III–IV was comparable between groups. However, TBF conditioning was associated with a marginally lower risk of cGVHD (HR=0.66; P=0.05) and a significantly lower risk of extensive cGVHD (HR=0.07; P=0.01) compared to the Flu/Bu group. Additionally, female donor to male

patient combination was a risk factor for extensive cGVHD (HR=2.41; P=0.01).
No significant difference was observed in OS, LFS, or RI between groups, but TBF conditioning was associated with a higher risk of NRM (HR=1.81; P=0.01). Earlier year of transplantation was associated with lower OS (HR=0.83; P=0.046). Older patient age was a prognostic factor for higher NRM (HR=1.06; P=0.002). Patient CMV seropositivity was a risk factor for OS (HR=1.48; P<0.001) and LFS (HR=1.33; P=0.008). Favorable and intermediate risk cytogenetics were prognostic factors for improved OS, LFS, and lower RI. Reduced intensity conditioning (RIC) was associated with lower OS (HR=1.39; P=0.004) and LFS (HR=1.4, P=0.007), as well as a higher risk of RI (HR=1.57; P<0.001).

Table 1. Patients characteristics

Conclusions: The addition of Thiotepa to Flu/Bu significantly increased NRM without improving survival or relapse outcomes, outweighing the benefit of reduced cGVHD. Consequently, the standard Flu/Bu regimen remains a safer and sufficient strategy for AML patients undergoing MSD/URD transplantation in CR1 with MRD+. Further studies are needed in other settings such as haploidentical transplants.

COMBINED PRE-TRANSPLANT MRD DETECTION BY FACS AND NGS MAY ENHANCE RELAPSE PREDICTION IN AML PATIENTS RECEIVING ALLO-SCT IN COMPLETE REMISSION

Evgeny Klyuchnikov[1], *Anita Badbaran*[1], *Radwan Massoud*[1], *Ina Rudolph*[1], *Catherina Lueck*[1], *Silke Heidenreich*[1], *Jochim Reinert*[1], *Boris Fehse*[1], *Nicolaus Kröger*[1], *Francis Ayuk*[1]
[1]*University Cancer Center, Hamburg-Eppendorf, Hamburg, Germany*

Background: Accurate assessment of measurable residual disease (MRD) before allogeneic hematopoietic stem cell transplantation (allo-HSCT) is critical for risk stratification and personalised treatment in acute myeloid leukaemia (AML). Flow cytometry (FACS-MRD) and error-free next-generation sequencing (NGS-MRD) are complementary techniques that differ in analytical principles, target specificity, and sensitivity. Their integration in the pre-transplant setting may improve prediction of relapse risk and post-transplant outcomes and guide post-transplant interventions.

Methods: Adult AML patients (n = 107) undergoing first allo-HSCT in first CR at the University Medical Centre Hamburg-Eppendorf (2020–2023) were evaluated for MRD in bone marrow aspirates obtained within 14 days before conditioning. Two approaches were used: (i) multiparameter flow cytometry (FACS-MRD) with sensitivity 10^{-4}–10^{-5}, and a cut-off of 0.1% for MRD positivity; (ii) error-corrected NGS-MRD (non-DTA) using the Oncomine Myeloid MRD (RUO)Assay (Thermofisher) (limit of detection ≈ 0.1 % of variant allele frequency). MRD results were dichotomised (positive/negative) and correlated with post-transplant outcomes (CIR, LFS, OS).

Results: Pre-transplant MRD was detected in 37% by FACS and in 45% by NGS. Concordance between both modalities was moderate to substantial (Cohen's κ = 0.60). NGS identified additional subclonal variants (e.g. *TP53*, *RUNX1*, *FLT3-ITD*) in 26% of FACS-MRD negative patients.
Patients who were MRD-positive in either single modality showed significantly higher relapse incidences (FACS: 5-year CIR 53% [95% CI, 37–69] vs 14% [95% CI, 8–24], p < 0.01; NGS: 5-year CIR 45% [95% CI, 31–60] vs 14% [95% CI, 7–25], p < 0.01) and inferior overall survival (FACS: 5-year OS 39% [95% CI, 25–55] vs 79% [95% CI, 68–87], p < 0.001; NGS: 49% [95% CI, 39–63] vs 76% [95% CI, 64–85], p = 0.006).
Patients with discordant MRD results had an intermediate risk profile, with a 5-year CIR of 20% (95% CI, 9–39) and OS of 60% (95% CI, 41–77). In contrast, patients positive in both MRD modalities had higher relapse risk (5-year CIR 62% [95% CI, 43–78] vs 15% [95% CI, 9–24], p < 0.01) and inferior survival (5-year OS 33% [95% CI, 18–50] vs 76% [95% CI, 65–84], p < 0.001).
In multivariate analysis, dual MRD positivity remained the strongest independent predictor of relapse (HR 6.8, 95% CI, 3.0–15.0; p < 0.001) and overall survival (HR 3.2, 95% CI, 1.6–6.1; p = 0.001).
With otherwise comparable predictive performance, the dual-modality MRD approach

demonstrated higher specificity (84%) and a higher positive predictive value (60%) than either single-modality strategy.

Conclusions: The dual-modality MRD approach (FACS + NGS) lowers the frequency of false positives and yields approximately 10% greater accuracy in relapse prediction, though without a marked improvement in prediction of overall survival. This combined strategy may enable more refined selection of patients who are appropriate candidates for early post-transplant interventions.

Disclosure: Nothing to declare.

Background: Secondary AML (sAML) is characterized by a unique cytogenetic and mutational profile that dictates inferior outcomes. NGS allows identification of secondary-type signatures, even in patients (pts) presenting with *de novo* disease (Lindsley C, *et al*.

Blood 2015). The specific role of allogeneic transplantation (HSCT) among pts harboring secondary-type gene mutations needs further investigation.

Methods: We aimed to compare NGS mutation profile (by multiple correspondence analysis and circle plot interaction schemes) and assess its prognostic impact in sAML *vs de novo* AML (dnAML) pts undergoing HSCT (92.8% in CR1) between 2010-2023. Donors were unrelated - 39.4%, matched related – 34.6%, haploidentical - 19.8% (other - 6.5%).

Results: 746 pts were included, sAML -63, dnAML -683. Follow-up was 2 years. Median year of transplant was 2019. Pts with sAML were older, 61.1 vs. 53.8 years (p<0.001). The two groups did not differ in gender, performance status, CMV seropositivity, gender combination, or time from diagnosis to transplant. Cytogenetic risk was intermediate in 67.2% vs 69.3% and adverse in 32.8% vs 25.5%, respectively (p=0.1). Pts with sAML received BM grafts (9.5% vs. 4%; p=0.051) and RIC (61.9% vs. 44.2%; p=0.007) more frequently. The 2-year LFS and OS rates were 47.5% vs. 59% (HR=0.88, p=0.557) and 55.5% vs. 68.9% (HR=0.74, p=0.2), in sAML vs. dnAML, respectively. 2-year RI was 35.4% vs. 27.7% (HR=1, p=0.996) and 2-year NRM was 17.1% vs. 13.2% (HR=0.71, p=0.342), for sAML vs dnAML (Figure 1A). The leukemia was the main cause of death, 58.3% vs. 57.2% of those who died. The incidence of day 180 acute GVHD grades II-IV was 25.1% vs. 24.2%, and grades III-IV was 5.5% vs. 7.9%, while 2-year total chronic GVHD was 36.6% vs. 38.8%, and of extensive chronic GVHD was 11.1% vs. 13.5%, respectively (Figure 1A). GRFS was 43% vs. 48.4 % (HR=0.86, p=0.448) in sAML vs. dnAML. Day 30 ANC $\geq$ 10^9/L was 89.8% vs. 95.7 % and day 60 platelet count $\geq$ 20x10^9/L was 91.4% vs. 92.5%. Mutations in JAK2 (11.5% vs. 1.7%, p<0.001); splicing factors SF3B1 (11.5% vs. 4.9%, p=0.04), SRSF2 (29% vs. 8.7%, p<0.001), U2AF1 (10% vs. 2.7%, p=0.011), ZRSR2 (11.6% vs. 1.5%, p=0.002), and TP53 (16.7% vs. 5.9%, p=0.004) were more prevalent among sAML pts. NPM1 (21.2% vs. 7.9%, p=0.012) and FLT3-ITD mutations (24.8% vs. 9.8%, p=0.008) were more frequent in dnAML (Figure 1B). On MVA, cytogenetic risk showed a negative impact on OS, LFS, RI, and GRFS. The number of mutated genes (0 vs 1 vs$\geq$2) did not affect outcome parameters. The association of mutations in TP53, RUNX1, ASXL1, and the splicing factors (SF3B1, SRSF2, U2AF1, and ZRSR2) is depicted in Figure 1C. Due to the small number of patients, the data should be interpreted with caution, and no definitive conclusions can be drawn.

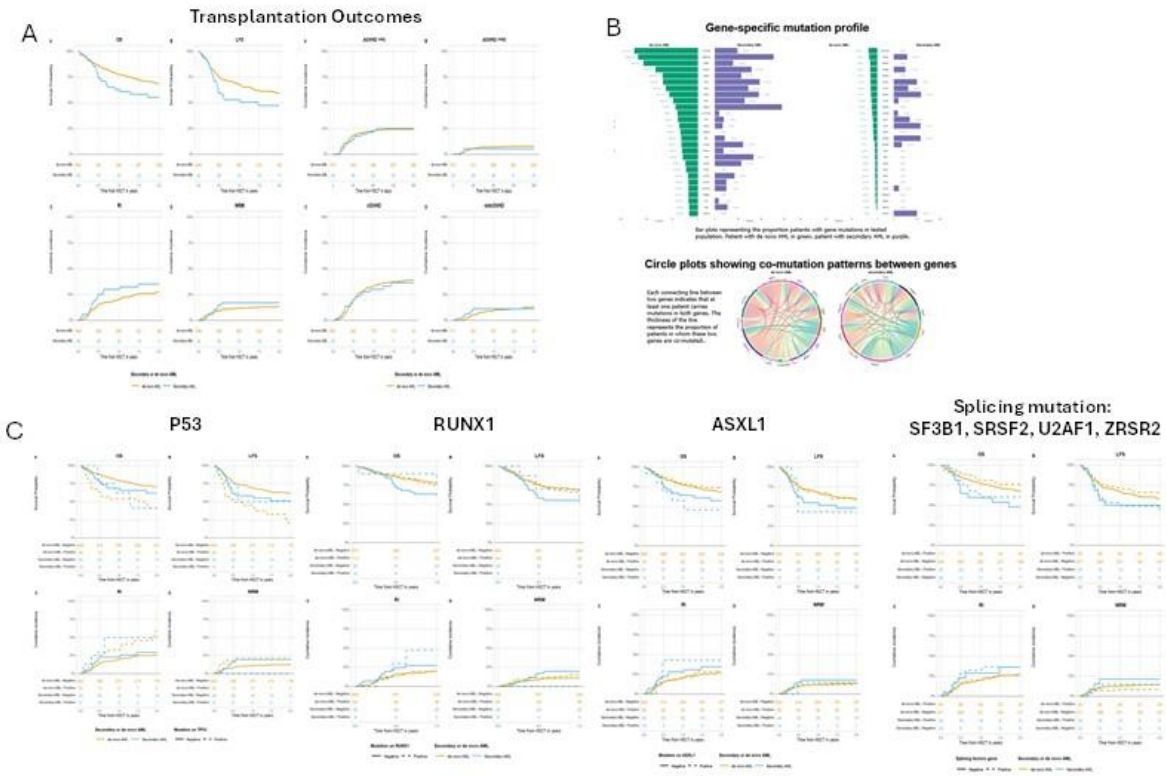

Figure legend: A. Outcomes of allogeneic HSCT in patients with secondary vs de novo AML: overall survival (OS); leukemia-free survival (LFS); relapse incidence (RI); non-relapse mortality (NRM); acute GVHD grade II-IV (>=II) and III-IV (>=III); chronic GVHD total(cGVHD) and extensive (extcGVHD). B. NGS mutation profile by multiple correspondence analysis and circle plot interaction schemes; C. Association between specific mutations in secondary vs de novo AML-TP53; RUNX1; ASXL1 and splicing factors (SF3B1, SRSF2, U2AF1 and ZRSR2) and transplantation outcomes: overall survival (OS); leukemia-free survival (LFS); relapse incidence (RI); non-relapse mortality (NRM) .

Arnon Nagler[1*] and Jordi Esteve[2*] contribute equally to the study

Conclusions: This study confirmed differences in the mutational landscape between sAML *and* dnAML. Nonetheless, AML presentation type did not show a prognostic impact, whereas the presence of TP53 mutation and adverse risk cytogenetics were the only genetic disease factors showing prognostic impact.

Disclosure: Nothing to disclose

Background: γ9δ2TCs drive *Graft Versus Leukemia* in the post-transplant and intra-tumor presence of γ9δ2TCs is prognostic. ICT01 is a first-in-class anti-butyrophilin 3A mAb who activates γ9δ2TC determining anti-leukemic cytotoxicity and NK/CD8 T cell activation. ICT01-Aza-Ven showed synergistic efficacy in a mouse model with adoptive γδTC transfer. From the dose-optimization phase 1/2 study investigating 10 mg ($ICT01^{LOW}$) and 75 mg ICT01 ($ICT01^{HIGH}$) with Aza-Ven, $ICT01^{LOW}$ was chosen as the RP2D (Maiti et al. Cancer Res. 2025) and that cohort expanded to 41 patients. Here, we report safety and efficacy results as of 6 Oct 25 DCO, including a preliminary analysis for OS from fully enrolled population in EVICTION.

Methods: ND-AML patients ≥ 75 years or unfit for intensive chemotherapy were randomized 1:1 to standard dosing of Aza-Ven plus ICT01 at either 10 mg ($ICT01^{LOW}$) or 75 mg ICT01 ($ICT01^{HIGH}$) on day 1 of each cycle. The primary objective was CR and CRc by ELN 2022; secondary endpoints were safety per NCI-CTCAE 5.0, ICT01 pharmacodynamics (PD) in peripheral blood (PB) and bone marrow (BM).

Results: 54 patients, 38 $ICT01^{LOW}$ and 16 $ICT01^{HIGH}$, were evaluable for efficacy. Median age was 75 yrs (range 51–87). Median baseline BM blasts was 40% (range 7–98%). Per refined ELN 2024 classification, 30%, 28% and 42% patients had favorable, intermediate and adverse risk disease. Median days (IQR) of venetoclax dosing in cycles 1, 2, 3,4 were 22 (20, 27), 20 (13, 21), 13 (6, 16), 12 (6, 20), respectively. Median duration (IQR) of cycles 1, 2, 3 was 31 (28, 38), 31 (28, 47), and 29 (28, 42) days. Patients who had $ICT01^{LOW}$ achieved 71% CR (95% CI, 54–85%) and 84% CRc (69–94%) vs 44% CR (95% CI, 20–70%) and 69% CRc (41–89%) from the $ICT01^{HIGH}$ (p=0.0715 and p=0.269 for CR and CRc respectively; χ2 test). For favorable, intermediate and adverse-risk patients who had $ICT01^{LOW}$, CRc was 100%, 83% and 67% and CR was 86%, 67% and 58%, with a time to first CRc response of 0.9 months (range, 0.7–2.9). After a median follow-up time of 10.8 months (95% CI, 8.9–12.8), 9-months OS was 67% (54–81%) in the $ICT01^{LOW}$ cohort and 56% (39–81%) in the $ICT01^{HIGH}$ (HR 0.4 [0.2–0.9] for OS [p=0.07; log rank]). Patients CRc or MLFS vs NR, had significantly higher baseline γ9δ2TC counts (p=0.001) and a greater increase in serum IFNγ 4h post first ICT01 dose (p=0.0001 vs. p=0.38; Wilcoxon test). Higher trough PB γ9δ2TC levels with $ICT01^{LOW}$ vs $ICT01^{HIGH}$ in subsequent cycles were

associated with higher efficacy. No DLT reported; 30-day mortality was 4%. No new safety signal detected for ICT01. Grade 3/4 febrile neutropenia occurred in 51% of the patients. No ICT01-related deaths or treatment discontinuations reported.

Conclusions: ICT01 was safe, well tolerated, and associated with high CR and CRc rates in older/unfit ND-AML patients. The high response rate and promising early OS signal, warrant further clinical investigation. Consistent PD effects suggest an individual contribution of ICT01 to the efficacy of the novel triplet regimen ICT01-Aza-Ven.

FLAMSA-BASED CONDITIONING IS ASSOCIATED WITH LOWER NRM AND HIGHER SURVIVAL IN PATIENTS WITH RELAPSED/REFRACTORY AML

Evgeny Klyuchnikov[1], *Normann Steiner*[2], *Radwan Massoud*[1], *Silke Heidenreich*[1], *Ina Rudolph*[1], *Catherina Lueck*[1], *Jochim Reinert*[1], *Nicolaus Kröger*[1], *Francis Ayuk*[1]
[1]*University Cancer Center, Hamburg-Eppendorf, Hamburg, Germany,* [2]*Innsbruck Medical University, Innsbruck, Austria*

Background: Allogeneic stem cell transplantation (allo-SCT) remains the only potentially curative option for patients with relapsed/refractory acute myeloid leukemia (rrAML). The

optimal conditioning regimen for these patients is still unclear. Studies investigating FLAMSA-based sequential conditioning protocols have reported lower non-relapse mortality (NRM), better disease control, and higher overall survival compared to classical myeloablative conditioning (MAC) or reduced-intensity conditioning (RIC) regimens. However, prospective randomized studies are lacking, and comparative real-world data on FLAMSA versus other conditioning strategies for rrAML remain limited.

Methods: This retrospective single-center study includes 245 patients with rrAML (59% male, median age 60 years, range 6-76) who underwent allo-SCT at the Department for Stem Cell Transplantation, University Medical Centre Hamburg Eppendorf, between 1995 and 2025. Ninety percent of the patients received their first allo-SCT. Most patients received grafts from unrelated donors (MUD, 47%; MMUD, 27%; MRD, 19%; haploidentical, 7%) after MAC (42%) or RIC (58%). FLAMSA-based conditioning was used in 132 patients (FLAMSA/Bu, n=68; FLAMSA/TBI, n=50; FLAMSA/Treo, n=14). Other regimens included TBF (n=29), Bu/Flu or Bu/Cy (n=21), TBI-based conditioning (n=34), and other regimens (n=29). Anti-thymocyte globulin (ATG) was used in 80% of patients.

Results: Median age did not differ between the FLAMSA and non-FLAMSA groups. FLAMSA-based regimens were more frequently used before 2020 (83% vs. 56%, p<0.001), with RIC regimens being significantly more common in the FLAMSA group (71% vs. 42%, p<0.001). Total body irradiation was more frequently applied in younger patients (<60 years) in both groups.
The cumulative incidence of relapse at 3 years was comparable between the FLAMSA and non-FLAMSA groups (47% [38-56%] vs. 45% [36-55%], p=0.73). However, the cumulative incidence of NRM at day 100 and 1 year was significantly lower in the FLAMSA group (day 100: 14% [9-21%] vs. 24% [17-33%]; 1 year: 19% [13-27%] vs. 36% [27-46%], p=0.003). The 3-year overall survival (OS) and leukaemia-free survival (LFS) were significantly higher in the FLAMSA group: 34% [26-42%] vs. 21% [14-30%], p=0.002 and 28% [21-36%] vs. 16% [10-25%], p=0.005, respectively. Within the FLAMSA group, the highest 3-year OS of 36% [22-50%] was observed after FLAMSA/TBI. Among other conditioning regimens, the highest 3-year OS of 27% [13-47%] was seen with thiotepa-based conditioning (TBF).
In multivariate analysis, FLAMSA-based conditioning and younger age were independently associated with reduced NRM (HR 0.42, 0.24-0.77, p=0.004 and HR 0.31, 0.29-0.99, p=0.045). FLAMSA-based conditioning also showed a favourable association with LFS (HR 0.66, 0.48-0.90, p=0.008) and OS (HR 0.66, 0.48-0.90, p=0.01).

Conclusions: In this large single-center cohort of rrAML patients undergoing allo-SCT, FLAMSA-based sequential conditioning was associated with significantly lower non-relapse mortality and improved survival compared to non-FLAMSA regimens, without increasing the risk of relapse. Among the FLAMSA variants, FLAMSA/TBI showed the most favourable long-term survival.

Disclosure: Nothing to disclose.

B300

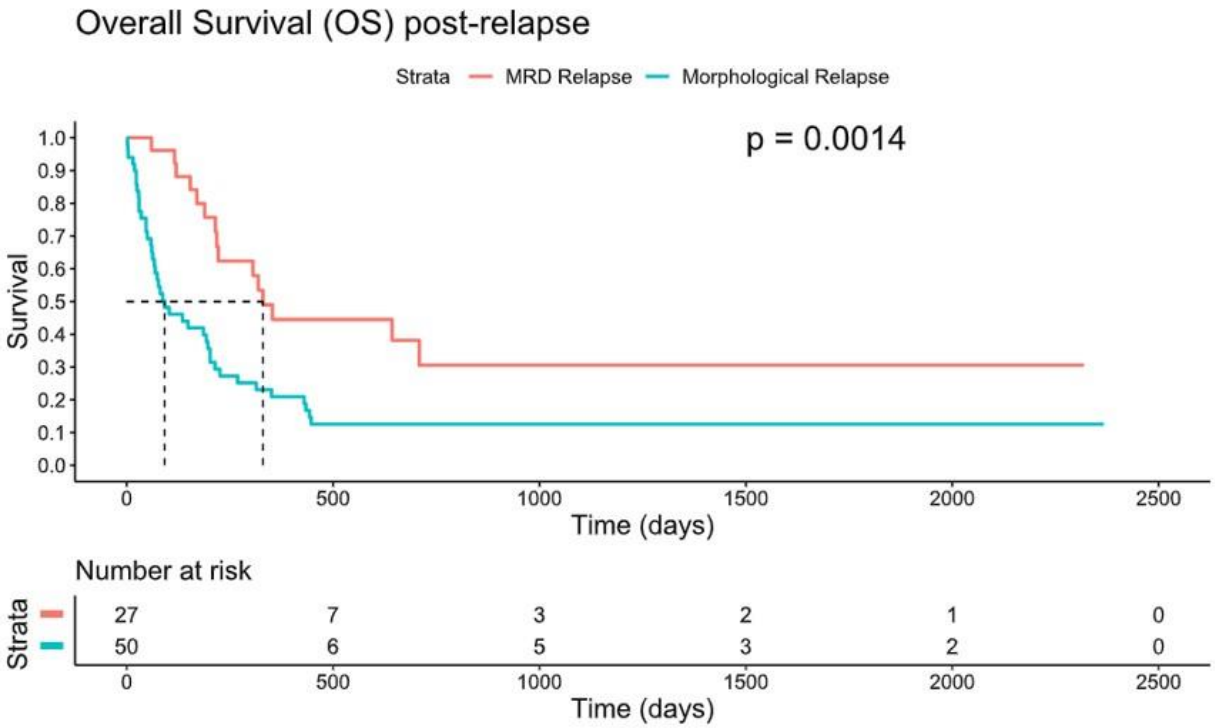
OUTCOMES OF MORPHOLOGICAL VERSUS MINIMAL RESIDUAL DISEASE (MRD) RELAPSE AFTER ALLOGENEIC TRANSPLANTATION (ALLO-HCT) FOR ACUTE MYELOID LEUKEMIA (AML)

Ishaan Garg[1], Anmol Baranwal[1], Aldo Acosta Medina[1], Mathias Palmer[1], Abhishek Mangaonkar[1], Mehrdad Hefazi Torghabeh[1], Aasiya Matin[1], Mark R. Litzow[1], William J. Hogan[1], Mithun V. Shah[1], ***Hassan B. Alkhateeb***[1]
[1]*Mayo Clinic, Rochester, United States of America (the)*

Background: Relapse remains the leading cause of mortality following allo-HCT for AML. With increasing use of sensitive methods to detect MRD, the prognostic impact of type of relapse detected morphologically versus at MRD level remains unclear. We evaluated treatment-patterns and outcomes of post-transplant morphological versus MRD-relapse.

Methods: We retrospectively reviewed all adult AML patients undergoing allo-HCT at Mayo Clinic Rochester between 2018–2025. Morphological relapse was defined as ≥5% marrow blasts and/or extramedullary disease (EMD). MRD relapse was defined by multiparametric flow cytometry (MRD^{F}), molecular testing by digital droplet polymerase chain reaction (MRD^{M}), or cytogenetic abnormalities (MRD^{C}).

Results: Among 272 consecutive AML allo-HCT recipients, 77(28%) relapsed at a median of 128 days (range 28–741). Median age was 57 years (IQR 43-64), 51% were male, and 64% had ELN-2022-adverse-risk disease. Most received myeloablative conditioning (51%) and matched-unrelated-donor-grafts (58%).
Fifty patients (65%) experienced morphological-relapse without preceding-MRD-detection, while 27 (35%) presented with MRD-relapse. Morphological-relapse was associated with a higher rates of ELN-adverse-risk (77.5% vs 22.4%; p=0.006) and adverse-cytogenetics (58% vs 14.8%; p<0.001). Conditioning-intensity and donor-source were similar; however, PTCy use was more frequent in the MRD-relapse-group (74% vs 34%; p=0.042).
Time-to-relapse did not differ between morphologic and MRD-relapse (119 vs 128 days; p=0.83). Morphologic-relapse was associated with inferior 1-&-2-yr OS compared with MRD-relapse (21% vs 44.5% and 12.6% vs 30.5%; p=0.0014)(Figure-1).



Among morphologic-relapse (n=50), median marrow-blast % at relapse was 26 (range 3-97%), with EMD in only 3 (6%) patients. First-line-therapy included hypomethylating agents (HMA) in 28 (56%) patients (frequently combined with-venetoclax/targeted agents), intensive chemotherapy in 5 (10%), single-agent-FLT3i in 3 (6%), immunosuppression-taper/withdrawal alone in 7 (14%) patients, radiation in 2 (4%); five (10%) received no therapy due to clinical decline. DLI was used in 4 (8%) patients, and 5 (10%) proceeded to 2nd allo-HCT. Eighteen patients (36%) achieved remission (13-MLFS, 4-CRi, 1-CR), with median-time-to-response of 73 days (range 14–296) and a median-duration-of-response being 146 days, after which 10(20%) subsequently relapsed.

Among MRD-relapse (n=27), pretransplant-MRD was negative in 11(41%), positive in 10 (37%), unknown in 5(19%), while 1(3%) patient had active-disease. Post-transplant-MRD-relapse presented as MRD^{M} in 8(30%), MRD^{F} 11(41%), MRD^{C} 6(22%), and mixed-MRD in 2(7%) patients (1-MRD^{M+F},1-MRD^{M+C}). First-line-therapy included HMA-based-therapy in 9(33%) patients (frequently combined with-venetoclax), low-dose HMA in 8(30%) patients, targeted therapy alone (6-FLT3i, 1-IDH2i) in 7(26%), a 2nd allo-HCT in 2(7%), immunosuppression taper/withdrawal alone in 1(4%). Later, DLI was used in 3 patients, and a 2nd allo-HCT in one. During a median 447-day follow-up, 18(67%) patients developed morphological relapse, while 9 (33%) remained morphological-relapse-free, of whom 8 achieved MRD negativity with a median of 69.5 days. MRD^{M} had numerically superior 1-yr morphological-relapse-free-survival (MRFS) and overall-survival (OS)(Table-1).

	MRD (n=27)	MRD^{M} (n=9 including 1 1-MRD^{M+F})	MRD^{F} (n=11)	MRD^{C} (n=7, including 1 MRD^{M+C})
1-yr MRFS	47.8% (95%CI, 30.9-73.9%)	77.8% (95%CI, 54.9-100%)	25.9% (95%CI, 5.75-100%)	28.57% (95%CI, 8.86-92.18%)
1-yr OS post MRD relapse	44.5% (95%CI, 28.2-70.3%)	55.6% (95%CI, 31-99.7%)	46.7% (95%CI, 21-100%)	28.6% (95%CI, 8.86-92.2%)

Conclusions: Post-transplant-relapse in AML continues to have dismal prognosis despite novel therapies. Morphological relapse-more frequently observed in ELN adverse-risk disease-confers significantly inferior survival compared with MRD relapse, likely reflection of aggressive disease biology. Among MRD-relapses, molecular-relapse appears to have more favorable-outcomes. These findings highlight the importance of standardized MRD surveillance following transplant to enable earlier therapeutic intervention prior to an overt morphological relapse.

Disclosure: Nothing to declare.

B301

PATIENTS WITH HIGH-RISK ACUTE MYELOID LEUKAEMIA UNDERGOING UNMANIPULATED G-CSF–PRIMED HAPLOIDENTICAL BONE MARROW TRANSPLANTATION: FAVOURABLE LONG-TERM OUTCOME IN FIRST REMISSION WITH POSITIVE MEASURABLE RESIDUAL DISEASE

*Camilla Page[1], **Gottardo De Angelis**[2], Giulia Ciangola[2], Benedetta Mariotti[2], Gianmario Pasqualone[1], Federica Frenza[1], Ilaria Mangione[1], Antoine Bruno[1], Francesco Buccisano[1,2], Adriano Venditti[1,2], Marco Andreani[3], Luca Cupelli[4], Mariagiovanna Cefalo[4], Luigi Rigacci[5], Enrico Santinelli[5], Maria Paola Bianchi[6], Michele Cedrone[7], Eleonora Ceresoli[7], Andrea Mengarelli[8], Francesco Marchesi[8], William Arcese[5], Raffaella Cerretti[2]*
[1]University of Rome "Tor Vergata", Rome, Italy, [2]Fondazione Policlinico Tor Vergata, Rome, Italy, [3]Bambino Gesù Children's Hospital, IRCCS, Rome, Italy, [4]Sant'Eugenio Hospital, ASL Roma 2, Rome, Italy, [5]Fondazione Policlinico Universitario Campus Bio-Medico, Rome, Italy, [6]Azienda Ospedaliera Sant'Andrea, Rome, Italy, [7]A.O. San Giovanni Addolorata, Rome, Italy, [8]IRCCS Regina Elena National Cancer Institute, Rome, Italy

Background: Haploidentical hematopoietic stem cell transplantation (haplo-HSCT) has become an increasingly feasible curative strategy for patients with high-risk acute myeloid leukaemia (AML). Moreover, positive measurable residual disease (MRD+) at transplant has been associated with poorer survival. Advances in graft-versus-host disease (GVHD) prophylaxis have markedly improved safety—particularly through ATG-based and post–cyclophosphamide platforms—broadening access to transplantation for patients lacking an

HLA-identical donor. Despite these developments, comparative analyses remain limited by heterogeneous cohorts and variable transplant approaches.

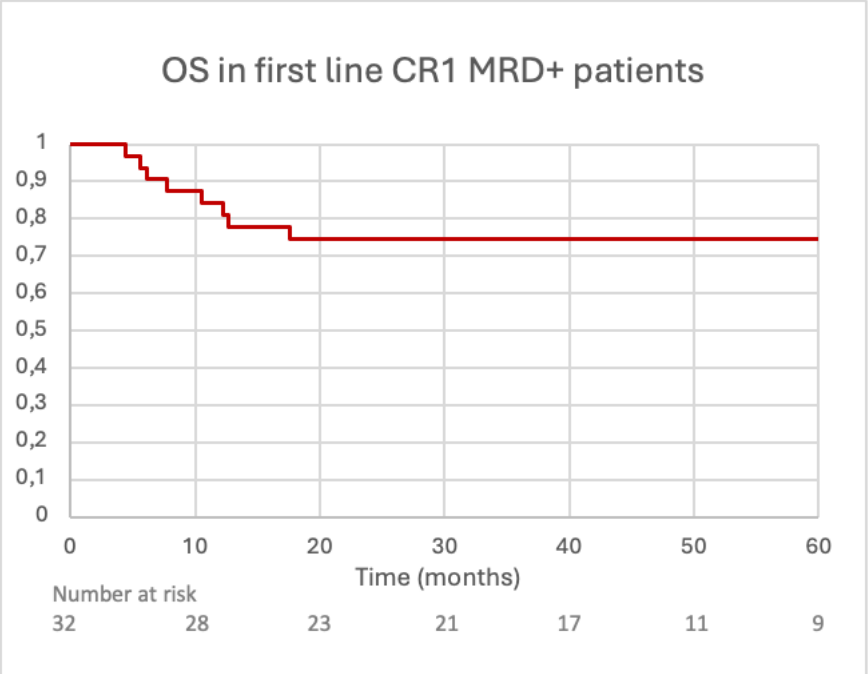
Methods: We conducted a retrospective single-center study including a population of 110 consecutive adult patients with high-risk AML who underwent unmanipulated G-CSF–primed bone marrow haplo-HSCT with intensified ATG and Basiliximab based GVHD prophylaxis between 2008 and 2023. The policy of donor selection, conditioning regimen including thiotepa-busulfan-fludarabine, graft source, supportive care, and infections prophylaxis were uniform across the cohort. Primary endpoints were overall survival (OS) and non-relapse mortality (NRM); secondary endpoints included GVHD and relapse incidence. MRD was assessed using multiparametric flow cytometry or molecular assay.

Results: The main characteristics of the patients are reported in the table. In the overall population, OS was 60% at 12 months and 46% at 5 years, with a 10-year OS of 44%. Cumulative incidence of acute GvHD grade II-IV and 5-yrs extensive chronic GvHD were 48% and 18% respectively. NRM was 24% at 12 months and 27% at 24 months. Disease status at transplant was the only independent predictor of NRM (p = 0.008), with significantly lower NRM among patients transplanted in complete remission.
Within the 72 patients transplanted in first complete remission (CR1), outcomes were markedly superior. NRM was 18% at 2 years, and relapse incidence was 22% and 28% at 12 and 24 months, respectively. These translated into a 5-year OS of 58% for the full CR1 cohort, reaching 74% among those 32 patients transplanted after first-line therapy with MRD+ (Graph).

Descriptive characteristics of the overall population (N=110)

Median patient age, years (range)	54 (14–70)
Median donor age, years (range)	36 (18–70)
Patient sex, male/female	54/56 (49%/51%)
Donor sex, male/female	68/42 (62%/38%)
Recipient/Donor sex combination	
Male/Male	34 (31%)
Female/Female	22 (20%)
Male/Female	34 (31%)
Female/Male	20 (18%)
Disease status at transplant	
CR1	72 (66%)
CR2	21 (19%)

≥ CR3 or active disease	17 (15%)
Conditioning regimen	
Myeloablative (TBF-MAC)	64 (58%)
Reduced-intensity (TBF-RIC)	46 (42%)



Conclusions: In this homogeneously treated population of adults with high-risk AML, unmanipulated G-CSF–primed haploidentical bone marrow transplantation with ATG and Basiliximab based prophylaxis yielded excellent long-term outcomes despite the moderately high NRM and the unfavorable disease-risk features. These results indicate that, while NRM remains a significant limitation, this strategy represents a *valuable therapeutic option* for appropriately selected high-risk AML patients—particularly when applied in first remission, even in patients with MRD+.

Disclosure: Nothing to declare.

B302

SYSTEMIC EVALUATION FOR EXTRAMEDULLARY DISEASE AND TREATMENT OUTCOMES IN ADULT PATIENTS WITH RELAPSED/REFRACTORY B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

Ruifeng Hou[1], *Lihong An*[1], *Huanhuan Guan*[1], *Xiao Lei*[1], *Junhan Yang*[1], *Jinglan Zhang*[1], *Tong Wu*[1], *Xinjian Yu*[1], *Qinlong Zheng*[1], *Shuangyou Liu*[1]
[1]*Beijing Gobroad Boren Hospital, Beijing, China*

Background: In leukemia, the extramedullary disease (EMD) is typically assessed by CT, MRI, or ultrasound when patients exhibit relevant symptoms, whereas 18F-FDG PET/CT is rarely used. The systemic evaluation for EMD is unavailable in B-cell acute lymphoblastic leukemia (B-ALL), and the prognosis of relapsed/refractory (r/r) B-ALL with non-central nervous system (non-CNS) remained poor even after treatment with CD19 chimeric antigen receptor-T (CAR-T).

Methods: In this cohort of patients with r/r B-ALL, EMDs were assessed in each patient regardless of whether the patient had EMD symptoms or not. EMDs were evaluated either using CT/MRI/ultrasound or using 18F-FDG PET/CT. CD19 and CD22 CARs were lentiviral vectors carrying the second generation CAR with 4-1BB and CD3ζ. The overall survival (OS) and progression-free survival (PFS) were calculated from the date of first CAR-T cell infusion. Data of patients were collected from October 2021 through March 2025.

Results: A total of 91 adult patients were included, 42 were male and 49 were female, with a median age of 34 years (range, 18 to 61). Of them, 48 (52.7%) patients underwent allogeneic hematopoietic cell transplant (allo-HCT), 28 (30.8%) received antibodies blinatumomab/inotuzumab ozogamicin and 17 (18.7%) had a history of CAR-T therapy.
For EMDs, 50 patients were assessed by PET/CT and 41 were assessed by CT/MRI/ultrasound. Of all 91 patients, 47 presented with EMD and most of them (85.1%, 40/47) had combined bone marrow involvement (seven cases with isolated EMD). The overall incidence of EMD including CNS leukemia was 51.6% (47/91), while the non-CNS EMD was 42.9% (39/91). Further analysis revealed that the frequency of non-CNS EMD was 60.0% (30/50) in PET/CT group and it was 22.0% (9/41) in non-PET/CT group (p=0.0003), Importantly, among patients with MRD-positivity, five who did not exhibit any EMD symptoms had concurrent non-CNS EMDs determined by PET/CT; whereas none of patients showed EMDs in non-PET/CT group.
Treatment outcomes of patients with non-CNS EMD were observed in PET/CT group. Twenty-five patients received CD19 (n=19) or CD22 (n=6) CAR-T therapy as the initial treatment, additional consolidations following CAR-T were administered to 23 patients, which included allo-HCT (n=13, 10 were second allo-HCT), reinfusion of CAR-T cells (CD22 CAR-T, n=11; CD19 CAR-T, n=2), and others. Long-term outcomes were assessed in the 23 patients who received initial CAR-T and subsequent consolidations. As of the last follow-up, four patients died, 12 maintained in progression-free survival, five relapsed again, one failed CAR-T but survived with disease, and one lost follow-up. Kaplan-Meier survival analysis showed that the estimated 12-month OS and PFS rates were 89.5% and 69.4%; and the 24-month OS and PFS rates were 70.3% and 45.8%, respectively.

Conclusions: Among heavily treated adult patients with r/r B-ALL, 18F-FDG PET/CT identified a higher incidence of non-CNS EMD and hidden EMDs in MRD-positive patients, suggesting that PET/CT scan could be as a routine approach for EMD evaluation in r/r B-ALL. CAR-T followed by consolidation treatments improved long-term survival of patients with non-CNS EMD, providing a promising option for these patients with poor prognosis.

SUPERIOR GVHD-FREE/RELAPSE-FREE SURVIVAL WITH HAPLOIDENTICAL TRANSPLANTATION USING TCRAB/CD45RA-DEPLETED GRAFTS IN AML: A COMPARATIVE ANALYSIS WITH MATCHED DONORS

Huirong Han[1], *Victor Wei Teik Ling*[1], *Yang Liang Boo*[1,2], *Michelle Limei Poon*[1], *Lip Kun Tan*[1], *Evelyn Aun*[1], *Ian Wu*[1,3], *Balamurugan Vellayappan*[1], *Joanne Lee*[1,4], *Teck Guan Soh*[1,5], *Christofer Thow*[1], *Jamie Chew*[1], *Yin Jie Koh*[1], *Wing Hang Leung*[5], *Liang Piu Koh*[1]
[1]National University Cancer Institute, Singapore, Singapore, [2]Hospital Sultanah Aminah, Johor Bahru, Malaysia, [3]Sengkang General Hospital, Singapore, Singapore, [4]Centre for Clinical Haematology, Singapore, Singapore, [5]KK Women's and Children's Hospital, Singapore, Singapore

Background: For patients with acute myeloid leukaemia (AML) lacking a matched donor, haploidentical hematopoietic cell transplantation (Haplo-HCT) with ex vivo T-cell depletion is an emerging option. We have previously reported favourable GVHD-free/relapse-free survival (GRFS) with this approach (Ref: *Koh LP et al. BMT 2025*).

Methods: We conducted a single-centre retrospective analysis of 64 consecutive adult patients (median age 55 years) in National University Cancer Institute, Singapore with AML who received Haplo-HCT with TCRαβ-depleted graft with CD45RA-depleted memory T-cell add-back (αβTCD+TMDLI) between 2017 and 2025. Most patients (77%) were measurable residual disease (MRD)-positive pre-HCT, and 42% had adverse-risk molecular-genetics per ELN 2022. Conditioning regimen comprised of fludarabine, thiotepa, melphalan, with either total lymphoid irradiation (TLI; n=12) or low-dose total body irradiation (TBI; 2 Gy; n=52). GVHD prophylaxis (tacrolimus, n=57/sirolimus, n=1/MMF, n=3) was given for 30 days. Outcomes were compared with contemporaneous cohorts receiving matched sibling donor (MSD; n=43) or matched unrelated donor (MUD; n=35) transplants.

Results: The Haplo-HCT cohort showed promising 2-year overall survival (OS, 70%), event-free survival (EFS, 66%), GRFS (59%), with low 2-year cumulative incidence (CI) of relapse (15%) and severe GVHD (grade III–IV acute GVHD: 8%; moderate/severe chronic GVHD: 5%). Pre-HCT MRD negativity predicted excellent outcomes (2-year OS: 93 %; relapse: 0%). In multivariable analysis, high/very high disease risk index predicted inferior OS, EFS, GRFS, and higher relapse, whereas TBI 2Gy was associated with favourable survival and lower non-relapse mortality.

Comparative analysis showed no significant difference in 3-year OS (Haplo: 70% vs. MSD: 71% vs. MUD 51%; p=0.278) or EFS (66% vs. 59% vs. 37%; p=0.168). Notably, 3-year GRFS was significantly superior in the Haplo cohort (59%) compared to MSD (21%) and MUD (27%) (p=0.0025). Among MRD-positive patients, Haplo-HCT was associated with significantly lower relapse (p=0.006) and the most favourable GRFS (p=0.008).

Conclusions: Haplo-HCT with αβTCD+TMDLI achieves survival rates comparable to matched-donor transplants while offering significantly better GRFS, underscoring a major advantage in quality of survival. For MRD-positive patients, this approach confers the lowest relapse risk and the best GRFS. It represents a highly effective and preferable alternative donor strategy, particularly for AML patients with detectable MRD pre-HCT.

B304

SECOND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FROM DIFFERENT DONOR FOR PATIENTS WITH ACUTE LEUKEMIA RELAPSED AFTER FIRST TRANSPLANTATION：A SINGLE CENTER REAL WORLD STUDY

Yue Lu[1], *Yan-Li Zhao*[1], *Jian-Ping Zhang*[1], *Min Xiong*[1], *Xing-Yu Cao*[1], *De-Yan Liu*[1], *Rui-Juan Sun*[1], *Zhi-Jie Wei*[1], *Jia-Rui Zhou*[1], *Fang Xu*[1], *Xian Zhang*[1], *Jun-Fang Yang*[1], *Pei-Hua Lu*[1]
[1]*Hebei Yanda Lu Daopei Hospital, Langfang, China*

Background: Allo-HSCT2 may be one possible and effectively way to treatment acute leukemia relapse after transplantation. but prognostic factors impact on survival have not been determined.

Methods: We analyzed the patients with acute leukemia who undergoing allo-HSCT2 relapsed post-HSCT1 from April 2012 to February 2024. The criteria for including patients were: second donors with allo-HSCT2 were different from the first transplant donors,HSCT1 donor are all derived from allogeneic.

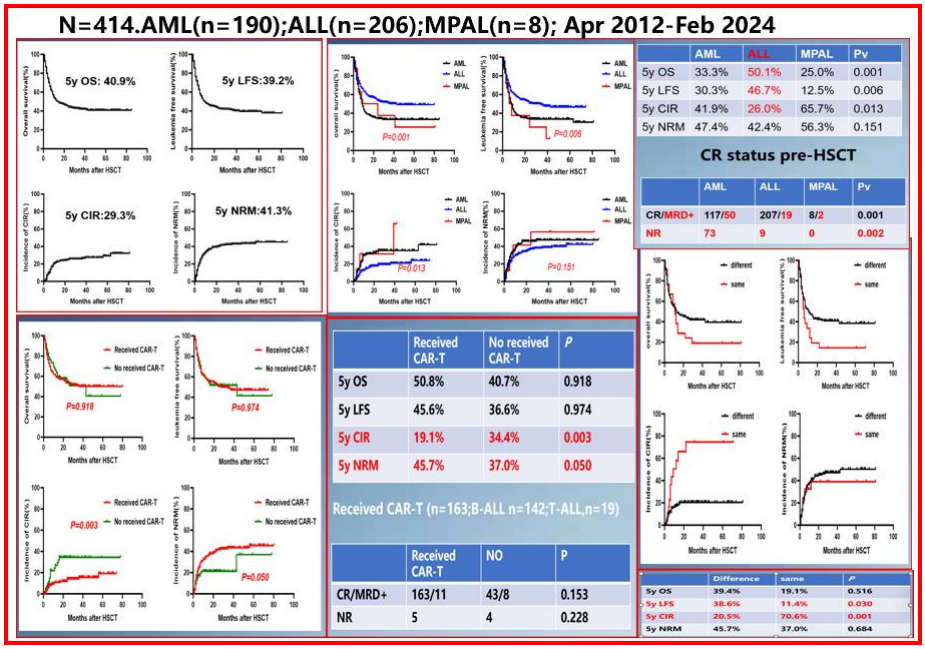
Table1 .Patients Characteristics

	Allo-HSCT1（n=414）	Allo-HSCT2（n=414）
Male/Female		231/183
Median age at HSCT,years	23(0.5-63) yrs	26(2-65) yrs
Age ≤18 year	172(41.5%)	144(34.7%)

Allo-HSCT1 versus allo-HSCT2 donor, difference		414(100%)
Donor type		
HID	241(58.2%)	327(78.9%)
MUD	40(9.6%)	78(18.8%)
MSD	119(28.7%)	5(1.2%)
UCBD	14(3.3%)	4(0.9%)
CR Status before HSCT(CR)	360(86.9%)	332(80.1%)
HCT-CI pre-allo-HSCT2(score 0)		232(56.0%)
With Extramendullary before HSCT	125(30.1%)	117(28.2%)
Received CAR-T before HSCT	125(30.1%)	117(28.2%)
Conditioning regimen(Intensified)		153(36.9%)
The median time to relapse after HSCT1(mon.) (range)		11（1-137）
Median time between HSCT1 and HSCT2 (mon.) (range)		18（2-159）
Median time from diagnosis to HSCT2 (mon.) (range)		26（8-162）
Developed of aGVHD post-HSCT1	119(28.7%)	
Developed of cGVHD post-HSCT1	350(84.5%)	

Results: Donor types for Allo-HSCT2: Haploidentical donor(HID) were 327(78.9%),matched unrelated donor(MUD) were 78(18.8%),matched sibling donor(MSD) were 5(1.2%) ,unrelated cord blood donor(UCBD) were 4(0.9%). The median age at Allo-HSCT2 was 26(range 2 to 65) years . The types of underlying diseases were Acute myeloid leukemia (AML)(n=190;); Acute lymphoblastic leukemia (ALL)(n=206), Mixed-phenotype acute leukemia(MPAL) (n=8). Disease status before Allo-HSCT2, 332(80.1%) patients at complete

remission(CR), and 82(19.8%) at non remission(NR). The median time to relapse after HSCT1 were 11(1-137）months, median time between HSCT1 and HSCT2 were 18（2-159）months. 119(28.7%) patients developed acute graft verse host disease(aGVHD) and 350(84.5%) cases developed chronic GVHD(cGVHD) post-HSCT1 respectively. In term of hematopoietic cell transplantation-specifc comorbidity index(HCT-CI) pre-allo-HSCT2, 47(11.3%) patients score more than 2. All patients received Myeloablative conditioning regimens(MAC) for allo-HSCT2,and 153(36.9%) received intensified MAC. the median follow-up time was 38(16-85) months.The 5-years overall survival(OS) and leukemia free survival(LFS) for the whole cohorts was 40.9% and 39.2% respectively,and 5-years cumulative incidence of relapsed(CIR) and non-relapsed mortality(NRM) were 29.3% and 41.3% respectively. Multivariate analysis for the whole cohorts showed that: Disease status pre-HSCT2 at CR status compared to NR status had higher 5-yrs OS[HR1.761,CI(1.305-2.378),P=0.001] and LFS [HR1.761,CI(1.305-2.378).P=0.001] due to lower CIR [HR3.184,CI(2.045-4.958),P=0.001]. HCT-CI score 0 compared to those ≥1 had higher 5-yrs OS[HR1.549,CI(1.202-1.872),P=0.001] and LFS [HR1.517,CI(1.257-1.829).P=0.001] due to lower NRM [HR1.638(1.312-2.045),P=0.001].the patient with intensified MAC compared to standard had higher NRM [HR1.536 ,CI(1.022-2.308),P=0.039],lower 5-yrs OS[HR1.511,CI(1.149-1.988),P=0.003] and LFS [HR1.673,CI(1.244-2.250).P=0.050].Occurrence of aGVHD post-HSCT1 had higher NRM [HR 1.579,CI(1.144-2.181),P=0.005],lower 5-yrs OS[HR 1.440,CI (1.040-1.994),P=0.048] and LFS [HR 1.459,CI(1.111-1.915).P=0.007].In term of three different primary disease subtype, in the ALL subgroup, more patients were MRD-negative before HSCT2 compared to the AML and MPAL subgroup(85.9% vs 35.2% vs 75.0,P=0.001),so had lower CIR (20.6% vs 41.9% vs 65.7%,P=0.013) ,therefore translates into higher 5-yrs OS(50.1% vs 33.3% vs 25.0%,P=0.001) and LFS(46.7% vs 30.3% vs 12.5%,P=0.006).For the ALL subgroup, the patients who received CAR-T pre-HSCT2 had lower (19.1%vs 34.4%,P=0.003),but had higher NRM(45.7% vs 37.0%,P=0.050), so did not translates into better OS and LFS finally. For subgroups both donors were from HID, the donor with new mismatched haplotype had lower CIR (20.5% vs 70.6%,P=0.001) therefore this translates into higher 5-years LFS(38.6% vs 11.4%,P=0.030). Survival was not associated with other factors.



Conclusions: Patients with HCT-CI 0, no GVHD developed post-HSCT1, and CR before HSCT2 are suitable factor candidates for Allo-HSCT2. The conditioning regimen is not recommended for intensification. Switching to a HID with a new mismatch haplotype can reduces CIR and improves survival when both donors are HID.

Clinical Trial Registry: No

ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION MAY OVERCOME THE ADVERSE PROGNOSTIC IMPACT OF *IKZF1* ALTERATIONS IN ADULT PRECURSOR B-ALL

Veronika Valkova[1,2], *Jan Vydra*[1,2], *Antonin Vitek*[1], *Marketa Stastna Markova*[1,2], *Mariana Koubova*[1], *Barbora Cemusova*[1], *Ludmila Novakova*[1], *Pavla Pecherkova*[1], *Petr Cetkovsky*[1,2], *Cyril Salek*[1,2]
[1]*Institute of Hematology and Blood Transfusion, Prague, Czechia,* [2]*Charles University, First Dept of Medicine, Prague, Czechia*

Background: B-cell acute lymphoblastic leukemia (B-ALL) is a genetically heterogeneous disease in which recurrent genomic alterations significantly influence prognosis. Alterations of *IKZF1*, a key regulator of lymphoid differentiation, are associated with aggressive disease biology and inferior outcomes in conventionally treated patients. Allogeneic hematopoietic

cell transplantation (allo-HCT) is an established therapeutic option for high-risk B-ALL; however, the prognostic impact of *IKZF1* alterations in the post-transplant setting remains insufficiently defined. We therefore analyzed transplant outcomes in adult patients with precursor B-ALL according to *IKZF1* status.

Methods: Between January 2007 and September 2024, adult patients undergoing allo-HCT for precursor B-ALL were retrospectively evaluated. *IKZF1* status was assessed using multiplex ligation-dependent probe amplification (MLPA). A total of 91 patients were included: 46 patients harbored *IKZF1* alterations (*IKZF1* deletion only, n=20; *IKZF1* plus, n=26), while 45 patients had other or no detectable aberrations. Median age was higher in the *IKZF1* group (46 vs. 40 years). No significant differences were observed between groups with respect to disease status at transplantation (CR1 75%, CR2 20%, active disease 5%), donor type (matched related 23%, matched unrelated 48%, mismatched unrelated 19%, haploidentical 10%), conditioning intensity (myeloablative conditioning [MAC] 85%, non-myeloablative [NMA] 15%), or use of TBI-based conditioning (87%). Prior to allo-HCT, 52% of patients were MRD-negative. The incidence of Ph-positive B-ALL was significantly higher in the *IKZF1* group (72% vs. 24%, p<0.0001).

Results: For the entire cohort, 3-year overall survival (OS), event-free survival (EFS), relapse incidence (RI), non-relapse mortality (NRM), and GVHD-free/relapse-free survival (GRFS) were 72%, 67%, 21%, 15%, and 59%, respectively. The 3-year cumulative incidence of acute and chronic GVHD was 14% and 38%. No significant differences were observed between patients with and without *IKZF1* alterations in terms of OS, EFS, or RI (3-year OS 65% vs. 79%, p=0.06; EFS 60% vs. 73%, p=ns; RI 20% vs. 21%, p=ns). However, NRM was significantly higher in the *IKZF1* group (25% vs. 2% at 3 years, p=0.01).
MRD-negative patients demonstrated superior OS compared with MRD-positive patients (84% vs. 67% at 3 years, p=0.05). Comparable OS was observed in MRD-negative patients transplanted in CR1 and CR2 (85% vs. 80% at 3 years, p=ns).
In multivariate analysis, MRD positivity was independently associated with inferior EFS (HR 2.15, p=0.046) and showed a trend toward worse OS (HR 2.2, p=0.059). Disease status at transplantation (CR2 vs. CR1) was associated with higher RI (HR 3.5, p=0.02). The presence of *IKZF1* alterations was independently associated with increased NRM (HR 3.8, p=0.023), potentially reflecting differences in patient-related characteristics, including the higher median age observed in this subgroup. Age itself was a strong predictor of OS (HR 0.96, p=0.01).

Conclusions: Allo-HCT appears to mitigate the adverse prognostic impact of *IKZF1* alterations in adult patients with precursor B-ALL. Achievement of MRD negativity prior to transplantation remains a key determinant of outcome. Importantly, selected patients transplanted in second complete remission may achieve outcomes comparable to those transplanted in first remission, particularly when MRD negativity is achieved.

Disclosure: Nothing to declare

B306

DEPTH OF REMISSION PREDICTS OUTCOME AFTER ALLOGENEIC HSCT FOR AML: A SINGLE-CENTER STUDY OF 263 PATIENTS

Maria Elisabetta Catini[1], Carmen di Grazia[1], Massimiliano Gambella[1], Stefania Bregante[1], Alida Dominietto[1], Giulia Francia[1], Anna Ghiso[1], Antonella Laudisi[1], Monica Passannante[1], Riccardo Varaldo[1], Silvia Luchetti[1], Alberto Serio[1], Alessandra Bo[1], ***Anna Maria Raiola***[1]*, Emanuele Angelucci[1]*
[1]*IRCCS Ospedale Policlinico San Martino, GE, Italy*

Background: The prognostic impact of measurable residual disease (MRD) at the time of allogeneic hematopoietic stem cell transplantation (allo-HSCT) for acute myeloid leukemia (AML) is well established. However, confirmation in contemporary real-world cohorts remains clinically relevant.

Methods: We retrospectively analyzed 263 consecutive AML patients undergoing a first allo-HSCT at the Hematology and Cellular Therapies Unit, IRCCS San Martino Hospital, Genoa, Italy, between January 2018 and June 2025. Disease status at transplant was categorized as MRD-negative complete morphological remission (MRD− CR, *n* = 152), MRD-positive complete morphological remission (MRD+ CR, *n* = 46), or active AML (*n* = 65).
MRD assessment was performed by multiparametric flow cytometry in patients with a leukemia-associated aberrant immunophenotype or by polymerase chain reaction (PCR) when a leukemia-specific molecular marker was available. The primary endpoint was event-free survival (EFS); secondary endpoints included overall survival (OS), relapse incidence, and transplant-related mortality (TRM).

Results: The median age was 59 years (range, 20–75), and 46% of patients had an HCT-Comorbidity Index score ≥3. According to the European LeukemiaNet (ELN) 2022 risk stratification, 12% of patients were favorable, 58% intermediate, and 30% adverse risk. Donor type distribution was as follows: haploidentical in 50%, MUD in 28%, MMUD in 12%, and HLA-identical related donors in 10% of patients. Median follow-up was 31.5 months (range, 3–91.1). In the overall cohort, the 48-month EFS was 49%. According to disease status at transplant, 48-month EFS was 63% in MRD− CR patients, compared with 32% in MRD+ CR and 29% in patients with active AML. EFS was significantly better in MRD− CR compared with both MRD+ CR ($p < 0.001$) and active AML ($p < 0.001$), whereas MRD+ CR and active AML showed comparable outcomes. The estimated 48-month OS in the overall cohort was 57.6% and OS showed the same pattern observed for EFS, being significantly superior in MRD- CR patients compared with both MRD+ CR and active AML. The cumulative incidence of relapse at 24 months was 31.6% in the overall cohort. According to disease status at transplant 24 -month relapse incidence was 19.1% in MRD- CR patients, 45.7% in MRD+ CR and 46.2% in patients with active AML ($p < 0.001$). The 24-month TRM was 13.1% overall, being 11.8%, 10.9%, and 23.1% in MRD− CR, MRD+ CR, and active AML patients, respectively, but these differences did not reach statistical significance. In multivariable analysis, ELN 2022 risk category, donor type, stem cell source, conditioning platform and intensity did not significantly affect EFS, OS, relapse and TRM incidence. MRD status at transplant remained the only independent predictor of post-transplant outcomes.

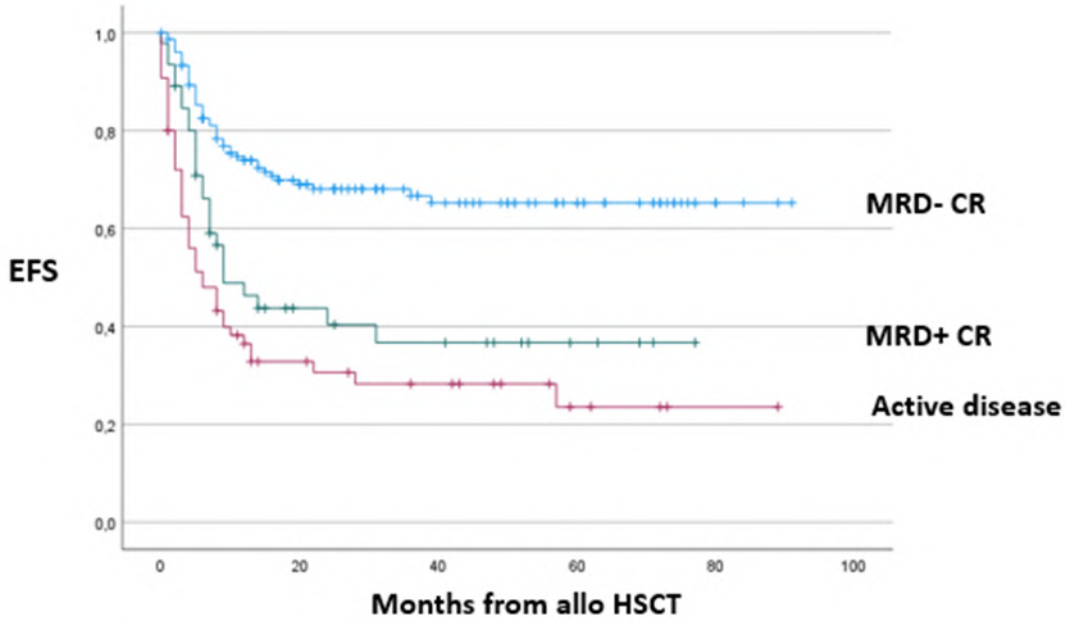

Figure 1

Conclusions: In this contemporary single-center cohort, MRD negativity at the time of allo-HSCT was the strongest determinant of post-transplant outcomes. Patients in MRD-positive complete morphological remission experienced relapse risk and EFS comparable to those transplanted with active AML. This finding indicates that MRD positivity neutralizes the effectiveness of morphological remission and confirms the need for new therapeutic strategies for these patients.

REAL-WORLD EXPERIENCE WITH GILTERITINIB MAINTENANCE FOLLOWING ALLOGENEIC TRANSPLANTATION IN RELAPSED/REFRACTORY AML PATIENTS HARBORING *FLT3* MUTATIONS

Xavier Cheng-Hong Tsai[1], *Yun-Tzu Lin*[1], *Feng-Ming Tien*[1], *Hsin-An Hou*[1], *Bor-Sheng Ko*[1], *Ming Yao*[1]
[1]*National Taiwan University Hospital, Taipei, Taiwan (Province of China)*

Background: *FLT3* mutations, especially *FLT3*-ITD, are associated with a high risk of relapse after allogeneic transplantation in patients with acute myeloid leukemia. Gilteritinib is an established treatment for relapsed or refractory *FLT3*-mutated disease and has been used as maintenance therapy after transplantation in patients who enter transplant in remission.

Evidence, however, is still scarce for patients who receive gilteritinib as salvage therapy during active relapsed or refractory disease, proceed to transplantation, and then continue gilteritinib as maintenance. This clinical sequence is not well represented in prior trials, and data from Asian populations remain limited. To describe the real world outcomes of patients with relapsed or refractory *FLT3*-mutated acute myeloid leukemia who received gilteritinib before transplantation and again as maintenance. The study also aimed to identify patient groups, based on measurable residual disease, that may derive the greatest benefit.

Methods: This was a prospective observational study conducted at a single medical center in Taiwan between 2017 and 2023. Forty two patients with relapsed or refractory *FLT3*-mutated acute myeloid leukemia received gilteritinib as salvage therapy and then underwent allogeneic transplantation. Maintenance therapy with gilteritinib was offered between day 30 and day 90 after transplantation for patients with stable engraftment and no significant acute graft versus host disease. Measurable residual disease was evaluated using multiparameter flow cytometry or quantitative polymerase chain reaction. The primary outcomes were relapse free survival and overall survival. Safety events and transplantation related complications were recorded.

Results: The median age was 48 years and most patients carried *FLT3*-ITD. Salvage treatment with gilteritinib produced a complete response rate of 76 percent. With a median follow up of more than 46 months, patients who received gilteritinib maintenance had longer relapse free and overall survival compared with those who did not receive maintenance. Relapse at one year was less common in the maintenance group. In multivariable analyses that included measurable residual disease and the presence of chronic graft versus host disease, gilteritinib maintenance remained an independent predictor of improved survival. The effect of measurable residual disease was clear. Patients who were negative for measurable residual disease before or after transplantation had the most pronounced benefit from maintenance therapy. In contrast, patients with persistent measurable residual disease had less evident benefit, in part because many received other post transplantation interventions such as venetoclax based therapy or donor lymphocyte infusion. Gilteritinib was well tolerated. No excess in clinically significant cytomegalovirus infection was observed. No patient developed severe graft versus host disease related to the drug. Adverse effects were limited to mild liver enzyme elevation or creatine kinase increase in a few patients.

Conclusions: This study provides real world evidence that gilteritinib used both before and after transplantation can offer meaningful clinical benefit in relapsed or refractory *FLT3*-mutated acute myeloid leukemia. Patients who are negative for measurable residual disease appear to benefit most. The findings support the use of targeted maintenance therapy in this clinical setting and help fill an important knowledge gap for Asian populations and for patients who undergo transplantation during active disease.

B309

REAL-WORLD OUTCOMES OF DONOR LYMPHOCYTE INFUSIONS AFTER ALLOGENEIC HCT FOR ACUTE LEUKEMIA: A 20-YEAR MULTICENTER STUDY

Martina Lorenzon[1], Maria Assunta Limongiello[2], Federica Frenza[3], Martina Canichella[4], Patrizia Chiusolo[2], Raffaella Cerretti[3], Paolo De Fabritiis[4], Martina Salvatori[1], Walter Barberi[1], ***Anna Paola Iori***[1]
[1]*University La Sapienza, Rome, Italy,* [2]*University Cattolica del Sacro Cuore, Rome, Italy,* [3]*University of Rome Tor Vergata, Rome, Italy,* [4]*St. Eugenio Hospital, Rome, Italy*

Background: Relapse of acute leukemia after HCT remains a major clinical challenge, and growing efforts are directed toward its prevention through pre-emptive strategies. DLIs are widely used both for relapse treatment and for disease control in the presence of residual disease (MRD) or mixed chimerism; however, their use remains heterogeneous due to the absence of prospective studies and standardized guidelines. Real-world data are essential to better define their efficacy, safety, and optimal timing, and to support a more uniform clinical practice.

Methods: We conducted a multicenter retrospective study of 79 adults with acute leukemia who received DLI between 2005 and 2025 across four centers in Rome. The primary endpoint was overall survival (OS), while secondary endpoints included treatment response, disease-free survival (DFS), graft-versus-host disease (GVHD), infection rates, and non-relapse mortality (NRM). Collected variables included demographic, biological, and transplant-related data such as diagnosis, disease status at HCT, donor type, conditioning regimen, leukemia subtype, number and timing of DLI infusions, pre-DLI therapies, concomitant treatments, and post-infusion complications. Statistical analyses were performed using SPSS 26.0. OS and DFS were estimated using the Kaplan–Meier method, and NRM was assessed using cumulative incidence analysis. Group comparisons were made using the Mann–Whitney U test and chi-square test. Prognostic factors were assessed through univariate and multivariate Cox regression models.

Results: Among the 79 patients, 72% had AML and 28% ALL; 38% received pre-emptive DLI and 62% therapeutic DLI, while 64% received concomitant treatments with DLI. At a median follow-up of 12 months, 45.5% were alive, and the 4-year OS was 37%. Older age, ALL, active disease at transplant, therapeutic DLI, and combination therapy were associated with poorer outcomes. In contrast, post-DLI GVHD and achievement of complete remission correlated with improved survival. CR was achieved in 41.8% of patients and was sustained in 70% of responders. The 4-year DFS was 44%, and was lower among patients receiving therapeutic DLI, those transplanted with active disease, and those treated with combination therapy. Sibling donors were associated with inferior CR rates and DFS compared with MUD donors. The apparent negative effect of combination therapy likely reflected selection bias and was not observed in the pre-emptive setting. GVHD occurred in 39% of patients, with five GVHD-related deaths. NRM reached 22.7%, while disease progression remained the leading cause of mortality.

CHARACTERISTICS	NUMBER OF PATIENTS (%)

DONOR • Sibiling • Matched Unrelated Donor (MUD) • Mismatched Unrelated Donor (MMUD) • Haploidentical	 26 (33) 26 (33) 6 (7.5) 21 (26.5)
NUMBER OF ADMINISTRATIONS • 1 • 2 • 3 • ≥ 4	 21 (26.5) 22 (28) 15 (19) 21 (26.5)
GVHD AFTER DLI	**31 (39)**

Acute GVHD	**19 (24)**
G1-2	11 (14)
G3-4	8 (10)
Chronic GVHD	**12 (15)**
Mild	4 (5)
Moderate/Severe	8 (10)
INFECTIOUS COMPLICATIONS	**14 (24)**
ACHIEVEMENT OF CR	**33 (41.8)**
RELAPSE AFTER DLI	**30 (38)**
Median (months)	16
Range (months)	1 - 103
DEATHS	**43 (54.4)**
	27 (63)
• Disease relapse/progression	7 (16)
• Infectious disease	7 (16)
• TRD	2 (5)
• Other causes	

Conclusions: This represents one of the longest real-world cohorts, demonstrating that pre-emptive DLI was associated with superior outcomes compared with DLI for overt relapse, highlighting the critical role of timing and the need for systematic MRD and chimerism monitoring. Post-DLI GVHD correlated with improved survival, reflecting an effective GVL effect, while NRM underscores the importance of optimizing infusion strategies. Active disease at transplant remained a major adverse prognostic factor, and combination therapy did not overcome the negative impact of aggressive **disease**. In this setting, the role of DLI remains incompletely defined, warranting further investigation. Future prospective, risk-adapted strategies are warranted to harmonize DLI use across centers and fully harness its curative potential, while minimizing GVHD risk and optimally integrating combination therapies.

AGE OVER SIBLING: YOUNGER UNRELATED DONORS PROVIDE SUPERIOR OUTCOMES COMPARED TO SIBLING DONORS IN FULLY MATCHED HCT IN OLDER AML/MDS PATIENTS

Witold Prejzner[1], Alicja Sadowska-Klasa[1], Johannes Lakner[2], Anastazja Szlauer-Stefańska[3], Anna Łojko-Dankowska[4], Maciej Majcherek[5], Ewa Karakulska-Prystupiuk[6], Patrycja Mensah-Glanowska[7], Christian Junghanss[2], ***Jan Maciej Zaucha***[1]

[1]Medical Univeristy of Gdansk, Gdansk, Poland, [2]Rostock University Medical Center, Rostock, Germany, [3]Maria Sklodowska-Curie National Research Institute of Oncology (Branch in Gliwice), Gliwice, Poland, [4]Poznan University of Medical Sciences, Poznan, Poland, [5]Wroclaw Medical University, Wroclaw, Poland, [6]Medical University of Warsaw, Warsaw, Poland, [7]Jagiellonian University Collegium Medicum, University Hospital in Cracow, Cracow, Poland

Background: Fully matched sibling donors (MSDs) have traditionally been the preferred graft source for allogeneic hematopoietic cell transplantation (HCT) in patients with acute myeloid leukemia (AML) or myelodysplastic syndromes (MDS). As patient age increases, sibling donor age also rises. Emerging evidence suggests that donor age may influence outcomes more than donor relatedness. To verify this hypothesis, we examined in the multicenter cohort study whether younger matched unrelated donors (MUDs) provide superior outcomes compared to MSDs in older patients with AML/MDS.

Methods: This retrospective study included patients aged ≥60 years with AML/MDS who underwent HCT at centers at the Polish Adult Leukemia Group and the University of Rostock between 2014 and 2024. Overall survival (OS), non-relapse mortality (NRM), and relapse incidence (RI) at 2 and 5 years post-HCT were estimated using the Kaplan–Meier method. Associations between risk factors and OS, NRM, and RI were assessed using Cox proportional hazards models.

Results: Of the 293 patients included in the study, the median age at HCT was 64 years (range: 60–76), and 44% were over 65 years old. The median follow-up was 21 months (range: 0–146). MSD and MUD groups differences are summarized in Table 1. The donor age of MSDs was higher, with a median of 60 years (range: 41–79), compared to 31 years (range: 19–57) for MUDs.
The estimated 2- and 5-year OS rates were 61% and 48% for MUD and 47% and 42% for MSD, respectively (Figure 1A). Relapses occurred in 27 MSD patients (38%) and 70 MUD patients (32%), with the highest incidence within the first 24 months. In multivariable analysis, 5-year OS was affected only by disease status prior-HCT (not in complete remission (CR): adjusted hazard ratio (aHR) 1.78, 95% CI 1.2–2.5, p<0.05). Neither ATG nor type of conditioning affected OS; however, there was a trend toward better outcomes in the MUD group (aHR 0.74, 0.5–1.08, p=0.12).
When OS, NRM, and RI were analyzed in the cohort with available donor age data (n = 221), the best outcomes were observed in patients who received transplants from MUDs younger than 30 years (Figure 1B). In this group, 5-year OS was 53% (p < 0.05), with the lowest NRM (Figure 1C). Causes of NRM were similar between groups, with infection-related deaths accounting for 50% of cases.
In the multivariate model, NRM was affected by recipient age over 65 years (aHR 1.9, 1.0–3.6, p=0.04) and donor age over 50 years (aHR 3.01, 95% CI 1.29–7.82, p<0.05). Relapse incidence was increased when HCT was done not in CR (aHR 1.77, 1.01- 3.0, p<0.05), with the lowest risk in the MUD group (aHR 0.28, 0.09 to 0.8, p<0.05), and showed a decreasing trend with an increasing donor age (aHR 0.96, 0.93–0.98, p<0.05).

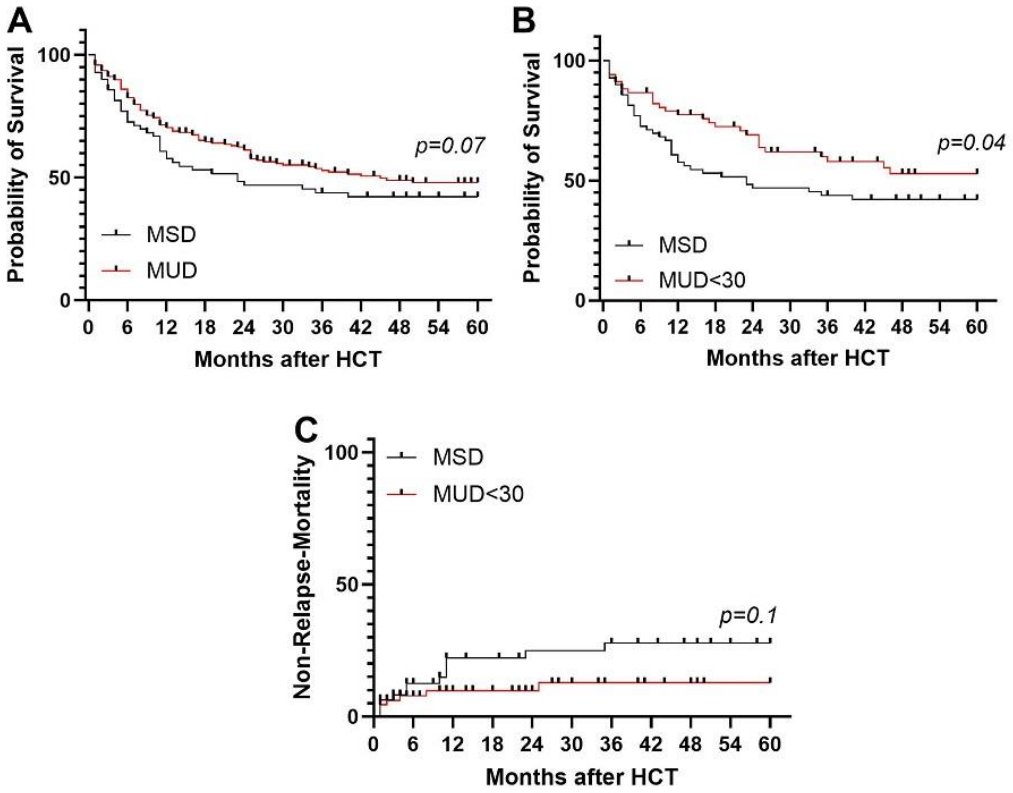

Figure 1. Kaplan–Meier plot of overall mortality within 5 years after transplantation, comparing matched sibling donor (MSD) and matched unrelated donor (MUD) in the overall cohort (A) and in the subset with available donor age data (B). Cumulative incidence of non-relapse mortality within 5 years after transplantation in the subset with available donor age data (C).

*Table1 : Baseline characteristics*of patients included in the study

		Matched sibling donor n=72	Matched unrelated donor =221	p
Age	Age ≥65	25 (34%)	104 (47%)	0.07
Sex	Female / Male	34 (47%) /38 (53%)	89 (40%) /132(60%)	
Uderlying disease	Acute myeloid leukemia	61 (85%)	187 (85%)	ns
	Myelodysplastic syndrome	11 (15%)	34 (15%)	

Disease status	Complete remission	51 (71%)	172 (78%)	ns
	Not-complete remission	18 (29%)	49 (22%)	
Conditioning intensity	TCI 1.5-3	52 (72%)	182 (82%)	0.03
	TCI 3.5-4	20 (28%)	35 (18%)	
ATG or PT-Cy	No	50 (69%)	4 (2%)	<0.001
	Yes	22 (31%)	217 (98%)	
Donor Age years	<30	0	68 (31%)	<0.001
	>30	72	81 (37%)	
	No Data	0	72 (32%)	
Engraftment	Yes	60 (83%)	189 (86%)	0.07
	No	7 (10%)	14 (6%)	
	No Data	5 (7%)	18 (8%)	
Graft-versus-host disease	Any aGvHD	18 (25%)	60 (27%)	ns
	Grade 3-4 aGvHD	10 (14%)	13 (6%)	0.04
	cGvHD	22 (31%)	52 (23%)	ns

Conclusions: MUD transplantation was associated with more favorable outcomes than MSD procedures, primarily due to lower NRM when donors were younger than 30 years, suggesting that younger unrelated donors may be preferable to older siblings.

Disclosure: Nothing to declare.

B311

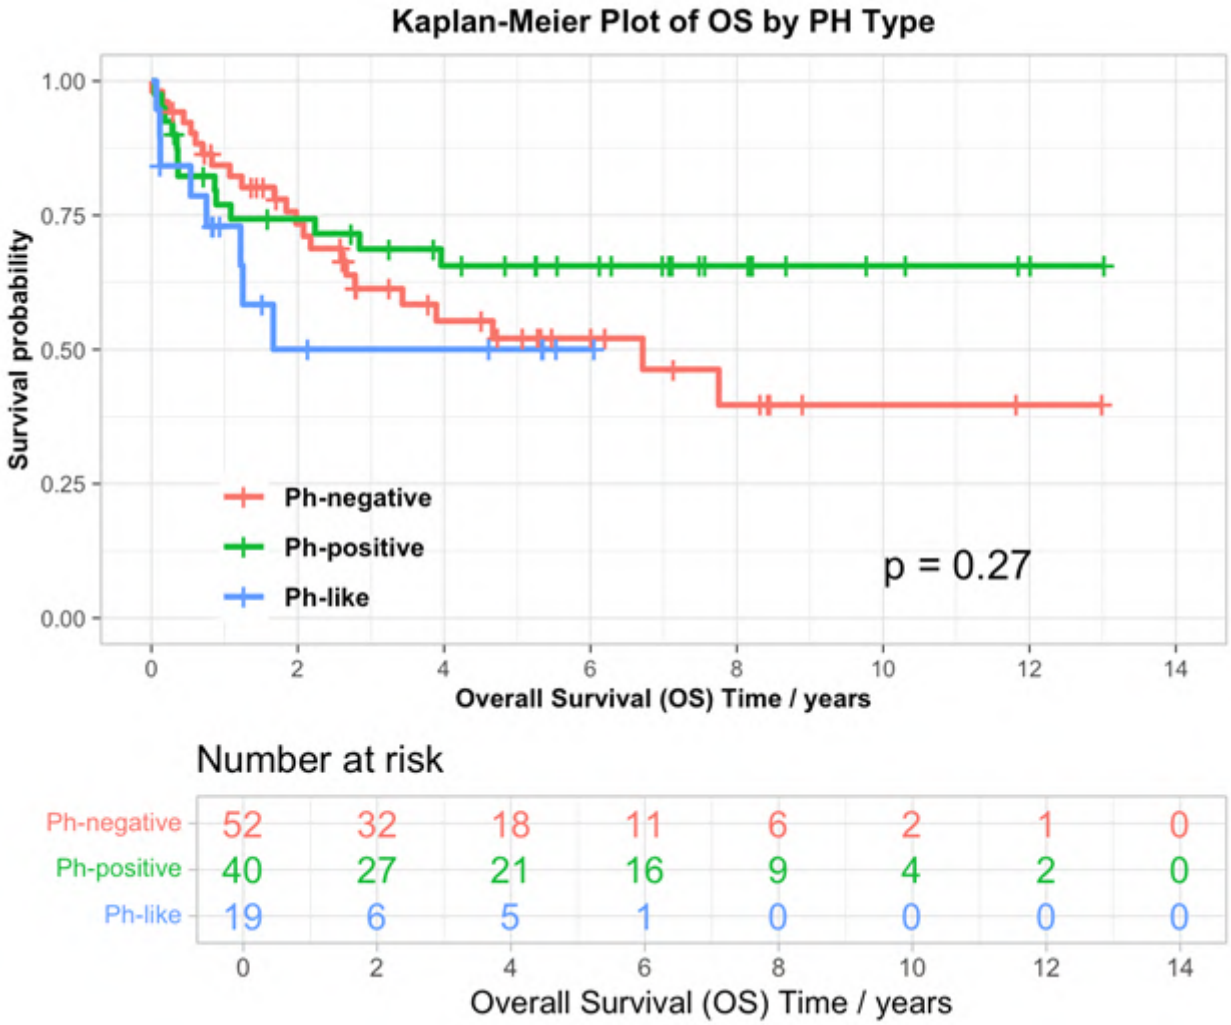
CHARACTERISTICS AND OUTCOMES OF ALLOGENEIC STEM CELL TRANSPLANTATION FOR ADULTS WITH PHILADELPHIA-LIKE B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: A SINGLE-CENTER ANALYSIS

Noa Holtzman[1], *Fei Ye*[2], *Rebecca Irlmeier*[2], *Denise Pereira*[1], *Amer Beitinjaneh*[1], *Trent Wang*[1], *Jay Spiegel*[1], *Mark Goodman*[1], *Cara Benjamin*[1], *Eric Wieder*[1], *Damian Green*[1], *Antonio Jimenez Jimenez*[1], *Lazaros Lekakis*[1]
[1]*Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, United States of America (the),* [2]*Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Division of Biostatistics and Bioinformatics, Miami, United States of America (the)*

Background: Philadelphia-like (Ph-like) B-cell acute lymphoblastic leukemia (B-ALL) is a genomically defined, high-risk subset that is associated with treatment resistance, increased relapse, and poor outcomes. Given its novelty as a disease subtype and related diagnostic challenges, more data is needed to delineate outcomes after allogeneic hematopoietic stem cell transplantation (HSCT).

Methods: We performed a retrospective cohort analysis of 111 adults with B-ALL undergoing first allogeneic HSCT between 2011-2025, grouped as Ph-negative (n=52), Ph-positive (n=40), and Ph-like (n=19). Baseline characteristics were summarized by group and compared using Fisher's exact tests for categorical variables and Kruskal-Wallis tests for continuous variables. Overall survival (OS) and relapse-free survival (RFS) were estimated by Kaplan-Meier from HSCT date and compared using log-rank tests (exploratory univariate log-rank screening for selected covariates). In the Ph-like subgroup, exploratory competing-risk analyses were summarized using cumulative incidence functions for relapse-related mortality (RRM) with non-relapse mortality (NRM) as the competing event, and for NRM with relapse as the competing event.

Results: Among 111 HSCT recipients, 46.8% were Ph-negative, 36.0% Ph-positive, and 17.1% Ph-like. Median age was 43 years (range 19-75), 50.5% were male, and 65.8% Hispanic; 78.4% received myeloablative conditioning and 65.8% received TBI. Baseline characteristics were broadly similar across groups, except time from diagnosis to HSCT was longer in Ph-negative patients (median 12.5 months vs 8.0 and 7.39 months, p=0.007) with a trend toward more ≥CR3 disease status at HSCT in Ph-negative/Ph-like (p=0.077).OS and RFS did not significantly differ by Ph subtype (log-rank p=0.27 and p=0.28), though curves suggested inferior early outcomes for Ph-like. Relapse occurred in 36.8% of Ph-like vs 34.6% of Ph-negative and 20.0% of Ph-positive patients. Day-100 TRM was highest in Ph-like (15.8%) vs 5.8% (Ph-negative) and 7.5% (Ph-positive). In univariate log-rank screening, donor type and TBI were associated with OS and RFS (both p≤0.014), and conditioning intensity showed a nominal association (p=0.03).
Among the Ph-like cohort, the most common genomic alterations involved CRLF2 in 53% (n=10), JAK2 in 26% (n=5), EPOR in 11% (n=2), PDGFR in 11% (n=2), and ABL in 5% (n=1). Exploratory competing-risk curves in the Ph-like subgroup suggested heterogeneity in the balance of relapse vs non-relapse events across transplant characteristics, but small numbers precluded formal comparisons.



Conclusions: Ph-like B-ALL patients are a high-risk cohort with higher relapse and mortality after HSCT. Alterations involving CRLF2 were the most common, introducing potential for post-HSCT targeted therapeutics. Given this rare subtype and small cohort, larger scale validation studies are warranted.

Disclosure: Nothing to declare.

B312

ALLOGENEIC STEM CELL TRANSPLANTATION DURING FIRST REMISSION IMPROVES SURVIVAL IN CORE-BINDING FACTOR ACUTE MYELOID LEUKEMIA

Congxiao Zhang[1], *Yanmin Zhao*[1], *Yi Luo*[1], *Jian Yu*[1], *Xiaoyu Lai*[1], *Yishan Ye*[1], *Lizhen Liu*[1], *Huarui Fu*[1], *Yi Yu*[1], *He Huang*[1], *Jimin Shi*[1]
[1]*Bone Marrow Transplantation Center, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: Core-binding factor acute myeloid leukemia (CBF-AML) represents a prognostically favorable AML subtype. However, while allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a standard therapy for relapse, its definitive role in first complete remission (CR1)—particularly for patients with high-risk features such as poor measurable residual disease (MRD) response—remains uncertain.

Methods: In this study, we retrospectively analyzed 165 consecutive CBF-AML patients who underwent allo-HSCT at our center between May 2016 and January 2024. We evaluated the impact of pre-transplant disease status and measurable residual disease (MRD) levels, assessed by both multiparameter flow cytometry (MFC) and RT-PCR, on survival and relapse outcomes.

Results: A total of 165 CBF-AML patients (median age 38.4 years; range 4-67) were enrolled. The cohort comprised 102 patients with AML1-ETO and 63 with CBFβ-MYH11 fusion gene. Based on pre-transplant disease status, patients were categorized as follows: first complete remission (CR1, n=108), second complete remission (CR2, n=38), beyond second remission (>CR2, n=6), primary refractory disease (NR, n=3), and relapsed disease (Relapse, n=10).
Survival outcomes were analyzed according to pre-transplant status. Patients transplanted in CR1 demonstrated the most favorable prognosis, with significantly superior outcomes compared to those in CR2 (3-year RFS: 93.1% vs. 78.4%, P = 0.028; 3-year OS: 92.5% vs. 77.5%, P = 0.011). Among the six patients transplanted beyond CR2, one experienced early relapse-related mortality. For patients transplanted in relapse, the 3-year OS and RFS were 58.3% and 50.0%, respectively.
We further stratified patients in pre-transplant CR1 and CR2 based on remission depth using flow cytometry and RT-PCT. Of the evaluable patients, 95 in CR1 and 27 in CR2 were MFC-MRD-negative, compared to 6 and 5 positive cases, respectively. Given the small number of positive patients, we pooled the two negative groups for comparison. This analysis yielded that CR1 patients with negative MFC-MRD had better overall survival and a lower trend towards relapse than their CR2 counterparts (CR1 vs. CR2, 3-year CIR: 5.6% vs. 16.4%, *P* = 0.1; 3-year OS: 92.6% vs. 71.0%, *P* = 0.007).
Stratification by molecular MRD yielded 14 PCR-MRD-negative and 58 PCR-MRD-positive cases in CR1, compared with 6 negative and 13 positive cases in CR2, respectively. Among CR1 patients, MRD status did not significantly affect outcomes (PCR-MRD- vs. PCR-MRD+, 3-year OS: 85.7% vs. 94.7%, P=0.223). In contrast, PCR-MRD+ patients in CR1 had better survival and a lower trend towards relapse than their PCR-MRD+ counterparts in CR2 (CR1

vs. CR2, 3-year CIR: 9.30% vs. 24.78%, P=0.16; 3-year OS: 94.7% vs. 74.0%, P=0.025). The interpretation of comparisons involving the CR2 PCR-MRD-negative group is cautioned due to its limited patient numbers.

Conclusions: We found that allo-HSCT in CR1 provided a survival benefit for CBF-AML patients. MRD monitoring is particularly important for the selection of transplantation timing.

Disclosure: Nothing to declare.

B313

FACTORS PREDICTING OUTCOME OF PATIENTS WITH ACUTE MYELOID LEUKEMIA WITH ACTIVE DISEASE UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Federica Frenza[1], Gottardo De Angelis[2], Benedetta Mariotti[2], Giulia Ciangola[2], Antonio Bruno[1], Ilaria Mangione[1], Marco Andreani[3], Adriano Venditti[1,2], William Arcese[4], ***Raffaella Cerretti***[2]
[1]*University of Rome "Tor Vergata", Rome, Italy,* [2]*Fondazione Policlinico Tor Vergata, Rome, Italy,* [3]*IRCCS "Bambin Gesù" Pediatric Hospital, Rome, Italy,* [4]*Fondazione Policlinico Universitario "Campus Biomedico", Rome, Italy*

Background: Up to 30% of adult patients with Acute Myeloid Leukemia (AML) experience a Primary Refractory Leukemia as they fail to achieve a Complete Remission (CR) after one or two courses of chemotherapy and almost 50% of those obtaining CR will eventually relapse. Despite salvage therapies, most patients do not achieve CR and their prognosis is dismal. However, hematopoietic stem cell transplantation (HSCT) remains a therapeutic option in this very high-risk category of patients and the identification of predictive prognostic factors could improve the selection of those who could most benefit from HSCT.

Methods: From March 2010 to October 2025, at the Department of Stem Cell Transplantation of Tor Vergata University in Rome, 35 patients affected by AML underwent HSCT with active disease, defined by the presence of ≥5% of blasts in bone marrow or extramedullary disease (EMD). The median age at transplant was 51 years (range 28-68); patients received a reduced intensity (RIC; n=16) or a myeloablative (MAC; n=19) conditioning regimen. All patients received chemotherapy-based conditioning consisting of Thiotepa, Busulfan and Fludarabine combination and a graft versus host disease (GvHD) prophylaxis according to the type of donor. 65% of patients received HSCT from a relative donors. Statistical analysis was performed using XLSTAT (Version 25.02.1414.0).

Results: With a median follow up of 48.3 months (9-133) for living patients, the 5-year Overall Survival (OS) and Disease-Free Survival (DFS) were 28.1% (95% confidence interval (CI), 12.3-43.8) and 27.7% (95% CI,12.6-42.8), respectively.
5-year cumulative incidence of relapse and transplant related mortality were 57.5% (95% CI,41.8-79.1) and 31.2% (95% CI,16-60.6), respectively. The cumulative incidence of aGvHD was 34.5% (95% CI,21.3-55.8).

In univariate analysis, 2-year OS and DFS were not significantly affected by intensity of conditioning regimen (RIC vs MAC), patient age (≤50 vs >50 years) and cytogenetic risk (low vs intermediate-high risk). The 2-year OS by the "interval time between diagnosis and transplantation" of <9 months vs >9 months was 40.8% and 7.7% (p=0.02) respectively, and by "disease burden" with ≤20% of blasts and absence of EMD vs >20% of blasts or with EMD was 41.1% and 8% (p=0.01), respectively. For the same variables, the 2-year DFS was 39.4% and 7.7% (p=0.05) by interval time and 38% and 8.3% by tumor burden, respectively (p=0.02).

Conclusions: This single-center retrospective study found that about 30% of the AML patients uniformly transplanted for active disease survive and supports the role of HSCT in such very high-risk category of patients. Post-transplant relapse remains the main reason for failure. In univariate analysis, patients transplanted earlier with low blast count and without EMD had a significantly better outcome. However, the small sample size of our population doesn't allow to draw solid conclusions or establish a prognostic scoring system. Our results emphasize the need for larger studies to identify predictive factors useful to select patients with overt AML that may benefit from HSCT. Furthermore, they underline the importance of developing post-transplant strategies such as maintenance therapies, Donor Lymphocyte Infusion, and modulation of immunosuppressive agents to reduce the risk of post-transplant relapse.

Disclosure: Nothing to declare.

B314

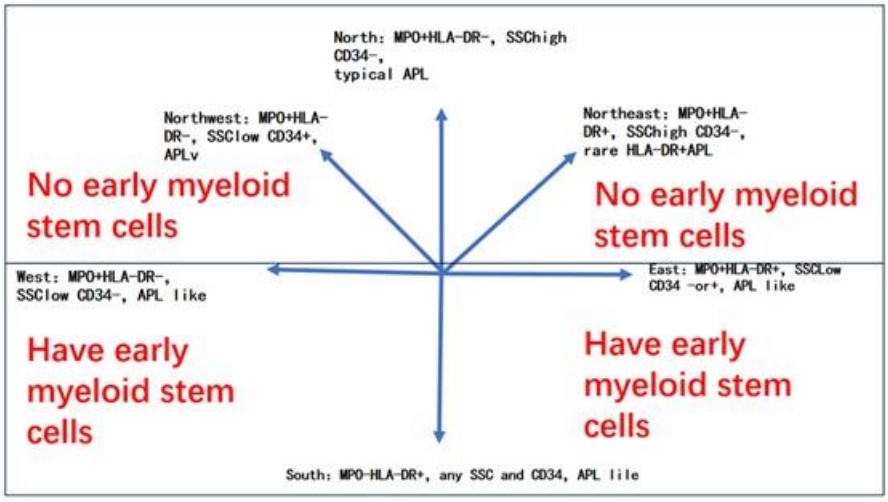
AN EARLY MYELOID STEM CELLS-BASED IMMUNOPHENOTYPIC PANEL CAN RAPIDLY AND EFFICIENTLY DISTINGUISH APL FROM APL-LIKE

Hui Wang[1], Ting Li[2], ***Man Chen***[2]
[1]Hebei Yanda Lu Daopei Hospital, Langfang, China, [2]Beijing Lu Daopei Hospital, Beijing, China

Background: Acute promyelocytic leukemia (APL) has unique morphology and immunophenotype in typical cases. However, 10-20% of cases show atypical changes, and some non-APL AML (especially NPM1-mutated or KMT2A-rearranged AML) can also present with APL-like morphology and immunophenotype, known as APL-like. Therefore, the clinical differentiation between APL and APL-like poses a significant challenge for flow cytometry detection.

Methods: A total of 313 cases of APL (165 males and 148 females) were treated at Hebei Yanda Lu Daopei Hospital from Jan. 1, 2016 to Dec. 20, 2024, including 236 cases of classic APL (124 males and 112 females) and 77 cases of APLv (41 males and 36 females). APL-like cases were 426 (311 cases of NPM1-mutated AML and 115 cases of other genetically abnormal AML), including 219 males and 207 females. Morphology, genetics, and clinical manifestations were used for simultaneous verification. The 2-tube 8-color panel was as follows: CD16 FITC/CD117 PE/CD34 PerCP-Cy5.5/CD13 PE-CY7/CD33 APC/HLA-DR APC-

CY7/CD11b BV421/CD45 V500; MPO FITC/CD64 PE/CD34 PerCP-Cy5.5/CD117 PE-CY7/CD14 APC/CD36 APC-CY7/CD38 BV421/CD45 V500. EMSC were defined as CD34+/SSCdim/CD117dim/CD33dim/HLA-DRdim/CD13+/CD11b-/CD38dim.



Results:

1. The detection rate of EMSC. The positive rate of EMSC in APL was 2/313 (0.64%), including 1/236 (0.42%) in classic APL and 1/77 (1.30%) in APLv. The positive rate in APL-like was 423/426 (99.30%). The sensitivity of using the presence of EMSC to distinguish APL from APL-like was 99.36%, and the specificity was 99.30%. The positive predictive value of the absence of EMSC for APL was 99.04%, and the negative predictive value was 99.53%. Combined with classic MPO, CD34, and HLA-DR, APL and APL-like can be easily, efficiently, and rapidly distinguished. 2. Other immunophenotypes. The immunophenotype of the APL group was relatively consistent, with typical cases expressing CD64 and MPO and not expressing HLA-DR and CD34. The expression rate of CD34 in APLv was the highest, exceeding APL-like. HLA-DR had significant predictive value for APL, with a very low positive rate. However, a considerable number of cases in the APL-like group presented with immunophenotypes extremely similar to APL. Due to the heterogeneity of APL-like, there were statistical differences in CD64, MPO, CD34, and HLA-DR.
3. A positioning map was designed based on EMSC and immunophenotypes (Figure 1). With MPO as the boundary, MPO and HLA-DR form one group, and CD34/SSC form another. South (MPO-HLA-DR+, SSC and CD34 positive or negative), East (MPO+HLA-DR+, small SSC, CD34 positive or negative), and West (MPO+HLA-DR-, small SSC, CD34-) are all non-APL, among which West is APL-like. North (MPO+HLA-DR-, large SSC, CD34-) is typical APL, Northwest (MPO+HLA-DR-, small SSC, CD34+) is APLv, and Northeast (MPO+HLA-DR+, large SSC, CD34-) is the rare HLA-DR+ APL. Most of the Northward ones lack EMSC, while most of the Southward ones have them. This can serve as a prototype for artificial intelligence diagnosis.

Conclusions: A multi-parameter immunophenotypic panel based on the detection of EMSC was discovered. By combining immunophenotypes and creating a four-quadrant orientation map, it can rapidly and efficiently distinguish APL from phenotypically similar leukemias, and is expected to serve as the foundation for artificial intelligence.

STUDY OF BONE MARROW-INFILTRATING NK CELLS (BINK) AND PERIPHERAL BLOOD NK CELL (PBNK) IN PEDIATRIC PATIENTS WITH ACUTE LYMPHOBLASTIC LEUKEMIA

*Carmen Mestre Duran[1], Odelaisy León-Triana[2], Sandra Hidalgo[3], Cecilia Pesini[3], Halin Bareke[1], Diego Barriles[4], Karima Al-Akioui Sanz[1], Lidia Pertíñez[1], Victor Galán[5], Berta González[5], Cristina Eguizabal[4,6], Cristina Aguirre-Portolés[1], Ariel Ramirez-Labrada[3], Julián Pardo[3,7], **Antonio Pérez-Martínez**[1,5,8]*
[1]CIBERER-ISCIII, IdiPAZ-CNIO Pediatric Onco-Hematology Clinical Research Unit, Madrid, Spain, [2]Biostatistics Unit, Institute for Health Research (IdiPAZ), Madrid, Spain, [3]Biomedical Research Centre of Aragón (CIBA), Aragón Health Research Institute (IIS Aragón), Zaragoza, Spain, [4]Cell Therapy, Stem Cells and Tissues Group, Biobizkaia Health Research Institute, Bilbao, Spain, [5]Pediatric Hemato-Oncology Department, La Paz University Hospital, Madrid, Spain, [6]Research Unit, Basque Centre for Blood Transfusion and Human Tissues, Bilbao, Spain, [7]Aragon I+D Foundation (ARAID), Zaragoza, Spain, [8]Pediatric Department at Faculty of Medicine, Universidad Autónoma, Madrid, Spain

Background: Leukaemia is the most common childhood cancer. While treatments cure 70-90% of children with acute lymphoblastic leukaemia (ALL), relapsed cases have poor survival rates (<40%). Immunotherapy has introduced innovative therapeutic strategies aimed at improving outcomes. The use of natural killer (NK) cells with anti-tumor activity has been proposed as a promising adjuvant or alternative treatment for leukemic patients. Our study analyzed bone marrow (BM) infiltrating NK (BiNK) and NK cells on peripheral blood (PbNK) of pediatric ALL patients at various stages of disease to understand the immunosurveillance, immunoscape and phenotype related to BiNK cells.

Methods: BM and PB samples were collected from pediatric patients with B-ALL at La Paz University Hospital in Madrid and HUMS/IIS Aragón in Zaragoza, Spain, between March 2019 and May 2023. Samples were obtained at diagnosis (n=48), the end of induction A (IA) phase (n=47), the end of induction B (IB) phase (n=45)and relapse (n=12). The percentages of BiNK and PbNK cells, and the expression of activating and inhibitory receptors and NK ligands in the blast cells, were monitored and analyzed using multiparametric flow cytometry. Additionally, the degranulatory capacity was assessed following co-culture with the K562 cell line at an effector-to-target ratio of 1:2. Furthermore, single-cell RNA sequencing (scRNAseq), cytokine profile and unsupervised analysis (tSNE-CUDA) was performed on a BM samples at both diagnosis and IB to evaluate transcriptomic and clustering changes over time.

Results: Regarding percentages of BiNK/PbNK cells, we observed a significant increase in BiNK cells at IA compared to diagnosis. Similarly, NK cells showed a significant increased at IA and IB phases compared to diagnosis. In contrast, both BiNK and NK cells exhibited a significantly lower percentage at relapse compared to rest time points. BiNK cells showed a

significant decrease in CD56dim, CD16, activating receptors (NKG2D, DNAM-1, and CD57), and inhibitory receptors (TIGIT, TIM-3, PVRIG, and KIRs) while NKG2A expression significantly increased at IA/IB phases compared to diagnosis. At relapse, BiNK cells demonstrated a significant decrease in activating receptors (NKG2D and CD7) and inhibitory receptors (NKG2A, TIM-3, andKIR3DL1), but an increase in CD57 and NKG2C receptors compared to both diagnosis and induction phases. PbNK cells showed a significantly higher percentage of activating receptors (NKG2D, CD7, CD57, CD16, and DNAM-1) and a lower percentage of immune checkpoint receptors (LAG-3, TIGIT, PD-1, and PVRIG) compared to BiNK cells. Furthermore, PbNK cells demonstrated a significant increase degranulation at IB phase compared to diagnosis. ScRNAseq revealed that BiNK cells at IB phase exhibit significant transcriptional changes, suggesting a shift toward a pro-inflammatory state accompanied by reduced functional capacity. Additionally, when comparing cytokine levels at different time points, IL-15, a pro-inflammatory cytokine, showed increased levels during treatment. Unsupervised analysis reveals treatment-dependent BiNK-cell clusters and subclusters. Finally, leukemia blasts showed a higher PD-L1 SFI and a lower HLA-II SFI at relapse compared to diagnosis in pediatric patients with B-ALL.

Conclusions: Our findings indicate that the biological characteristics of BiNK cells are shaped by the specific microenvironment in which they reside, whether within the leukemic niche or during the different phases of treatment.

EARLY TRANSPLANTATION FOLLOWING INDUCTION CHEMOTHERAPY IN ADULT AML PATIENTS WITH A *NUP98* REARRANGEMENTS LEADS TO MRD-NEGATIVE REMISSION

Hannah Al-Yousuf[1], *Anamay Shetty*[1], *Kate Stringaris*[1], *Rajeev Gupta*[2], *Jenny O'Nions*[1,2], *Kavita Raj*[1]
[1]*Department of Haematology, University College London Hospital, London, United Kingdom of Great Britain and Northern Ireland (the),* [2]*UCLH Specialist Integrated Haematology Malignancy Diagnostic Service, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: NUP98 rearrangements (NUP98r) are seen in 5-10% paediatric and 2-4% adult AML and confer a poor response to induction chemotherapy and poor overall survival (OS). Outcomes can be improved with progression to HSCT, however evidence on the optimal timing of HSCT and role of Minimal residual disease (MRD) is lacking. We report on our single centre experience of HSCT in NUP98r AML at University College London Hospitals (UCLH), a UK tertiary referral centre, incorporating MRD data pre- and post-HSCT to determine optimal HSCT timing.

Methods: Ten patients with NUP98r AML were treated with intent-to-transplant at UCLH between 2022-2025.

Results: Median age was 30 years (20-65). 80% were standard risk by ELN 2022, 20% were adverse risk. 70% had a NUP98::NSD1 fusion and 80% had a co-existing FLT3-ITD mutation. The median number of chemotherapy cycles pre-HSCT was 3 (2-8). 90% received intensive induction chemotherapy first-line. 80% received venetoclax containing regimes in induction or consolidation (VEN/AZA, GAV, or FLAV-IDA). 60% received FLT3i. 80% achieved cCR with chemotherapy, within a median of 114 days. Two patients (20%) did not achieve cCR; one died of infection during induction, the other was transplanted with refractory disease. Eight patients (80%) achieved HSCT, within a median of 174 days [130-297]. Of these, three died of relapsed AML post-HSCT, whilst five (62.5%) were alive at last follow up. The median OS in transplanted patients is 29 months from diagnosis and median PFS post-transplant is 13.5 months. Patients who received 1-3 lines chemotherapy pre-HSCT had an improved OS compared to those who received 4+ lines pre-HSCT (15 months vs 5 months, p=0.01).

Patient outcomes were stratified according to disease state pre-HSCT. Two were transplanted with refractory disease, three in MRD positive MLFS, two in MRD positive cCR, and one patient in MRD negative cCR. Both patients transplanted with refractory disease died of relapsed disease post-HSCT, with a median LFS of 48 days post HSCT. However, there was no difference in outcomes between patients who were in MLFS vs those in cCR pre-HSCT. 87.5% patients who were MRD positive at the time of HSCT became MRD negative post-HSCT (MLFS n=3/3; cCR n=4/5). Median time to MRD negativity post HSCT was 104 days (21-182).

Figure 1A: Survival stratified on number of chemotherapy cycles pre-transplant

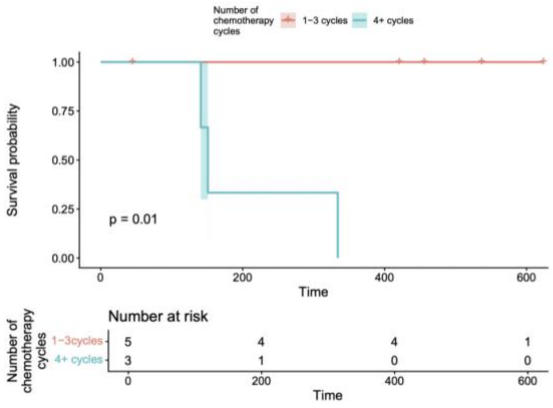

Figure 1B: Survival based on disease status pre-transplant

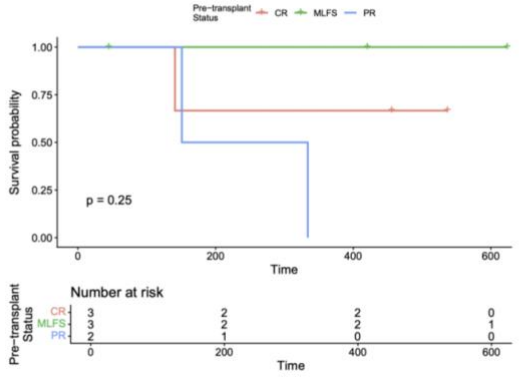

Conclusions: This cohort had a poor response to standard induction chemotherapy with prolonged time to first cCR and low levels of MRD negativity. We identify a trend towards improved response following targeted therapy and venetoclax; only two patients achieved cCR with standard chemotherapy alone, whilst the remainder required either targeted therapy with FLT3i (n=2), venetoclax (n=2) or GAV (n=2). Although patients transplanted with residual leukaemia had poor outcomes, those in MRD positive cCR or MLFS at the time of HSCT had improved outcomes, with no difference observed between MLFS and cCR. We recommend early transplantation following induction chemotherapy in MLFS or CR to offer potential molecular remission and long-term disease-free-survival in adult patients with NUP98r AML.

OUTCOMES OF SECOND ALLOGENEIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKAEMIA AT THE IRISH NATIONAL ADULT STEM CELL TRANSPLANT UNIT

James Dillon[1], *Sarah Kelliger*[1], *Mairead Ni Chonghaile*[1], *Chistopher Fox*[1], *Carmel Ann Galligan*[1], *Greg Lee*[1], *Catherine M. Flynn*[1], *Eibhlín Conneally*[1], *Chris Armstrong*[1], *Nina Orfali*[1]
[1]*St James's Hospital, Dublin, Ireland*

Background: Allogeneic stem cell transplantation (AlloSCT) is the only curative treatment for high-risk AML. However, 30% of patients suffer relapse with dismal subsequent survival. While salvage treatment may re-capture disease response, re-harnessing a graft-versus-leukaemia (GVL) effect through the use of donor lymphocyte infusions (DLI) or a second transplant (AlloSCT2) is usually the only avenue to secure long-term survival. Patient candidacy for AlloSCT2 is challenged by the cumulative toxicity of prior therapies.

Methods: We conducted a 10-year retrospective review of patients who underwent AlloSCT2 (2016-2025) at the Irish National Adult Stem Cell Transplant Unit. Total AlloSCT2 numbers were extracted from our EBMT dataset. The electronic patient record was interrogated for patients who had an initial diagnosis of AML as well as patients relapsing post-AlloSCT1 as a high-grade myeloid malignancy (>10% blasts). Overall survival (OS) and progression free survival (PFS) were estimated using Kaplan-Meier methodology.

Results: Our cohort comprised 20 patients: 13(65%) male and 7(35%) female. Seven (35%) of AlloSCT2s were performed from 2016-2020, and 13 (65%) from 2021-2025.
AlloSCT1: The median age was 37.5 years (IQR 28.5-42y). Original diagnoses were AML (75%), MPAL (5%), MDS (5%) and MDS/MPN (15%). Sixteen patients (80%) received myeloablative conditioning (MAC) and 4(20%) patients reduced intensity conditioning (RIC). Twelve patients (60%) received cells from matched siblings (SIB), 6(30%) from fully-matched unrelated donors (MUD) and 2(10%) from single antigen-mismatched unrelated donors (MMUD). The median time to relapse after AlloSCT1 was 4.1 years (IQR 2.0-8.2y). Only 3 patients had relapsed <1y from AlloSCT1.
AlloSCT2: The median age was 43.8 year (IQR 41-49y). Nineteen (95%) were re-transplanted due to relapse and 1 for primary graft failure (n=1). Nineteen patients. (95%) received RIC or non-myeloablative conditioning; 1 was myeloablated. Of the RIC transplants, 12 (60%) received melphalan, 4 (20%) received sequential regimens. Four patients (20%) were re-transplanted using the same donor. There was an increase in alternative donor sources compared to AlloSCT1: 3 (15%) haplo-identical and 1 (5%) cord blood.
With a median follow-up of survivors of 1.8y, median OS was 5.25y. One and two-year OS were estimated at 66% and 52% respectively. Median PFS was 2.7y, with one and two-year PFS estimated at 60% and 52%. Variable analyses were limited by sample size, but no significant association was observed between survival outcomes and duration of remission after AlloSCT1, choice of donor for AlloSCT2 or conditioning regimen employed for AlloSCT2. At the time of this review 9 patients had died post-AlloSCT2. Causes of death were relapse (n=5), sepsis (n=3) and GVHD (n=1). All non-relapse mortalities (23%) occurred within 1 year of AlloSCT2.

Conclusions: Acknowledging limited numbers, we demonstrate the potential for long-term survival after AlloSCT2 in patients with AML relapsing after AlloSCT1. Room for improvement remains and our cohort is biased against patients relapsing <1yr from AlloSCT1, who are often considered poor AlloSCT2 candidates and suffer dismal outcomes. Further research into the mechanisms of post-transplant relapse in AML may allow a precision approach to treatment, refining our use of targeted therapy, AlloSCT2 and DLI, in order to maximize survival while sparing unnecessary toxicity.

EFFICACY AND SAFETY OF BLINATUMOMAB AS COMBINATION OF INDUCTION OR EARLY CONSOLIDATION THERAPY IN NEWLY DIAGNOSED B CELL ACUTE LEUKEMIA

Fang Xu[1], *Yun Wang*[1], *Baiqing Sun*[1], *Xueshuang Zhang*[1], *Yuhuang Wang*[1], *Haiyan Hu*[1], *Zhicong Du*[1], *Lu Yue*[1]
[1]*Department of Bone Marrow Transplantation, Hebei Yanda Lu Daopei Hospital, Lang Fang, China*

Background: For patients with newly diagnosed acute B-lymphoblastic leukemia (B-ALL), intensive chemotherapy is frequently associated with significant toxicity and a high risk of infection. In contrast, blinatumomab, a novel immunotherapy, has demonstrated favorable efficacy and a promising safety profile.

Methods: This study was conducted at Hebei Yanda Lu Daopei Hospital and included all consecutive pediatric and adult patients with newly diagnosed acute leukemia who received blinatumomab as induction or early consolidation therapy between January 1, 2023 and June 30, 2025. Indications for blinatumomab were: intolerance to intensive chemotherapy, minimal residual disease (MRD) positivity, or failure to achieve remission after chemotherapy.

Results: A total of 21 newly diagnosed acute leukemia patients were enrolled, comprising 2 cases of mixed-phenotype acute leukemia (MPAL, B/myeloid) and 19 cases of B-ALL, among whom 2 had a history of antecedent chronic myeloid leukemia (CML) （Table 1）. The median age was 35 years (range 6–57), 11 (52.4%) were male, and 6 (28.6%) were pediatric. Blinatumomab was used as induction therapy in 13 patients and as consolidation in 8. Prior to blinatumomab, 7 patients had no remission (NR), 14 were in first complete remission (CR1), 12 were MRD-positive, and 2 were MRD-negative. After blinatumomab treatment (median duration 2 weeks), 6 of the 7 NR patients achieved CR1 (CR rate 85.7%), with 5 attaining MRD-negative CR. One NR patient received only 3 days of blinatumomab due to severe cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) and remained MRD-positive. Another NR patient discontinued blinatumomab after 2 days due to ICANS and remained NR. Among the 12 MRD-positive patients, 10 became MRD-negative (MRD-negative rate 83.33%), and 2 showed reduced MRD levels. Adverse events included CRS in 2 patients (grade 3 and grade 1, respectively)

and ICANS in 2 patients. All patients proceeded to allogeneic hematopoietic stem cell transplantation (allo-HSCT, Figure 1). After a median follow-up of 10 months (range 3–28), the estimated 1-year overall survival was 100% and 1-year leukemia-free survival (LFS) was 83.29% (95% CI: 63.47–100). Univariate analysis showed that patients with a presenting WBC $>300 \times 10^9$/L had significantly lower LFS (P=0.013; 94.44% [95% CI: 83.86–100] vs. 33.33% [95% CI: 0–86.68]) and higher relapse rates (P=0.016; 66.67% [95% CI: 29.95–100] vs. 5.56% [95% CI: 10–44.28]). Similarly, extramedullary disease (EMD) before transplant was associated with lower LFS (P=0.049; 93.33% [95% CI: 80.71–100] vs. 33.33% [95% CI: 0–86.68]) and higher relapse (P=0.016; 66.67% [95% CI: 29.95–100] vs. 5.56% [95% CI: 10–44.28]). Two relapses occurred at a median of 6 months, involving one CNS infiltration and one ocular relapse .

PROGNOSTIC FACTORS FOR EARLY LEUKEMIA-FREE SURVIVAL IN NPM1-MUTATED AML UNDERGOING ALLOGENEIC TRANSPLANTATION WITH ACTIVE DISEASE

Alessia Fraccaroli[1], *Michael Hoberger*[1], *Klaus Hirschbühl*[2], *Elena Stauffer*[1], *Katrin Koch*[3], *Stephan Breitkopf*[4], *Sarah Haebe*[1], *Quentin Fichaux*[1], *Moritz Schmidt*[1], *Markus Hentrich*[5], *Andreas Hausmann*[4], *Mareike Verbeek*[3], *Christoph Schmid*[2], *Tobias Herold*[1], *Johanna Tischer*[1]
[1]*Department of Medicine III, LMU, Munich, Germany,* [2]*Department of Hematology and Oncology, University Hospital of Augsburg, Augsburg, Germany,* [3]*Department of Internal Medicine III, School of Medicine, University Hospital Rechts der Isar, Technical University of Munich (TUM), Munich, Germany,* [4]*Department of Hematology, Oncology, Immunology, Palliative Care, Munich Clinic Schwabing, Munich, Germany,* [5]*Department of Hematology and Oncology, Red Cross Hospital Munich, Ludwig Maximilian University of Munich, Munich, Germany*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) represents the only potentially curative treatment option for patients with relapsed or refractory NPM1-mutated acute myeloid leukemia (AML). Although this entity is generally considered chemosensitive, a substantial proportion of patients proceed to transplantation with active disease, a clinical scenario associated with inferior outcomes. Up to now, there is limited evidence to guide risk stratification in the transplant setting.

Methods: We analyzed 49 patients with NPM1-positive AML transplanted with active disease. Leukemia-free survival (LFS) was dichotomized as ≤6 versus >6 months. Logistic regression with backward selection based on the Akaike Information Criterion was used to identify factors associated with LFS > 6 months.

Results: Extramedullary disease was the only variable independently associated with inferior LFS > 6 months ($\beta = -1.43$; $p = 0.03$; odds ratio ≈ 0.24). Age, sex, secondary AML, ECOG performance status, donor type, conditioning intensity, CMV matching and acute graft-versus-host disease did not significantly contribute to the final model. Reduction to the final model resulted in a moderate improvement in model fit ($\Delta AIC \approx 5$). Molecular risk factors such as FLT3 status and ELN risk could not be analyzed due to insufficient variance within this selected cohort.

Conclusions: In *NPM1*-mutated AML patients undergoing allo-HSCT with active disease, extramedullary manifestation is a strong adverse prognostic factor for early leukemia-free survival. These findings emphasize the high-risk nature of transplantation in active disease and support the incorporation of extramedullary involvement into transplant-specific risk stratification and decision-making.

Disclosure: Nothing to declare.

P247

REDUCED RELAPSE RATES IN LEUKEMIA PATIENTS UNDERGOING HAPLOIDENTICAL VERSUS MATCHED RELATED ALLOGENIC BONE MARROW TRANSPLANT: RESULTS FROM A COLOMBIAN BONE MARROW TRANSPLANTATION UNIT

Jorge Cuervo-Sierra[1], *German Velasquez-Quintero*[1], *Wang N. Montoya-Arbelaez*[1], *Alfaddy Castaño-Pelaez*[1], *Jurany Marin-Montoya*[1], *Deisy Giraldo-Gomez*[1], *Luisa F. Castro Quintero*[1], *Maribel Londoño-Buitrago*[1], *Maira Mesa-Giraldo*[1], *Tatiana Valencia-Diaz*[1]
[1]*Clinica Somer Bone Marrow Transplantation Unit, Rionegro, Colombia*

Background: Some studies have shown enhanced anti leukemic activity of transplants from haploidentical donors versus identical related donors in leukemia patients (1); most patients lack an identical related donor available and access to unrelated donors in Colombia is significantly limited. Haploidentical transplant with post-transplant high dose Cyclophosphamide (PTCy) is associated with similar overall survival compared with identical

related donor or matched unrelated donors with less graft versus host disease in Acute Lymphoblastic Leukemia patients (2).

Methods: We retrospectively reviewed clinical records of leukemia patients who had undergone a bone marrow transplantation in our unit between January 1st 2017 and July 30th 2025.

Results: 143 allogenic bone marrow transplants were performed, the most frequent transplant was from haploidentical donor (n=101, 70.6 %) versus allogenic related identical sibling (n=42, 29.4%). The median age was 36 years (11-66 years), and most were male (89, 62.2 %). The most frequent diagnosis were Acute Lymphoblastic Leukemia (82, 57.3 %) followed by Acute Myeloid Leukemia (45, 31.5 %). Most patients received 2 or more treatment regimens before the transplant (103 patients, 71 %). A minority received myeloablative conditioning (33 patients, 23,1%) with a significant difference between transplants modalities, receiving myeloablative conditioning more frequently patients in related identical donors vs haploidentical (47.6 % vs 13.5 %, Chi square p <0.001).All but one patient were in complete response or in chronic phase (in the case of chronic myeloid leukemia) at the time of transplant. Minimal residual disease (MRD) assessment determined by flow cytometry was detectable in 34 patients (24.3 %) with no difference between haploidentical vs identical related allogenic transplant (22.4% vs 28.6 %, Chi square test p=0.44).
Relapse rate was significantly reduced in haploidentical transplant versus identical related donors (33.3 % vs 51.2 %, Chi square test p=0.003, RR: 0.48 CI 95 % 0.31-0.76).
With a median follow up of 274 days, the time free from relapse was significantly higher in transplant from haploidentical donors versus transplant from related identical donors [non reached, (1198 – non reached) vs 511 days (303-non reached), log rank test: 5.25, p = 0.022].
There was not a significant difference in overall survival between the two types of transplants (47,5 % vs 61,9%, Chi square test p=0.117, RR: 1.38 CI 95% 0.9-2.12).
The median survival time was similar between transplant types [754 days in haploidentical (565-199) vs 586 days in identical (369-non reached) log rank test: 0.704, p=0.401] because a possible higher non relapse mortality in haploidentical transplants (Chi square test p=0.037, RR:1.66, CI 95% 0.99-2.78) and possible better rescue therapies in relapsed patients after transplant.

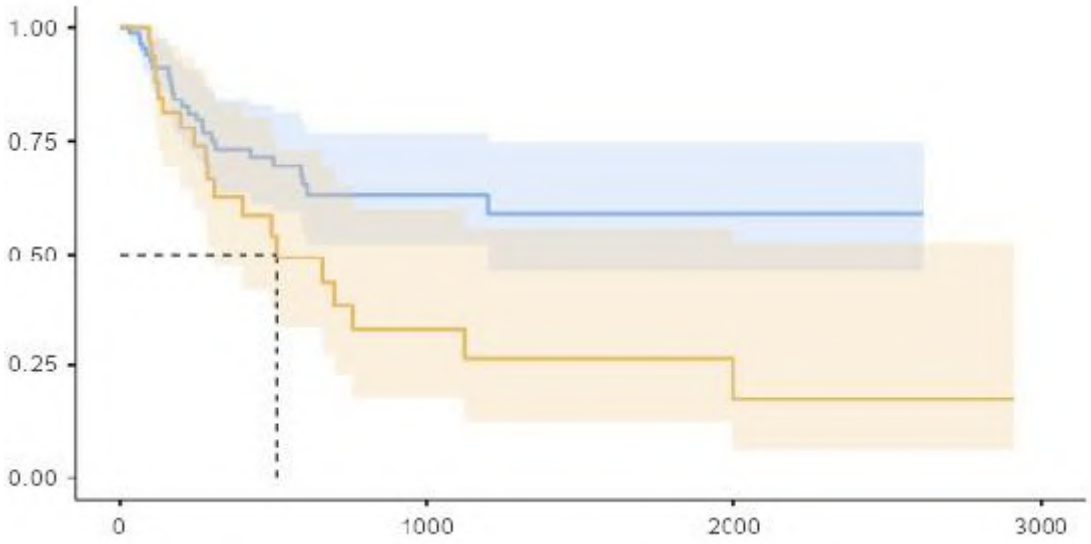

Figure1: relapse free survival, blue line: haploidentical , golden : identical related

Conclusions: Lower relapse rate was observed in transplants from haploidentical donors versus related identical donors without a difference in overall survival in this high risk leukemia patients despite a lower frequency of myeloablative conditioning use in haploidentical transplants suggesting enhanced graft versus leukemia effect in haploidentical transplants. Longer follow up and better supportive care could show that this finding translate in a better overall survival in the future.

P248

POST-TRANSPLANT OUTCOMES IN ADULT ALL: INSIGHTS FROM A SINGLE-CENTER EXPERIENCE

Ons Dagdoug[1], Rihab Ouerghi[1], Insaf Ben Yaiche[1], Dorra Belloumi[1], Lamia Torjemane[1], Rimmel Kanoun[1], Anna Chabaan[1], Tarek Ben Othman[1], ***Nour Ben Abdeljelil***[1]
[1]*Service d'Hématologie et de Greffe, Centre National de Greffe de Moelle Osseuse, Tunis, Tunisia*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a standard consolidation therapy for adult patients with high-risk acute lymphoblastic leukemia (ALL). The present study aimed to evaluate the post-transplant outcomes adult ALL including the cumulative incidence (CI) and severity of graft-versus host disease (GVHD), overall survival (OS), event-free survival (EFS), non-relapse mortality (NRM) and (CI) of relapse.

Methods: We conducted a retrospective study on adult patients with ALL who underwent allo-HSCT from HLA-identical sibling donors between January 2017 and December 2024. Conditioning regimens included Total Body Irradiation (TBI)-based protocols (associated with

etoposide or cyclophosphamide) or chemotherapy-only-regimens consisting of thiotepa–busulfan–fludarabine (TBF) or thiotepa–treosulfan–fludarabine (TTF). Graft-versus-host disease (GVHD) prophylaxis consisted of cyclosporine and short course of methotrexate with or without antithymocyte globulin (ATG). Stem cell sources were bone marrow (BM) or peripheral blood stem cells (PBSCs). Minimal residual disease (MRD) was assessed using multiparametric flow cytometry (6–8 colors) and/or RT-PCR in patients with Philadelphia chromosome–positive B-cell ALL (Ph-positive ALL).

Results: Fifty-three patients were included (20 women and 33 men) with a median age of 33 years (range, 18-55). Underlying disease included Ph-negative B-ALL, Ph-positive B-ALL and T-ALL in 24 (45%), 8 (15%) and 21 (40%) cases, respectively. The median time from diagnosis to allo-HSCT was 7 months (range, 4-135). Prior to transplant, 75% of patients were in first complete remission (CR1), 19 % in CR2. Three patients were transplanted with refractory disease. Minimal residual disease (MRD) status was available in 49 patients, of whom 53% were MRD-positive prior to allo-HSCT. Twenty-two patients (42%) received a TBI-based conditioning regimen, and BM was the source of graft in 60% of patients. The median time to engraftment was 14 days for neutrophil count (range, 10–23 days) and 20 days for platelet count (range, 15–38 days) with significant differences between BM and PBSCs ($p=0.011$ and $<10^{-3}$, respectively). CI of grade II-IV acute GVHD and chronic GVHD were 64% and 61%, respectively, with 22 patients presenting with the extensive form of chronic GVHD. The 2-year CI of relapse was 35%, with a median time of 7 months (range, 2–19 months). The 2-year CI of NRM was 14%, mainly attributable to infections. After a median follow-up of 25 months (range, 1-7 years), the 2-year OS and EFS were 64% and 52%, respectively, without significant differences between patients receiving a TBI-based conditioning and those receiving a CT-based regimen ($p=0.2$ and $p=0.16$), respectively. In subgroup positive MRD patients, TBI-based regimen was significantly associated with better EFS $p=0.048$ compared to CT-based regimen. This EFS benefit is explained by the significantly lower CI of Relapse observed in MRD+ patients receiving TBI ($p=0.036$).

Conclusions: Our experience showed favorable post-transplant outcomes in adult ALL patients with significantly lower relapse in the subset of patients with positive pretransplant MRD who received TBI-based conditioning. These findings support the need for broader access to TBI and targeted therapies to optimize outcomes in this high-risk population.

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ADULT AND PEDIATRIC T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA

Mounira Baazizi[1], Farih Mehdid[1], Nadia Rahmoune[1], Dina Ait Ouali[1], Sabrina Akhrouf[1], Hanane Bouarab[1], Sara Zerkout[1], Belkis Dekhili[2], Hanane Moussaoui[1], Farida Harieche[1], Rose-Marie Hamladji[1], Redhouane Ahmed Nacer[1], ***Malek Benakli***[1]
[1]Pierre and Marie Curie Center, Algiers, Algeria, [2]Department of Hematology-Bone Marrow Transplantation, Pierre and Marie Curie Center, Algiers, Algeria*

Background: T-cell acute lymphoblastic leukemia (T-ALL) is an aggressive precursor lymphoid neoplasm. Chemotherapy alone does not allow for long-term survival in high risk forms. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) offers a curative therapeutic alternative in these cases. We report the results of this procedure in a series of 56 pts.

Methods: From July 2007 to December 2024, 56 allo-HSCT were performed, including 41 geno-identical, 14 haplo-identical, 1 pheno-identical. At the time of transplant, 28 pts (50%) were in first complete remission (CR1), 26 pts (46, 4%) in second complete remission (CR2), and 2 pts in third CR. The median age of the pts is 20 years (5-56), with 21 pts (37,5%) under 18 years old. The sex-ratio (M/F) is 3. The average time from diagnosis to transplant was 19 months (3-72). Various conditioning regimens, without total body irradiation (TBI), were used, including Busulfan-Cytarabine-Melphalan in 13 pts (23,2%), Busulfan-Cyclophosphamide in 6 pts (10,7%), Busulfan-Cyclophosphamide-Thymoglobulin (5 mg/kg) in 4 pts (7%), and Busulfan-Cyclophosphamide-Etoposide in 19 pts (34%). For haploidentical HSCTs, conditioning regimens included Cytarabine-Busulfan-Cyclophosphamide-Thymoglobulin (10 mg/kg) in 6 pts (10,7%) and Busulfan-Thiotepa-Fludarabine in 8 pts (14,2%). GVHD prophylaxis consisted on association of ciclosporine-methotrexate (HLA-identical sibling), ciclosporine-methotrexate-MMF (Beijing Protocol), ciclosporine-MMF-PTCy (TBF). Peripheral blood stem cells (PBSC) as graft was used in 49 pts (87,5%), bone marrow (BM) graft in 1 pt, and a combination of BM and PBSC in 6 pts (Beijing Protocol). As of June 30, 2025, the minimum follow-up is 8 months, and maximum follow-up 215 months.

Results: Aplasia was observed in all pts with median duration of 16 days (8-45). The median day of neutrophils engraftment was 15 days (10-45). VOD occurred in 3 pts including 1 severe. Acute GVHD occurred in 20 pts (36, 3%) including 6 pts grade IV (30%). Chronic GVHD was seen in 13 pts (33,3%) with extensive form in 10 pts (25,6%). CMV reactivation is noted in 12 pts (21,4%). Relapse was observed in 15 pts (27,7%), after a median time of 3 months (2-18). After a median follow-up of 68 months (8-215), 24 pts are alive (42,8%) in CR and 32 pts (57,2%) are died including 18 (32%) of TRM (early infection: 1, acute GVHD: 7, chronic GVHD: 1, VOD: 1, late infection: 3, others: 5) and 14 pts of relapse. The overall survival (0S) and disease-free survival (DFS) at 18 years are 42,9% and 41,1% respectively. The OS and DFS for patients in the first CR and second CR are 64,3%, 23,1% (p : 0,008); and 60,7%, 23,1% (p :0,007), respectively.

Conclusions: TBI-free Allo-HSCT in high-risk T-ALL allows about half of pts to hope for long-term remission, as shown in our series, although with relatively high rates of TRM and relapse.

DURABLE REMISSION AFTER ALLOGENEIC HSCT AND FLT3 INHIBITION IN PEDIATRIC REFRACTORY AML HARBORING A NOVEL FLT3 EXON 14 IN-FRAME INSERTION IDENTIFIED BY NEXT GENERATION SEQUENCING

Walid Ballourah[1], *Mohammed Al-Rimawi*[2], *Farah Malaeb*[3], *Abdulrahman Alsultan*[4], *Abdul Ali Peer Zada*[3]
[1]*King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia,* [2]*College of Medicine, Alfaisal University, Riyadh, Saudi Arabia,* [3]*King Fahad Medical City, Riyadh, Saudi Arabia,* [4]*Department of Pediatrics, College of Medicine, King Saud University, Riyadh, Saudi Arabia*

Background: Refractory pediatric acute myeloid leukemia (AML) remains a major therapeutic challenge. FLT3 (OMIM #136351) encodes a class III receptor tyrosine kinase on 13q12–q13, related to KIT, FMS, and PDGFR. In AML, activating FLT3 lesions are common—primarily internal tandem duplications (exons 14–15) and tyrosine kinase domain mutations (e.g., D835, I836, Y842, N676, F691). FLT3 variants are traditionally detected by PCR-based assays.

Methods: Targeted next-generation sequencing (NGS) was performed to identify actionable alterations in a child with AML refractory to multiple therapies.

Results: Targeted NGS identified a novel FLT3 exon 14 in-frame insertion, c.1780_1781insGGGTCCCTCCGCCTACCC (NC_000013.11:g.28034138_28034139insGGGTAGGCGGAGGGACCC; NM_004119.3(NP_004110.2): p.Phe594delinsTrpValProProProThrLeu), confirmed by Sanger sequencing, in a 13-year-old girl with refractory AML. She failed multiple chemotherapy regimens but achieved remission with chemotherapy plus sorafenib; relapse occurred after sorafenib discontinuation due to cardiomyopathy. With persistent disease after unsuccessful salvage, she underwent allogeneic HSCT with melphalan 140 mg/m² (day −11), fludarabine 30 mg/m² (days −6 to −3), and fractionated TBI 2 Gy twice daily on days −2 and −1 (total 8 Gy), followed by PBSC infusion. Sorafenib was restarted post-transplant at a reduced dose and continued for two years. She has been in complete remission for 56 months following her hematopoietic stem cell transplantation (HSCT) at the time of this report..

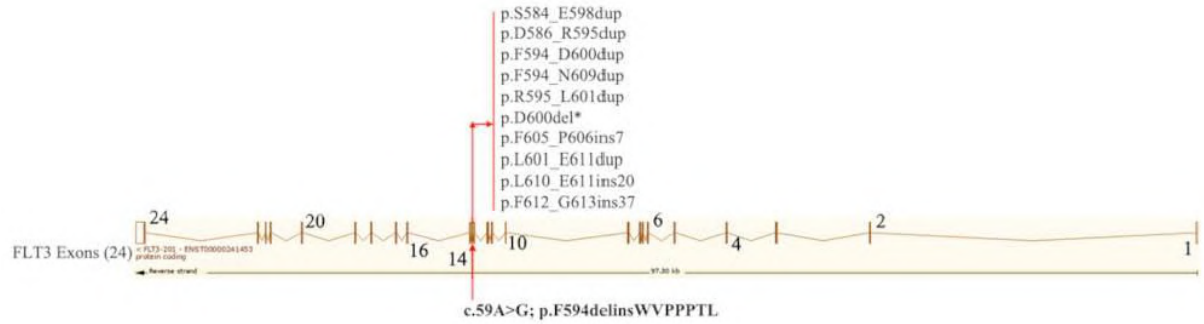

Figure 1: Exon map of FLT3 gene with the novel variant identified in exon 14 and known variants (ITD). Detailed exon map of FLT3 gene in reverse direction with the solid bars representing exons (right to left) and arrows showing the variants at specific exons. The number beside the gene name represents total number of exons in FLT3 gene.

Conclusions: In a child with refractory AML harboring a novel FLT3 exon 14 in-frame insertion, melphalan–fludarabine–TBI (8 Gy) conditioning with allogeneic HSCT, complemented by post-transplant FLT3 inhibition, achieved durable long-term remission, supporting the pathogenicity and therapeutic targetability of this novel mutation.

RISKS FACTORS FOR HEMORRHAGIC CYSTITIS IN LEUKEMIA PATIENTS FROM A COLOMBIAN BONE MARROW TRANSPLANTATION UNIT: A RETROSPECTIVE COHORT STUDY

Jorge Cuervo- Sierra[1], *German Velasquez-Quintero*[1], *Alfaddy Castaño- Pelaez*[1], *Wang N. Montoya-Arbelaez*[1], *Jurany Marin-Montoya*[1], *Luisa Castro-Quintero*[1], *Maribel Londoño-Buitrago*[1], *Deisy Giraldo-Gomez*[1], *Maira Mesa-Giraldo*[1], *Tatiana Valencia-Diaz*[1]
[1]*Clinica Somer Bone Marrow Transplantation Unit, Rionegro, Colombia*

Background: Hemorrhagic cystitis (HC) is a common complication occurring after allogenic bone marrow transplantation and is associated with important morbidity and costs.

Methods: We retrospectively reviewed clinical records of leukemia patients who had undergone a bone marrow transplantation in our unit between January 1 st 2017 and July 30 th 2025.

Results: One hundred forty three (143) allogenic bone marrow transplants were performed, the most frequent transplant was from haploidentical donor (n=101, 70,6 %) versus allogenic transplant from a related identical sibling (n=42, 29,4%). The median age of patients was 36 years (11-66 years), and most patients were male (n:89, 62,2 %). The most frequent diagnosis was Acute Lymphoblastic Leukemia (n:82, 57,3 %) followed by Acute Myeloid Leukemia (n:45, 31,5 %). Most patients had received 2 or more regimens before proceeding to transplantation (n:103, 71 %). HC occurred in 28 transplants (19,6 %) and was grade 3 or 4 in 23 transplants (16,1 %).
Variables significant associated with HC in univariate analysis were age (Mann Whitney U test, p =0,016), type of transplant (haploidentical vs identical related donor**,** Chi square test p =0.016, RR: 3.75, CI 1.47-9.56), having received a combination of Busulfan at least 6.4 mg/kg and total body irradiation (TBI) dose of 200 or 400cGy as part of the conditioning regimen (Chi square test p < 0.001, relative risk (RR) : 4.8 , CI 1.93-11.9), having had mucositis (Chi square test p < 0.001, RR 4.46, CI 1.63-12.2) and having had Cytomegalovirus reactivation (Chi square test p=0.001, RR: 3.97, CI 1.56-10.1).
Having received a myeloablative (MAC) conditioning regimen was not significant associated with HC compared with a reduced intensity (RIC) or a non-myeloablative (NMA) regimen (Chi square test p=0.252, RR:0.58, CI 0.21-1.54).
HC was not associated with death (Chi square test p=0.675, RR: 1.09, CI 0.72-1.65).
In a multivariable logistic regression analysis having received conditioning with Busulfan and TBI, type of transplant, mucositis and CMV reactivation persisted as significant associated with HC while age was only marginally significant (Odd Ratio p=0,06, CI 1-1.07). This model had a sensibility of 94 % and an area under the curve of 0.847 for predicting HC.

Conclusions: HC is a common complication following allogenic transplant in leukemia patients; haploidentical transplant, mucositis, Busulfan plus TBI conditioning and CMV reactivation were variables significant related with HC occurrence.

Disclosure: we have no conflict of interest, the source of funding are own resources

P252

SAFETY AND EFFICACY OF LIPOSOMAL MITOXANTRONE-INTENSIFIED BUSULFAN-BASED CONDITIONING REGIMEN FOR ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH HEMATOLOGICAL MALIGNANCIES

Tingting Cheng[1], Fenfang Tong[1], Jie Peng[1], Yanfeng Liu[1], Shuanghui Yang[1], Yan Chen[1], ***Yajing Xu***[1]
[1]*Xiangya Hospital of Central South University, Changsha, China*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) remains the only effective curative method for hematological malignancies. However, some patients experience relapse after undergoing allo-HSCT, and reducing the post-transplant recurrence rate remains a major challenge of transplantation. Conditioning is the first step of allo-HSCT

and plays a significant role in preventing relapse after transplantation. The active ingredient of Liposomal Mitoxantrone (Lipo-MIT) is mitoxantrone, and the encapsulation with liposomes does not alter its inherent mechanism of action, which is expected to reduce toxicity and enhance antitumor effects after being encapsulated in liposomes, making it an ideal choice for modified conditioning regimen. However, its efficacy and safety in the conditioning of allo-HSCT remain uncertain. We conducted this study to evaluate the preliminary efficacy and safety of Lipo-MIT intensified busulfan (Bu)-based conditioning regimens (combined with cyclophosphamide or fludarabine) for allo-HSCT in patients with hematological malignancies.

Methods: A retrospective study was conducted at Xiangya Hospital of Central South University. Patients with acute myeloid leukemia (AML) or acute lymphoblastic leukemia (ALL) or myelodysplastic syndrome (MDS) aged ≥14 years old and underwent allo-HSCT after receiving Lipo-MIT intensified Bu-based conditioning were included. Lipo-MIT was administered at a dose of 30 mg/m²/day for one day.

Results: Data were collected from 28 eligible patients between March 2023 and October 2025, comprising 18 patients with AML, 8 patients with ALL (including 2 with T-ALL and 6 with B-ALL), and 2 patients with MDS. The median age was 41 years (range: 14-62). Prior to transplantation, 16 patients were in first complete remission (CR1) with negative minimal residual disease (MRD-), 5 were in CR1 MRD(+), 1 was in CR2 MRD(+), 2 had non-remission (NR), 3 had relapsed disease, and 1 was in partial remission (PR). Risk stratification: among AML patients, 11 were classified as high risk, 5 as intermediate risk, and 2 as standard risk. Among ALL patients, 7 were standard risk and 1 was high risk. MDS patients were all IPSS high risk.
Two patients died of serious infection before engraftment. Among the remaining patients, the median time to neutrophil engraftment was 13 days (range: 10-17 days), and of platelet engraftment was 13 days (range: 10-20 days). As of November 30, 2025, the median follow-up time was 13.82 months (range: 0.23-29.43 months).
The 12-month cumulative incidences of relapse, non-relapse mortality, disease-free survival, and overall survival were 7.4% (1.2-21.4%), 11.4% (2.7-27.0%), 76.4% (61.3-95.1%), and 88.6% (77.3-100.0%), respectively. By day 100 after allo-HSCT, 10 patients (35.7%) developed acute graft-versus-host disease (aGVHD), all of which were grade I-II. Until the follow-up cutoff date, chronic GVHD (cGVHD) developed in 5 patients (17.9%), including 2 mild cases and 3 moderate/severe cases. A total of 5 patients (17.9%) died after transplantation, with causes of death being relapse (1 case) and infection (4 cases).

Conclusions: It is concluded that Lipo-MIT-enhanced Bu-based conditioning regimens were feasible and effective for allo-HSCT in AML, ALL, or MDS patients. However, the sample size needs to be expanded for further observation and evaluation of long-term survival and recurrence rates.

Disclosure: The authors declare no competing financial interests.

IMPLEMENTING EBMT RISK SCORE AS A PREDICTOR FOR OVERALL SURVIVAL IN PATIENTS WITH ACUTE LEUKEMIA AND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT. SINGLE CENTER EXPERIENCE

Lazar Chadievski[1], *Sonja Genadieva Stavrik*[1], *Zlate Stojanoski*[1], *Bozidar Kocoski*[1], *Milche Cvetanoski*[1], *Merve Purde*[1], *Arita Fazliu*[1], *Martin Stojanoski*[1], *Sanja Trajkova*[1], *Aleksandra Pivkova Veljanovska*[1]
[1]*University Clinic for Hematology, Skopje, Republic of North Macedonia*

Background: Allogeneic hematopoietic stem cell transplant (HSCT) is a standard therapeutic procedure incorporated in the treatment algorithm of patients with acute leukemia. This procedure could be followed with numerous post-transplant complications and sometimes could be challenging to make a good estimation of the treatment benefit. EBMT risk score is a tool that is used in estimating the OS and TRM in patients where allogeneic HSCT is planned by using well defined variables.

Methods: We have analyzed 85 patients with acute leukemia treated with allo HSCT. We have used the well established form of EBMT risk score and its variables defined by Gratwohl et al. 2009 (Age, disease status, interval to HSCT, Donor, Gender of donor-recipient.) In our group of transplanted patients 69 (81%) were diagnosed with AML, while 16 (19%) with ALL. The average age of the patients was 39.5 years, in the AML group the median age was 42 years, while in the ALL group was 28 years. 76% of the patients had higher disease risk profile. 95% of the patients were transplanted in CR-1, while 5% in CR-2. We have calculated EBMT risk score to all of our patients. We grouped them in four groups (EBMT risk score 0/1, EBMT risk score 2, EBMT risk score 3, EBMT risk score >4).

Results: The 24 months overall survival (OS) post-transplant was 62.2 %, for patients with EBMT risk score of 0-2, while those with higher scores (3 and >4) had significantly worse OS of 45.4% (p value=0.05). We have also calculated the disease free survival (DFS) of these patients. The 36 months post-transplant DFS was 35.7% for those with EBMT risk score >4, 29.8% for those with score of 3, 53.3% for those with score 2 and 66.5% for the patients with EBMT risk score of 0-1. We have calculated that the DFS was statistically beter for patients with EBMT risk score of 0,1,2 compared with those with EBMT risk score of 3 and >4 (p=0.0257).

Conclusions: As a conclusion we have noticed that EBMT risk score could be an effective tool in anticipating the risk of allogeneic HSCT of patients with acute leukemia, translated in lower rates of OS and DFS for those patients that had higher EBMT risk score, especially 3 and >4.

Disclosure: No disclosures.

SUBGROUP ANALYSIS OF THE GREATER CHINA REGION IN THE RANDOMIZED PHASE 3 AGILE STUDY OF IVOSIDENIB+AZACITIDINE VERSUS PLACEBO+AZACITIDINE IN PATIENTS WITH NEWLY DIAGNOSED MIDH AML

*Jianxiang Wang[1], Kuan-Ming Lai[2], **Su-Peng Yeh**[3], Yuping Gong[4], Hsin-An Hou[5], Hui-Hua Hsiao[6], Jie Jin[7], Qingsong Yin[8], Xin Du[9], Jianan Hui[10], Fancy Liao[11], Gao Jian[12], Sheng-Yen Hsiao[13], Jian Li[14]*
[1]Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences, Tian Jin, China, [2]Changhua Christian Hospital, Changhua, Taiwan (Province of China), [3]China Medical University Hospital, Taichung, Taiwan (Province of China), [4]West China Hospital, Sichuan University, Chengdu, China, [5]National Taiwan University Hospital, Taipei, Taiwan (Province of China), [6]Kaohsiung Medical University Chung-Ho Memorial Hospital, and Kaohsiung Medical University, Kaohsiung, Taiwan (Province of China), [7]The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China, [8]Henan Cancer Hospital, Zhengzhou, China, [9]Guangdong Provincial People's Hospital, Guangzhou, China, [10]Servier BioInnovation, Boston, United States of America (the), [11]Servier Taiwan, Taipei, Taiwan (Province of China), [12]Servier China, Tianjin, China, [13]Chi Mei Medical Center, Tainan, Taiwan (Province of China), [14]Peking Union Medical College Hospital, Beijing, China

Background: Ivosidenib (IVO) is an oral targeted inhibitor of mutant *IDH1 (mIDH)*. In the AGILE study (NCT03173248) on patients with newly diagnosed *mIDH1* AML, the median overall survival (OS) was 29.3 months for IVO+azacitidine (AZA) compared with 7.9 months for placebo (PBO)+AZA (HR, 0.42; 95% CI, 0.27, 0.65; *P*<0.0001), at a median follow-up of 28.6 months. We conducted an ad-hoc analysis of the AGILE phase 3 study to assess the efficacy and safety of IVO+AZA in newly diagnosed and unfit patients from the Greater China region.

Methods: In the double-blind AGILE study, patients were randomized 1:1 to receive either IVO 500 mg QD plus AZA 75 mg/m² SC or IV for 7 days in 28-day cycles or PBO+AZA. Data from the Greater China region for OS, event-free survival (EFS), blood count recovery, and safety are reported here. EFS was defined as the time from randomization until treatment failure (ie, the patient did not achieve complete response (CR), CR with incomplete hematologic recovery, or morphologic clearance of leukemic cells from the marrow after at least 24 weeks of treatment), relapse from remission, or death from any cause, whichever occurred first.

Results: From 23-Aug-2018 to 07-Jan-2021, 23 Greater China region patients were randomized: 12 to IVO+AZA (mean age 70.0 [6.71] years) and 11 to PBO+AZA (mean age 68.2 [8.89] years). Patients aged ≥75 years in the two arms were 25% and 18.2%, respectively, and male patients were 75% vs 45.5%, respectively. In the IVO+AZA arm, all patients had intermediate or high ELN risk, and one had extramedullary disease; in the PBO+AZA arm, 81.8% had intermediate or high risk. Median treatment duration was 164 days for IVO+AZA and 82 days for PBO+AZA. At a median follow-up of 7.2 months for EFS in the IVO+AZA arm, the median EFS was not reached in the IVO+AZA arm, and was 9.33

months (95% CI, 0.66-NE) in the PBO+AZA arm, the 12 month-EFS rate was 67.5% (IVO+AZA) vs 0 (PBO+AZA). At median follow-up of 22.4 months for OS in the IVO+AZA arm, median OS was 30.6 months (95% CI, 3.7-NE) for IVO+AZA vs 11.2 months (95% CI, 0.9-NE) for PBO+AZA. The CR rate was 50% (95% CI, 21.1%-78.9%) for IVO+AZA vs 27.3% (95% CI, 6.0%-61.0%) for PBO+AZA. Mean platelet count recovered from baseline (55.25 x 10^9/L) by cycle 4 (day 1) and stabilized within the normal range; mean neutrophil counts rapidly increased from baseline (0.652 x 10^9/L) on day 15(4.44 x 10^9/L) and remained above 1.5 x 10^9/L. For adverse events of special interest, no differentiation syndrome was observed in either group. In the IVO+AZA group, 1 case of ≥grade 3 QT interval prolongation occurred, while no ≥grade 3 cases were reported in the PBO+AZA group.

Conclusions: The data indicate that IVO+AZA provides significant therapeutic benefits for patients with newly diagnosed mIDH1 AML in the Greater China region with higher mOS, better hematologic responses, and faster blood count recovery, while maintaining a manageable safety profile vs PBO+AZA.

TARGETING FLT3: A REAL-LIFE, SINGLE-CENTER ANALYSIS OF FLT3 INHIBITORS USE IN THE ALLOGENEIC TRANSPLANT SETTING

Francesca Duca[1,2], *Elsa Masedu*[1,2], *Stefano Bonfanti*[1,2], *Silvia Viola*[1,2], *Fabrizio Cavalca*[2], *Monica Fumagalli*[2], *Elisabetta Terruzzi*[2], *Andrea Aroldi*[2], *Marilena Fedele*[2], *Paola Perfetti*[2], *Carlo Gambacorti-Passerini*[1,2], *Matteo Parma*[2]
[1]*University of Milano-Bicocca, Monza, Italy,* [2]*Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy*

Background: FLT3 mutations occur in about 30% of Acute Myeloid Leukemia (AML), conferring adverse prognosis and high relapse rates. Often coexisting with NPM1, RUNX1, and DNMT3A alterations, FLT3-mutated AML is highly heterogeneous. FLT3 inhibitors (FLT3is) improve outcomes across disease phases, including upfront, relapsed/refractory, and maintenance. Our study presents real-life experience with FLT3is in the allo-HSCT setting, assessing clinical efficacy, graft impact, and tolerability in a complex population.

Methods: We retrospectively analyzed 17 adult patients with FLT3-mutated AML who underwent allo-HSCT at our center between 2020-2025 and received FLT3is therapy before and/or after transplant. Based on primary indication and timing, patients were categorized into: 1. Post-transplant maintenance with Sorafenib once in complete remission (CR) (n=10); 2. Gilteritinib as second-line therapy bridging to transplant in refractory/relapsed (R/R) disease (n=3); 3. Post-transplant relapse treatment without prior FLT3is maintenance (n=2); 4. Complex pathways with sequential FLT3is exposure (n=2). Primary endpoints were efficacy, graft outcomes, and toxicity.

Results: Group 1: It demonstrated median OS of 22.5 months (range 10-99) and PFS of 20 months (3-75), with 2/10 patients relapsing during or after maintenance. Among relapsed patients, both were treated with Gilteritinib: one achieved transient response, the other successfully proceeded to second allo-HSCT. Overall, 8/10 are still alive (median follow-up 23 months, range 10-99).
Group 2: Gilteritinib successfully bridged all refractory/relapsed patients to transplant. All three patients maintained durable remissions when Gilteritinib was continued post-transplant, with median OS 44 months (11-53) and PFS 38 months (11-50). All patients are still alive and in CR.
Group 3: These 2 patients treated after post-transplant relapse showed poor outcomes with median OS 16.5 months (14-19) and median PFS 6.5 months (4-9). Neither patient survived.
Group 4: One patient received Azacitidine-Venetoclax-Sorafenib before transplant for R/R AML and continued with Sorafenib as maintenance after transplant. The second one received Azacitidine-Venetoclax-Sorafenib for a relapse one year after transplant. After 5 months, the treatment was shifted to Gilteritinib for a second relapse achieving a third remission. Both are still alive (median follow-up 32 months, range 22-42).
Graft outcomes and tolerability: FLT3is before transplant did not compromise engraftment across all groups, with median neutrophil recovery ranging from day +17 to +29 and platelet recovery from day +17 to +33. Acute GVHD incidence was low to moderate overall (range 20-50% across groups), while chronic GVHD varied from 0-100%. The most common grade 3-4 toxicities were manageable cytopenias requiring dose modifications. One case of myopericarditis occurred in group 4. Infectious complications, predominantly viral reactivations and bacterial infections, occurred in approximately 50% of patients and were manageable with standard therapy.

Infectious events, n	5	1	0	2

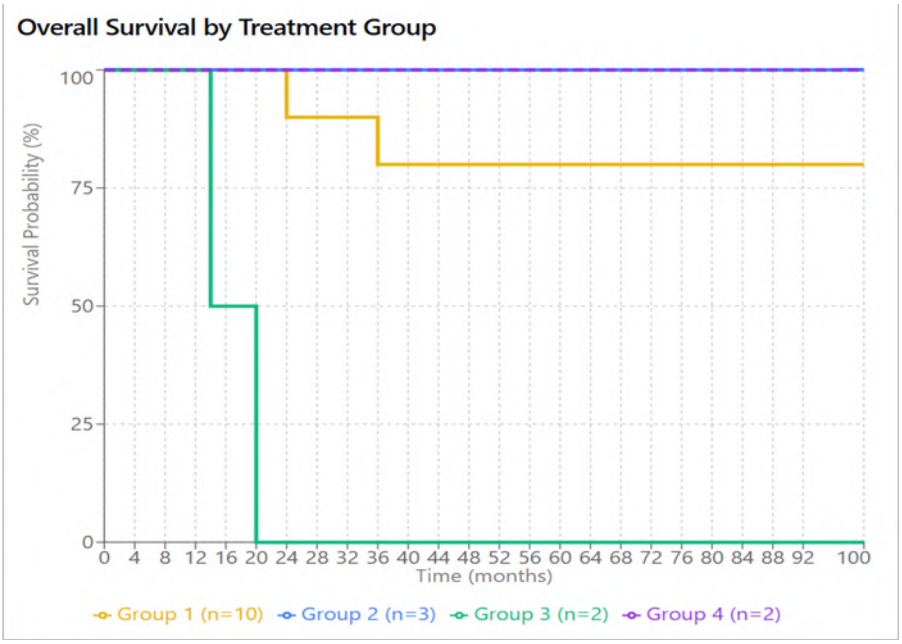

Figure 1. Kaplan-Meier survival curves: Overall Survival by treatment group: Group 1 (Sorafenib maintenance, n=10), Group 2 (Gilteritinib bridge, n=3), Group 3 (post-transplant relapse, n=2), and Group 4 (complex pathways, n=2).

Conclusions: This real-world experience demonstrates safe, effective integration of FLT3is into the allo-HSCT setting. Sorafenib maintenance achieved low relapse rates and high survival, while Gilteritinib successfully bridged refractory patients to transplant with

sustained remissions. Post-transplant relapse without prior FLT3is remains challenging, underscoring the value of early FLT3is use. Importantly, FLT3is did not impair engraftment or significantly increase GVHD. These findings support FLT3is as standard peri-transplant management, although further studies should refine patient selection and dosing.

CLINICAL CASE OF TREATMENT OF CONGENITAL ACUTE MYELOID LEUKEMIA

*Maryia Navumovich[1], Volha Mishkova[1], Natalia Kirsanava[1], Aliaksei Lipnitsky[1], Katsyaryna Vashkevich[1], Nina Minakovskaya[1], Inna Praleskouskaya[1], Ilia Kolchanov[1], Dzmitry Lutskovich[1], **Juliya Mareika**[1], Maryna Horbach[1], Anzhalika Solntsava[1]*
[1]Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Borovlyany, Belarus

Background: Congenital acute myeloid leukemia (AML) is a sporadic aggressive disease diagnosed within the first 28 days of life. Early diagnosis and treatment are crucial, emphasizing the responsibility of clinicians to act promptly, including intensive chemotherapy and, possibly, hematopoietic stem cell transplantation (HSCT). Survival rates remain low, mainly due to treatment-related mortality.

Methods: A patient with refractory congenital acute myeloid leukemia was treated at the Belarusian Research Center for Pediatric Oncology, Hematology, and Immunology. Diagnostic procedures were performed by the Center's clinical, molecular genetic, cytological, and other laboratories.

Results: The patient, a 20 days old boy born using IVF, was hospitalised with hyperleukocytosis and leukemic infiltrates on the skin. Bone marrow (BM) examination revealed hypercellularity, 68% blasts, M5 (FAB). An unbalanced rearrangement of the KMT2A gene was detected. Immunophenotyping: acute monocytic leukemia. Based on the diagnostic results, the final diagnosis was established: congenital acute myeloid leukemia.
Treatment began in the ICU: prophase (DNR, VP), ADE (DNR, VP, ARA-C) with a 1/3 dose reduction. Chemotherapy was stopped on day +6 due to infectious and toxic complications, with an initial response in the form of disappearance of leukemic infiltrates, a decrease in leukocytes, and the absence of blast cells in the peripheral blood. A month later, the myelogram showed 24% blasts, and leukemic infiltrates appeared on the skin. An AI block (ARA-C, IDA) was performed; on day +16 after the block – progression. FLAG+Mit was performed against the background of infectious complications, but it was unsuccessful; further progression was noted.
As a salvage therapy, a Clo+VP+Cy+Venetoclax block was performed with three infusions of allogeneic haploidentical donor NK cells (donor: father). A week after the latest NK cell infusion, the CBC showed WBC $1.4x10^9$/L, and the BM examination showed myelokaryocytes $2x10^9$/L. Over the next few days, the condition worsened - seizures, fever, cytopenia,

mechanical ventilation was started.
On day +40 from the start of Clo+VP+Cy+Venetoclax block, the child was diagnosed with secondary hemophagocytic lymphohistiocytosis with no response after month of therapy (dexamethasone, VP, CSA, intralumbar administration of cytostatics, ruxolitinib). Severe toxicity occurred, and the patient experienced several episodes of sepsis. The patient was diagnosed with left-sided lung mucormycosis. Due to persistent aplasia and failure of prior therapies, a decision was made to perform allogeneic related (haploidentical) HSCT as the definitive salvage option, emphasizing the criteria guiding this choice.
Allogeneic related HLA-mismatched peripheral blood HSCT with CD3αβCD19 depletion was performed (donor: father) after fludarabine, cyclophosphamide, ATG, and Rituximab conditioning. G-CSF stimulation on days +1 to +5. By day +9, WBC recovery was more than $1x10^9$/L, and granulocytes were more than $0.5x10^9$/L. On day +14 – 100% donor chimerism (peripheral blood).
Currently (+18 days after allo-HSCT), despite the restoration of granulocytopoiesis and combined antifungal therapy, the patient shows further progression of mucormycosis with lesions of the lungs, heart, skin, and liver.

Conclusions: Intensive polychemotherapy combined with immunotherapy can effectively induce remission in congenital refractory AML. Recognizing the importance of early intervention, allogeneic HSCT should be considered promptly when profound hematopoietic aplasia occurs.

Disclosure: Nothing to declare.

REAL-WORLD EXPERIENCE WITH VENETOCLAX, AZACITIDINE, AND SORAFENIB IN RELAPSED/REFRACTORY FLT3-ITD AML: A SINGLE-CENTRE CASE SERIES

Titas Tiškevičius[1], *Domas Vaitiekus*[1,2], *Ignas Gaidamavičius*[1,2], *Rolandas Gerbutavičius*[1,2], *Audronė Vaitiekienė*[1,2], *Milda Rudžianskienė*[1,2], *Rūta Dambrauskienė*[1,2], *Miglė Kulbokė*[1,2], *Martyna Beitnerienė*[1,2], *Egidija Kukarskytė*[1], *Rima Jūratė Gerbutavičienė*[2]
[1]*Hospital of Lithuanian University of Health Sciences Kaunas Clinics, Kaunas, Lithuania,*
[2]*Lithuanian University of Health Sciences, Kaunas, Lithuania*

Background: Azacitidine in combination with Venetoclax is increasingly used in acute myeloid leukaemia (AML), including cases with FLT3 mutations, where responses to therapy are often short lived due to rapid emergence of resistance mechanisms. FLT3-ITD and FLT3-TKD mutations are well recognized drivers of treatment failure, particularly under selective pressure from venetoclax-based therapy. Adding Sorafenib, a multikinase inhibitor with FLT3-inhibitory activity, to the Azacitidine and Venetoclax backbone is being explored as a strategy to enhance antileukemic activity and potentially improve outcomes in patients with FLT3-mutated relapsed or refractory AML.

Methods: We conducted a retrospective single-centre study at the Hospital of the Lithuanian University of Health Sciences Kaunas Clinics. Adult patients with relapsed or refractory FLT3-mutated AML treated with Azacitidine 75 mg/m², Venetoclax 400 mg once daily, and Sorafenib 400 mg BID between February and November 2025 were included. Key clinical, molecular, treatment, transplant, and survival data were extracted from medical records. Overall survival (OS) was defined from treatment initiation to death or last follow-up, and progression-free survival (PFS) from treatment initiation to relapse, progression, or death. Survival outcomes were analysed using the Kaplan-Meier method. Due to the low number of events, no comparative statistical testing was performed.

Results: A total of 4 patients with relapsed/refractory FLT3-ITD mutated AML were treated with the triplet combination of Venetoclax, Azacitidine, and Sorafenib. The cohort included patients with median age of 42 (range 21 – 75) with an ECOG performance status of (0 – 2), all of whom had received at least one prior line of therapy, and three had previously undergone allogeneic transplantation. The overall response rate (CR/CRi) was 100%, as all four patients achieved remission after the first treatment cycle. Among the three patients who had previously undergone allogeneic transplantation, all were successfully bridged to a second allo-HSCT following remission. One patient later experienced disease progression and subsequently died during the follow-up, while the remaining three remained alive and progression free at last contact. Median OS and PFS were not reached, with a median follow-up of 225 days (range 90 – 270 days). Estimated 6-month OS and PFS were both 100%, and the estimated 12-month OS and PFS were both 67%, demonstrating notable durability of disease control. Due to the very low number of events, statistical comparisons were not feasible. These findings highlight the activity of Venetoclax – Azacitidine combined with Sorafenib in heavily pretreated FLT3-ITD AML, including patients undergoing a second HSCT.

Conclusions: The combination of Venetoclax, Azacitidine, and Sorafenib demonstrated promising activity in heavily pretreated relapsed/refractory FLT3-ITD AML, with encouraging PFS and OS despite substantial prior therapy and high-risk disease biology. Although limited by small sample size and low event rates, these real-world findings provide a strong rationale for prospective evaluation of this triplet approach, including its integration into pre- and post-transplant therapeutic strategies. Larger multicentre studies are warranted to validate these early signals of efficacy.

Disclosure: Nothing to disclose.

Giuseppe Moscati, Avellino, Italy,* [2]*SAAWP of the EBMT, Leiden, Netherlands (the),* [3]*King's College, London, United Kingdom of Great Britain and Northern Ireland (the),* [4]*La Sapienza University, Rome, Italy,* [5]*Saint-Louis Hospital and Université de Paris, Paris, France,* [6]*St James's University Hospital, Leeds, United Kingdom of Great Britain and Northern Ireland (the),* [7]*IRCCS Institute G.Gaslini Childrens' Hospital, Genoa, Italy*

Background: In our recent EBMT RACE phase-3, randomized, prospective trial (NCT02099747) investigating Immuno-Suppressive Treatment (IST) with/without Eltrombopag in Aplastic Anemia (AA), the CUB and Sushi Multiple Domains 1 (*CSMD1*) gene emerged as a commonly mutated gene. Here we investigate *CSMD1* mutations, looking for the frequency of mutations, their association with clinical variables and other somatic mutations, the dynamics of the mutated clones across the 2-year study period and a in silico structural analysis predicting functional consequences.

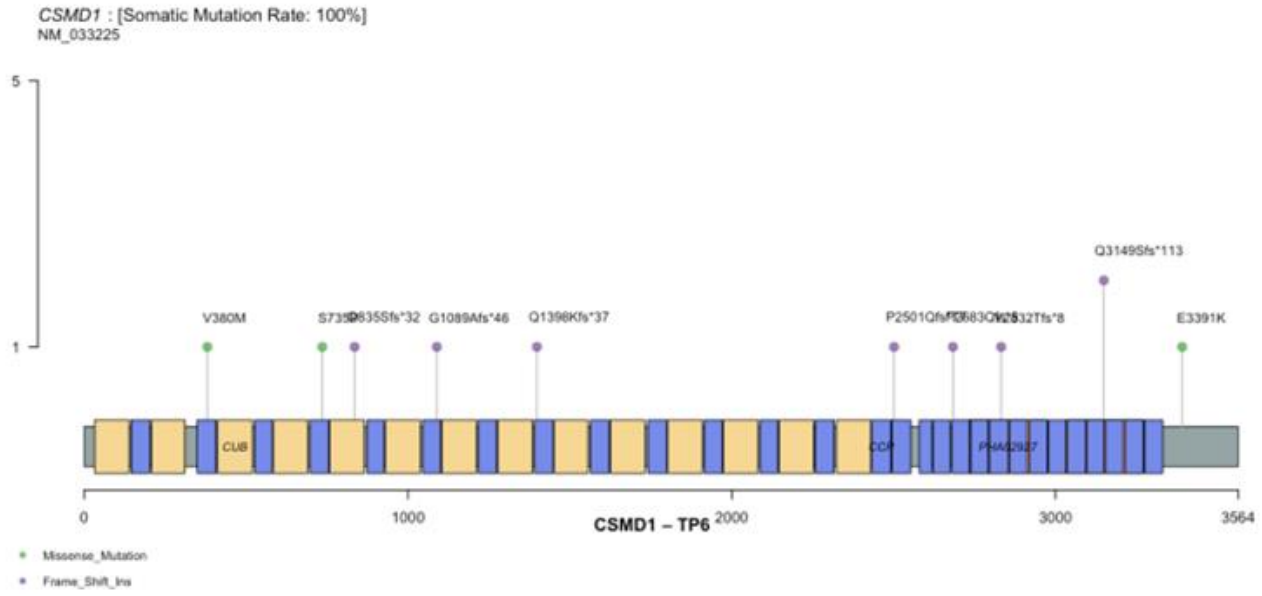
Methods: Somatic mutations analysis using the HaloHS 31 gene panel was performed at King's College London on 170, 150 and 103 patient bone marrow samples collected at baseline, 6 and 24 months after randomization, respectively. Appropriate variant caller protocols were utilized to identify candidate variants, using an arbitrary Variant Allele Frequency (VAF) threshold of 0.2% to define mutations.

Results: No *CSMD1* mutation was found at baseline (n=170). Then mutations in the *CSMD1* gene were found in 4/150 (2.7%) patients at TP6 and in 16/103 (15.5%) patients at TP24. Since many patients harbored more than one *CSMD1*-mutated clone, the mean number of *CSMD*1 mutations per patients was 0.07 and 0.47 at 6 and 24 months after IST, respectively. The presence of *CSMD1* mutations was not associated with age, disease severity at baseline, presence of somatic mutations in myeloid-cancer genes at baseline, treatment arm and hematological response. The VAF of *CSMD*1-mutated clones was usually very low, with 9/11 (81.8%) and 42/48 (87.5%) clones remaining below a 5% VAF at TP6 and TP24. Mutations in *CSMD1* were often associated with mutations in *ETV6, PHF6, PPM1D, PTPN11, RAD21* and *STAG2* genes.
The CSMD1 protein consists of 14 CUB domains alternated with 14 Sushi domains, followed by further 15 Sushi domains, and then a transmembrane domain and an intracytoplasmic tail at the C-terminus. Looking structurally at the specific mutations, no hotspot mutation was

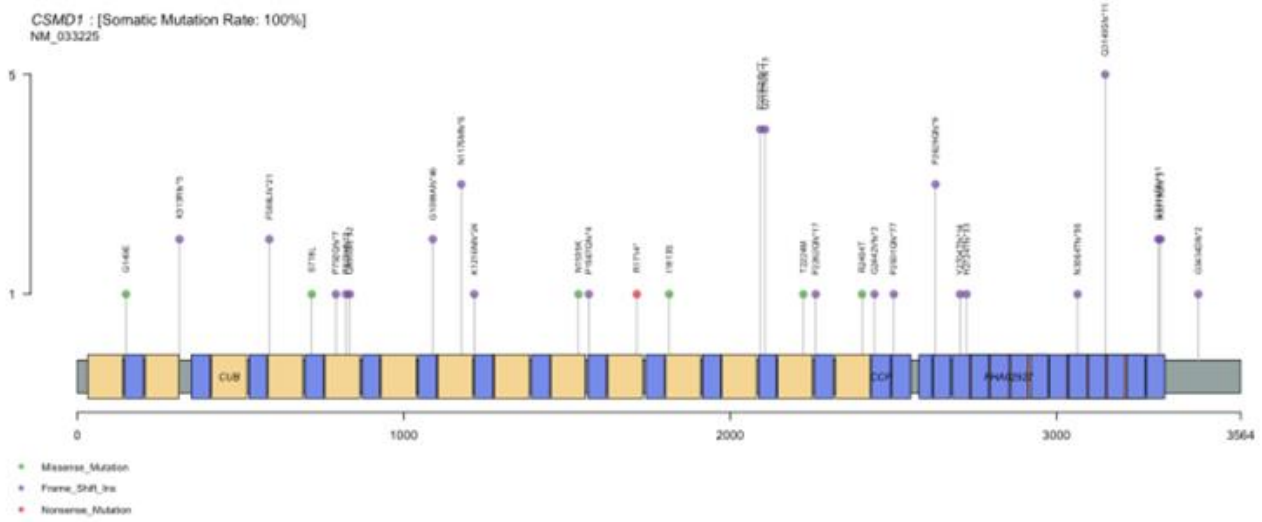
found; lollipop plots (**Figure 1**) illustrate that the majority of mutations are frameshift mutations located in the first half of the protein (thus not affecting the signal-transduction domain of its intracytoplasmic tail). Rather they result in truncated versions of the protein lacking its transmembrane domain, retaining their complement-regulatory activity associated with the multiple Sushi domains of its N-terminus. We hypothesize that the secretion of truncated CSMD1 proteins retaining complement regulator activity may result in an autocrine effect which may spare mutated hematopoietic cells from a complement-mediated damage triggered by immune-complexes associated with anti-thymocyte globulin treatment. Thus, major structural changes associated with *CSMD1* mutations would result in a gain-of-function phenotype accounting for negative clonal selection.

The Lollipop Plots for CSMD1

TP6



TP24



Conclusions: *CSMD1* is the most commonly mutated gene in AA patients after 2 years from IST, even more than *PIGA*), strongly suggesting a non-random mechanism of selections for the mutated HSC/HPC. Although *CSMD1* is also known as a tumor-suppressor gene, in the context of AA clones *CSMD1* mutations seems to rather represent an example of in vivo "*pruning selection*", with selected clones developing a transient survival advantage emerging at the time of treatment with anti-thymocyte globulin and subsequent hematological recovery.

Background: In the absence of a fully matched donor, upfront mismatched donor transplantation as an initial strategy rather than immunosuppressive therapy in paediatric SAA needs to be evaluated.

Methods: Retrospective data were collected on HSCTs performed for paediatric patients (< 16 years) with idiopathic/acquired SAA from 1st January 2017 to 31st March 2025 across England and Ireland. Patients with inherited bone marrow failure syndromes were excluded.

Mismatched transplants were defined as single-allele mismatches by high-resolution typing of HLA-A, -B, -C, -DRB1, and -DQB1.

Results: 201 patients underwent HSCT for SAA, of whom 159 (79%) received HSCT from matched donors (56 related (MRD), 103 unrelated (MUD)), while 33 (16%) received HSCT from mismatched donors (4 related (MMRD), 29 unrelated (MMUD)). 9 (5%) were from haploidentical donors and excluded from this analysis. The two mismatched groups were combined due to the low number of MMRD HSCTs.
Median age at transplant was 9 years, with no significant differences between groups ($p = 0.8$). Median follow-up time was 36 months (IQR 17-57). No significant differences were observed in median engraftment time, cumulative incidence of engraftment at day 30 (Figure 1), or incidence of graft failure, acute graft-versus-host disease (aGVHD), or veno-occlusive disease (VOD) between MRD, MUD, and mismatched donor cohorts (Table 1). No difference in overall survival was observed in the three groups (Figure 1c, $p=0.2$). The mismatched cohort had a significantly longer time to HSCT from diagnosis (median 8 months, $p < 0.001$), a considerably higher pre-transplant serum ferritin level (median 2328, IQR 1370-3282, $p < 0.001$), and a higher proportion of major ABO incompatibility (36%, $p = 0.03$). There was a significantly higher incidence of viral reactivation/infection requiring treatment in the mismatched cohort. Eight treatment-related deaths were reported overall (MRD: 1, MUD: 4, mismatched: 3).
Within the mismatched cohort, donors were HLA-A mismatched in 55% (18/33), HLA-C mismatched in 24% (8/33), HLA-DQB1 mismatched in 9% (3/33), and HLA-B and HLA-DR mismatched in 6% (2/33). 66.7% (22/33) of patients had prior immunosuppressive therapy (IST), 18.1% (6/33) developed side effects from ciclosporin use before HSCT (mainly renal impairment), and 15.2% (5/33) were receiving chelation at the time of HSCT (MUD 0/103, MRD 1/56). 36.4% (12/33) of patients in the mismatched group developed invasive fungal or serious bacterial infections before HSCT. In line with the national recommendation, the conditioning regimen used in 94% (32/33) consisted of Fludarabine 150mg/m2, cyclophosphamide 120 mg/kg and Alemtuzumab 0.9/1.0 mg/kg, with 81.8% (27/33) of patients receiving a combination of a calcineurin inhibitor and MMF for GVHD prophylaxis. 78.8% (26/33) received a single fraction of total-body irradiation (TBI), with 65% (17/26) receiving 3 Gy and the remainder (9/26) receiving 2 Gy. The incidence of thrombotic microangiopathy (TA-TMA) in the mismatched cohort was 12% (4/33, 3 deaths).

Table 1: Outcomes of HSCT for SAA

	Total (n=192)	Matched Related Donor (MRD) (n=56)	Matched Unrelated Donor (MUD) (n=103)	Mismatched Donor (MMD) (n=33)	P value

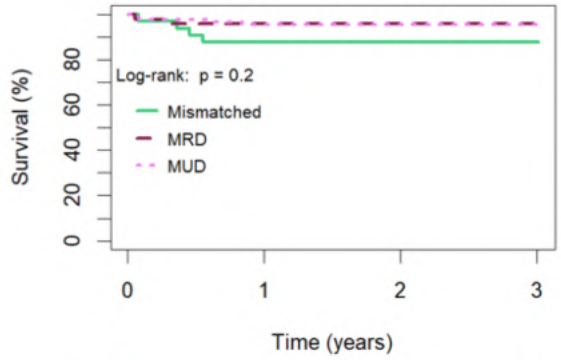
Figure 1C: Overall survival



Mismatched	33	28	22	14
MRD	50	44	33	24
MUD	98	84	65	50

Conclusions: Mismatched HSCTs, primarily using MMUD, have outcomes comparable to those of fully matched donors. TA-TMA led to treatment-related mortality in this cohort. Prospective evaluation is needed to confirm optimal placement of mismatched donors within the therapeutic algorithm for paediatric SAA.

Disclosure: Nothing to declare.

PREVIOUS ANTITHYMOCYTE-BASED IMMUNOSUPPRESSIVE THERAPY INCREASED THE RISK OF VIRUS REACTIVATION IN HAPLOIDENTICAL HEMATOPOIETIC CELL TRANSPLANTATION FOR SEVERE APLASTIC ANEMIA

*Fan Lin[1], Tingting Han[1], Yun He[1], **Zhengli Xu**[1], Yuanyuan Zhang[1], Yifei Cheng[1], Yu Wang[1], Xiaodong Mo[1], Xiaohui Zhang[1], Xiaojun Huang[1], Lanping Xu[1]*
[1]Peking University People's Hospital, Beijing, China

Background: Allogeneic hematopoietic stem cell transplantation (HCT) and immunosuppressive therapy (IST) are two effective treatments for patients with severe aplastic anemia (SAA). For patients fail to respond to or relapse after IST, salvage haploidentical HCT is widely adopted. Several studies have demonstrated that salvage HCT leads to inferior outcomes compared to upfront HCT. This is partially attributed to impaired organ function, increased infections, and heavier transfusion burdens due to the delayed HCT. However, donors for haplo-HCT can be easily available in a really short time. To date, comparisons between upfront haplo-HCT and salvage haplo-HCT are limited.

Methods: Patients undergoing upfront (n = 437) or salvage haplo-HCT (n = 97, defined as haplo-HCT conducted after failure or relapse to ATG-based IST) between 2008 and 2022 at PKUPH were reviewed. To minimize the impact of selection bias and confounding factors, we performed a propensity score matching (PSM) analysis. Patient age, sex, and conditioning regimen were included in the propensity score model (1:1). Finally, 94 patients in each cohort (upfront cohort and salvage cohort) were included for analysis. No letermovir prophylaxis for cytomegavirus (CMV) reactivation was used during the study period.

Results: Overall, upfront or salvage haplo-HCT resulted in comparable survival. The 5-year overall survival (OS) were 89.71% and 85.33% in the upfront and salvage cohorts (P = 0.534), respectively. And the 5-year graft-versus-host disease/failure-free survival (GFFS) were 74.50% and 72.14% in the corresponding cohorts (P = 0.832), respectively. Multivariable analysis again confirmed that neither upfront nor salvage haplo-HCT was associated with worse survival outcomes. Moreover, the two cohorts had similar cumulative incidences of 28-day neutrophil engraftment, 100-day platelet engraftment, 100-day acute graft-versus-host disease (aGVHD), and 5-year chronic graft-versus-host disease (cGVHD). However, the cumulative incidence of 100-day virus reactivation was significantly higher in the salvage cohort, which is 82.31%, compared to the upfront cohort (70.04%). In particular, salvage haplo-HCT was associated with higher risks of Epstein-Barr virus (EBV) reactivation (19.36% vs. 11.20%, P = 0.042) and adenovirus (ADV) reactivation (11.44% vs 5.34%, P = 0.037). Multivariable analysis showed that salvage haplo-HCT was a risk factor for virus reactivation (hazard ritio [HR] = 1.471, P = 0.024). In subgroup analysis, we found that among patients who did not respond to IST, salvage haplo-HCT conducted 12 months after IST showed slightly inferior OS (78.50%, P = 0.072) and GFFS (66.83%, P = 0.109) compared to the upfront cohort, while salvage haplo-HCT conducted within 12 months resulted in comparable OS (89.86%, P = 0.842) and GFFS (75.33%, P = 0.956).

Conclusions: In conclusion, salvage haplo-HCT led to an increased risk of virus reactivation, especially EBV and ADV reactivation. However, comparable survival rates to those of upfront haplo-HCT were achieved. Preliminary subgroup analysis suggested that, for patients who failed to respond to IST, timely consideration of haplo-HCT could be beneficial.

Disclosure: Nothing to declare.

IMPROVING THE OUTCOME OF STEM CELL TRANSPLANTATION IN PATIENTS WITH SEVERE APLASTIC ANEMIA

Sabrina Giammarco[1], *Andrea Bacigalupo*[2], *Marica Laurino*[3], *Carmen Di Grazia*[3], *Alida Dominietto*[3], *Stefania Bregante*[3], *Riccardo Varaldo*[3], *Federica Sorá*[2], *Elisabetta Metafuni*[1], *Patrizia Chiusolo*[2], *Simona Sica*[2], *Emanuele Angelucci*[3], *Anna Maria Raiola*[3]
[1]*Fondazione Policlinico Universitario A. Gemelli-IRCCS, Rome, Italy,* [2]*Universitá Cattolica del Sacro Cuore, Rome, Italy,* [3]*IRCCS Policlinico San Martino IST, Genova, Italy*

Background: Stem cell transplantation (SCT) from an HLA–matched sibling donor (MSD) is considered the standard of care for younger patients with severe aplastic anemia (SAA). Due to the use of high resolution HLA matching, specifically designed conditioning regimens, together with improved supportive care and GvHD prophylaxis, SCT can be a therapeutic option also for patients lacking a suitable MSD . With changing donor types and transplant platforms, the question is whether the outcome has improved over time.

Methods: We retrospectively analyzed 194 patients with SAA undergoing SCT in two transplants Unit (IRCCS Policlinico San Martino IST, Genova and Fondazione Policlinico Universitario A.Gemelli, IRCCS, Rome.
Patients' characteristics are summarized in Table 1, according to three different time periods: 1976-1990 (n=69); 1991-2010 (n=81), 2011-2024 (n=44).
The median age (range) was respectively: 19 (5-48); 25 (9-60); 28 (13-70). The median interval from diagnosis to transplant was respectively: 85 days range 22-442) vs 149 (26-1482) vs 208 (28-1401).
There was a significant change in donor type (P<0.00001), with an increased use of alternative donor and increased use of fludarabine based conditioning regimen (P<0.00001).
GvHD prophylaxis also changed, from the initial use of methotrexate, then the association of methotrexate and cyclosporine and the more recent use of PTCY (P<0.00001).
Bone marrow was the predominantly stem cell source in all period, with a small number of patients receiving peripheral blood grafts in the more recent period. (P<0.00001).

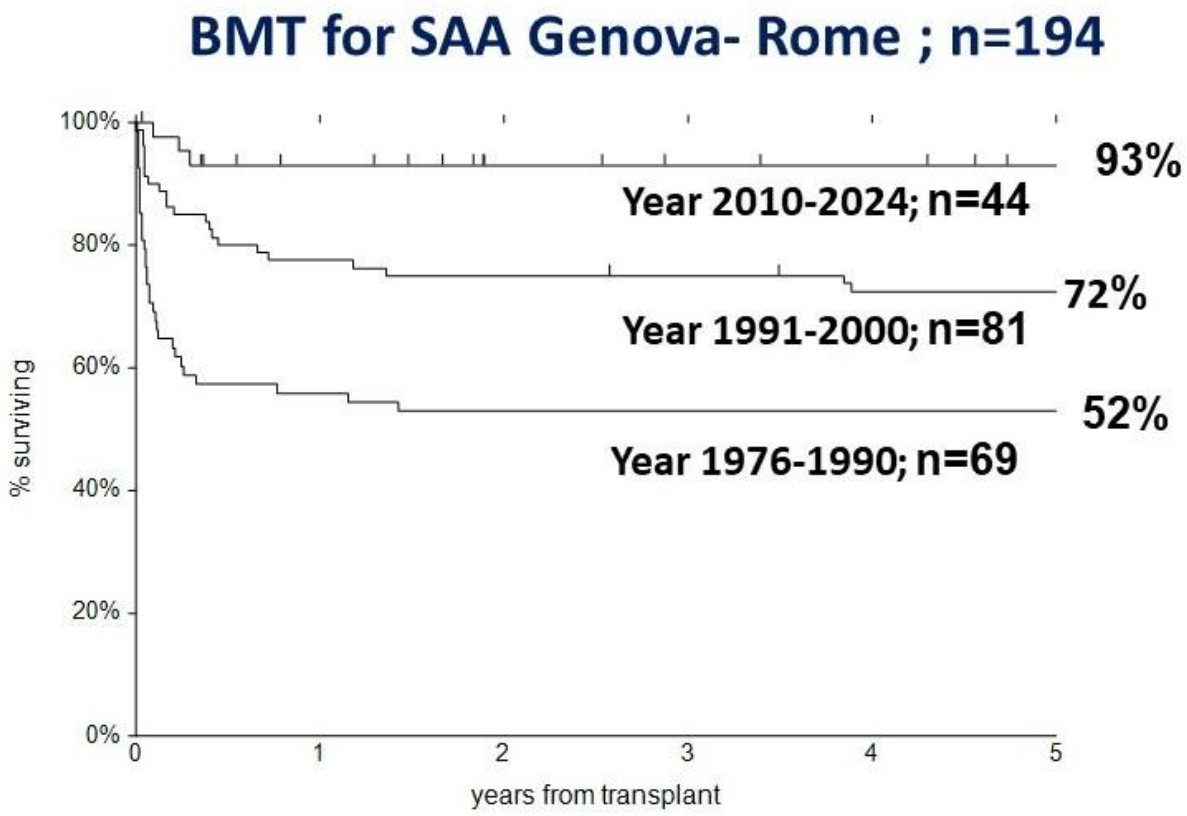
Stem cell source BM PBSC CBU	 100% 0% 0%	 98% 1% 1%	 75% 24% 1%	p<0,0001
GvHD II-IV GvHD III-IV cGvHD mod-severe	36 (52%) 18 (26%) 11 (16%)	14 (17%) 3 (4%) 10 (19%)	15 (34%) 2 (4%) 5 (12%)	p=0.004 P=0.0009 P=0.5

Results: Acute GvHD grade II-IV in the three time periods developed in 52%, 17% and 34% of patients (p=0.004); acute GvHD grade III-IV developed in 26%, 14% and 4% of patients (p=0.0009). Moderate-severe chronic GvHD developed in 16%, 19%, 12% (p=0.5). The 5 years actuarial survival was respectively: 52%, 72%, and 93% in the three time periods (P<0.0001) Figure 1.
Major causes of death were infections (14%, 12%, 2%) and GvHD (12%, 6%, 2%) (p<0.001).

Figure 1: 5 years actuarial survival according to time period



Conclusions: Improved outcome with time is clearly shown in this study, with a 5 year overall survival exceeding 90% beyond year 2010. This is seen despite older patients age (P<0.001), increased use of alternative donors (p<0.00001) and a longer interval between diagnosis and (P<0.001). Reduced GvHD and infectious complication appear to be the 2 crucial finding, possibly due to different conditioning regimens, better GvHD prophylaxis, and better supportive care.

Background: Nonmyeloablative conditioning has decreased mortality after hematopoietic cell transplantation (HCT) for severe aplastic anemia (SAA) but management of mixed chimerism remains a challenge. Better understanding of its prevalence, kinetics, and clinical impact is needed.

Methods: We studied 140 pediatric patients who underwent HCT for SAA (Image 1).

Patient & HCT Characteristics	N=140

Abbreviations: ATG, Anti-Thymocyte Globulin; CSP, Cyclosporine; CY, Cyclophosphamide; D, Day; GVHD, Graft Versus Host Disease; HCT, Hematopoietic Cell Transplantation; FLU, Fludarabine; MMF, Mycophenolate; MTX, Methotrexate; n, Number; PTCY, Post-Transplant Cyclophosphamide; TBI, Total Body Irradiation

Rejection, GVHD, death, and when available, longitudinal lymphoid (CD3) and myeloid (CD33/CD15) chimerism, defined by full (>95%), high-level (50-95%), low-level mixed (5-49%), and rejection (<5%) were recorded. The association of chimerism with age, donor type, stem cell source, donor/recipient sex, TNC cell dose, and TBI-vs non-TBI-conditioning was assessed using generalized estimating equations, and the association with GVHD was assessed using Cox regression with chimerism level modeled as a time-varying covariate. Donor type and use of TBI were combined given the strong correlation between use of TBI and match status in the related population.

Results: Of the 140 patients, 4 experienced rejection (n=3) or death (n=1) prior to D+100. Among patients with lineage-specific chimerism data available, 92/96 (96%) and 81/87 (93%) had full donor myeloid engraftment at D+100- and 1-year post-HCT respectively. In contrast, 32/104 (31%) and 45/93 (48%) had full donor lymphoid engraftment at D+100 and 1-year post-HCT. Of patients with mixed (5-95%) donor lymphoid chimerism at D+100 (n=72) who had 1-year data available (n=54), 18 (33%) achieved full donor by 1-year (Table 1). One patient developed secondary graft rejection.

Table 1: Day +100 and Subsequent Chimerism Status at 1-year, 2-years, and 3-5 years post-HCT

	Day +100 Donor Chimerism*	Years post-HCT	Total (n)	Full Donor n, (%)	High-Level Mixed n, (%)	Low-Level Mixed n, (%)	Secondary Graft Rejection** n, (%)
Lymphoid (CD3)	Full Donor (n=32)	1	25	24 (96)	1 (4)	0	0
		2	15	15 (100)	0	0	0
		3-5	15	15 (100)	0	0	0
	High-Level Mixed (n=47)	1	39	17 (43.6)	22 (56.4)	0	0
		2	19	10 (52.6)	9 (47.4)	0	0
		3-5	17	12 (70.6)	5 (29.4)	0	0
	Low-Level Mixed (n=25)	1	15	1 (6.7)	13 (86.7)	0	1 (6.7)
		2	13	1 (7.7)	12 (92.3)	0	0
		3-5	9	3 (33.3)	6 (66.7)	0	0
Myeloid (CD33/CD15)	Full Donor (n=92)	1	73	70 (95.9)	2 (2.7)	0	1 (1.4)
		2	43	41 (95.3)	2 (4.7)	0	0
		3-5	38	38 (100)	0	0	0

	High-Level Mixed (n=4)	1	1	1 (100)	0	0	0
		2	1	1 (100)	0	0	0

*Of the 140 patients, 104 had lymphoid chimerism and 96 had myeloid chimerism data available at Day +100
**One patient with secondary graft rejection (CD3<5% and CD33<5%) did not have chimerism data available at Day +100 and is therefore excluded.
Abbreviations: HCT, Hematopoietic Cell Transplantation; n, Number
Definitions: Full Donor (>95%); High-Level Mixed (50-95%); Low-Level Mixed (5-49%); Rejection (<5%)

In univariate analysis, recipients of mismatched related donor (MMRD) grafts had 15.2% (95% CI, 7.4 to 23.0%) higher absolute mean lymphoid chimerism than MRD-graft recipients. Likewise, recipients of TBI-conditioning and mismatched unrelated donor (MMURD) or MURD-grafts had 25.4% (95% CI, 19.8 to 31.0%) and 0.4% (95% CI, -11.3 to 12.1%) higher absolute mean lymphoid chimerism respectively than the MRD group. Absolute mean lymphoid chimerism was 3.4% (95% CI, -10.9 to 17.7%) higher for the non-TBI MMURD group and 3.1% (95% CI, -6.6 to 12.8%) higher for the non-TBI MURD than the MRD group. Males transplanted from female donors had an absolute mean myeloid chimerism 5.1% (95% CI, -10.4 to 0.3%) lower than other patient/donor sex combinations. No other factors showed meaningful associations with myeloid or lymphoid chimerism.
The impact of chimerism on survival was not examined due to the limited number of deaths. As donor lymphoid chimerism increased 10%, the risk of acute and chronic GVHD increased 20% (95% CI, 0-45%) and 44% (95% CI, 11-88%), respectively. There was little evidence of an association between myeloid chimerism level and GVHD.

Conclusions: HCT after nonmyeloablative conditioning results in excellent myeloid engraftment in patients with SAA. Donor lymphoid chimerism is initially often mixed and increases thereafter. Our observation of just one secondary graft rejection suggests that early mixed lymphoid chimerism is not necessarily associated with subsequent graft rejection, particularly when full donor myeloid engraftment coexists. Future studies should examine donor engraftment kinetics in other non-malignant diseases where there may be greater barriers to engraftment.

Background: The combination of anti-thymocyte globulin (ATG) and cyclosporin (CsA) is an effective immunosuppressive treatment (IST) for aplastic anemia (AA). Recent research has focused on improving response rates and (event-free) survival through the addition of eltrombopag. However, both the disease and its treatment can affect quality of life (QoL), while data on QoL of AA patients remain scarce. In a recent study among AA patients treated with IST, patients with partial recovery of blood values (PR) experienced lower QoL than patients with complete recovery (CR). The EBMT RACE study, a multicenter randomized clinical trial comparing first-line ATG and CsA with or without eltrombopag, incorporated self-reported QoL assessments. No significant differences in QoL were found between treatment arms. This post-hoc analysis evaluated the effect of treatment response on QoL of AA patients treated within the RACE trial.

Methods: Patients were invited to complete the EORTC-QLQ-c30 questionnaire at baseline, 6, 12 and 24 months. The questionnaire consists of 30 items evaluating QoL. Subscales include overall Global Health status/QoL (GH), 5 functional scales and 9 symptom scales. We used the separate subscales (range: 0-100) to assess different aspects of QoL from baseline until a year after starting treatment. QoL scores of patients with PR and CR were compared using unpaired t-tests. Paired t-tests were used to analyze changes in QoL over time.

Results: 192 patients were included in the analysis, of whom 166 completed the questionnaire at baseline. At 6 and 12 months, 151 and 136 questionnaires were completed respectively. GH scores were lowest of all subscales at baseline (mean 52). After one year, GH scores had increased 18 points, with the biggest improvement (12 points) taking place in the first 6 months. Other subscales improved significantly as well, with pronounced changes in role functioning and social functioning (both increasing 22 points).

After 6 months, 45 patients in PR and 38 in CR completed the questionnaire, whereas after one year the number of completed questionnaires was 28 in the PR group and 53 in the CR group. Patients in CR scored 7 points higher on GH than patients in PR at both time points (p=0.053). Most outspoken between-group differences were seen in Fatigue, with differences of 9 (p=0.055) and 6 points (p=0.167) at 6 and 12 months respectively. Patients improving from PR at 6 months to CR at 12 months (n=17) had better QoL scores as well: a 7 point increase in GH (p=0.051) and a remarkable increase in social functioning of 12 points (p=0.045), whereas here fatigue improved only 2 points. Patients who remained in PR between 6 and 12 months (n=28) showed no clear change in QoL.

Conclusions: Overall, QoL of AA patients receiving ATG-based IST improved during the first year of treatment. There was a discernable trend that patients reaching PR as best response experienced lower QoL than patients in CR. Moreover, improving from PR to CR was associated with increasing GH and Social functioning scores. This study shows that QoL of AA-patients benefits from aiming for the best hematological response after IST.

Disclosure: Nothing to declare.

QUALITATIVE ASSESSMENT OF PREDICTORS OF RESPONSE TO IMMUNOSUPPRESSIVE THERAPY IN APLASTIC ANAEMIA: A SYSTEMATIC LITERATURE REVIEW

Phillip Scheinberg[1], *Stephanie MacLeod*[2], *Meryem Bektas*[2], *Raj Gokani*[3], *Kevin M. Kallmes*[4], *Shahnaz Khan*[2], *Barbara Możejko-Pastewka*[3], *Alicia Rovo*[5]
[1]*Hospital A Beneficência Portuguesa, Sao Paulo, Brazil,* [2]*RTI Health Solutions, Research Triangle Park, North Carolina, United States of America (the),* [3]*Pfizer, Inc, New York City, United States of America (the),* [4]*Nested Knowledge, St Paul, Minnesota, United States of America (the),* [5]*Inselspital Bern University Hospital, Bern, Switzerland*

Background: Recommended aplastic anaemia (AA) treatments include haematopoietic stem cell transplantation or immunosuppressive therapy (IST) with horse antithymocyte globulin and cyclosporine (double therapy) ± eltrombopag (triple therapy). Predictive evidence of individual response to IST remains limited. This systematic literature review (SLR) was conducted to combine all findings to date and expand AA knowledge, with the primary objective of evaluating predictors of response to IST.

Methods: A PRISMA-compliant SLR was undertaken on PubMed and Embase published records (1980-2025). Studies reporting double or triple IST response rates and AA predictors (any disease severity/age) were included in this qualitative analysis. Dual screening with independent adjudication was performed, supported by a validated AI screening tool (Robot Screener, [Nested Knowledge; NK]) as a second reviewer. Data pertaining to the primary objective were extracted using AI and reviewed by humans. Information on predictors was categorised as clinical, immunologic, or genetic/molecular for the qualitative analysis.

Results: The search identified 2,335 candidate studies. Overall, 89 studies reported IST use for AA, of which 45 reported on predictors of response to IST in AA (**Figure 1**). Across the 45 studies (6,254 patients of all ages), key clinical predictors of improved response rate in AA included younger age and lower-severity AA (definitions varied by study), although children with non-severe AA (per Camitta criteria) had higher relapse rates.
Additional predictors were higher baseline absolute reticulocyte count (ARC), absolute lymphocyte count (ALC), and absolute neutrophil count (ANC), in effect, residual haematopoiesis. The presence of PNH clones was the most conflicting predictor. Some studies associate PNH positivity with improved overall survival (N=259, retrospective), others examined its association with complete response, showing mixed results—ranging from negative predictive value (N=98, paediatric RCT) to positive associations (N=125, prospective, all ages), with some studies finding no clinical outcome association (N=51, observational, adults). Furthermore, immunologic markers such as lower CD57+ CD8+ naïve T-cells, higher CD8+ memory stem T-cells, and higher natural killer cell proportions at baseline and post-treatment were associated with higher response rates.
Genetic and molecular findings were heterogeneous: interferon gamma (IFNG) and transforming growth factor beta 1 (TGFB1) polymorphism presence correlated with improved response. Longer telomere length showed improved response in one study (N=92, prospective, all ages), but no association with response in other studies (N=51, observational, adults and N=314, retrospective, paediatric). Sustained elevated thrombopoietin correlated with non-response. Delayed initiation of IST (>6 months from diagnosis) and older age (≥40 years) were associated with worse complete response.

Conclusions: Qualitative analysis of articles in this SLR showed age, haematopoietic reserve, and immune cell profiles as potential predictors of response to IST in patients with AA. Poorer response with delayed therapy underscores the importance of timely diagnosis and treatment. Despite study design variability and limited statistical power, these findings support the potential for personalised AA treatment, enabling clinicians to better assess the likelihood of haematologic recovery with IST. Further analyses are planned to elucidate details regarding the identified predictors, investigate conflicting findings and explore additional predictors.

AB T-CELL DEPLETION VERSUS PTCY IN UNRELATED DONOR HSCT FOR PEDIATRIC PATIENTS WITH APLASTIC ANEMIA

Daria Shasheleva[1], *Larisa Shelikhova*[1], *Dmitry Balashov*[1], *Maria Ilushina*[1], *Maria Klimentova*[1], *Evelina Lyudovskikh*[1], *Elena Kurnikova*[1], *Yakov Muzalevsky*[1], *Alexey Kazachenok*[1], *Varvara Brilliantova*[1], *Elena Raykina*[1], *Olga Goronkova*[1], *Dina Baydildina*[1], *Alexey Maschan*[1], *Galina Novichkova*[1], *Michael Maschan*[1]
[1]*Dmitry Rogachev National Medical Research Centre for Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation (the)*

Background: Hematopoietic stem cell transplantation (HSCT) from a fully matched unrelated donor (MUD) is an established treatment for patients with severe aplastic anemia (SAA) who do not respond to ATG and CsA therapy. To improve key outcomes, we used two platforms of GVHD prevention: αβ T-cell depletion (2012-2022) and post-transplant cyclophosphamide (PTCy) (2022-2025). This study presents a comparative retrospective analysis of these approaches.

Methods: The analyses included 61 patients with SAA, who received their first allogeneic HSCT from MUD using TCRαβ depletion (αβ-depletion group – G-αβ), n=47 and PTCy (PTCy group – G-PTCy), n=14 as the primary method for GVHD prevention from May 2022 to February 2025.
The main characteristics of the group are presented in Table 1.

Table 1. Clinical Characteristics of Patients

N=61	TCR αβ group, n=47	PtCy group, n=14	p

Date of HSCT	November 2012 - February 2022	March 2022 - July 2025	
Age (range)	12.4 (3-22.7), 21f/26m	7.4 (3.1-14.2), 4f/10m	0.003
gender	21 females and 26 males	4 females and 10 males	0.3
IST courses before HSCT	1 course - 3 2 courses - 44	1 course - 3 2 courses - 11	0.1
PNH+ vs -	5	0	
Refractory Relapse	36 10	11 3	0.9
Median time to HSCT	1.2 (0.5-11.8)	1.4 (0.8-3.5)	0.9
CMV serology D+/R+ D+/R- D-/R+ D-/R-	 29 6 10 2	 13 1 0 0	
Serotherapy ATG (rabbit) ATG (horse)	 20 27	 14 0	
Condition regimen TAI 4-6Gr cyclophosphamide 100mg/kg fludarabine 150mg/kg thiotepa 10mg/kg rituximab at 200mg/m^2	 47 47 47 12 35	 14 14 14 0 3	

GVHD prophylaxis	tacrolimus until day 180	CsA until day 365 MMF until day 60 PTCy on days +3, +4, 100mg/kg total dose	
Graft source	PBSC	BM	
CD34 (*10^6/kg)	7.15 (2.76-13.2)	6.7 (1.7-12.1)	
TCRαβ (*10^3/kg)	23 (1.1-184)	NA	
CD3 (*10^6/kg)	19.61 (7.27-66.5)	73.35 (17.6-748.2)	

Results: Primary engraftment was achieved in 45 patients in G-αβ and 13 in G-PTCy. Cumulative incidence (CI) of engraftment was 0.96 (95% CI 0.9–1) in G-αβ and 0.93 (95% CI 0.8-1) in G-PTCy with the medians for white blood cells (WBC) 14 (7-24) days in G-αβ and 21(15-26) days in G-PTCy, p=0.003; for platelets 12 (9-18) in G-αβ and 18 (11-24) days, p=0.001.
Secondary graft failure was reported in 8 cases at a median of 72 (18-194) days in G-αβ, CI 0.15 (95% 0.08-0.3) and in 1 patient in 66 days CI 0.07(95% CI 0.01-0.54), p=0.4. 3 patients in G-αβ and 1 patient in G-PTCy were successfully retransplanted.
Prolonged stable mixed chimerism in T-cell compartment was detected in G-αβ, but not in the G-PTCy.
Ten patients died in G-αβ and one in G-PTCy. In G-αβ five patients died of various complications with donor-type hematopoiesis, one patient died after graft failure while awaiting salvage HSCT, and in 4 cases lethal complications developed after the second HSCT. In G-PTCy one patient died from complications following primary graft failure after two consecutive HSCTs.
CI of aGVHD grade II-IV was 0.15 (95% 0.08-0.3) and 0.29 (95% 0.12-0.65) in G-αβ and G-PTCy, respectively, p=0.2. No cases of grade III-IV aGVHD were registered. CI of cGVHD was 0.11 (95% 0.05-0.25) and 0.33 (95% 0.15-0.74) in G-αβ and G-PTCy, respectively, p=0.06. EFS was 72% (95% 60-85) and 86% (95% 67-100) in G-αβ and in G-PTCy, respectively, p= 0.4. OS was 79% (95% 67-90) in G-αβ and 92% (95% 78-100) in G-PTCy, p=0.3 (fig.1). GVHD–Free, Relapse-Free Survival (GRFS) was 72% (95% 60-85) in G-αβ and 79% (95% 57-100) in G-PTCy, p=0.3 (fig.1). A median follow-up was 10.5 (3.7-13.2) years in G-αβ and 1.7 (0.8-3.6) in G-PTCy years.

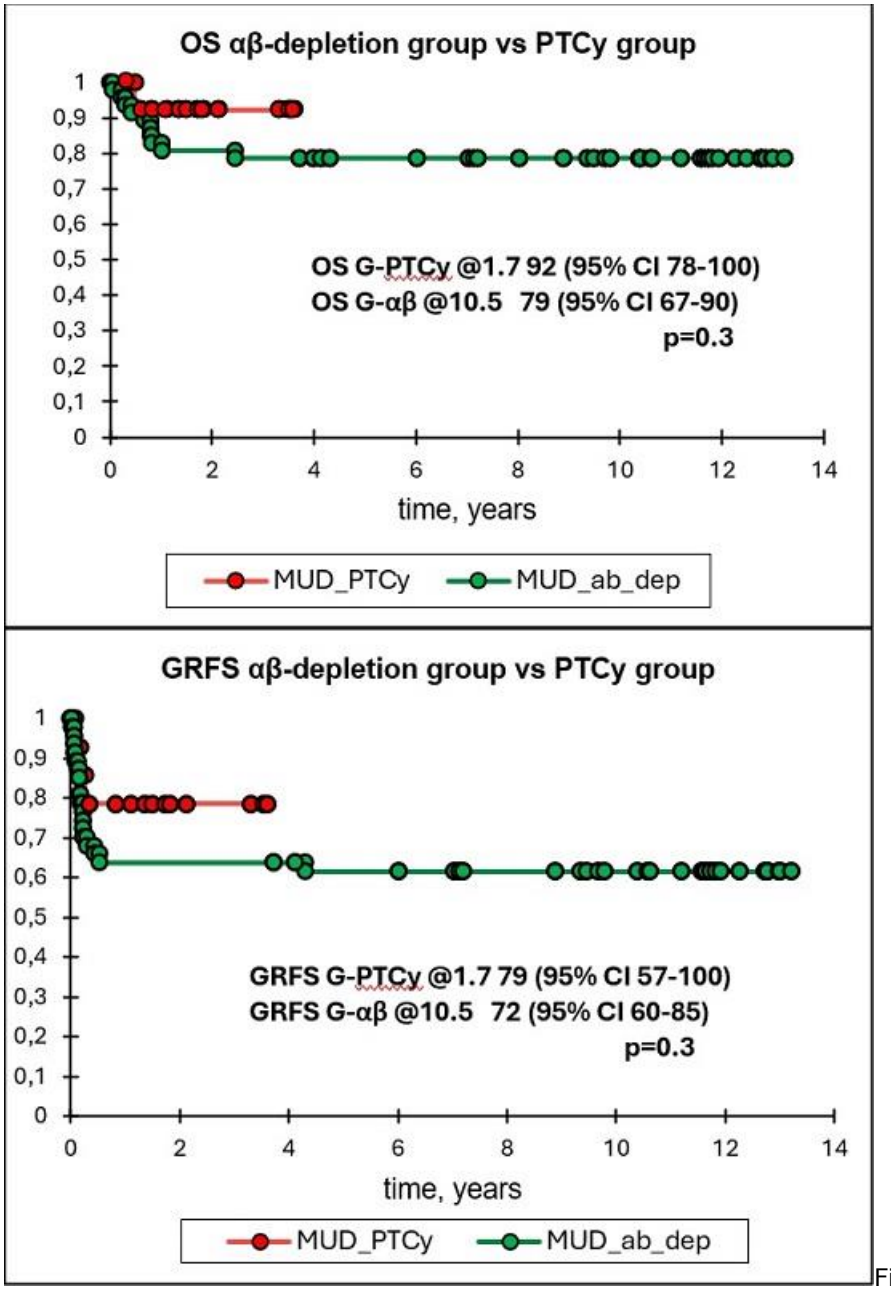

Fig.1 OS and GRFS for G-αβ and G-PTCy after MUD HSCT in pediatric patients with AA

Conclusions: PTCy and αβ T-cell depletion provided comparable engraftment and survival outcomes in unrelated donor HSCT for SAA. The PTCy group showed lower rejection rates but a higher incidence of chronic GVHD. Overall, PTCy appears to be an effective alternative GVHD prophylaxis, warranting further evaluation in larger cohorts.

EXCELLENT OUTCOMES AFTER HAPLOIDENTICAL TRANSPLANTATION WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE IN CHILDREN WITH ACQUIRED SEVERE APLASTIC ANEMIA SUPPORT EARLY TRANSPLANTATION

Gisele Loth[1,2], *Rafaella Muratori*[2], *Cilmara Kuwahara*[1], *Carolina Martins de Almeida Peixoto*[1], *Rafael Marchesini*[2], *Ana Paula Azambuja*[2], *Samantha Nichele*[3], *Adriana Mello Rodrigues*[1], *Polliany Pelegrina*[1], *Adriana Koliski*[2], *Carmem Bonfim*[2]
[1]*Hospital Pequeno Principe, Curitiba, Brazil,* [2]*Hospital de Clinicas da UFPR, Curitiba, Brazil,* [3]*Hospital Nossa Senhora das Graças, Curitiba, Brazil*

Background:

Severe aplastic anemia (SAA) in children and adolescents is a life-threatening condition with distinct therapeutic challenges. Immunosuppressive therapy (IST) is commonly used in patients lacking a matched sibling donor but is associated with lower response rates and higher risks of relapse and clonal evolution in pediatric patients. Matched unrelated donor transplantation represents an alternative but often requires prolonged donor searches, delaying definitive treatment and increasing transfusion burden and complication risk. Haploidentical HCT has emerged as a widely accessible alternative, allowing earlier access to curative therapy. We conducted a multicenter retrospective study evaluating the safety and efficacy of haploidentical HCT performed both upfront and after prior IST in pediatric patients with acquired SAA.

Methods:

This retrospective, longitudinal, non-randomized observational study included 60 pediatric patients with SAA transplanted at three HCT centers from 2012 to 2025. Clinical data were obtained from institutional databases and medical records, and statistical analyses were performed using EZR. All patients underwent haploidentical HCT with reduced-intensity conditioning. Most patients received low-dose cyclophosphamide (29–50 mg/kg), fludarabine (150 mg/m²), and total-body irradiation (200–400 cGy); three patients transplanted with peripheral blood received an alternative busulfan-based regimen. Antithymocyte globulin (ATG) was administered to 27 patients (45%), with total doses ranging from 3.3 to 6.4 mg/kg. Graft-versus-host disease (GVHD) prophylaxis consisted of post-transplant cyclophosphamide, mycophenolate mofetil, and cyclosporine.

Gender, n (%)	Female 28 (46.7%) Male 32 (53.3%)
Age at HCT, median (range)	9.9 years (2.9-17 years)
Previous immunosuppression for ≥3 months, n (%)	Yes 30 (50%) No 30 (50%)

Stem cell source, n (%)	Bone Marrow 56 (93.3%) Peripheral Blood 4 (6.7%)
Donor, n (%)	Father 38 (63.3%) Mother 9 (15%) Sibling 12 (20%) Other 1 (1.7%)
Donor age, median (range)	32.5 years (10-55 years)
Cytomegalovirus status for donor/recipient, n (%)	Negative/negative 0 (0%) Positive/negative 4 (6.7%) Positive/positive 56 (93.3%)
ABO compatibility, n (%)	Compatible 39 (65%) Minor incompatibility 10 (16.7%) Major incompatibility 11 (18.3%)
DSA status, n (%)	Positive 0 (0%) Negative 60 (100%)
Conditioning regimen, n (%)	Cyclophosphamide-based (93.3%) Busulfan-based 4 (6.7%)
ATG	Yes 27 (45%) No 33 (55%)
TBI dosis, n (%)	No 3 (5%) 200 cGy 14 (23.3%) 300 cGy 1 (1.7%) 400 cGy 42 (70%)
TNC (x108/kg), median (range)	5.6 (2.6-10.9)
CD34 (x106/kg), median (range)	4.5 (1.2-15)
Follow-up, median (range)	992.5 days (83-4619 days)

Results:

Primary graft failure occurred in 4 patients (6.7%) and secondary graft failure in 2 (3.3%), with a 1-year cumulative incidence of 10.0% (95% CI, 4.0–19.2). All patients with primary graft failure underwent rescue transplantation, and 4 of 6 patients with graft failure are alive.

No significant differences in graft failure were observed between TBI doses (200 vs. 400 cGy;p=0.59) or ATG use (p=1).

The 100-day cumulative incidence of grade II–IV acute GVHD was 15.0% (95% CI,7.3–25.2). The 2-year cumulative incidence of chronic GVHD of any grade was 6.8% (95% CI,2.1–15.1). Neither TBI dose nor ATG use was associated with differences in acute or chronic GVHD incidence.

The 100-day cumulative incidence of cytomegalovirus reactivation was 65.0% (95% CI,51.3–75.7), with a median onset at 40.5 days. Hemorrhagic cystitis occurred in 13.3% of patients (95%CI,6.2–23.3).

Five patients died, mainly due to infection (n=4) and graft failure–related complications, including one cytomegalovirus-related death. The 1-year event-free survival was 85.0%(95% CI,73.2–91.9).

The 1- and 2-year overall survival (OS) was 91.7%(95% CI,81.1–96.4). Notably, patients aged ≤12 years showed superior 2-year OS compared with those >12 years (97.9%vs.66.7%, p=0.00041).

Patients transplanted after 2020 showed higher 2-year OS than earlier transplants (95.0%vs. 85.0%), although this difference was not statistically significant (p=0.174). No other evaluated variables were significantly associated with overall survival.

Two-year overall survival did not differ between patients with and without prior IST (90.0%vs. 93.3%,p=0.61), nor did graft failure rates.

Conclusions: Haploidentical HCT is safe and effective in pediatric SAA, achieving excellent survival with low toxicity, particularly in children younger than 12 years, regardless of prior immunosuppressive therapy, serotherapy use, or TBI dose. These results strongly support

haploidentical transplantation as an early curative strategy.

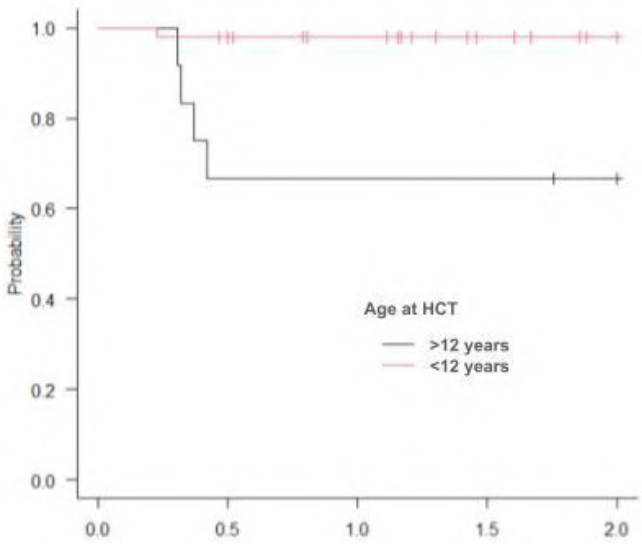

Figure 1. Overall survival according to age at transplantation. Patients aged ≤12 years showed significantly superior OS compared with those >12 years (97.9% vs. 66.7%, $p = 0.00041$).

AN EPIGENOME-WIDE ASSOCIATION (EWAS) STUDY IN FANCONI ANEMIA AND APLASTIC ANEMIA

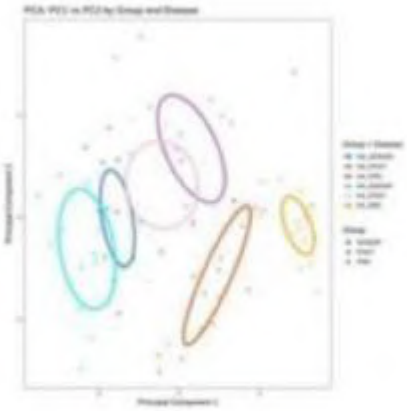
Filomena Pierri[1], Giovanni Fiorito[1], Silvia Ravera[2], Matilde Balbi[2], Fabio Corsolini[1], Stefano Regis[1], Federica Raggi[1], Carlo Dufour[1], Enrico Cappelli[1], ***Maura Faraci***[1]
[1]*IRCCS Istituto G. Gaslini, Genova, Italy,* [2]*University of Genova, Genova, Italy*

Background: The epigenetic landscape of Fanconi anemia (FA) and Aplastic Anemia (AA), and its evolution after Hematopoietic Cell Transplantation (HCT), remains poorly characterized.

Methods: We aimed to characterize disease-specific and shared DNA methylation (DNAm) patterns and to evaluate post-HCT epigenetic changes in donor-derived hematopoietic cells. We conducted an epigenome-wide association study (EWAS) using peripheral blood

mononuclear cells collected from 15 FA and 15 AA trios (PRE-HCT, POST-HCT and DONORS). Genome-wide DNAm was assessed with the Illumina Methylation Screening Array.

Results: Comparative EWAS identified distinct and shared epigenetic alterations (Table 1). Further, we tested the applicability of the FA episignature previously described [1], confirming its ability to distinguish FA patients from AA patients and donors. Notably, FA POST-HCT DNAm profiles appeared intermediate between PRE-HCT and DONOR, indicating a partial reversion of the signature toward the pre-transplant state (Figure 1).



FA PRE vs AA PRE	HLA-DPB1 promoter hypomethylation and gene body hypermethylation in AA vs FA
FA PRE vs FA DONOR	Significant hypermethylation in the gene bodies of *MILRET7BHG*, *XRCC3*, *PRDM16*, and *VARS1* in FA PRE vs DONOR
FA PRE vs FA POST	The promoter of *PPCDC* is hypermethylated and the gene body of *NFIX* is hypomethylated in FA PRE vs FA POST
FA POST vs DONOR	No significant differences in *MILRET7BHG* methylation comparing FA DONOR vs FA POST POST samples displayed intermediate methylation at *XRCC3*, *PRDM16*, and *VARS1** In *PPCDC* and *NFIX* loci, normalization of methylation pattern POST HCT, maintaining the DONOR pattern*

Conclusions: We identify a disease-specific HLA-DPB1 signature in AA and coordinated DNAm changes in FA involving XRCC3, PRDM16, VARS1, and MIRLET7BHG, which may contribute to disease pathophysiology. Critically, the post-HCT epigenetic shift in donor cells suggests a persistent influence of the patient's environment on engrafted hematopoietic system, with potential implications for long-term outcomes.

Clinical Trial Registry: Not applicable.

Disclosure: Nothing to declare.

B329

HIGH CD34⁺ CELL DOSE SIGNIFICANTLY REDUCES EBV REACTIVATION AND IMPROVES SURVIVAL IN APLASTIC ANEMIA PATIENTS UNDERGOING UCBT

*Zhang Jianping[1], Xiong Min[1], Wei Zhijie[1], Cao Xingyu[1], Lu Yue[1], Liu Deyan[1], Li Nannan[1], He Junbao[2], **Long Jing**[2,3], Lu Peihua[2,3,1]*
[1]Hebei Yanda Lu Daopei Hospital, Langfang, China, [2]Beijing Lu Daopei Hospital, Beijing, China, [3]Beijing Lu Daopei Institute of Hematology, Beijing, China

Background: Umbilical cord blood transplantation (UCBT) is effective for hematologic disorders, and recommended CD34⁺ cell doses have been established for malignant diseases. However, optimal CD34⁺ dosing for UCBT in aplastic anemia (AA) remains undefined. This study aimed to determine the appropriate CD34⁺ infusion dose for AA patients undergoing ATG-based UCBT.

Methods: We retrospectively analyzed 63 pediatric AA patients who received ATG-based UCBT at Hebei Yanda Lu Daopei Hospital and Beijing Lu Daopei Hospital from March 2013 to April 2024. The optimal infused CD34⁺ cell-dose threshold for predicting 180-day EBV viremia was determined using Fine-Gray competing-risk modeling with death as a competing event. Patients were then stratified into low-(≤0.16×10⁶/kg) and high-(> 0.16×10⁶/kg)CD34⁺ groups based on this cutoff. Clinical outcomes including 180-day EBV viremia, overall survival (OS), and GVHD-free/Failure-free survival (GFFS) were evaluated by univariable and multivariable analyses. Immune reconstitution was compared between groups by assessing serial lymphocyte-subset recovery.

Results: Patient Characteristics: Among 63 patients, 29 were male and 34 female, with a median age of 5 years (range, 1–16). Conditioning was predominantly BU/CY/FLU/ATG (98.4%). ATG formulations included Rabbit Anti-human T Lymphocyte Immunoglobulin (ATLG) (14.3%) and Rabbit Anti-human Thymocyte Immunoglobulin (rATG) (85.7%). Median cell doses were: MNC 0.61, CD3⁺ 0.06 and CD14⁺ 0.07 (×10⁸/kg),CD34⁺ 0.203(×10⁶/kg) . Neutrophil and platelet engraftment rates were 95.2% and 88.9%, with median times of 16 and 29 days, respectively.
Optimal CD34⁺ cell-dose threshold for predicting outcomes: The optimal CD34⁺ cell-dose threshold for predicting 180-day EBV viremia was identified as 0.16 × 10⁶/kg. CD34⁺high group had a significantly lower 180-day EBV viremia incidence compared with CD34⁺low group (7.89% [95% CI, 2.66–23.39] vs. 28.63% [95% CI, 15.29–53.61]; *P* = 0.024) (Figure 1A). The 5-year OS was higher in the CD34⁺high group (89.0%, 95% CI 78.9–99.2) vs. CD34⁺low group (75.6%, 95% CI 58.5–92.6), though the difference did not reach statistical significance (log-rank *P* = 0.126) (Figure 1B). A similar trend was observed for 5-year GFFS (Figure 1C).
Multivariable Fine-Gray competing-risk model results: Multivariable Fine-Gray competing risk model were constructed by entering the following covariates: ATG dose, HLA match, CD34⁺ ,

CD3⁺, CD4⁺ and CD8⁺ (Table 1). The infused CD34⁺ cell dose emerged as the strongest independent predictor of day-180 EBV viremia. CD34⁺high dose markedly reduced EBV risk (HR 0.05; 95% CI 0.00–0.82; P=0.035). A similar protective trend was observed for CMV viremia. ATG dose and infused CD3⁺, CD4⁺, and CD8⁺ cell counts did not demonstrate independent associations.
Immune reconstitution after UCBT: Immune reconstitution profiles were broadly comparable between groups (all P>0.05), with a modest advantage in CD4⁺T cells recovery among patients receiving high CD34⁺ cells (Figure 2).

Conclusions: Infused CD34⁺ dose >0.16×10⁶/kg emerged as the strongest independent predictor of reduced early EBV reactivation and showed favorable trends in long-term survival in pediatric AA undergoing UCBT. This data-driven cutoff remained robust in multivariable analyses and was accompanied by a modest advantage in late CD4⁺ immune recovery.

Disclosure: There's no Conflict of Interest to declare.

A SYSTEMATIC REVIEW OF REAL-WORLD EVIDENCE ON THERAPIES FOR MODERATE APLASTIC ANAEMIA

Britta Hoechsmann[1,2], *Marc Bierings*[3], *Frank R. Ernst*[4], *Raj Gokani*[4], *Morag Griffin*[5], *Kevin M. Kallmes*[6], *Stephanie MacLeod*[7], *Barbara Możejko-Pastewka*[4], *Sujith Samarasinghe*[8], *Carlo Dufour*[9]
[1]*Institute of Transfusion Medicine, University of Ulm, Ulm, Germany,* [2]*Institute of Clinical Transfusion Medicine and Immunogenetics, German Red Cross Blood Transfusion Service and University Hospital Ulm, Ulm, Germany,* [3]*Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands (the),* [4]*Pfizer, Inc, New York City, United States of America (the),* [5]*St James Hospital, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom of Great Britain and Northern Ireland (the),* [6]*Nested Knowledge, St Paul, Minnesota, United States of America (the),* [7]*RTI Health Solutions, Research Triangle Park, North Carolina, United States of America (the),* [8]*Great Ormond Street Hospital, London, United Kingdom of Great Britain and Northern Ireland (the),* [9]*IRCCS G. Gaslini Children's Hospital, Genova, Italy*

Background: Moderate aplastic anaemia (mAA) is clinically heterogeneous with substantial variation in its definitions, and no universally accepted guidelines or therapies. Treatment choices depend on blood counts, transfusion dependency or other significant symptoms and include supportive care, monotherapy (cyclosporine [CSA], tacrolimus, daclizumab, thrombopoietin receptor agonists [TPO-RA], androgens), double or triple therapy, (combining horse or rabbit anti-thymocyte globulin [hATG or rATG], CSA/tacrolimus, and eltrombopag [EPAG]/TPO-RA or androgens), and/or haematopoietic stem-cell transplantation (HSCT). Comprehensive documentation of the treatment landscape and impact is limited. To inform evidence-based decision-making, we conducted a systematic literature review (SLR) of therapeutic outcomes in mAA.

Methods: This artificial intelligence (AI)-assisted review followed a prespecified protocol. Study searches for any mAA therapy (adults and/or children) were conducted in Embase and PubMed/Medline (January 1980–November 2025). This SLR was assisted by validated human-in-the-loop AI review tools, with expert oversight over AI throughout. All searches, screening, extraction, and quality-control workflows were performed using AI and experts as independently adjudicated dual screeners and expert-curated extractions. Eligible study designs included randomised controlled trials (RCTs), observational, and non-randomised interventional studies; case reports were excluded. Key outcomes were overall survival (OS) and response rate (ORR).

Results: Of 2,539 unique records screened, 65 studies (5 RCT [n=374], 5 non-RCT single-arm [n=1,100], 14 prospective cohort [n=974], and 41 other observational [n=2,679]) reporting on patients with mAA were included. Studies spanned diverse eras (most reported in 2020-2025 [n=32]) and geographies (most reported in Asia [n=47]) with substantial heterogeneity in populations treated and outcomes reported. 'Non-severe' AA was reported in 43 and 'moderate' in 22 studies; Camitta criteria were mentioned in four studies, and Seattle criteria in one. Eleven studies closely matched the Camitta definition and 14 the Seattle criteria; 13 studies provided no definition.
OS was 83.9% for supportive care; for monotherapies it was: 84.3% for CSA; 98.0% for tacrolimus; 95.0% for daclizumab; 93.5% for EPAG; 72.7% for androgens. OS in double therapies was 94.3% for eATG+CSA; 86.0% for rATG+CSA; 93.3% for unspecified ATG+CSA; 94.4% for CSA+TPO-RA; 93.5% for CSA+androgens; and OS was 81.7% for HSCT. OS was not reported for triple therapy (**Table 1**).
ORR for monotherapies was: 48.5% for CSA; 38.6% for tacrolimus; 42.6% for daclizumab; 53.1% for EPAG; 42.6% for androgens. Among double therapies, ORR was 60.1% for eATG+CSA; 64.6% for rATG+CSA; 64.3% for unspecified ATG+CSA; 69.4% for CSA+TPO-RA; 41.7% for CSA+androgens. ORR for HSCT was 79.3%, and 100% in all 5 patients treated with triple therapy (ATG+CSA+EPAG; **Table 1**).
OS across the therapies was generally consistent but ORR seemed to vary widely. Outcome reporting by severity was highly variable.

Table 1. Overall Survival (OS) and Overall Response Rate (ORR) by Intervention Category for Moderate Aplastic Anaemia

Intervention Category	OS, n/N (%)	ORR, n/N (%)	Follow-up period (months)
Supportive Care	78/93 (83.9%)	--	3-278
CSA monotherapy	166/197 (84.3%)	242/499 (48.5%)	1-278
Tacrolimus monotherapy	99/101 (98.0%)	39/101 (38.6%)	14-36
Daclizumab monotherapy	57/60 (95.0%)	26/61 (42.6%)	1-278
EPAG monotherapy	43/46 (93.5%)	113/213 (53.1%)	1-278
Androgens monotherapy	40/55 (72.7%)	26/61 (42.6%)	1-174

eATG+CSA	216/229 (94.3%)	86/143 (60.1%)	1-221
rATG+CSA	86/100 (86.0%)	64/99 (64.6%)	1-166
Unspecified ATG+CSA	140/150 (93.3%)	171/266 (64.3%)	1-278
CSA/Tacrolimus+TPO-RA (including EPAG)	51/54 (94.4%)	109/157 (69.4%)	6-278
CSA+androgens	419/448 (93.5%)	10/24 (41.7%)	9-132
Triple therapy (ATG+CSA+EPAG)	--	5/5 (100.0%)	14-104
HSCT	49/60 (81.7%)	23/29 (79.3%)	1-166

Conclusions: Across heterogenous studies, OS and ORR have been documented for monotherapies, double, and triple therapies; HSCT was only reported in small, heterogeneous cohorts. Due to varied timepoints, missing data, and cohort selection, there was insufficient homogenous data for quantitative analysis. This SLR demonstrates a clear need for uniform definition of mAA and for comparative, prospective studies to enable the comparison of therapeutic effectiveness and to develop sufficient treatment algorithms.

HAPLOIDENTICAL VS MATCHED UNRELATED DONOR TRANSPLANTATION IN SEVERE APLASTIC ANEMIA: A SINGLE-CENTER COHORT

Mohamed I. Sharif[1,2], *Nihar Desai*[1,2], *Carol Chen*[1,2], *Eshrak Al-Shaibani*[1,2], *Tommy Alfaro-Moya*[1,2], *Arjun D. Law*[1,2], *Igor Novitzky-Basso*[1,2], *Ivan Pasic*[1,2], *Fotios V. Michelis*[1,2], *Auro Viswabandya*[1,2], *Dennis Dong Hwan Kim*[1,2], *Jonas Mattsson*[1,2], *Rajat Kumar*[1,2]
[1]*Princess Margaret Cancer Center, Toronto, Canada,* [2]*University of Toronto, Toronto, Canada*

Background: In severe aplastic anemia (SAA), matched unrelated donors (MUD) are standard alternatives for allogeneic hematopoietic cell transplantation (HCT) when a matched sibling donor is unavailable. Recent data demonstrate excellent outcomes with haploidentical (Haplo) HCT using the BMT CTN 1502 protocol (DeZern et al., *Lancet Haematol*, 2022). Given the rapid identification and availability of Haplo donors, comparative evaluation of Haplo versus MUD HCT in SAA is warranted.

Methods: We conducted a retrospective study of consecutive patients with SAA who underwent HCT from either a haploidentical (Haplo) or matched unrelated donor (MUD) between March 2011 and March 2025. All Haplo recipients received a BMT CTN 1502–based protocol with post-transplant cyclophosphamide (PTCy). Among MUD recipients, 17 received fludarabine (Flu), cyclophosphamide (Cy), and total body irradiation (TBI) 2 cGy with anti-thymocyte globulin (ATG; 4.5 mg/kg), methotrexate (MTX), and cyclosporine (CsA), while six did not receive TBI. Of these, five received Flu/Cy/alemtuzumab and one received Flu/Cy/ATG with MTX/CsA. The primary endpoint was overall survival (OS); secondary endpoints included primary graft failure (PGF) and major infectious complications.

Results: Overall, 34 patients were included, with a median age of 27 years (IQR, 21–32); 17 were male. There were 23 MUD and 11 Haplo donors. Half of the cohort (n=17) had received prior immunosuppressive therapy before HCT. Graft source was bone marrow in 16 MUD and 9 Haplo recipients, and peripheral blood in the remainder. There were no significant differences between groups in $CD34^+$ cell dose or donor–recipient CMV/ABO compatibility. Neutrophil recovery occurred at a median of 21 days in the MUD group and 22 days in the Haplo group (p=0.60). Platelet engraftment occurred at 19 days for MUD and 26 days for Haplo recipients (p=0.47). PGF occurred in four MUD patients, all of whom underwent second HCT.
The cumulative incidence of bloodstream infection at day +60 was 54.4% (95% CI, 21–79) in the Haplo cohort and 26.1% (95% CI, 10–45) in the MUD cohort (p=0.30). At day +100, clinically significant EBV reactivation (>30,000 copies/mL) occurred in 20% (95% CI, 3–49) of Haplo recipients and 56.5% (95% CI, 34–74) of MUD recipients (p=0.09). CMV reactivation was comparable (0% Haplo vs. 4.3% MUD; p=0.56).
At day +100, grade II–IV and III–IV acute GVHD occurred in 29.5% (95% CI, 6–59) and 10.1% (95% CI, 1–38) of Haplo recipients, respectively, and in 22% (95% CI, 8–41) and 0% of MUD recipients (p=0.82 and p=0.13). At 24 months, moderate-to-severe chronic GVHD was 0% in Haplo versus 4.8% (95% CI, 1–20) in MUD recipients (p=0.57).
With a median follow-up of 30.3 months (95% CI, 24–56), the 24-month overall survival was

90.9% (95% CI, 74.3–97). Survival was comparable between the Haplo and MUD groups, 90.9% (95% CI, 51–99) and 91.1% (95% CI, 69–98), respectively (p=0.90).

Conclusions: Haploidentical HCT using a PTCy platform is an effective and feasible alternative to MUD HCT in SAA, with comparable engraftment, GVHD, and survival outcomes.

Disclosure: Nothing to declare.

B332

THIOTEPA-BASED BUSULFAN-SPARING CONDITIONING OPTIMIZES ENGRAFTMENT AND MITIGATES CHRONIC GVHD IN PEDIATRIC HAPLOIDENTICAL HSCT FOR SAA: A MATCHED CASE-CONTROL STUDY

*Shier Cheng[1], **Shaoyan Hu**[1], Qingwei Wang[1], Li Gao[1], Peifang Xiao[1], Jun Lu[1], Jie Li[1], Hailong He[1], Yi Wang[1]*
[1]Children's Hospital of Soochow University, JiangSu, China

Background: For pediatric patients with severe aplastic anemia (SAA) undergoing haploidentical hematopoietic stem cell transplantation (HSCT), balancing the need for robust engraftment against the risks of conditioning-related toxicity remains a critical therapeutic challenge. We hypothesized that a Thiotepa (TT)-intensified, Busulfan-sparing regimen could optimize the therapeutic index by leveraging Thiotepa's unique dual properties—profound immuno-ablation and myelo-ablation—while specifically minimizing Busulfan-associated organ damage.

Methods: In this retrospective study, 30 pediatric SAA patients (TT-group) were matched 1:2 with 60 historical controls based on age and disease status. All patients received a standard conditioning backbone of Fludarabine, Cyclophosphamide, and Rabbit ATG. The TT-group utilized a modified protocol where Thiotepa (10 mg/kg) was substituted for one day of Busulfan, resulting in significantly de-escalated total Busulfan exposure (median 3.50 vs. 6.40 mg/kg, $P < 0.001$). Standard consensus criteria were used for GVHD and toxicity grading. Primary endpoints included engraftment kinetics, GVHD incidence, safety profiles, and survival.

Results: 1. Graft Characteristics & Engraftment: Graft cellularity was well-balanced between groups, with comparable mean CD34+ cell doses (6.88 ± 1.78 vs. 6.70 ± 1.63 × 10^6/kg, $P = 0.638$) and MNC doses (7.23 ± 2.11 vs. 7.80 ± 2.17 × 10^8/kg, $P = 0.249$). The TT-group achieved a 100% engraftment rate (30/30). Recovery kinetics were significantly accelerated, with faster neutrophil (median 11 vs. 12 days, $P = 0.033$) and platelet reconstitution (median 10.5 vs. 12.0 days, $P = 0.025$) compared to controls. 2. GVHD Reduction: With a median follow-up of 313 days for the entire cohort, the TT-group demonstrated a striking reduction in chronic GVHD incidence (10.00% vs. 30.00%, $P = 0.034$), suggesting that the intensified Thiotepa regimen fosters a potent tolerogenic environment. Acute GVHD rates (Grade 2-4) remained comparable ($P = 0.916$). 3. Safety & Toxicity: Gastrointestinal toxicity was more frequent in the TT-group (40.00% vs. 20.00%, $P = 0.043$) but was fully reversible.

Notably, a numerical increase in TA-TMA/VOD incidence was observed in the TT-group (13.33% vs. 1.67%; P = 0.074). While this represents a clinically notable signal warranting vigilance, crucially, all cases resolved with supportive care, and no associated mortality occurred. Incidence of Grade 3-4 liver injury was comparable (P = 0.607). 4. Survival & Viral Reactivation: Overall Survival (OS) was 100% in the TT-group, with zero transplant-related mortality (TRM). Additionally, a strong trend toward reduced CMV reactivation was noted in the TT-group (30.00% vs. 51.67%, P = 0.051), indicating preserved immune reconstitution.

Conclusions: Thiotepa intensification facilitates a Busulfan-sparing strategy that ensures rapid, stable engraftment and significantly reduces chronic GVHD in pediatric SAA. Despite a signal for manageable endothelial toxicity, this regimen establishes a compelling new paradigm with a superior efficacy-safety profile, effectively trading short-term, reversible toxicity for enhanced long-term immunological recovery and survival. These findings strongly support the design of prospective, randomized trials to validate this regimen as a standard of care.

Disclosure: Nothing to declare.

B333

SECOND ALLOGENEIC STEM CELL TRANSPLANTATION FOR SEVERE APLASTIC ANEMIA: REAL-WORLD OUTCOMES FROM A SINGLE CENTRE IN PAKISTAN

*Kashaf ad Duja Awais[1], Maryam Khan[1], Nighat Shahbaz[1], **Bushra Ahsan**[2], Tariq Ghafoor[1], Mehreen Ali Khan[1], Hira Tariq[1], Zainab Bibi[3], Miriam Baba[1], Raheel Iftikhar[1]*
[1]AFBMTC, Rawalpindi, Pakistan, [2]Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore, Pakistan, [3]Army Medical College, Rawalpindi, Pakistan

Background: Primary and secondary graft failure following second allogeneic Hematopoietic Stem Cell Transplantation (HSCT) for Aplastic Anemia (AA) remain critical complications associated with high morbidity and mortality. Large Western cohort studies report favorable survival with salvage HSCT. However, data from low- and middle-income countries (LMICs) is scarce. This study reports real-world outcomes of second HSCT for AA from one of Pakistan's largest transplant centers.

Methods: We conducted a retrospective analysis of 37 patients with AA who underwent a second matched related donor or haploidentical HSCT with unmanipulated/unselected peripheral/bone marrow stem cells at the Armed Forces Bone Marrow Transplant Centre (AFBMTC) from 2002 to 2025 out of a total cohort of 495 patients undergoing HSCT for AA. Our primary outcomes were engraftment kinetics and overall survival (OS). Secondary endpoints included disease-free survival (DFS), graft-versus-host disease–free relapse-free survival (GRFS), and transplant complications. We performed Kaplan–Meier with log-rank test, Mann–Whitney U, chi-square/Fisher's exact, and multivariate analysis using Cox regression where required.

Results: The median age of the study cohort at second HSCT was 16 years (IQR 9.5-25.5), and the male-to-female ratio was 1.3:1. The median interval between the first and second HSCT was 145 days (IQR: 25-406). Among all patients receiving a second transplant, 78.4% received grafts from related donors and 21.6% from haploidentical donors. Indications for second transplant were primary graft failure (48.5%), secondary graft failure (45.5%), and poor graft function (6.1%). The most common graft source was PBSCs (45.9%). Conditioning regimens included fludarabine, cyclophosphamide, and ATG (39.4%), followed by no conditioning (33.3%), non-ATG regimens (15.2%), ATG alone (3%), and other regimens (9.1%). Median time to neutrophil engraftment and platelet engraftment was 13 days (IQR: 10-22) and 27 days (IQR: 21-40), respectively. Neutrophil engraftment was significantly associated with conditioning (p=0.001), occurring in 100% with ATG-based regimens, 55.6% without conditioning, and 0% with non-ATG regimens. Transplant-related mortality was 32.4%, caused by graft failure (48%), infectious complications (8.1%), and organ failure (8.1%). The incidence of grade II-IV aGVHD was 11%, and chronic GVHD was 10.8%. Survival outcomes were OS: 50%, DFS: 43.2%, and GRFS: 32.4%. On univariate analysis, OS and DFS were significantly associated with HSCT type (OS $p < 0.001$), neutrophil engraftment (OS/DFS $p < 0.001$), and CMV reactivation (OS $p < 0.001$). On multivariate Cox regression these associations were no longer significant, reflective of the limited statistical

power in our small study population.

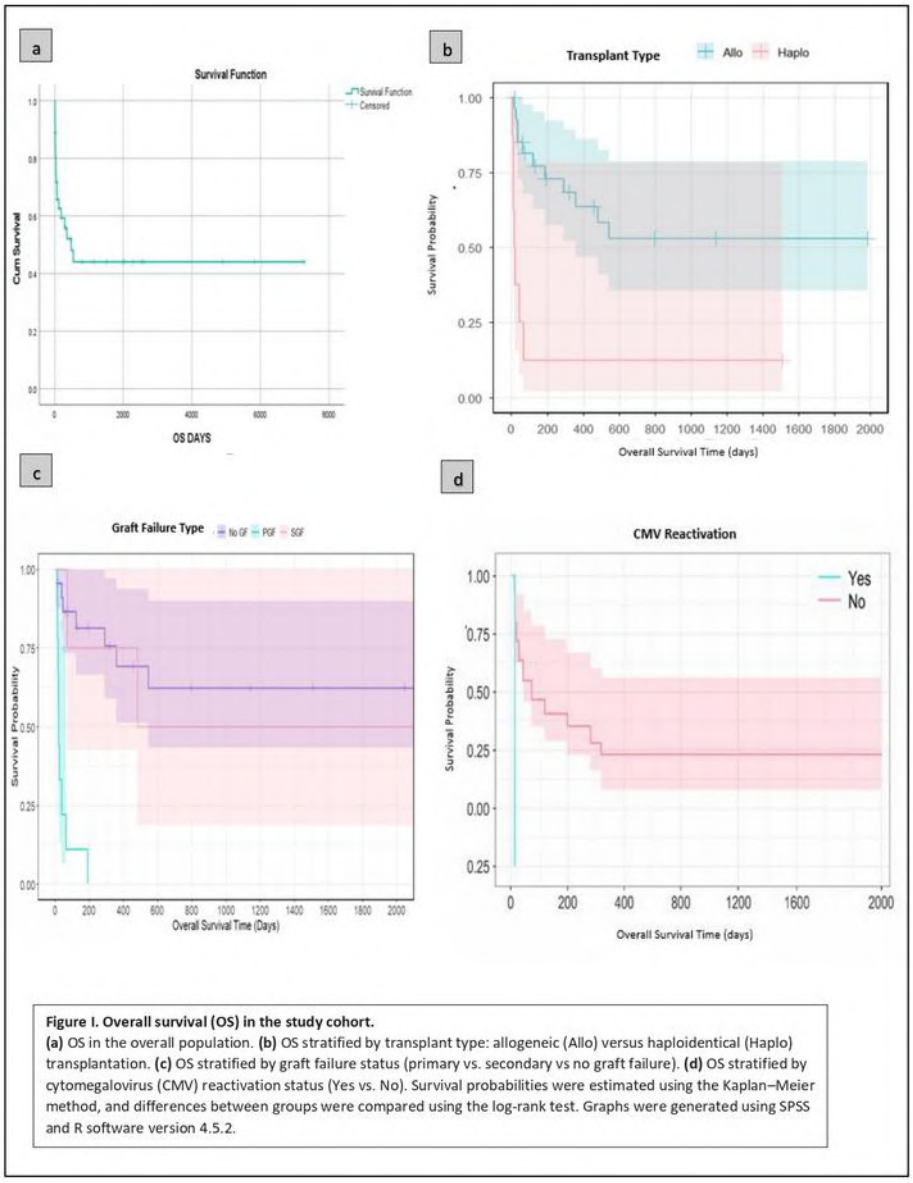

Figure I. Overall survival (OS) in the study cohort.
(a) OS in the overall population. **(b)** OS stratified by transplant type: allogeneic (Allo) versus haploidentical (Haplo) transplantation. **(c)** OS stratified by graft failure status (primary vs. secondary vs no graft failure). **(d)** OS stratified by cytomegalovirus (CMV) reactivation status (Yes vs. No). Survival probabilities were estimated using the Kaplan–Meier method, and differences between groups were compared using the log-rank test. Graphs were generated using SPSS and R software version 4.5.2.

Conclusions: In comparison to outcomes reported by large Western registry-based studies, survival in our region remains inferior. This is mainly attributable to the use of unmanipulated stem cells due to the excess cost associated with CD34 selection/αβ T-cell depletion, which is otherwise standard of care in graft failure. Other causes include delayed engraftment and infectious complications. Results from our study underscore the need for optimal conditioning strategies, better infection control measures, and early referral pathways in LMIC settings.

There is a need for multicenter collaborations across South Asia to provide more high-quality evidence to refine salvage transplant approaches for AA globally.

PEDIATRIC ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN FANCONİ ANEMIA: A CASE SERIES OF SINGLE CENTER EXPERIENCE

Bulent Antmen[1], *Ilgen Sasmaz*[1,2], *Nurgul Yonyul*[1], *Moslem Eshghi*[1]
[1]*Acibadem Adana Hospital, Adana, Turkey,* [2]*Cukurova University, Adana, Turkey*

Background:

Fanconi anemia (FA) is a a rare multi-organ hereditary disease characterized by defective DNA repair mechanism that manifests as congenital malformations, progressive bone marrow failure, and a predisposition to malignancy. Hematological abnormalities occur in patients with FA at a median age of 7 years (range, birth to 31 years). Allogeneic Hematopoietic Stem Cell Transplantation (HSCT) remains the only potential curative treatment for bone marrow failure in patients with FA. We aimed to present our transplant experiences in pediatric patients with FA at Acibadem Adana Hospital, Pediatric Bone Marrow Transplantation Unit.

Methods:

A total of 650 allogeneic hematopoietic stem cell transplantations were performed at Acıbadem Adana Hospital Pediatric Bone Marrow Transplantation Unit in Turkey from 2013 to 2025. 17 of 650 pediatric patients were FA. In this retrospective analysis of medical records and treatment modalities were evaluated.

Results:

In this retrospective analyses, 17 patients were evaluated, age ranging from 3 to 17 years with an average of 8.9 years. Ten patients were males, seven were female. Five patients had HSCT from an unrelated donor. We included all patients conditioning with ATG, fludarabine and cyclophosphamide. Two patients experienced secondary graft failure and this patients underwent a second transplant. Nine CMV reactivation developed in our patients. Acute GVHD ≥ Grade III was observed in only one patient. Chronic GVHD was seen in three patients. Two patients died. One of them died on day 38 due to central posterior reversible encephalopathy syndrome. Another patient, who underwent second transplant due to primary graft failure, died on the 27th post-transplant day due to sepsis and veno-occlusive disease. No serious toxicity was observes in other patients. 15 patients are alive and still following up GVHD free.

Conclusions:

HSCT is the only potentially curative treatment option for the hematologic complications that occur in patients with FA. In this retrospective study, we showed the results of our reduced toxicity myeloablative conditioning regimen is excellent overall survival, negligible GVHD, and low toxicity among in pediatric patients with FA even in those with high-risk pre-HSCT clinical features or those with no HLA-identical family donor who transplanted match unrelated donor.

Disclosure: No disclosure.

EXPERIENCE IN HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ACQUIRED APLASTIC ANEMIA BETWEEN 2010-2015 IN A SINGLE CENTER

Blanca Vegas[1], *Jimena Cannata*[1], *Ana Garcia-Noblejas*[1], *Rafael De La Camara*[1], *Laura Sánchez-Calvo*[1], *Peio Pérez-Uria*[1], *Carmen Corrales*[1], *Adrian Alegre*[1], *Valle Gómez-García de Soria*[1]
[1]*Hospital de La Princesa, Madrid, Spain*

Background: With evolving advances in conditioning regimens, immunosuppression and supportive care, Allogeneic Hematopoietic stem cell transplantation (HSCT) remains a curative option in acquired severe and very severe aplastic anemia (SAA/VSAA) and should be carefully considered after evaluating response to immunosuppression, age, comorbidities and donor availability.

Methods: The objective of this study was to assess the outcomes of Allogeneic HSCT in patients with AA during the last 15 years in a single center.All AA adult patients who underwent an HSCT at a single center between 2010-2025 were retrospectively identified.

Results: In total, 13 patients with SAA/VSAA underwent an Allogeneic HCT between 2010-2025 at a single institution, the median follow-up was 126 months. 7 out of 13 (54%) were females, 6 (46%) were males and the median age at HCT was 44 years (60-18). The median duration from diagnosis to alo-HSCT was 223 days (41-1573), with only one patient undergoing alo-HSCT upfront and the remaining patients after insufficient response to immunosuppresive therapy (IST). Most patients had received prior IST (12 (92%)), the majority with Cyclosporine (CsA) plus rabbit ATG (rATG) (11 (85%)). In all patients, the graft source was bone marrow, and the median total nucleated cells (TNC) and CD34+ stem cell doses were above the recommended threshold of 3×10^8/kg and 3×10^6/kg respectively. Most of the donors were matched (10 (77%), half of them unrelated). Two patients had mismatched unrelated donors and one patient a haploidentical unrelated donor.
All the patients received anti-thymocyte globulin (ATG) based conditioning regimens, 10 (77%) of them, received fludarabine based regimens, with modifications according to individualized assessment of their comorbidities. Two patients received post-transplant high-dose cyclophosphamide (PTCy) for GVHD prophylaxis as they were receiving mismatched unrelated or haploidentical unrelated donors respectively. For acute graft versus host disease

(GVHD) prophylaxis most of the patients received CsA plus methotrexate (MTX) (11 (85%)) except for 2 patients who received Mycophenolate Mofetil (MMF) plus CsA due to mismatched and haploidentical transplantation.
During follow-up 3 patients (23%) died due to transplant-related complications, all had received matched transplants and all experienced primary graft failure. One of these patients is the oldest in the cohort (60 years old), and another was the only patient that developed mild acute GVHD. No patients developed grade III-IV aGVHD. The rate of cytomegalovirus (CMV) reactivation was 46% and the rate of Epstein-Barr virus (EBV) reactivation was 15% (2 patients, both developing post-transplantation lymphoproliferative disorder (PTLD)).

Table 1. Characteristics of the patients.

Characteristics	All patients no. = 13
Gender:	
Male	6 (46%)
Female	7 (54%)
Median age (years)	44
Disease severity:	
Severe Aplastic anemia (SAA)	12 (92%)
Very severe Aplastic anemia (VSAA)	1 (8%)
Immunosuppresive therapy:	
Cyclosporine (CsA) + rabbit ATG (rATG)	11 (85%)
Horse anti thymocyte globulin (hATG)	2 (15%)
No immunosuppresive therapy	1 (8%)
Median duration from diagnosis to alo-HSCT	223 (days)
<1 year from diagnosis to alo-HSCT	9 (69%)
≥1 year from diagnosis to alo-HSCT	4 (31%)
Median Follow-up	126 months
Graft source:	
Bone marrow	13 (100%)
Stem cell dose:	
Median TNC (total nucleated cells) dose	3.7 × 108/kg
Median CD34 dose	4 × 106/kg
Donor:	
Matched related donor (MRD)	5 (39%)
Matched unrelated donor (MUD)	5 (39%)
Mismatched unrelated donor	2 (15%)
Haploidentical (Haplo) unrelated donor	1 (8%)
Donor/recipient sex match:	
Donor (male)/ receptor (male)	5 (39%)
Donor (female)/receptor (male)	1 (8%)
Donor (female)/receptor (female)	4 (31%)
Donor (male)/receptor (female)	3 (23%)

Characteristics	All patients no. = 13
ABO compatibility:	
compatible	6 46%)
minor incompatibility	4 (31%)
major incompatibility	3 (23%)
Conditioning regimen:	
- Cy-rATG	3 (23%)
- Flu based	10 (77%)
Cy-Flu-rATG	8 (62%)
Cy-Flu-rATG-TBI	1 (8%)
Flu-rATG	1 (8%)
GVHD prophylaxis	
CsA-MTX	11 (85%)
CsA-MMF	2 (15%)
Engraftment:	
Median time to ANC engraftment	24 (days)
Median time to platelets engraftment	25 (days)
Primary graft failure rate	3 (23%)
GVHD:	
Grade III-IV aGVHD	0
Grade 1-II aGVHD	1 (8%)
Rate of CMV reactivation	6 (46%)
Rate of EBV reactivation	2 (15%)
PTLD	2 (15%)
Chimerism analysis at last follow-up:	
Mixed chimerism	4 (31%)
Full chimerism	9 (69%)
Deaths	3 (23%)

Conclusions: Although the small sample size limits the strength of the findings, it seems that in our cohort the outcome of MUD transplants for acquired AA is similar compared with MRD transplants. Transplants from non conventional donors (mismatched and haploidentical) also showed comparable outcomes in our series, reflecting the improvement in conditioning,

GVHD prophylaxis and supportive care. In our population the patients who experienced primary graft failure had the worst outcomes.

Disclosure: Nothing to declare.

CASE REPORT: THE USE OF PEGCETACOPLAN PERI-HAEMATOPOIETIC STEM CELL TRANSPLANT FOR PAROXYSMAL NOCTURNAL HAEMOGLOBINURIA / APLASTIC ANAEMIA

Alma Corker[1,2,3], *Gai Fairnham*[1], *Alana Paterson*[1], *Vinita Agarwal*[2], *Adam Bryant*[1,2,3], *Lindsay Dunlop*[1,2,3], *Ashley McEwan*[1,2,3], *Anne-Marie Watson*[1,2,3], *Danny Hsu*[1,2,3], *Bartlomiej Getta*[1,2,3]
[1]*South Western Sydney Local Health District, Sydney, Australia,* [2]*NSW Health Pathology, Liverpool, Australia,* [3]*University of New South Wales, Sydney, Australia*

Background: Parxyosmal nocturnal haemoglobinuria (PNH) is a rare, acquired condition that results in chronic complement-mediated haemolysis. Pegcetacoplan is a pegylated peptide that targets the proximal complement C3 and is a novel management strategy for PNH refractory to terminal complement inhibitors (eculizumab and ravalizumab). The only potential cure for PNH is allogeneic haematopoietic stem cell transplant (allo-HSCT), however allograft is infrequently performed solely for PNH and usually is undertaken for coexistent aplastic anaemia.

Methods: We describe the case of a 23-year-old female diagnosed with classical PNH with a somatic PIGA variant in March 2022. Initially managed at a tertiary hospital in Sydney, Australia with ravalizumab. She remained transfusion-dependent and severely pancytopenic. Repeat bone marrow biopsy in July 2022 was consistent with development of severe aplastic anaemia. Bone marrow failure panel did not detect any underlying pathogenic variants. She did not have an adult fully matched sibling donor so underwent immunosuppression with horse anti-thymocyte globulin (hATG), cyclosporin and eltrombopag. Six months following immunosuppresion and eltrombopag, the patient remained severely pancytopenic with no haematological response (ANC 0.5x10*9/L Hb 82g/L Plt 26x10*9/L). At this point, due to ongoing haemolysis she was changed to pegcetocoplan 1080mg twice weekly and referred for allo-HSCT. On extended testing of her younger siblings an 11-year- old male sibling was found to be HLA match.

Results: Given the presence of a large Type 2 and 3 PNH clone, and ongoing haemolysis, a decision was made that she remained on pegcetacoplan throughout conditioning. This was done to reduce the risk of thrombosis and veno-occlusive disease (VOD). The conditioning regimen consisted of rATG, fludarabine, cyclophosphamide and one fraction of 2.00 Gy total body irradiation as per the protocol by DeZern et al (Blood 2023). Graft-versus-host disease (GVHD) prophylaxis consisted of post-transplant cyclophosphamide, tacrolimus and mycophenolate. We elected to use peripheral blood stem cells to ensure rapid engraftment as the donor was age 11 and of low weight relative to the recipient, and given the recipient had been severely neutropenic for 5 months. On day +9 she developed septic shock (*Klebsiella*

pneumoniae and *Streptococcus mitis*) requiring intensive care admission. Due to development of severe sepsis pegcetacoplan was ceased on D+9. Neutrophil and red cell engraftment occurred at D+26, with platelet engraftment occurring at D+41. The patient had no evidence of acute GVHD and two years post allograft has no cGVHD and is off immune suppression with no detectable PNH clone, normal blood count and full donor chimerism. *Figure 1* demonstrates clearance of the PNH clone and neutrophil engraftment.

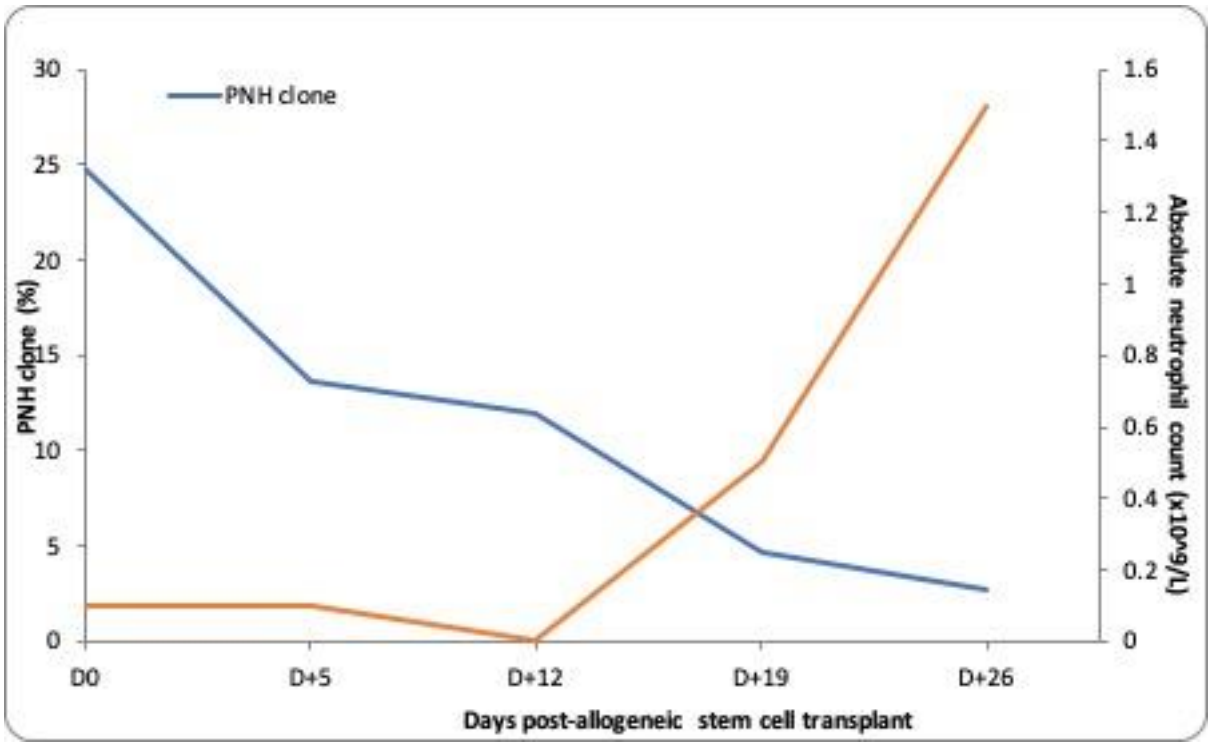

Figure 1: Rate of clearance of PNH clone and engraftment post-transplant

Conclusions: Use of eculizumab during the peri-transplant period has been described. We are not aware of any previously described cases of pegcetacoplan as a bridging therapy to allograft for patients with PNH and AA. The case demonstrates that this novel complement inhibitor can be used during the transplant conditioning and continued after stem cell infusion with successful engraftment and clearance of the PNH clone.

AUTOLOGOUS UMBILICAL CORD BLOOD TRANSPLANTATION WITHOUT CHEMOTHERAPY-BASED CONDITIONING IN A CHILD WITH SEVERE APLASTIC ANEMIA: A CASE REPORT

Katarzyna Bobeff[1], *Jowita Frączkiewicz*[2], *Olga Wegner*[1], *Szymon Janczar*[1], *Wojciech Młynarski*[1], *Marek Ussowicz*[2]
[1]*Medical University of Lodz, Lodz, Poland,* [2]*Wrocław Medical University, Wrocław, Poland*

Background: Severe aplastic anemia (SAA) is a rare, life-threatening hematopoietic disorder characterized by profound bone marrow failure and severe pancytopenia, requiring prompt diagnosis and treatment, typically including immunoablative therapy or allogeneic hematopoietic stem cell transplantation. Here, we report a 2.5-year-old boy with SAA treated with an immunoablative regimen without chemotherapy, followed by autologous umbilical cord blood transplantation (auto-UCBT).

Methods: The boy was diagnosed with SAA at 2.5 years of age. At diagnosis, testing was negative for Fanconi anemia and germline inherited bone marrow failure syndromes. In the absence of a matched sibling donor, immunosuppressive therapy was chosen.

Results: Immunoablation was initiated with four doses of equine antithymocyte globulin (Atgam, 40 mg/kg), after which a substantial number of residual T lymphocytes was observed (818/μL). To intensify the immunoablation, the patient subsequently received a 3-day course of antithymocyte globulin (Grafalon, 5 mg/kg), followed by a 2-day course of antithymocyte globulin (Thymoglobulin, 3.75 mg/kg), administered with methylprednisolone and cyclosporine A. Subsequently, the child underwent auto-UCBT containing 0.13×10^6 CD34+ cells/kg and continued treatment with cyclosporine A and prednisone. Leukocyte recovery above 1000/μL was achieved on post-transplant day +26, and neutrophil recovery above 500/μL on day +28. Transfusions of packed red blood cells and platelet concentrates were required until day +28 and +38 respectively. The post-transplant period proceeded without severe complications. Immunosuppression with cyclosporine A has been continued for 11 months after auto-UCBT, as the patient has not yet met the criteria for complete remission.

Conclusions: Early neutrophil recovery may indicate better underlying stem cell reserve, due to auto-UCBT infusion, though this interpretation remains speculative. Auto-UCBT after immunosuppression-based protocol appears to be a promising curative option for pediatric SAA patients with stored autologous cord blood and without available matched sibling. A key prerequisite for autoUCBT in SAA is excluding inherited bone marrow failure syndromes via clinical assessment, and germline genetic testing.

ALEMTUZUMAB-CONDITIONED HAPLOIDENTICAL HEMATOPOIETIC CELL TRANSPLANTATION CONFERS EXCELLENT SURVIVAL WITH LIMITED GVHD IN FANCONI ANEMIA

Rafaella Muratori[1,2], *Gisele Loth*[1,3], *Adriana Koliski*[1], *Samantha Nichele*[1,2], *Adriana Mello Rodrigues*[1,3], *Joanna Trennepohl*[1], *Lara Gouvea*[1], *Rebeca Toassa Gomes*[1], *Alberto Cardoso Martins Lima*[1], *Daniela Vandresen Pilonetto*[1], *Ana Paula Azambuja*[1], *Lismeri Wuicik Merfort*[1], *Fernanda Moreira de Lara Benini*[3], *Juliana Bach*[3], *Carolina Martins de Almeida Peixoto*[3], *Polliany Pelegrina*[3], *Cilmara Kuwahara*[3], *Celso Arrais*[4], *Juliana Folloni Fernandes*[5], *Luiz Guilherme Darrigo Jr*[6], *Ricardo Pasquini*[1], *Carmem Bonfim*[1]
[1]*Hospital de Clinicas da UFPR, Curitiba, Brazil,* [2]*Hospital Nossa Senhora das Graças, Curitiba, Brazil,* [3]*Hospital Pequeno Principe, Curitiba, Brazil,* [4]*Hospital São Paulo, Universidade Federal de São Paulo (UNIFESP), São Paulo, Brazil,* [5]*Instituto de Tratamento do Câncer Infantil (ITACI), Hospital das Clínicas HCFMUSP, São Paulo, Brazil,* [6]*Faculdade de Medicina de Ribeirão Preto - Universidade de São Paulo, Ribeirão Preto, Brazil*

Background: Fanconi anemia (FA) is the most common inherited bone marrow failure, and Hematopoietic cell transplantation (HCT) can cure hematological complications associated with the disease. When a matched donor is unavailable, a haploidentical donor may be a suitable option. Given the DNA frailty intrinsic to the disease, FA patients should receive a reduced-intensity conditioning (RIC) regimen while ensuring engraftment and low rates of Graft-Versus-Host Disease (GVHD). We present outcomes for patients with FA who underwent haploidentical transplantation with alemtuzumab-based conditioning and GVHD prophylaxis with a modified post-transplant cyclophosphamide (PTCY).

Methods: A retrospective, longitudinal, non-randomized, observational study including 44 patients with a median age of 8.9 years (range 3.5-44.8), transplanted in six HCT centers, between 2019 and 2025. Patients were classified as having bone marrow failure (FA-BMF) or aberration of indeterminate potential associated with FA (FA-AIP), such as 1q duplication. Patients with advanced disease (AML or MDS) were not included. All subjects received bone marrow from haploidentical donors and conditioning with Fludarabine 150mg/m², Total Body Irradiation (TBI) 200cGy, and Alemtuzumab 0,6-0,7mg/kg. GVHD prophylaxis consisted of PTCY 50-60 mg/kg (total dose), Cyclosporin, and Mycofenolate Mofetil. The database was revised, and statistical analyses were performed using EZR. Patients' characteristics are summarized in Table 1.

Gender, n (%)	Female 21 (47.7%)

	Male 23 (52.3%)
Age at HCT, median (range)	8.9 years (3.5-44.8)
FANC mutation, n (%)	FANCA 23 (52%) FANCG 5 (11.3%) Other 2 (4.5%) Unidentified 14 (31.5%)
Disease status at HCT, n (%)	FA-BMF 39 (88.6%) FA-AIP 5 (12.8%)
Donor, n (%)	Father 24 (54.5%) Mother 3 (6.8%) Other 17 (38.6%)
Donor age, median (range)	30.5 years (6-46)
Cytomegalovirus status for donor/recipient, n (%)	Negative/negative 3 (6.8%) Positive/negative 3 (6.8%) Positive/positive 38 (86.4%)
DSA status, n (%)	Positive 2 (4.5%) Negative 42 (94.5%)
TNC (x108/kg), median (range)	5.21 (2.6-10.5)
CD34 (x106/kg), median (range)	5.3 (1.6-13.1)
Follow-up, median (range)	25.5 months (6-67.1)

Results: With a median follow-up of 25.5 months, the 1- and 2-year overall survival (OS) was 93.2% (95%CI:80.3-97.7%). Four patients died, three from transplant-related complications (bleeding, viral, and fungal infection), while one 44-year-old patient died from oral cancer four years post-transplant.

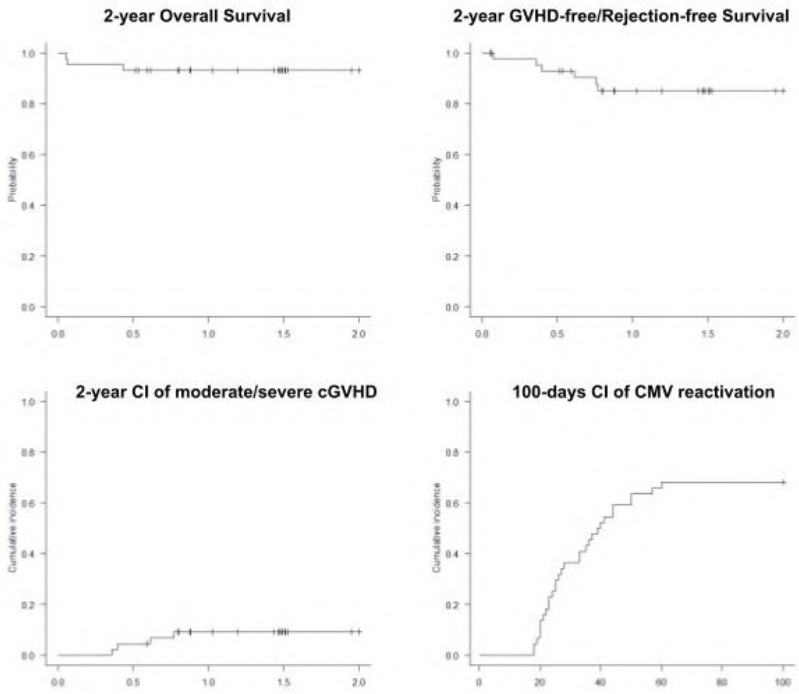
Only one patient experienced primary graft failure (GF) and was successfully rescued. There were no secondary graft failures. The 1-year cumulative incidence of GF was 2.3% (95%CI:0.2-10%). All engrafted patients sustained complete donor chimerism at the last follow-up.

Early cytomegalovirus (CMV) reactivation was frequent, with a 100-day CMV reactivation CI of 68.2% (95%CI:51.8-80%). Patients didn't receive letermovir prophylaxis but were successfully treated with preemptive therapy, with no evidence of CMV disease. The incidence of hemorrhagic cystitis was 20.6% (95%CI:10.1-33.7%).

The 100-day cumulative incidence of grade II-IV acute GvHD (aGVHD) was 4.5% (95%CI:0.08-13.8%), and the 2-year CI of any-grade and moderate/severe chronic GvHD (cGVHD) were 22.9% and 9.2% respectively (95%CI:11.7-36.3% and 2.9-20.1%).

Long-term outcomes and quality of life are significantly affected by GF and GVHD; therefore, patients were also evaluated for extensive (grade III-IV aGVHD, moderate/severe cGVHD) GVHD associated with rejection as a composite endpoint. The 2-year GVHD-free/Rejection-free survival was 85.1% (95% CI:69.9-93%). Given the low incidence of events in this cohort, no risk factor for worse outcomes (such as donor/patient age or sex mismatch) was identified in the statistical analysis.

Conclusions: The modified haploidentical approach incorporating alemtuzumab and PTCY achieves excellent survival outcomes in FA by decreasing rejection and TRM. The RIC approach minimizes toxicity, but careful consideration of TBI exposure and GVHD-associated malignancy risk remains a concern. The addition of alemtuzumab reduced the incidence and severity of GVHD compared to previously reported data. Haploidentical donors are promptly available and should be considered before disease progression to MSD/AML.



Disclosure: Nothing to declare.

Background: Allogeneic hematopoietic cell transplantation (HCT) remains the only curative option for bone marrow failure (BMF) or clonal evolution in Fanconi anemia (FA). However, most available evidence is derived from pediatric cohorts, and outcomes in adolescents and adults remain poorly defined. To address this gap, we conducted a study to characterize the clinical profile and transplantation outcomes of FA patients aged ≥12 years.

Methods: This national retrospective multicenter study through the Spanish Group for Hematopoietic Transplantation and Cell Therapy (GETH-TC) included all FA patients who underwent first HCT at ≥12 years of age between 2000–2024 across 17 centers. Primary endpoints were overall survival (OS) and event-free survival (EFS). Secondary endpoints included engraftment, graft failure (GF), acute and chronic graft-versus-host disease (aGVHD, cGVHD), relapse, non-relapse mortality (NRM), and secondary malignancies.

Results: Forty-five patients were included. Median age at diagnosis was 12 years (range, 2-38). Median time from diagnosis to HCT was 7 years (range, 3m-34y). The median age at HCT was 20 years (range, 12–44). Disease status at transplant was BMF 49%, MDS 45% and AML 13%. The donor was a MSD in 35.6%, MUD in 33.3% and alternative donor in 31%. Most patients received a fludarabine-based reduced-intensity conditioning regimen and 42,2% TBI. The cumulative incidence (CI) of neutrophil recovery by day 30 was 88.6% (95% CI, 78.8–98.5%), with a median engraftment time of 13 days (range, 8–41). GF occurred in 6 patients (4 primary and 2 secondary), with a CI at day 100 of 8.8% (95% CI, 2.2–17.7%). The CI of grade II–IV aGVHD at day 100 was 36.4% (95% CI, 21.9–50.4%), and grade III–IV was 24.4% (95% CI, 13.3–37.8%). The 2-year CI of moderate/severe cGVHD was 12.2%

(95% CI, 2–22.4%). Infections and organ toxicities were frequent (table1). Relapses and NRM occurred early, plateauing after month 6. The 2-year CI of relapse reached 31% (95% CI, 16.7–45.2) and NRM of 16.7% (95% CI, 5.2–28.1).
With a median follow-up of 88.1 months (IQR, 27–166), 2-year OS and EFS were 57% (95% CI, 42–72) and 51% (95% CI, 36–65), respectively. Survival differed significantly by disease status (p=0.013): patients with BMF had a 2-year OS of 68% (95% CI, 50-85%), compared with 16% (95% CI, 0-34%) in MDS/AML cohort. Secondary malignancies occurred in 5 patients, with a median of 63 months (range, 8–177) post-HCT, predominantly squamous cell carcinoma (n=4). At last follow-up, 22 patients were alive. Among the 23 deaths, main causes were organ toxicity and infection (n=11), relapse (n=7), GVHD (n=3) and secondary malignancies (n=2).

Table 1. Patient, donor, and transplant characteristics and complications in patients with Fanconi anemia		
	Total patients (n=45)	%
Patient characteristics Gender		
• Male	20	44.4%
• Female	25	55.6%

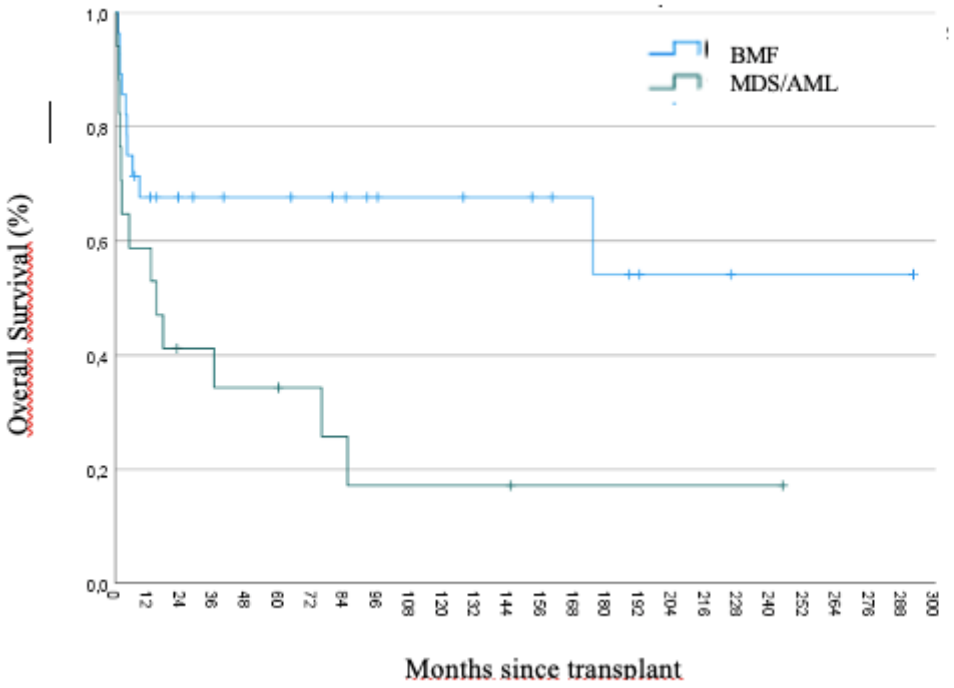
Figure 1. Overall survival in patients with Fanconi anemia according to disease status at transplantation



Conclusions: HCT in adolescents and adults with FA results in high engraftment rates but is associated with substantial toxicity, reflecting the vulnerability of older FA patients to treatment-related damage. Survival was strongly conditioned by disease status at transplant, with markedly inferior outcomes in those with MDS/AML. These findings underscore the need for early referral, optimized conditioning strategies, and tailored supportive care to mitigate toxicity and improve outcomes, particularly in the setting of clonal evolution.

T CELL-DEPLETED HAPLOIDENTICAL AND MATCHED UNRELATED DONOR HEMATOPOIETIC STEM CELL TRANSPLANTATION REPRESENT SAFE AND EFFICIENT THERAPEUTIC APPROACHES FOR PEDIATRIC PATIENTS WITH BONE MARROW FAILURE SYNDROMES

Anja Troeger[1], *Alexandra Matschiner*[1], *Tarek Hanafee-Alali*[1], *Katharina Kleinschmidt*[1], *Stephanie Leszczak*[1], *Marcus Jakob*[1], *Sonja Kramer*[1], *Patrick Schlegel*[1], *Peter Offner*[1], *Andreas-Michael Brosig*[1], *Florian Bayer*[1], *Melissa Woller*[1], *Chris Kurzweil*[1], *Juergen Foell*[1], *Selim Corbacioglu*[1]
[1]*University Hospital Regensburg, Regensburg, Germany*

Background: Hematopoietic stem cell transplantation (HSCT) is a valuable treatment option for patients with bone marrow failure syndromes (BMF). Limited availability of matched donors and disease-associated increased acute and long-term toxicity pose significant challenges. Thus, T cell-depleted haploidentical donor models (T-haplo-HSCT), may offer a promising alternative.

Methods: Nine patients with BMF, including three Fanconi anemia (FA), two dyskeratosis congenita (DC), two Schwachman-Diamond syndrome (SD), and two Diamond-Blackfan anemia (DBA), underwent HSCT. Four (2DC, 2SD) received matched-unrelated grafts (MUD; median age: 2 years; range 1-19): two bone marrow (BM), one cord blood (CB), one peripheral blood stem cells (PBSC). Five patients (3FA, 2DBA) received a CD3+/CD19+ or α/CD19+ T-cell-depleted graft (median age: 11 years; range 9-20). The indication for HSCT in all was transfusion-dependent pancytopenia caused by BMF. Five patients received a conditioning regimen based on fludarabine and cyclophosphamide (FC) and three fludarabine, thiotepa, treosulfan (FTT), along with ATG-Grafalon® or thymoglobulin. One SD patient received a MUD-PBSC, conditioned with fludarabine, thiotepa and melphalan (FTM). Immunosuppression (IST) consisted of tacrolimus (or cyclosporine) and mycophenolate mofetil (MMF) in all nine patients.

Results: The graft consisted of 7.6 x 10^8 TNC/kg (range: 6-9.2 x 10^8) and 10 x 10^6 T-cell depleted CD34+ cells/kg (range: 2,51-18,37 x 10^6). Leukocyte engraftment was achieved after a median of 20 days (range: 10-20) in MUD and only 11 days (range: 9-14) in T-haplo-HSCT. The median follow-up was longer for MUD (37.5 months; range: 8-62) compared to T-haplo-HSCT (6 months; range: 5-24). Overall survival was 5/5 in T-haplo-HSCT patients and 2/4 for MUD-HSCT. One deceased patient received MUD-PBSC and developed GvHD grade IV of skin and gut, along with infectious complications within 6 months post HSCT, the other one died of progressive liver disease 5.5 years post HSCT. One patient received two consecutive MUD-BM grafts due to primary graft failure. Transfusion independence was achieved in all MUD patients (median: 63 days; range: 18-134 days after transplant) and T-haplo-HSCT patients (median: 11 days; range: 10-18 days after transplant). Median Chimerism was 97% (85-100) in MUD-HSCT and 100% (87-100) in T-haplo-HSCT.
The FC and FTT conditioning regimens were tolerated with manageable transplant-related toxicity, except for extensive squamous dermatitis and mucositis in one FA patient with MDS

who received full myeloablative conditioning (Flu/Cy/Treo). One case of veno-occlusive disease (VOD) in a T-haplo-HSCT patient with FA resolved completely after treatment with defibrotide. Two cases of severe grade III-IV acute GvHD affecting the skin and gut, and one case of chronic graft-versus-host disease of the lung (cGvHD), were observed in the MUD group. Among T-haplo-HSCT recipients, mild grade I aGvHD of the skin was seen in one patient, and another patient experienced ocular cGvHD. With preemptive antibiotic treatment during neutropenia and antiviral prophylaxis, there were no life-threatening infectious complications, except for one case of septicemia in a MUD patient.

Conclusions: This single-center, retrospective series supports feasibility and safety of T-haplo-HSCT in rare BMF syndromes and indicates favorable outcomes in T-haplo-HSCT with fast engraftment, low GVHD, and a reduced risk of severe toxicity compared to MUD-HSCT in children.

Background: Pearson syndrome (PS) is a rare unique primary mitochondrial disorder (PMD) caused by single large-scale mitochondrial DNA deletions (SLSMDs), characterized by bone marrow failure, predisposition to myeloid malignancy, lactic acidosis, and progressive multi-organ complications. Spontaneous recovery of anemia is observed in two-third of patients. Recently, PS patients have opportunity to participate in clinical trials such as a cell therapy called mitochondrial augmentation therapy (MAT, ClinicalTrials.gov, NCT06017869). The marked clinical heterogeneity and lack of reliable biomarkers pose major challenges in

evaluating treatment efficacy and defining clinically meaningful endpoints. In the MAT trial some clinical improvement such as weight gain and stabilized height standard deviation score (SDS) was reported (Jacoby, et al 2022). Although short stature and abnormal growth are common clinical features in PMD, there is still limited data on growth in children with PS.

Methods: We retrospectively evaluated anthropometric data (height, weight, and body mass index (BMI) SDS from 25 patients with PS (14 males /11 females) during disease course. A diagnosis of PS was suspected from typical bone marrow features including vacuolized marrow precursors and ring-sideroblasts and subsequently confirmed by detection of SLSMDs in blood cells.

Results: Patients presented with anemia, occurring at a median age of 5 months (range 0 to 31 months). Variable organ failures developed during the course including, pancreas insufficiency in 14 patients (56%), renal disease in 8 (56%), endocrine dysfunctions in 7 (28%) and cardiac dysfunction or arrhythmia in 5 (20%). Fourteen patients required tube feeding and/or parenteral nutrition due to feeding difficulties and/or failure to thrive. The median age at last follow-up was 49 months (range: 7–183 months); 11 patients were alive and 14 had died (acute metabolic acidosis: n=9, arrhythmia: n=2, respiratory infection: n=2, and acute liver and renal failure: n=1).
The most recent median height, weight, and BMI SDS were −2.12 (range: −7.32 to 1.08), −1.70 (range: −12.25 to 0.11), and −1.44 (range: −4.74 to 2.19), respectively; 50%, 40%, and 35% of patients, respectively, had values below −2 SDS. Longitudinal data from 18 patients showed that height and weight SDS declined progressively with age in most patients (median -0.2, -1.9 and -3.4 SDS, $p<0.01$ and median -0.9, -1.7 and -3.7 SDS, $p<0.01$ in the age group of <36 months, 36-<72 months and >=72 months, respectively), whereas BMI SDS fluctuated without a clear age-related trend. Initiation of nutritional support improved weight and BMI SDS in some patients, while height SDS continued to decline without catch-up growth. Patients with at least one of the organ failures in the first 36 months of life exhibited an earlier decline in height SDS achieving -2 SDS than those without organ failure ($p=0.03$).

Conclusions: Patients with PS are generally short and underweight, and their short stature worsens over time. The presence of organ failure further exacerbates growth impairment. The results suggest that height SDS, in particular, could be a reliable marker of disease progression and treatment response in PS and serve as a meaningful clinical endpoint in future clinical trials.

OUTCOMES OF ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION AS THE ONLY TREATMENT AVAILABLE FOR PATIENTS WITH PAROXYSMAL NOCTURNAL HEMOGLOBINURIA IN VENEZUELA

Marcos Hernandez[1], *Maria Antonietta Aray*[2], *Rosmelvic B*[2], *Maylu Collazo*[3], *Amyibel Paradas*[2], *Laura Saavedra Salazar*[2]
[1]*Bone Marrow Transplante Center Abraham Sumoza/ Universidad de Carabobo/LABMT, Valencia, Venezuela (Bolivarian Republic of),* [2]*Bone Marrow Transplante Center Abraham Sumoza, Valencia, Venezuela (Bolivarian Republic of),* [3]*Bone Marrow Transplante Center Abraham Sumoza/LABMT, Valencia, Venezuela (Bolivarian Republic of)*

Background: Nowadays, the therapy with Eculizumab has proven to be effective in controlling the symptoms and preventing complications associated with Paroxysmal Nocturnal Hemoglobinuria (PNH). However, because of its high cost, this therapy is not available in Venezuela; therefore, allogeneic Stem Cell Transplantation (HCT) is the only therapeutic option for these patients in Venezuela.

Methods: A retrospective study was conducted, and all the patients who underwent an allogeneic HCT for PNH in the Bone Marrow Transplant Center Abraham Sumoza from 2019 to 2025 were included.

Results: Patients' characteristics:
A total of 3 patients were included; all were male patients with a median age of 30.3years
The three cases presented classic PNH, the main indication for allogeneic HCT was hemolysis with constant need for red blood cell transfusion, the median time between diagnoses of PNH and AHCT was 26 months, and the therapies received before the AHCT were steroids, androgens, folic acid, and iron supplementation.
HCT and donor characteristics
There was only 1 patient who had an Identical Matched Related Donor (MRD), and two with HLA- haploidentical donor. The conditioning regimens used were: RIC with a combination of Busulfan, Fludarabine, and Cyclophosphamide for the HLA-haploidentical HCT cases, and MAC that consisted of a combination of Busulfan and Cyclophosphamide. In two of the cases, the source of the graft came from granulocyte colony-stimulating factor-mobilized Peripheral Blood CD34 cells, with a median dose of 2.35 × 10^6 cells/kg. As Graft vs Host Disease (GVHD) prophylaxis, high-dose Cyclophosphamide on days 3 and 4 followed by CsA and Micofenolato Mofetilo starting on day 5 was used for the HLA-haploidentical HCT, and the combination of CsA plus 4 doses of Metrotexate was used for the patient who received MAC conditioning.
Engratment:
Evidence of neutrophile and platelet recovery was seen on days 16 and 11, respectively, for the patient who received the MAC conditioning; this patient did not attend the follow-up consultation. Only one case of primary graft failure was registered and eventually passed away due to infection. At the time this study was conducted one of the patients was still in the recovery phase of the HCT.

Retrospective studies have shown the rate of graft failure is low in these patients; therefore, we presumed that the only case in this study was associated with a low dose of CD34 cells and perhaps the fact that they were harvested from bone marrow.

Conclusions: Allogenic HCT is recognized worldwide as the only curative treatment for patients with PNH, offering an Overall Survival (OS) of 70 to 80% at 5 years of follow-up after HCT. However, there is no guide on how or when to proceed to HCT as front-line therapy.
In our institution, it is feasible to carry out an allogeneic HCT as front-line therapy for PNH patients, using a RIC regimen and an identical MRD or HLA-haploidentical donor. Long-term follow-up is necessary to evaluate OS, incidence of GVHD, and other complications post HCT.

Rheumatology and Clinical Immunology, Charité - Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, Germany, [15]Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, University of Milan, Milano, Italy, [16]Hospital Clínic of Barcelona, Department of Haematology, Barcelona, Spain, [17]Hospital Clínic of Barcelona, Department of Autoimmune Diseases, Barcelona, Spain, [18]Leiden University Medical Center, Department of Hematology, Leiden, Netherlands (the), [19]Hôpital Saint-Louis, AP-HP Assistance Publique des Hôpitaux de Paris, Centre de Référence des Maladies Auto-Immunes Systémiques Rares d'Ile-de-France, Paris, France

Background: Systemic sclerosis (SSc) is a rare and heterogenous autoimmune disease with the highest mortality rate amongst all rheumatic diseases and still very limited treatment options. In the ADWP EBMT non interventional NISSC-1 study [Henes J et al. Hematologica 2021] that included 80 adults treated with a first aHSCT with a 24 months median follow-up, 81.8% progression free survival (PFS) and 90% overall survival (OS) were observed at 2 years, but the NISSC-1 long term follow-up data were not yet available.

Methods: Long-term extension follow-up of all the NISSC-1 patients was obtained from the participating centres. Primary endpoint was progression free survival (PFS), defined as survival from baseline without evidence of SSc progression. Main secondary endpoints were overall survival (OS), non-relapse mortality (NRM), and incidence of progression.

Results: Among the NISSC-1 80 patients who had undergone aHSCT, with a median follow-up of 9.2 (IQR : 8.9-9.6) years, at respectively five and ten years, the PFS was 72% (60.6-80.6) and 58.5% (44.7-69.9) and the OS was 86% (76.2-92) and 71% (56.1-81.6). The non-relapse mortality was 7.6% (3.1-14.8) and 13.5% (5.7-24.8) and the incidence of progression 20.4% (17.4-42.3) and 26.3% (16.9-36.7) at five and ten years.
Late complications showed six malignancies diagnosed in five patients (two breast cancer, one lung cancer, one pancreatic cancer and two myelodysplasias), which occurred after a median of 80 months (range 30-121). Three patients experienced a major adverse cardiac event (MACE) and 12 had a late serious infection (after 29 months; 11-115). In nine patients one or two secondary AID appeared (51 months; 3-99).

Conclusions: This multicenter EBMT NISSC-1 long-term extenion study with 80 SSc patients and a median follow-up of 9.2 years after first aHSCT is the longest experience reported so far in the literature. We demonstrate a long-lasting effect of aHSCT in SSc with an overall survival >70% in this extremely high risk selected patients. Incidence of progression from 20.4% to 26.3%, suggesting that patients remain at risk of relapse/progression after 5 years. The extended timeframe of nearly ten years enables robust assessment of late complications.

CO-INFUSION OF ANTI-CD19 AND ANTI-BCMA CAR-T CELLS FOR RELAPSED OR REFRACTORY NMOSD: A PHASE 1 CLINICAL TRIAL AND MECHANISTIC INSIGHTS

Jingjing Feng[1], *Ruili Wei*[1], *Dawei Huo*[1], *Xuexiao Jin*[1], *Rui Wen*[1], *Benyan Luo*[1], *Ruimin Hong*[1], *Mingming Zhang*[1], *Shan Fu*[1], *Wenli Zhu*[1], *Dongrui Wang*[1], *Guoqing Wei*[1], *Huijun Xu*[1], *Jiazhen Cui*[1], *Simao Huang*[1], *Alex Hongsheng Chang*[2], *Linrong Lu*[1], *Hui Liang*[1], *Yongxian Hu*[1], *He Huang*[1]
[1]*Zhejiang University, Hangzhou, China,* [2]*Shanghai YaKe Biotechnology Ltd, Shanghai, China*

Background: Neuromyelitis optica spectrum disorder (NMOSD) is a severe autoimmune disease of the central nervous system, characterized by pathogenic antibodies against aquaporin-4 (AQP4). B-cell depletion with monoclonal antibodies controls neuromyelitis optica spectrum disorder (NMOSD) but requires continuous dosing and fails to eradicate long-lived autoreactive clones. We identified the cellular source of AQP4 antibodies and evaluated dual-target chimeric antigen receptor (CAR)-T cells directed at CD19 and BCMA in refractory disease.

Methods: Using single-cell RNA/B-cell-receptor (BCR) sequencing and in-vitro antibody re-expression we traced AQP4-IgG production to both $BCMA^+$ plasma cells and $BCMA^-CD19^+$ memory B cells. We then conducted an open-label, single-center, phase 1 dose-escalation study (NCT05828212). Adults with relapsed or refractory, AQP4-IgG-seropositive NMOSD received lymphodepletion followed by a single infusion of autologous anti-CD19 and anti-BCMA CAR-T cells ($1{\cdot}0 \times 10^6$ or $2{\cdot}0 \times 10^6$ cells kg^{-1} for each product). Primary endpoint was safety; secondary endpoints included relapse rate, AQP4-IgG titers, disability scores. Exploratory endpoints include immune reconstitution, peripheral blood levels of anti-CD19 and anti-BCMA CAR-T cells, serum immunoglobulins, and complement components.

Results: Nine patients (median age 45 y, range 23–65; 8 women) were treated between Apr 4, 2023, and Mar 28, 2024. Grade 1 cytokine-release syndrome occurred in eight (89%); no immune-effector-cell–associated neurotoxicity was observed. Grade ≥3 cytopenia was transient and reversible. All patients entered clinical remission; seven (77·8%) remained relapse-free and off all NMOSD therapy after a median follow-up of 505 days (291–687). Serum AQP4-IgG became undetectable in every participant within three months. One patient relapsed at eight months with de-novo pathogenic B-cell clones; single-cell analysis revealed loss of $CD16^+$ non-classical monocytes, reduced regulatory $CD4^+$ T cells, expansion/exhaustion of $CD8^+$ effector T cells, and enrichment of interferon-γ and lymphotoxin signaling.

Conclusions: Simultaneous CD19 and BCMA CAR-T-cell therapy was safe, induced deep molecular remission, and permitted drug-free disease control in most patients with highly refractory NMOSD. Relapse arose from newly generated autoreactive clones within a pro-inflammatory immune milieu, indicating that long-term success may depend on adjunctive strategies aiming at immune-regulation. Controlled trials are warranted.

Background: CAR T-cell therapy represents an emerging, promising approach in the field of autoimmune diseases (ADs), providing a deep B cell depletion and striking clinical responses through their ability to infiltrate tissues. This strategy is rapidly expanding globally, offering a treatment option to patients with refractory systemic lupus erythematosus (SLE), systemic sclerosis (SSc), and other difficult-to-treat ADs. As interest rapidly increases, the real-world landscape regarding where and how centers are beginning to implement this transformative therapy remains largely unknown.

Methods: To address this knowledge gap, we conducted a cross-sectional survey across EBMT centers on behalf of the Autoimmune Disease Working Party (ADWP) and the Cellular

Therapy Immunobiology Working Party (CTIWP). The aim was to characterize current activity, indications, challenges, and future directions in the emerging field of CAR T-cell therapy for ADs.

Results: The survey was distributed to 557 EBMT centers, with 103 (18%) centers responding directly to the complete survey and additional 66 centers who provided information regarding their experience with CAR T cells for ADs, resulting in 169 (30%) total responses. Overall, 29 centers had already initiated (2019-2025) CAR T-cell therapy for AD indications, while 41 others reported their plans to start within 2025, spanning most surveyed countries (Figure 1A). Among centers already treating ADs with CAR T cells, rheumatological and neurological diseases were the most frequent indications, and most treatments were administered within clinical trials (Figure 1B-C). SLE was the leading planned indication, particularly lupus nephritis, followed by SSc, idiopathic inflammatory myopathies, and multiple sclerosis. Most responding centers performing or planning to perform CAR T-cell therapy also had established HCT programs for ADs (60%) and reported multidisciplinary management models (72%) with AD specialist and CAR T specialist on-site. Autologous CAR T-cell products were most commonly available, though some centers had or will have access to both autologous and allogeneic products (20%). CD19 was the predominant target antigen (86%), followed by BCMA, CD19/CD20, or CD19/CD22 (Figure 1D). The most frequently used co-stimulatory domains were 4-1BB and CD28 (60% and 23%, respectively, Figure 1E). Lymphodepletion regimens largely mirrored those used in hematologic settings, with the majority of centers (93%) combining fludarabine and cyclophosphamide; only a small proportion of centers reported incorporating busulfan or bendamustine into their lymphodepleting regimens (5% and 2%, respectively). A total of 147 patients with ADs were reported as having received treatment, including five who had concurrent hematologic malignancies (3%). One center alone accounted for 63 treated patients (43%). Follow-up practices varied considerably across centers: 45% reported using joint disease-specific multidisciplinary visits; another 50% conducted in parallel separate hematology and disease-specialist visits; and in 5% of centers, follow-up procedures had not yet been defined.

Figure Legend

A. Outlined the locations of all participating centers. Sites already active in delivering CAR T-cell therapy are highlighted in green, while centers scheduled to begin soon are shown in yellow. B. Overview of CAR T-cell therapy indications for autoimmune diseases across participating centers that already started performing CAR T-cell therapies. C. Overview of CAR T programme types across participating centers. D. CAR T-cell antigen specificity: targeted antigens across centers. E. Co-stimulatory domains employed in CAR design across centers. *Abbreviations: AD – Autoimmune Diseases; Haem – Haematological; Rheum – Rheumatological; Neuro: Neurological; Gastro – Gastrointestinal: CT – Clincial Trial*

Conclusions: This multinational EBMT survey provides the first broad overview of the rapidly evolving adoption of CAR T-cell therapy for ADs. The field is expanding quickly, with increasing numbers of centers initiating programs, targeting both rheumatological and neurological diseases. Standardization of indications, right patient selection, multidisciplinary

follow-up strategies, and reporting data in large multinational registries will be essential to guide this strategy toward wider clinical implementation.

OS20-05

THE "WINDOW OF OPPORTUNITY" IN CAR-T FOR LUPUS NEPHRITIS: AUTOLOGOUS BISPECIFIC CD19/BCMA RESCUE IN PATIENTS REFRACTORY TO UNIVERSAL-CD19 CAR-T — A TALE OF TWO BIOPSIES

Ruijiao Zhang[1], Guoai Su[1], Yue Wu[1], Peihao Zheng[1], Huihui Zhao[1], Fangfang Cheng[1], Ruijie He[1], Chen Zheng[1], Xuelin Han[1], ***Yajing Zhang***[1]
[1]*Beijing Gobroad Boren Hospital, Beijing, China*

Background: Universal CD19 CAR-T therapy faces high relapse rates in Systemic Lupus Erythematosus (SLE) due to host rejection and the escape of CD19-negative/BCMA+ long-lived plasma cells (LLPCs). While autologous bispecific CD19/BCMA CAR-T offers a definitive immunological salvage by depleting the entire B-cell lineage, the potential for renal recovery in advanced disease remains undefined. We hypothesized that while bispecific CAR-T can reliably reset the immune system, the clinical outcome is dictated by the pre-existing Renal Chronicity Index (CI).

Methods: We analyzed two patients with refractory Class V Lupus Nephritis (LN) who failed prior single-target CD19 CAR-T therapy and were salvaged with autologous bispecific CD19/BCMA CAR-T. We correlated immunological depth of response (B-cell aplasia, serology) with histological markers of kidney damage (biopsy Chronicity Index) and clinical outcomes (proteinuria).

Results: 1. Immunological Uniformity (The "Salvage" Success):
Both patients achieved robust CAR-T expansion and deep immunological remission post-rescue, overcoming the limitations of prior therapies.
•Seroconversion: Anti-dsDNA and ANA turned negative in both patients within 45 days.
•Biomarker of Eradication: Sustained B-cell aplasia (0/μL) and low IgG levels confirmed the complete destruction of the pathogenic LLPC reservoir.
2Divergent Renal Outcomes (The "Point of No Return"):
Despite identical immune clearance, clinical trajectories diverged sharply based on histological chronicity.
•Patient 1 (Functional Cure): Had a history of active inflammation but preserved renal architecture. Following a "lag phase," her massive proteinuria normalized (<0.15 g/24h) by Month 9, allowing for Drug-Free Remission.
•Patient 2 (33y, Class V LN, 11y history):
◦Clinical Status: Despite successful salvage (no CRS/ICANS vs. Grade 2 CRS in prior trial)

and serological improvement, she presented with massive nephrotic syndrome (Proteinuria 13.14 g/24h, Albumin 23.4 g/L) at 1-month post-rescue.
◦The "Smoking Gun": Renal biopsy revealed a Chronicity Index (CI) of 5 (Glomerulosclerosis 1, Fibrous Crescents 2, Interstitial Fibrosis 1).
◦Mechanism: While CAR-T successfully extinguished the autoimmune "fire," the "burnt structure" (fibrosis and sclerosis) prevented proteinuria resolution. The massive proteinuria reflects irreversible podocyte injury and basement membrane damage, rather than active immune complex deposition.

Table 1: Immunological Rescue vs. Histological Reality

Parameter	Patient 1 (Functional Cure)	Patient 2 (Irreversible Damage)	Clinical Implication
Prior History	Refractory LN (11y)	Refractory Class V LN (11y)	Long disease duration
Prior CAR-T	Failed Universal-CD19 CART	Failed Universal CD19 CART	Need for "Salvage"
Rescue Therapy	Autologous 19-BCMA	Autologous 19-BCMA	Successful Engraftment
Immunology	Seroconversion (Neg)	Seroconversion (Neg)	Universal Immune Efficacy
Renal Biopsy	Active Inflammation	Chronicity Index (CI) = 5	The Determining Factor
Proteinuria	Normalized (<0.15 g)	Persistent Massive (13.1 g)	Structural Damage
Outcome	Drug-Free Remission	Symptomatic Management	Limit of Regeneration

Conclusions: Autologous 19-BCMA CAR-T is a highly effective salvage strategy for immunological relapse, reliably inducing deep serological remission where universal CD19 therapy fails. However, our data unmask a critical limitation: Immunological cure does not guarantee organ restitution if the "Window of Opportunity" is missed. A Chronicity Index (CI) ≥ 5 may predict persistent proteinuria despite successful B-cell eradication. This underscores the urgent need to deploy dual-targeting CAR-T earlier in the disease course, before irreversible organ damage precludes functional recovery.

OS20-06

GENOMIC INSTABILITY AND HIGH MUTATION BURDEN IN FIBROBLASTS OF SYSTEMIC SCLEROSIS PATIENTS ARE IMPROVED IN CLINICAL RESPONDERS TO AUTOLOGOUS HSCT

Jan Storek[1], *Mohammed Osman*[2], *Dylan Hennessey*[2], *Lamia Khan*[2], *Aishwarya Iyer*[2], *Desiree Redmond*[2], *Charmaine van Eeden*[2], *Lisa Willis*[2], *Janet Pope*[3], *Caylib Durand*[1], *Robert Gniadecki*[2]
[1]*University of Calgary, Calgary, Canada,* [2]*University of Alberta, Edmonton, Canada,* [3]*University of Western Ontario, London, Canada*

Background: Diffuse cutaneous systemic sclerosis (dcSSc) is a lethal rheumatic disease that is characterized by progressive skin and visceral fibrosis. Autologous hematopoietic stem cell transplant (AHSCT) is known to improve the quality of life and survival of dcSSc patients. However, the mechanism of action is poorly understood. We and others have recently shown that, similar to cancer cells, genomic instability is an important feature of dcSSc fibroblasts. In this cross-sectional study, we compared the genomic instability and mutational landscape in skin/fibroblasts from dcSSc patients not treated with AHSCT (dcSSc patients) vs treated with AHSCT (post-AHSCT patients).

Methods: We recruited 25 dcSSc patients and 9 post-AHSCT patients (median 12 months posttransplant). We performed whole exome sequencing (WES) on microdissected dermis from each patient and determined the mutational frequencies by comparing DNA sequences from the microdissected dermis with autologous DNA from buccal samples using two pipelines (MuTect2 and Strelka). We also generated dermal fibroblasts (DFs) from the patients and from age&sex-matched healthy controls, and measured the number of double strand breaks (DSB, using pH2AX immunostain).

Results: We identified frequent recurrent mutations in dcSSc patients, including in genes commonly mutated in cancer. The most frequently mutated gene was MUC16, also called CA125. (Fig. 1A). MUC16 mutations were associated with SSc severity (Fig.1A, patients with severe dcSSc are marked red). AHSCT resulted in decreased MUC16 mutations (in particular) as well as recurrent mutations (in general) – the number of mutations per genome was 678 in the dcSSc patients vs 74 in the postAHSCT patients ($p<0.01$), with particularly low number of mutations in AHSCT responders (dark green in Fig. 1B, non-responders are marked in yellow). Importantly, the number of DSBs was higher in dcSSc patients compared to post-AHSCT patients (mean 15 vs 5 pH2AX foci per nucleus, $p<0.05$) as well as compared to healthy controls (mean 5 pH2AX foci per nucleus, $p<0.05$). Preliminarily, patient fibroblasts also appeared resistant to apoptosis, further supporting their cancer-like characteristics.

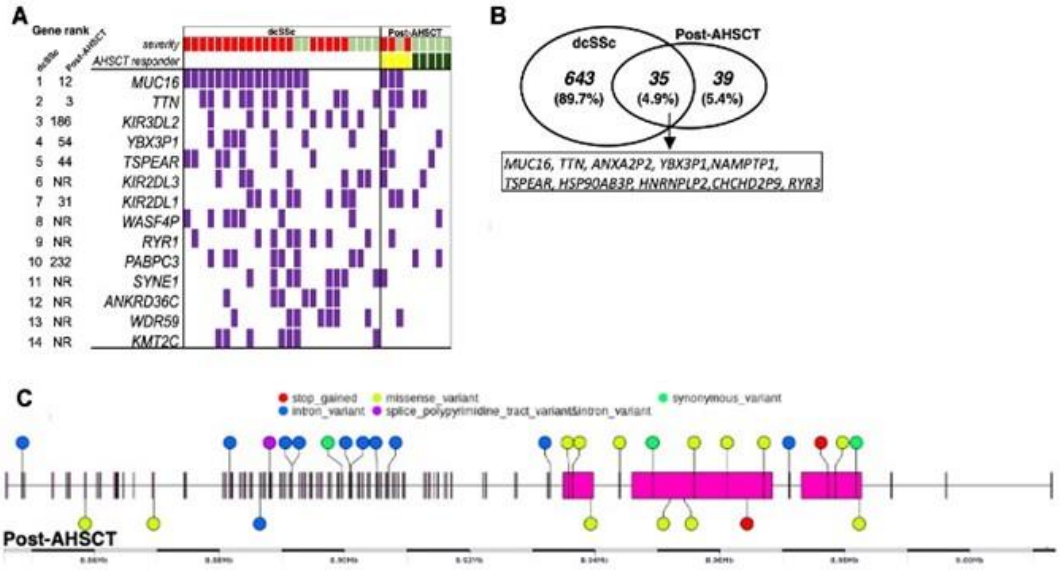

Fig. 1. A. MUC16 is the most frequently mutated gene in the dermis of dcSSc patients. B. AHSCT reduces recurrent mutations. C. Map showing types/locations of the recurrent mutations present in MUC16.

Conclusions: Genomic instability-associated high mutation burden in fibroblasts from dcSSc patients is virtually abrogated in AHSCT responders. We speculate that the AHSCT conditioning chemo/radiotherapy kills the cancer-like fibroblasts and that these cells are replaced by healthy fibroblasts, which might originate from hematopoietic stem cells.

[1]King's College Hospital, National Institute for Health Research and Welcome King's Clinical Research Facility and King's College, London, United Kingdom of Great Britain and Northern Ireland (the), [2]St James's Hospital, NHS Teaching Hospitals, Leeds, United Kingdom of Great Britain and Northern Ireland (the), [3]Johns Hopkins Medicine, Baltimore, United States of America (the), [4]Osaka University Graduate School of Medicine, Osaka, Japan, [5]University Health Network, Toronto, Canada, [6]Institute of Transfusion Medicine, University of Ulm, Ulm, Germany, [7]Institute for Clinical Transfusion Medicine and Immunogenetics, German Red Cross Blood Transfusion Service Baden-Württemberg-Hessen and University Hospital Ulm, Ulm, Germany, [8]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [9]Hospital Clínic de Barcelona, Barcelona, Spain, [10]Alexion, AstraZeneca Rare Disease, Boston, United States of America (the), [11]National French Reference Center for Aplastic Anemia and PNH (CeRAMIC), Assistance Publique des Hôpitaux de Paris, Hôpital Saint-Louis, Paris, France, [12]Hanyang University Seoul Hospital, Seoul, Korea (the Republic of)

Background: Danicopan (oral factor D inhibitor) add-on therapy showed significant clinical improvements in adult patients with ravulizumab- or eculizumab-treated paroxysmal nocturnal hemoglobinuria (PNH) and clinically significant extravascular hemolysis ([csEVH] hemoglobin [Hb] <9.5 g/dL; absolute reticulocyte count [ARC] ≥120×10^9/L), in phase 3 ALPHA trial (NCT04469465). There is limited evidence whether this translates to advanced age patients (≥65 years [y]). This study characterized efficacy and safety of danicopan add-on therapy in advanced age patients with PNH and csEVH from ALPHA trial.

Methods: This sub-analysis focused on primary treatment period, during which adult patients (≥18y) with PNH and csEVH with ≥6 months of ravulizumab or eculizumab treatment were randomized 2:1 to add-on danicopan or placebo for 12 weeks. Outcomes were evaluated by age at study enrollment (≥65y and <65y): change from baseline in Hb concentration, ARC, and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) score up to 12 weeks; proportion of patients who were transfusion-independent at 12 weeks; and proportion of patients with adverse events (AEs) during 12-week period.

Results: Eighty-six patients were enrolled into ALPHA; 57 randomized to add-on danicopan (≥65y, n=16; <65y, n=41), and 29 randomized to add-on placebo (≥65y, n=6; <65y, n=23). Mean (SD) baseline clinical characteristics were similar between age groups in danicopan (≥65y vs <65y: Hb, 7.6 [0.9] vs 7.7 [1.0] g/dL; ARC, 216.0 [40.4]×10^9/L vs 260.0 [109.8]×10^9/L; FACIT-F, 36.0 [8.5] vs 33.2 [12.2]) and placebo arms (≥65y vs <65y: Hb, 8.3 [0.8] vs 7.8 [0.1] g/dL; ARC, 201.1 [69.1]×10^9/L vs 228.6 [125.7]×10^9/L; FACIT-F, 38.3 [9.2] vs 29.9 [10.9]). In danicopan arm, both age groups showed increase in mean (SD) Hb from baseline to week 1 (≥65y vs <65y: 2.7 [1.0] vs 1.9 [1.0] g/dL); maintained in patients aged ≥65y and improved in those aged <65y through week 12 (≥65y, 2.8 [1.7] g/dL, 50.0% with ≥2.0 g/dL increase; <65y: 3.1 [1.4] g/dL, 56.1% with ≥2.0 g/dL increase). Both age groups demonstrated meaningful reduction in ARC (≥65y, −51.2 [74.4]×10^9/L; <65y, −105.3 [97.7]×10^9/L) and increases in FACIT-F score (≥65y, +4.9 [6.4]; <65y, +9.4 [7.9]). Conversely, placebo arm showed no improvements in Hb, ARC or FACIT-F from baseline to week 12 (≥65y vs <65y: Hb, 0.5 [0.6] vs 0.8 [0.9] g/dL; ARC, 9.0 [39.0]×10^9/L vs 0.1 [54.2]×10^9/L; FACIT-F, −4.0 [6.1] vs 4.6 [9.4]). In danicopan arm, proportion of transfusion-independent patients at week 12 was similar between age groups

(≥65y vs <65y: 75.0% vs 80.5%) and higher than placebo arm (30.4% vs 16.7%). Proportion of patients experiencing AEs in danicopan arm was similar between age groups (≥65y vs <65y: 68.8% vs 78.0%) and lower in placebo arm (≥65y vs <65y: 50.0% vs 65.2%).

Conclusions: This sub-analysis demonstrates that danicopan add-on to ravulizumab or eculizumab has positive efficacy and safety profile in advanced age patients with PNH and csEVH. During 12 weeks of danicopan therapy, patients reported meaningful improvements in Hb and ARC, maintained transfusion avoidance, and reported low rate of AEs.

HETEROGENEOUS NON-HEMATOLOGIC AUTOIMMUNE COMPLICATIONS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PEDIATRIC LEUKEMIA: INCIDENCE, SPECTRUM, AND OUTCOMES IN A SINGLE-CENTER COHORT

Amir Ali Hamidieh[1], *Pooya Ashkevari*[1], *Maryam Behfar*[1], *Leila Jafari*[1], *Sarina Ansari*[1]
[1]*Pediatric Cell and Gene Therapy Research Center, Gene, Cell and Tissue Research Institute, Tehran University of Medical Sciences, Tehran, Iran (Islamic Republic of)*

Background: Autoimmune diseases (ADs) are rare, non-GvHD immune-mediated complications, often underdiagnosed after Allo-HSCT. The precise mechanisms remain poorly understood due to the complex interactions between impaired immune-system reconstitution and various transplant-related factors. The clinical manifestations vary widely, depending on the underlying disease, ranging from hematologic to non-hematologic, organ-specific, or systemic involvement. Diagnosis and treatment of ADs are challenging, and the response to immunosuppressive therapies is often either incomplete or transient, with no standardized guidelines addressing the optimal approach to managing this potentially life-threatening complication. We aimed to evaluate the incidence, risk factors, and treatment of non-hematologic ADs after HSCT in pediatric patients with leukemia. To our knowledge, this study provides the first report of non-hematologic ADs in pediatric leukemia patients following Allo-HSCT.

Methods: We retrospectively analyzed 140 pediatric leukemia patients (95 ALL, 43 AML, 2 CML) who underwent Allo-HSCT from Jan 2017 to Mar 2023 at the Children's Medical Center, the country's central HSCT department.

Results: The incidence of non-hematologic ADs after Allo-HSCT was 5.7% (8/140), with a median time to the onset of autoimmunity of 13.73 months [7.54-29.31]. The median age at transplant was 9.04 years [0.83-17.9] for the non-AD group and 9.62 years [7-15] for the AD group (p=0.515). Observed ADs included Nephrotic Syndrome (n=3), Autoimmune Hepatitis accompanied by nephrotic syndrome (n=1), Vitiligo (n=2), Scleroderma (n=1), and Transverse myelitis (n=1).
All patients underwent a non-TBI myeloablative conditioning regimen (Busulfan, Cyclophosphamide, +/- rabbit-ATG). The majority of patients received HSCT from a fully matched donor, with PB as the primary graft source (127 non-AD, 8 AD). No statistically significant differences were observed between the two groups regarding donor or recipient gender, donor relationship, graft source, HLA matching, cytomegalovirus reactivation, aGvHD, or graft rejection. The relapse rate was 29.5% in the non-autoimmune group and 12.5% in the autoimmune group (p=0.439). cGVHD was significantly higher in the Autoimmune Group (75% vs. 36.4%, p=0.05).
Three patients with nephrotic syndrome were treated with systemic steroids and Mycophenolate in 2 cases, and cyclosporin in 1. The patient with autoimmune hepatitis and nephrotic syndrome received steroids, tacrolimus, and azathioprine. Two patients with vitiligo, initially resistant, were finally treated with prednisolone and Ruxolitinib. The patient with Transverse myelitis was treated with corticosteroid pulse, IVIG, and plasmapheresis.

The patient with Scleroderma was treated with systemic steroids and sirolimus. All achieved complete response.
The 3-year OS and DFS rates were 61% and 58.7% in the non-autoimmune group, compared with 83% and 82.3% in the autoimmune group (p=0.096 and 0.81, respectively).

Conclusions: Post-HSCT non-hematologic ADs in pediatric leukemia patients are diverse and differ from those in non-malignant diseases. The rate of AD incidence is consistent with prior research findings. cGvHD was associated with the development of ADs in this study, potentially due to a shared mechanism with autoimmunity, attributable to dysregulated immune reconstitution and impaired self-tolerance post-HSCT. Additionally, the relapse rate may reflect an increased graft-versus-leukemia effect in autoimmune patients. Early recognition and standardized management strategies are essential, as timely, tailored immunomodulatory therapy leads to high response rates and may improve long-term outcomes.

FROM VISION TO REALITY: EVALUATING SAFETY OF THE FIRST IN HOUSE IMPLEMENTED CD19 CAR-T IN UNITED ARAB EMIRATES FOR SLE PATIENTS

Mohamed Abu-Haleeqa[1], *Nameer Al Saadawi*[1], *Tahir Khan*[1], *Gianina Statache*[1], *Inas El Najjar*[1], *Jayakumar Dennison*[1], *Mansi Sachdev*[1], *Aseel Muhieddin*[1], *Sakher Obeidat*[1], *Yara Afifi*[1], *Sheima Ali*[1], *Shayma Alblooshi*[1], *Shinnette Lumane*[1], *Charisma Castelo*[1], *Yandy Marx Castillo-Aleman*[1], *Fatema Al Kaabi*[1], *Yendry Ventura*[1], *Rasha Wahdan*[1], *Asia Ibrahim*[1], *Lana Iskandarani*[1], *Loubna Hadi*[1], *Antonio Bencomo Hernandez*[1]
[1]*Abu Dhabi Stem cell Transplant, Abu Dhabi, United Arab Emirates (the)*

Background: SLE poses a substantial burden in the UAE and Middle East, with an age-standardized incidence of ~8.6/100,000 per year, a prevalence of ~103/100,000, and a mean diagnostic age of 28 years in Emirati patients. Biologic B-cell–targeted therapies such as rituximab and BAFF (BlyS) inhibitor therapy such as belimumab have advanced disease control by reducing autoantibody production and modulating immune activation. For refractory cases, autologous stem cell transplantation provides an immune reset, achieving remission in approximately two-thirds of patients but with notable treatment-related mortality. CD19 CAR-T cell therapy offers a deeper and more durable immune reprogramming by eliminating a broad spectrum of B-cell populations, with early data showing sustained disease control. This poster presents the first implementation and safety outcomes of locally manufactured CD19 CAR-T therapy in the UAE.

Methods: Patients meeting stringent disease-specific criteria—including the 2019 ACR/EULAR SLE classification, active organ involvement (≥1 BILAG A or ≥2 BILAG B), persistent seropositivity, and failure of at least two to three immunosuppressive agents—are first evaluated by rheumatologists. Multidisciplinary meetings with rheumatology and

hematology ensure coordinated assessment and eligibility. Three candidates were identified and underwent comprehensive screening to confirm fitness for the CAR-T process, including tolerance of leukapheresis, lymphodepletion chemotherapy, and appropriate immunosuppressive washout. Autologous leukapheresis was performed using the Spectra Optia platform to collect approximately 2 × 10^9 $CD3^+$ T cells, subsequently transduced in a GMP-compliant facility using the CliniMACS Prodigy system and a CD19-targeted lentiviral vector. After rigorous quality control—including sterility, immunophenotyping, and vector copy number—patients received lymphodepletion with fludarabine (25 mg/m^2 for three days) and cyclophosphamide (1,000 mg/m^2 for one day). A single infusion of 1.0 × 10^6 CD19 CAR-T cells/kg was administered, with expansion monitored by flow cytometry and clinical response evaluated through serologic markers and organ assessments. Adverse events were graded per 2018 ASTCT consensus criteria.

Results:

Characteristics	Patient 1	Patient 2	Patient 3
Age	61	39	42
Sex	F	M	F
Disease Duration	21 years	25 years	7 years
Indication	SLE with refractory ITP and AIHA (BILAG A)	SLE with antiphospholipid syndrome & acquired haemophilia (BILAG A)	Refractory lupus nephritis (IV/V A) (SELENA-SLEDAI 17)
ICU Admission	1 day	0	0
WBC Recovery	Day +11	Day +9	Day +7
CAR-T Expansion	Day +10 (69.0%)	Day +10 (47.18%)	Day +10 (41.20%)
CRS	Grade 1 (Tocilizumab)	Grade 1 (Tocilizumab)	Grade 0
ICANS	0	0	0
Admission (days)	30	22	14
Post CAR-T Follow-up	12 months	7 months	4 months
Post-discharge Infections	CMV reactivation (valganciclovir)	URTI	CMV reactivation (valganciclovir)
Hypogammaglobulinemia	No	No	No
B cell Recovery	D+124	D+54	Pending
Clinical condition	Drug-free remission; active, exercising, No episode of ITP or AIHA (BILAG D)	Drug-free lupus remission; improved life quality & fatigue; LMWH prophylaxis (BILAG D)	Off all IS; Prednisolone 3 mg daily; C3/C4 NL; remission (SLEENA-SLEDAI 2)

The three patients with systemic lupus erythematosus (SLE) treated with CD19 CAR-T therapy had a mean age of 47 years (range 39–61) and included two females and one male. Median disease duration was 21 years (range 7–23), with significant baseline comorbidities including refractory immune thrombocytopenia, autoimmune hemolytic anemia, recurrent thrombosis, life threatening bleeding episodes complicated with acquired hemophilia A and class IV/V active lupus nephritis. Hematologic recovery was rapid, with a mean WBC

recovery by Day +9 (range Day +7 to Day +11), and CAR-T expansion averaged 52% (range 41–69%). Treatment demonstrated a favorable safety profile: two patients developed grade <3 cytokine release syndrome resolving after a single tocilizumab dose, and no grade ≥4 CRS or ICANS occurred. One patient developed Local Immune Effector Cell–Associated Toxicity Syndrome (LICATS), which resolved within a month on steroids. Two patients experienced CMV reactivation, managed successfully with oral valganciclovir. All patients are alive and off immunosuppressive therapy at a median six-month follow-up, with one maintaining remission for one year.

Conclusions: UAE's locally produced CD19 CAR-T therapy for SLE shows feasibility, safety, and powerful efficacy, inspiring a bold new era of accessible cellular treatments transforming autoimmune care worldwide for patients.

REDUCTION OF INTERLEUKIN-6 AND INTERLEUKIN-8-MEDIATED INFLAMMATION AND PROLIFERATION IN SKIN FIBROBLASTS IN SYSTEMIC SCLEROSIS AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION MEASURED BY GENE EXPRESSION ANALYSES

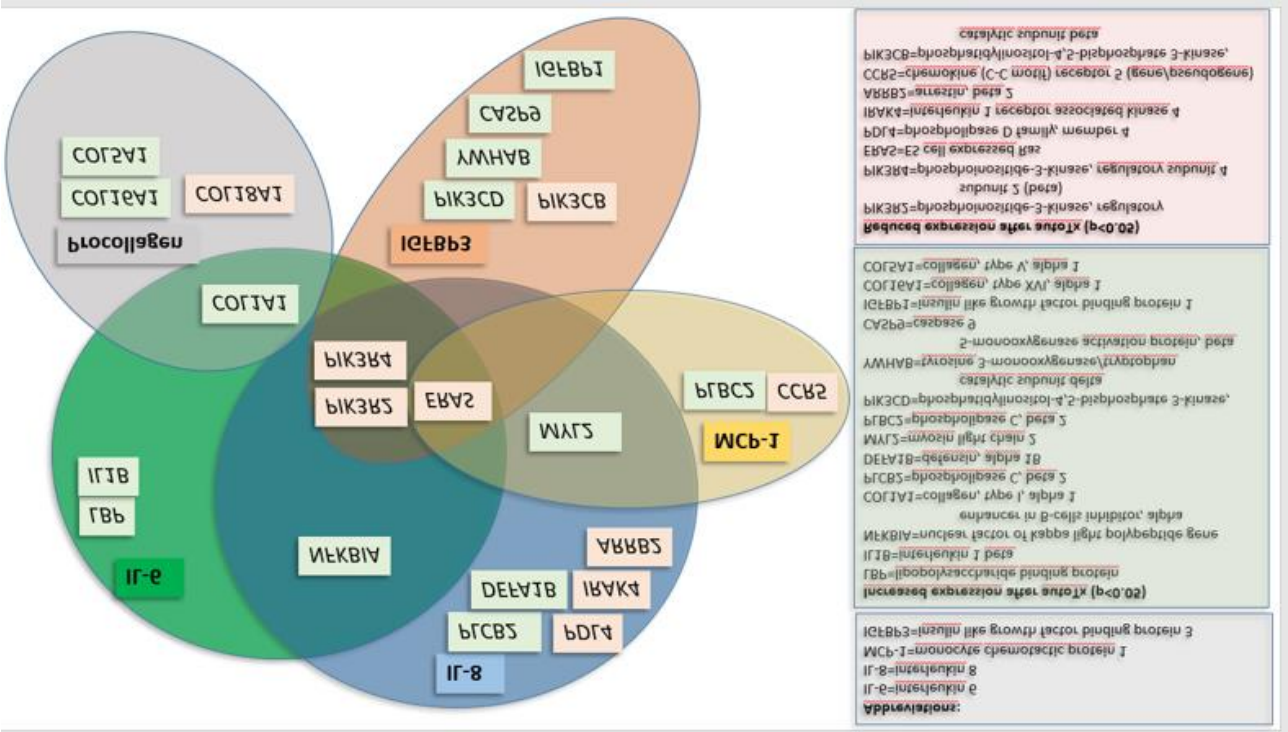
Gunter Assmann[1], *Felix Dust*[1], *Christoph Rittich*[2], *Alina Boll*[1], *Christoph Moehle*[3], *Ann-Christin Pecher*[4], *Joerg Henes*[4], *Frank Neumann*[5]
[1]*RUB University Hospital Minden JWK, Minden, Germany,* [2]*Practical Office of Rheumatology, Daun, Germany,* [3]*Kompetenzzentrum für Fluoreszente Bioanalytik (KFB), Regensburg, Germany,* [4]*Centre for Interdisciplinary Clinical Immunology, Rheumatology and Auto-inflammatory Diseases and Department of Internal Medicine II (Oncology, Haematology, Immunology and Rheumatology), University Hospital Tuebingen, Tuebingen, Germany,* [5]*José Carreras Center for Immuno- and Gene Therapy, University of Saarland, Homburg/Saar, Germany*

Background: Systemic sclerosis (SSc) is an autoimmune connective tissue disease defined by fibrosis of the skin and internal organs. Early severe courses of SSc should be treated with intensified therapy such as hematopoietic stem cell transplantation (autoTx). The effect of the therapy is evident, particulary, in a reduction in skin fibrosis and its complications. However, it is not yet sufficiently clear which pathogenetic mechanisms can be influenced by autoTx.

Methods: Here we investigated cultures of skin fibroblasts derived from 4 SSc patients by skin biopsy (4 months) prior to and after successful autoTx. SSc patients (n=4, aged 43 to 59 years, male/female: 2/2) underwent a skin biopsy of the lateral abdominal wall or forearm. After 4 passages of the cell culture according to standard procedure (native or TGF-beta stimulated), the cell supernatant was tested for concentrations of the following

chemokines: interleukin-6, interleukin-8, MPC-1 (monocyte chemotactic protein–1), procollagen, IGFBP3 (insulin-like growth factor binding protein 3); in addition, the genes (n=341) belonging to the gene family of the above-mentioned chemokines were examined and evaluated with microarray (mRNA concentrations) before and after autoTx. The differences in expression before and after autoTx were evaluated using t-test (and Fisher's correction). The ethics committee of the Saarland Medical Association has approved the experimental study (EK120/23).

Results: IL-6, IL-8, MCP-1, and IGFPB3 secreted by skin fibroblasts showed a reduced cell supernatant concentration in SSc patients after autoTx whereas the procollagen secretion increased: IL-6 (native) 0.13 vs. 0.07 ng/ml, p=0.06; IL-8 (TGF-beta stimulated) 1688 vs. 728 ng/ml, p=0.01; MCP-1 (native) 0.38 vs. 0.36, p=0.79; IGFBP3 (native) 18.7 vs. 5.5, p=0.02; procollagen (native) 800 vs. 1232 pg/ml, p=0.03. Following gene expression analysis of the cell supernatant, Figure 1 shows the change in expression of the respective gene when it increases (green) or decreases (red) significantly ($p<0.05$) in comparison to pre-autoTx. For several chemokines at the same time, the significant upregulation of the NFKBIA gene (nuclear factor of kappa light polypeptide gene enhancer in B-cells inhibitor, alpha) appears to be important for the inhibition of inflammation, and the MYL2 gene (myosin light chain 2) preferentially for the activation of repair mechanisms; On the other hand, PIK3R2 (phosphoinositide-3-kinase, regulatory subunit 2beta), PIK3R4 (phosphoinositide-3-kinase, regulatory subunit 4), and ERAS (ES cell expressed Ras) are significantly downregulated by autoTx as inflammation/proliferation-mediating genes.



Conclusions: Consecutive skin biopsies in SSc patients after therapy with autoTx show activation of certain genes at the molecular level with predominantly anti-inflammatory

and/or anti-fibrotic regenerative effects. The extent to which the data suggest staging with skin biopsy for therapy management in SSc remains unclear due to the small number of cases.

Clinical Trial Registry: n.a.

SAFETY OF RAVULIZUMAB USE IN PREGNANCY: INSIGHTS FROM A GLOBAL PHARMACOVIGILANCE ANALYSIS

*Heather Sherrard[1], Cynthia Carrillo-Infante[1], Arshad Mujeebuddin[1], **Cory Williams**[2]*
[1]Alexion, AstraZeneca Rare Disease, Boston, United States of America (the), [2]Alexion, AstraZeneca Rare Disease, New Haven, United States of America (the)

Background: Ravulizumab, a second-generation C5 complement inhibitor and an analog of eculizumab, is approved for the treatment of hematologic and complement-mediated disorders including paroxysmal nocturnal hemoglobinuria (PNH) and atypical hemolytic uremic syndrome (aHUS) in adults and pediatric patients, as well as rare autoimmune diseases (generalized myasthenia gravis [gMG] and neuromyelitis optica spectrum disorder [NMOSD]) in adults. PNH and aHUS are disorders associated with high maternal and fetal morbidity in pregnancy. There are multiple reports on the use of eculizumab (approved for the same four indications) in pregnant patients where no safety signals have been observed. However, the safety profile of ravulizumab with respect to use during pregnancy and lactation, including its potential effects on fetal development and breastfed infants remain incomplete. This analysis aims to provide insights into pregnancy-related safety following ravulizumab exposure using data from global post-marketing surveillance.

Methods: Here, we analyze all pregnancy cases reported globally in the post-marketing setting of ravulizumab, with ≥1 documented dose of exposure. Data from both spontaneous and solicited cases recorded in the Alexion pharmacovigilance database from the initial market approval up to June 26, 2025 were included in the analysis. Descriptive statistics were used to summarize patient demographics, treatment patterns, and pregnancy outcomes.

Results: Among the 256 identified pregnancy cases with ≥1 dose of ravulizumab exposure, hematologic conditions represented a substantial proportion of underlying maternal diagnoses (PNH [n=117], aHUS [n=56]). Of the non-hematologic conditions, underlying maternal diagnosis included gMG (n=29) and NMOSD (n=12). Among 79 cases with data on pregnancy outcomes, the distribution of ravulizumab exposure included full-pregnancy exposure in 26.6%, ravulizumab to eculizumab switch during pregnancy in 26.6% and incomplete exposure details reported in 43.1%. Pregnancy outcomes included live births (n=51), spontaneous abortions (n=22), fetal deaths (n=3), and elective terminations (n=3). Moreover, in a subset of 38 pregnancies (PNH [n=19]) more detailed information was available on ravulizumab exposure. Maternal co-morbidities reported, predominantly in PNH,

were aplastic anemia (n=4), Budd-Chiari syndrome (n=2), hypertension including gestational (n=3), and gestational diabetes (n=1). In this subset, 29 were live births (PNH [n=15]), of which, 16 had ravulizumab exposure throughout all trimesters, 3 had exposure beyond 12 weeks but discontinued prior to delivery, and 8 had exposure limited to the first trimester (≤12 weeks).

Conclusions: This analysis provides real-world insights on the use of ravulizumab in pregnancy and suggests no unexpected safety signals, similar to analyses on the use of eculizumab during pregnancy. These findings may inform clinical decision-making. As additional data are needed, a global observational study (NCT06312644) evaluating the safety of ravulizumab during pregnancy is currently ongoing.

Disclosure: Heather Sherrard was an employee of Alexion, AstraZeneca Rare Disease at the time of the analysis.
Cynthia Carrillo Infante, Arshad Mujeebuddin and Cory Williams are employees of Alexion, AstraZeneca Rare Disease.

MMR SEROLOGIC STATUS IN MULTIPLE SCLEROSIS AFTER AUTOLOGOUS STEM CELL TRANSPLANTATION

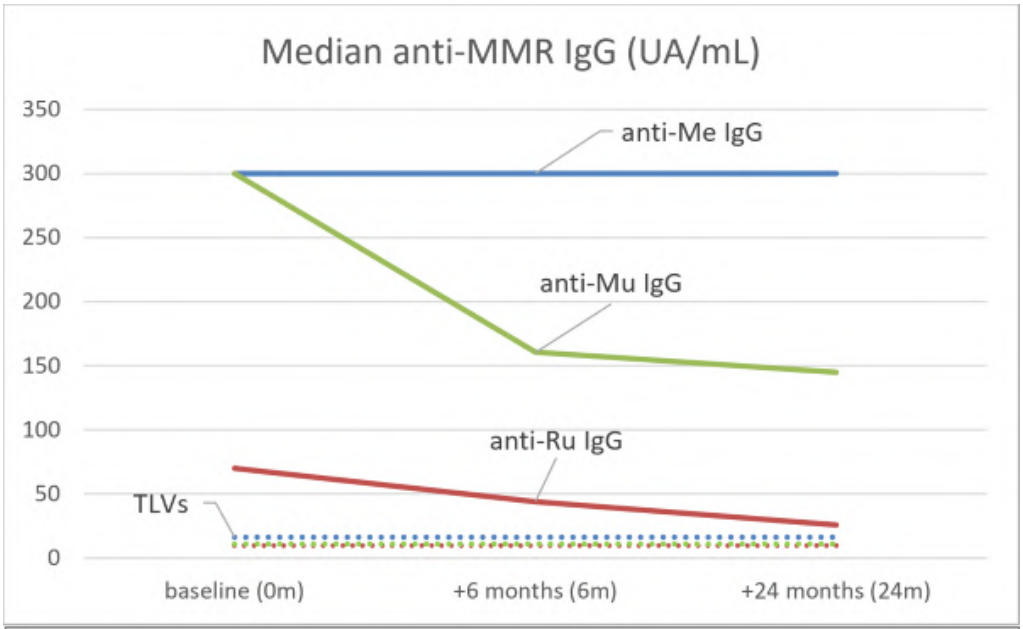
Edoardo Simonetti[1], *Alice Mariottini*[2], *Maria Pia Amato*[2], *Matteo Betti*[2], *Anna Maria Repice*[1], *Ilaria Cutini*[1], *Antonella Gozzini*[1], *Chiara Camerini*[1], *Giacomo Coltro*[1], *Riccardo Boncompagni*[3], *Chiara Innocenti*[4], *Mirella Giordano*[1], *Gaia Mirabella*[2], *Roberta Lepori*[1], *Sabrina Castiglione*[1], *Claudia Boglione*[1], *Luca Massacesi*[2], *Chiara Nozzoli*[1]
[1]*Careggi University Hospital, Florence, Italy,* [2]*University of Florence, Florence, Italy,* [3]*Santa Rosa Hospital, Viterbo, Italy,* [4]*Livorno Hospital, Livorno, Italy*

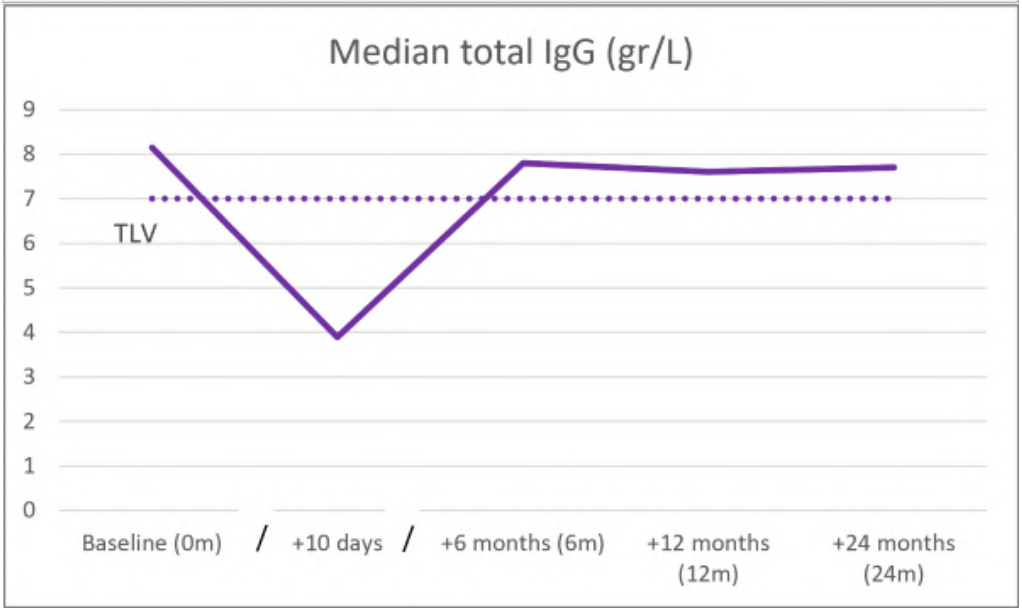
Background: Multiple sclerosis (MS) patients undergoing autologous stem cell transplantation (ASCT) after carmustine, cytarabine, etoposide, melphalan (BEAM) or cyclophosphamide (Cy) chemotherapy plus rabbit anti-thymocyte globulin (rATG) are considered as naïve to vaccines and offered revaccination; live vaccines as measles/mumps/rubella (MMR) are not recommended before 24 months from ASCT with concern about vaccine-induced infectious disease.

Methods: We retrospectively analysed MMR specific IgG at baseline (0m), 6 months (6m); 24 months (24m) in MS patients transplanted in Florence over a 10-year period (29/04/2015 - 07/04/2025). Due to a laboratory-technique change, qualitative data (positive, intermediate, negative) were available for the whole study population while quantitative IgG titles were available only for a subgroup. Median IgG titles at 0m, 6m, 24m were compared with median total IgG trend in the same patients at the same time points and in two additional at 10 days and 12 months (12m) after ASCT.

Results: Among 65 patients transplanted in the index period, 39 had at least one post-ASCT assessment at 6m or 24m (M/F ratio: 8/31; median age: 40; median prior lines of therapy: 3, range 1-7; BEAM-rATG/CY-rATG conditioning: 36/3; rATG dose 7.5 mg/5 mgKg: 37/2).

None of patients experienced clinical MMR infection or received immunization after ASCT.Data were available at all the timepoints (0m; 6m; 24m) for 16/39 patients (41%); 14/39 (35.9%) were evaluable at baseline and at a single post-ASCT timepoint (eight at 6m; six at 24m), whereas 9/39 (23.1%) had the 24m assessment only. All the patients except for two (28/30) maintained baseline MMR serologic status post-ASCT. The two patients who lost either MMR (ID23) or rubella immunity (ID35) had both low titles at baseline; prior to ASCT, they had received interferon and 3 lines of therapy (interferon, fingolimod, ocrelizumab), respectively. The 9 patients evaluable at 24m only were all MMR IgG positive, hence putatively maintaining a pre-ASCT positivity.
In the whole cohort 37/39 (94.9%) patients maintained MMR baseline immune status at 6m and 29/31 (93.5%) at 24m.
Regarding MMR IgG title,14/39 (35.9%) patients were evaluable between 0-6 and 24 months: median values over time in comparison with median total IgG and relative threshold limit values (TLVs) are shown in figure 1. Measles specific IgG were the most stable, while mumps and rubella declined over time. Total IgG decreased earlier with a nadir at +10 days and full recovery before 6m after ASCT.





Conclusions: In our real-life population of ASCT-treated MS, the vast majority of patients retained MMR immunity with a slight decline of vaccine titres over time confirming that MMR revaccination could be safely postponed after 24 months from ASCT and probably offered only in selected patients at high risk (i.e. low titles at baseline, work exposure). The different time trend between total and specific IgG titres, rapidly returning to normal and stable values and declining over time, respectively, may represent an indirect demonstration of a reassortment of IgG idiotypes following plasma cells and B cells repertoire modification in the context of the well-known immune-reset after ASCT in MS.

INFECTIOUS COMPLICATIONS IN DUTCH MS-PATIENTS WITHIN THE FIRST YEAR AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A FOREIGN COUNTRY

Lara Suzanne Oosterom[1], *Sanne Haar*[1], *Aisa L. Scheper*[1], *Melissa S. Wolf*[1], *Goda C W. Choi*[2], *Ellen P.A. Kramer*[3,4], *Gerald JD Hengstman*[4]
[1]*Rijksuniversiteit Groningen, Groningen, Netherlands (the),* [2]*Univerity Medical Centre Groningen, Groningen, Netherlands (the),* [3]*Amsterdam University Medical Centre, Amsterdam, Netherlands (the),* [4]*Upendo, Boxtel, Netherlands (the)*

Background: Autologous hematopoietic stem cell transplantation (aHSCT) is only imbursed to a limited extent as a treatment for Multiple Sclerosis (MS). This results in Dutch patients looking for aHSCT treatment abroad. The aim of the study is to investigate infectious complications and mortality in self-referred MS patients who have traveled abroad to undergo HSCT.

Methods: Through retrospective cohort examination of 53 patient files of Dutch MS-patients who have been treated on their own initiative with aHSCT in a foreign country, the number of infections and mortality within a year after the treatment, have been analysed using descriptive statistics. The results are compared to data that have been found through literature research concerning MS-patients who have undergone aHSCT in their own country.

Results: 53 patients were included (71.7% women, the average age at the time of treatment is 41.6 (range: 24-62). Of these 50.9% had relapsing remitting MS (RRMS), 26.4% had secondary progressive MS (SPMS) and 22.6% had primary progressive MS (PPMS). The treatment they received was in the following countries: 37 patients in Mexico, 12 in Russia (Moscow), 1 in Norway, 1 in Sweden, and 2 in Belgium. The number of infections the patients had was compared with that of 507 American MS-patients who underwent aHSCT in the United States (62.3% women), average age 36.6 (range: 17-60), 81.7% had RRMS, 18.3% had SPMS, none had PPMS. The Dutch patients had, on average, 1 infection during the year after aHSCT. The American reference group had, on average, 0.51 infections in the year after aHSCT. In the population as a whole, people on average have 2-4 infections per year. The mortality (0 deceased patients) among the Dutch patients was compared to patients who underwent aHSCT in their own country (United States (507 patients, 1 deceased (0.19%)).

Conclusions: This study shows that among patients with MS who travel abroad on their own initiative to undergo aHSCT, there is no increased mortality after returning home compared with MS patients treated within their own country. The number of infections is, while higher than the group treated in their own country, still low and not statistically significant. Compared with the literature, patients who self-referred include a higher proportion with

progressive MS, a condition known to make patients more prone to infections due to a usually higher level of disability and higher age compared to patients with RRMS.

Disclosure: Nothing to declare

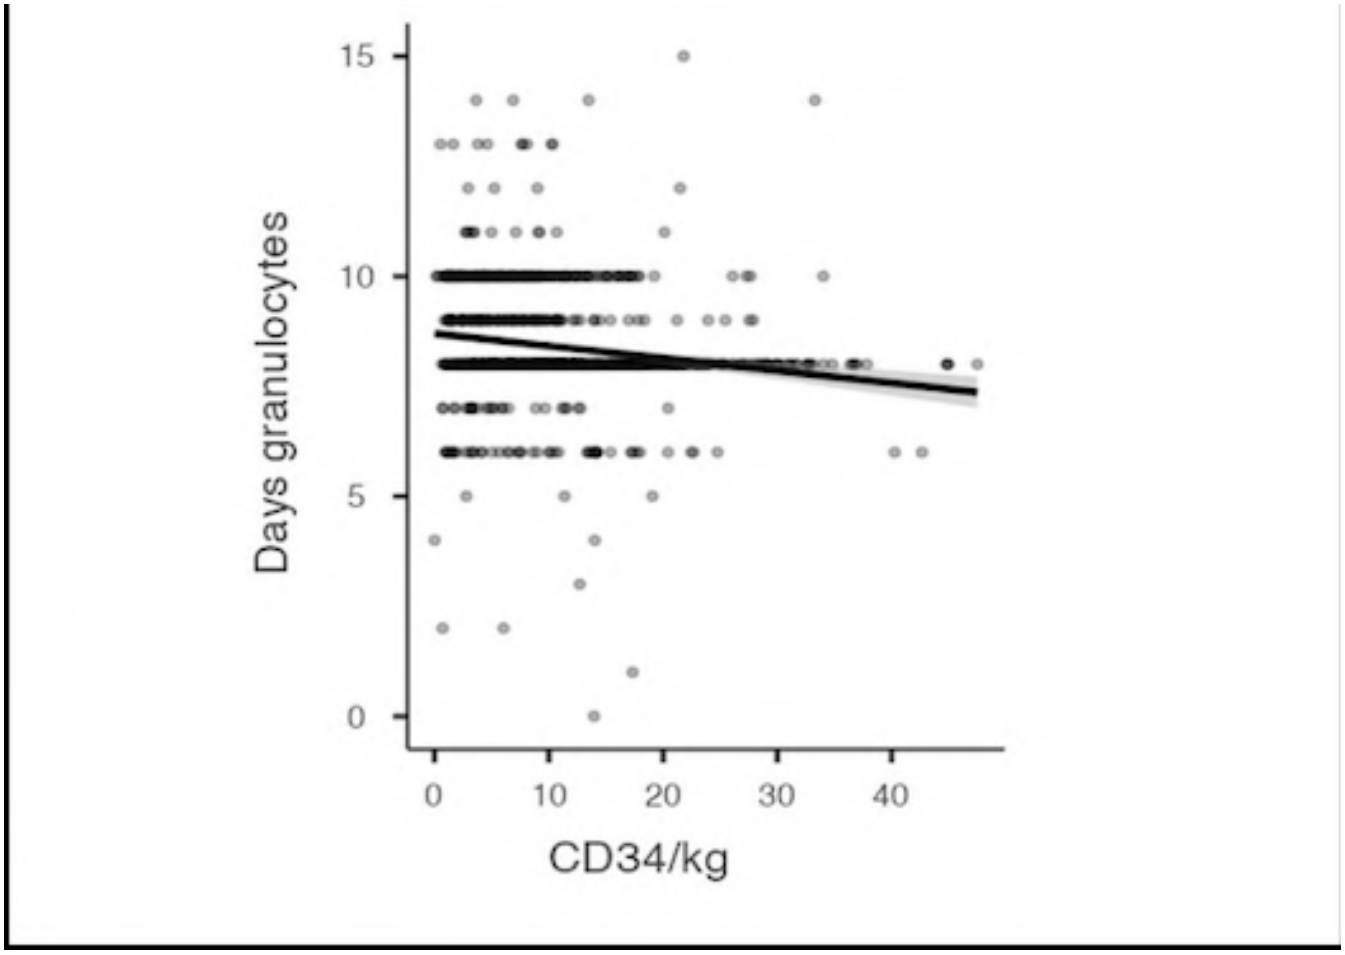
NUMBER OF CD34 CELLS EMPLOYED IN AUTOLOGOUS HEMATOPOIETIC STEM-CELL TRANSPLANTATION FOR PERSONS WITH MULTIPLE SCLEROSIS IS NOT RELATED TO THE NEUROLOGICAL OUTCOME OF THE PROCEDURE

Guillermo J. Ruiz-Argüelles[1], *Michelle Lavoignet-Cisneros*[1], *Olivia Lira-Lara*[1], *Miguel Angel Viveros-Lugo*[1], *Sofia Chávez-Martínez*[1], *Monica Daniela Salgado-Cabrera*[1], *Lidia Joanna Alberto-López*[1], *Juan Carlos Olivares-Gazca*[1], *Max Robles-Nasta*[1], *Guillermo J. Ruiz-Delgado*[1]
[1]*Centro Hematología y Medicina Interna, Clínica Ruiz, Puebla, Mexico*

Background: CD34 is expressed on hematopoietic stem and progenitor cells (HSPCs) and is widely used to assess graft adequacy in transplantation. Autologous HSCT (aHSCT) has become an effective treatment for multiple sclerosis (MS), but the relationship between infused $CD34^+$ cell dose and neurological outcomes remains unclear.

Methods: We retrospectively analyzed 1 417 MS patients (64.6% women; median age 46 years) who underwent aHSCT at HSCT Mexico between June 2015 and March 2025. Mobilization used cyclophosphamide (50 mg/kg) and filgrastim (10 µg/kg/day); products were infused fresh without cryopreservation. Conditioning followed the "Mexican Method" (high-dose cyclophosphamide + rituximab). Neurological response was defined as stabilization or improvement in EDSS after transplant. Median $CD34^+$ dose was 8.27×10^6 cells/kg (IQR 4.4–12.9).

Results: Median recovery for granulocytes > 0.5×10^9/L and platelets > 20×10^9/L was 8 and 10 days. Correlations between $CD34^+$ dose and hematologic recovery were weak ($r = -0.169$ and -0.012). Among 564 patients with follow-up, 460 (81%) achieved neurological stabilization or improvement, with similar rates across MS subtypes (RRMS 81.3%, PPMS 82.5%, SPMS 83%). The correlation between $CD34^+$ dose and neurological response was negligible ($r = 0.016$).



Conclusions: Thus, aHSCT induces neurological benefit in MS independent of CD34⁺ dose, supporting the efficacy of the outpatient "Mexican Method".

BEYOND STEM CELLS; DUAL NK-CELL POPULATION IN STEM CELL GRAFT MAY CONTRIBUTE TO IMMUNE RESET POST AUTOLOGOUS STEM CELL TRANSPLANTATION FOR MULTIPLE SCLEROSIS

Shahna Barrett[1], *Latoya Reid*[1], *Oliver Gittner*[2], *Matthias Klammer*[3]
[1]*University Hospital of the West Indies, Kingston, Jamaica,* [2]*Steve Mills Stem Cell and Immunotherapies Laboratory, Southampton, United Kingdom of Great Britain and Northern Ireland (the),* [3]*St. George`s University Hospital, NHS Foundation Trust, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Autologous stem cell transplantation (ASCT) is emerging as an important therapeutic modality for patients with relapsing-remitting multiple sclerosis (MS) after previous lines of highly effective disease-modifying treatments. We previously described immune recovery post ASCT in MS and reported early NK-cell reconstitution post ASCT. Now we further investigate the immune cell composition of the stem cell graft for 12 patients.

Methods: 16 patients undergoing ASCT for MS were monitored with serial lymphocyte subset analyses (CD4, CD8, NK and B cells) monthly for three months and at 6 and 12 months. Autologous stem cells were mobilized with Cyclophosphamide 1.5 mg/m^2 and G-CSF and patients underwent ASCT after conditioning with Cyclophosphamide and ATG. In 12 patients, the non-stem cell component of the graft was analyzed by flow cytometry for lymphocyte subsets using defrosted cryovials.

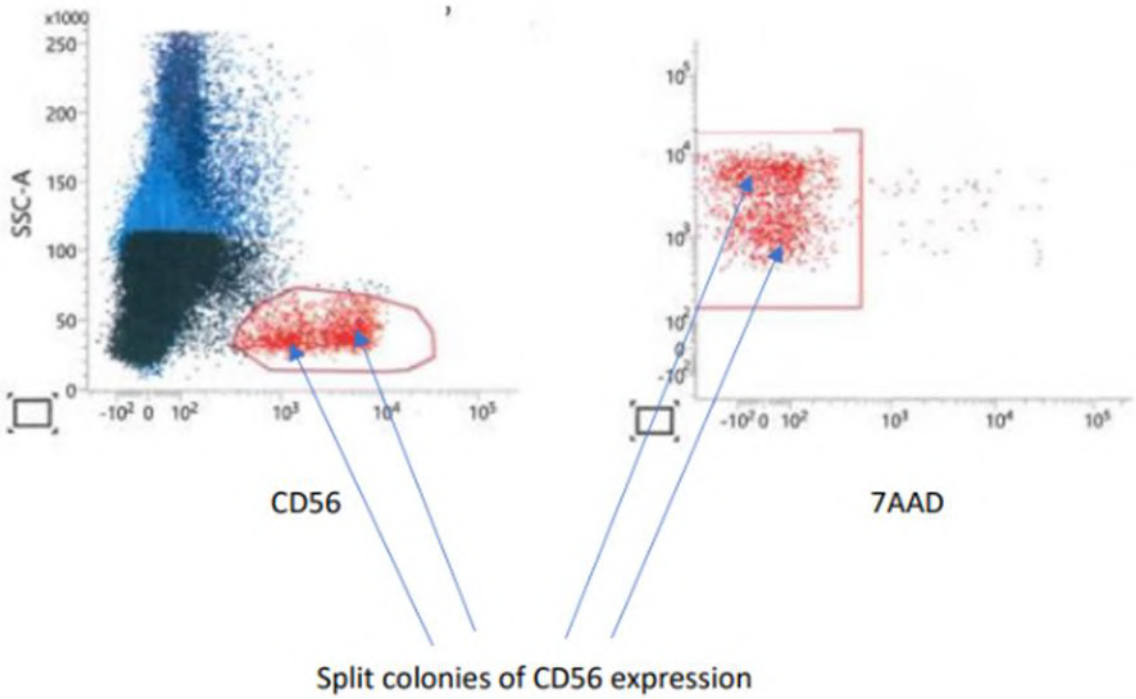
Results: Patient and disease characteristics for the 12 patients analyzed are summarized in table 1. There was a high degree of variability in immune cell composition in stem cell product for all the patients studied. Nonetheless, early NK-cell reconstitution was a consistent feature in this patient cohort. In the early post-transplant period (day +30), the highest absolute number of NK cells was seen with a decline to low normal numbers in subsequent time points. 8 of the 12 patients studied showed a dual population of NK cells in the stem cell product, with variable CD56 expression, possibly representing CD56 dim and CD56 bright populations, although more work is required to characterize these populations further.

Table 1: Patient and Disease Characteristics for 12 Patients who Underwent ASCT for MS Between 2019 and 2023

Number of Patients	12
Sex No. (%)	
Male	5 (42%)
Female	7 (58%)
Age (years)	
Median	29.5
Range	24- 49
Duration of MS (years)	
Median	6
Range	1-23
Expanded Disability Status Scale (EDSS) Score	
Median	3.75

Lines of Therapy	
Median	2
Last Immunosuppresive Therapy prior to ASCT No. (%)	
Alemtuzumab	4 (33%)
Natalizumab	5 (42%)
Ocrelizumab	3 (25%)
Duration between Last Disease-Modifying Therapy and ASCT (months)	
Median	12

Figure 1: Flow Cytometric Analysis Demonstrating Dual NK-Cell Colonies



Conclusions: There is no clear correlation between immune-cell composition of the graft and dynamics of reconstitution post ASCT for MS. We focused our interest on the consistent early NK reconstitution encountered in this patient cohort. The presence of two distinct NK-

cell populations in the majority of stem cell grafts needs to be studied further. CD56 bright NK cells have been reported to effect immune modulation and autoreactive T cell control.

Disclosure: Nothing to declare.

B347

AUTOLOGOUS STEM CELL TRANSPLANTATION FOR ANTI-SYNTHETASE SYNDROME: LONG-TERM OUTCOMES FROM TWO REFRACTORY CASES

Michel Lu[1], *Karuna Keat*[2], *John Moore*[1]
[1]*St Vincent's Hospital, Sydney, Australia,* [2]*Campbelltown Hospital, Sydney, Australia*

Background: Anti-synthetase syndrome (ASSD) is a rare, heterogenous autoimmune disorder characterized by the presence of anti-aminoacyl-tRNA synthetase antibodies, such as anti-Jo-1. Although pathogenesis remains unclear, immune dysregulation with loss of self-tolerance is the hypothesised key pathogenic mechanism. The treatment paradigm for ASSD is not well-defined, particularly in steroid-refractory cases. Various therapies have been trialed, including intravenous immunoglobulin (IVIg), immunosuppressants like cyclophosphamide and rituximab, and more recently chimeric antigen receptor T-cell (CAR-T) therapy.

Methods: This case series presents two cases successfully treated with autologous stem cell transplant (ASCT) using nonmyeloablative conditioning, consisting of cyclophosphamide and thymoglobulin. Disease activity was assessed using biomarkers such as creatine kinase (CK) and measures of respiratory function, including Forced Expiratory Volume in 1 second (FEV_1), Forced Vital Capacity (FVC), and Diffusing Capacity of the Lungs for Carbon Monoxide (DLCO).

Results: **Case 1:** A 65-year-old man presented in 2019 with anti-Jo1–positive ASSD, manifesting as arthritis, interstitial lung disease (ILD) and myositis with myocardial involvement. Initial therapy of pulse methylprednisolone, cyclophosphamide, and IVIg induced a partial response. Over the following 18 months, he experienced multiple relapses despite sequential immunosuppressive strategies including mycophenolate mofetil, rituximab, ciclosporin, tacrolimus, and repeated corticosteroid pulses. Due to persistent progression and limited treatment options, the patient underwent an ASCT in July 2021. Post-transplant, he achieved sustained clinical and biochemical remission with follow up now extending beyond 4 years. He remains stable on a reducing dose of prednisone, weaned to 5mg for the last 2 years from the initial 50mg dose, and maintenance IVIg.
This first case illustrates an optimal outcome following ASCT, with sustained remission allowing a significant reduction of DMARD therapy and corticosteroid use with durable disease control despite multiorgan involvement initially. Disease response to various treatments is summarised in Figure 1.

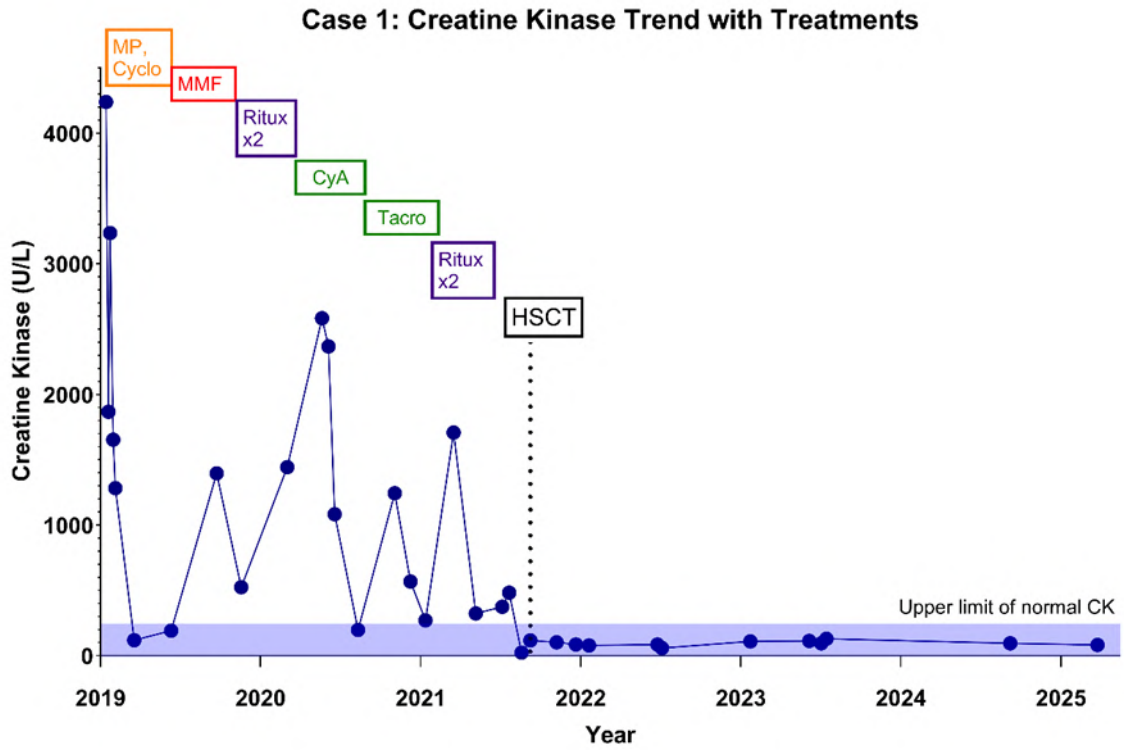


Figure 1: Creatine Kinase trend with treatments

Case 2: A 46-year-old woman with Jo-1–positive ASSD initially responded to glucocorticoids, cyclophosphamide, and hydroxychloroquine but experienced multiple relapses requiring escalation to IVIg, tofacitinib, and rituximab. Progressive disease led to an ASCT in March 2024, followed by nine months of stability. Two later flares were controlled with lower-dose prednisone, maintenance IVIg, and six-monthly rituximab. CAR-T therapy remains on hold due to improvement. Pre-relapse flow cytometry showed B-cell reconstitution and an inverted CD4:CD8 ratio driven by elevated CD8+ T cells.
This second case, while less favourable, demonstrates that ASCT can control the most aggressive ASSD phenotypes, enabling disease stability with lower-toxicity maintenance therapy. It also provides insight into ASSD pathophysiology, suggesting lymphocyte subset monitoring may help predict relapse and informing how ASCT and emerging options like CAR-T might be sequenced.

Conclusions: Our cases support ASCT as a viable option for selected ASSD patients amid growing interest in advanced cellular therapies such as CAR-T. While CAR-T shows promise, its long-term outcomes and accessibility remain uncertain. In contrast, ASCT offers multi-year follow-up data and comparatively lower cost, at approximately $60,000 AUD (internal costings).

Disclosure: Nothing to declare.

B348

OUTCOMES OF AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH MULTIPLE SCLEROSIS: EXPERIENCE FROM SOUTH AFRICA

*Justin du Toit[1], **Adam Setzer**[1], Saiesha Dindayal[1], Adam Mohamed[1], Jenna Damelin[1], David Brittain[2], Andrew McDonald[2], Devan Moodley[1], Jackie Thomson[1]*
[1]University of the Witwatersrand, Johannesburg, South Africa, [2]ACTlife Netcare, Pretoria, South Africa

Background: Multiple sclerosis (MS) is a chronic, immune-mediated demyelinating disease that remains a major cause of neurological disability in young adults. While disease-modifying therapies (DMTs) can delay progression, many patients with highly active relapsing–remitting MS (RRMS) continue to experience breakthrough disease. Autologous haematopoietic stem cell transplantation (ASCT) offers durable immune reconstitution and remission but remains underutilised in upper-middle-income settings such as South Africa.

Methods: We conducted a retrospective review of all MS patients who underwent ASCT between 1 January 2009 to 31 December 2024 at two JACIE-accredited tertiary centres (Wits Donald Gordon Medical Centre, Johannesburg; and Netcare Pretoria East Hospital, Pretoria). Data were extracted from institutional transplant records and analysed using descriptive statistics and Kaplan–Meier survival estimates.

Results: Thirty-two patients were included (median age 42 years; 53% female; 94% RRMS). Median disease duration was 7.4 years, and 97% had received prior DMTs. Conditioning included cyclophosphamide (97%), anti-thymocyte globulin (69%), and fludarabine (34%). Treatment-related adverse events occurred in 63%, most commonly neutropenic fever (50%) and mucositis (16%), with no transplant-related mortality. Median neutrophil and platelet engraftment occurred at 10 and 14 days, respectively. Disease-free survival was 100% at one year and 91% (95% CI, 68–98%) at five years. Approximately 90% of evaluable patients demonstrated neurological improvement or stabilisation at one year.

Conclusions: ASCT is safe, feasible, and highly effective for aggressive, treatment-refractory RRMS in South Africa. Its earlier use in selected patients may offer durable remission and substantial cost savings compared with long-term DMTs. Expansion of accredited national ASCT programmes and registry-based outcome monitoring is warranted.

Disclosure: No conflicts of interest and no funding was required for this project.

ANTI-CD38 MONOCLONAL ANTIBODY FOR TREATING IMMUNE THROMBOCYTOPENIA:A CASE REPORT

Chun lan Chen[1], *Min Dong*[1], *Chang jiu Liang*[1], *Caizhu Fu*[1]
[1]*Department of Hematology, The Second Affiliated Hospital of Hainan Medical University, Haikou, China*

Background: Immune thrombocytopenia (ITP) is an autoimmune disorder characterized by platelet destruction mediated by anti-platelet antibodies. Some patients who do not respond to conventional treatments are classified as refractory ITP, which occurs in approximately 0.4-3.8% of adults. The residual CD138/38-positive lymphocyte population is a key factor contributing to treatment failure. Daratumumab, an anti-CD38 monoclonal antibody, targets and eliminates CD38-positive cells (including plasma cells). In a multicenter Phase II study, 21 previously treatment-resistant ITP patients receiving daratumumab monotherapy achieved remission rates of 38%-48%, demonstrating the potential therapeutic value of Anti-CD38 monoclonal antibodies in refractory ITP.

Methods: This report describes a middle-aged female patient who developed thrombocytopenia during pregnancy. After undergoing repeated diagnostic tests including bone marrow aspiration, biopsy, loss-of-cell immunophenotyping, chromosomal analysis, fusion gene testing, and autoimmune disease evaluation, the patient met the diagnostic criteria for idiopathic thrombocytopenic purpura (ITP). Despite treatment with first-line therapies such as glucocorticoids, intravenous immunoglobulin (IVIG), platelet-receptor agonists, and decitabine, the platelet count remained persistently below 10×10^9/L, leading to a diagnosis of refractory ITP. The patient received daratumumab targeted therapy (16 mg/kg, once weekly for 1-8 weeks), with continuous monitoring of Platelet count, NK cell ratio and adverse reactions.

Results: After treatment with daratumumab, the patient's platelet count rapidly returned to normal within 8 weeks, with all values remaining ≥100×10^9/L. No adverse events such as infusion reactions or infections occurred during treatment, demonstrating good tolerability. The therapeutic mechanism may involve inhibiting antibody-dependent cell-mediated platelet destruction (ADCC) and reducing platelet phagocytosis by spleen macrophages.

Conclusions: Daratumumab demonstrated significant efficacy and favorable safety in this refractory ITP patient, providing clinical evidence for Anti-CD38 monoclonal antibody therapy in such cases. Further large-scale studies are required to clarify its long-term safety profile and optimal dosing regimen.

OS21-02

ASS-T CELL DEPLETED HAPLOIDENTICAL HSCT FOR PEDIATRIC AND ADULT PATIENTS WITH SICKLE CELL DISEASE: INTERIM ANALYSIS OF THE T-HAPLO-HSCT FOR SCD TRIAL (NCT04201210)

Selim Corbacioglu[1,2], *Anja Tröger*[1,2], *Tarek Hanafe*[2], *Katharina Kleinschmidt*[1,2], *Stephanie Leszczak*[1,2], *Marcus Jakob*[1,2], *Patrick Schlegel*[1,2], *Felix Seyfried*[1,2], *Sonja Kramer*[1,2], *Robert Offner*[1], *Andreas-Michael Brosig*[1], *Peter Lang*[3], *Stefan Schönberger*[4], *Christine Bayer*[1], *Florian Bayer*[1,2], *Melissa Woller*[1,2], *Christian Seitz*[5], *Herbert Pichler*[6,7], *Udo Kontny*[8], *Nicolas von der Weid*[9], *Peter Bader*[10], *Anette Hoferer*[11], *Susanne Ellinger*[1,2], *Matthias Wölfl*[12], *Matthias Eyrich*[12], *Chris Kurzweil*[1,2], *Daniel Wolff*[1], *Jürgen Föll*[1,2]
[1]*Regensburg, Regensburg, Germany,* [2]*Department of Pediatric Hematology, Oncology and Stem Cell Transplantation, Regensburg, Germany,* [3]*Tübingen, Tübingen, Germany,* [4]*Essen, Essen, Germany,* [5]*Heidelberg, Heidelberg, Germany,* [6]*Vienna, Vienna, Austria,* [7]*St. Anna Children's Hospital, Vienna, Austria,* [8]*Aachen, Aachen, Germany,* [9]*Basel, Basel, Switzerland,* [10]*Frankfurt, Frankfurt, Germany,* [11]*Robert-Bosch-Hospital, Stuttgart, Germany,* [12]*Würzburg, Würzburg, Germany*

Background: Sickle cell disease (SCD) is one of the most common and severe monogenic disorders worldwide. Matched sibling donor (MSD) stem cell transplantation (HSCT) is the standard curative treatment. Haploidentical stem cell transplantation offers a potential alternative for patients with no available MSD. aß T cell-depleted haploidentical HSCT (aß-Haplo-HSCT) provides nearly universal donor availability, along with a well-controlled graft composition, consisting of a high stem cell dose and low aß T cell count. This results in rapid engraftment and minimal acute (aGVHD) or chronic graft-versus-host disease (cGVHD). Therefore, aß-Haplo-HSCT could become a viable alternative for patients with an elective transplant indication where the highest level of safety and efficacy is required.

Methods: We report the outcomes of 84 SCD patients (45 males/39 females; 13 HbSß°; median age was 14 years [range 4-40]; median follow-up 49 months [range 2-146]) who received 88 transplants between 2013 and 2025. All patients underwent a standardized, myeloablative conditioning regimen, which included ATG (Grafalon; 45mg/kg for haplo-HSCT respectively 30mg/kg for MSD HSCT), treosulfan, fludarabine, and thiotepa (FTT), followed by post-transplant immunosuppression with tacrolimus and mycophenolate mofetil for 240 and 180 days, respectively for haplo-HSCT and MSD HSCT.

Results: Thirty-five patients received an MSD transplant, and 49 underwent an aß-Haplo-SCT. The overall survival (OS) for the entire cohort was 93%. Disease-free survival (DFS) was 98%, with 6% experiencing graft failure (GF), which was rescued with a second transplant. The incidence of Grade 1/2 aGVHD was 24%, mild-to-moderate cGVHD occurred in 8% and 1 case of severe cGVHD. All cases resolved by 24 months post-transplant. Following a single-center pilot series with 43 patients (15 MSD and 28 aß-Haplo SCT), 57

patients enrolled in a prospective international multicenter trial (T-Haplo-HSCT for SCD; NCT04201210), stratified by donor availability. Forty-one evaluable patients are included in the analysis (20 MSD and 21 aß-Haplo SCT). In 35 MSD transplants, median age was 13.75 years, with a median follow-up of 49.4 months. The overall survival (OS) and disease-free survival (DFS) were both 97%, with a median chimerism of 96.8%. The incidence of grade 1/2 aGVHD and mild/moderate cGVHD was 20% and 5.7%, respectively. In 49 aß-Haplo-SCT, median age was 14 years, with a median follow-up of 46 months. The OS and DFS were 90% and 92%, respectively, with a median total chimerism of 96.8%. The incidence of grade 1/2 aGVHD and mild/moderate cGVHD was 20% and 5.7%. The patients treated in the multicenter Haplo-HSCT for SCD trial had an OS of 100% and a DFS of 91%, with a DFS of 100% after re-transplant. Transient grade 1/2 aGVHD was observed in only 5%, with no cGVHD. The time to neutrophil (16.5 versus 26.5 days) and platelet (16 versus 24 days) engraftment in the haplo-SCT arm was, as expected, significantly shorter compared to MSD HSCT.

Conclusions: aß-depleted haploidentical HSCT is currently being evaluated in a prospective stratified international trial (NCT04201210). The interim results of the ongoing trial show promising outcomes, comparable to MSD HSCT.

A DECADE OLD EXPERIENCE OF OPTIMISING CONDITIONING TO IMPROVE HEMATOPOIETIC STEM CELL TRANSPLANTS OUTCOMES IN SICKLE CELL DISEASE

Vaibhav Chadha[1], *Garima Nirmal*[1], *Nikhil Gupta*[1], *Eby P. Baby*[1], *Shruti Saxena*[1], *Swetlana Mukherjee*[1], *Anjali Jain*[1], *Sanjay Sharma*[1], *Himshikha Yadav*[1], *Gaurav Kharya*[1]
[1]*Centre for Bone Marrow Transplant & Cellular Therapy, Indraprastha Apollo Hospital, New Delhi, India*

Background: Best outcomes of Hematopoietic stem cell transplantation (HSCT) for Sickle cell disease(SCD) are reported for children <12 years of age with matched sibling donor(MSD). Haplo-family donor(HFD) transplant is emerging as a promising alternative. Our experience in HFD HSCT for SCD with APOLLO protocol has been reported. With this study we aim to evaluate a decade long post HSCT overall survival(OS), acute graft vs host disease(GVHD) free & graft failure(GF) free survival for SCD patients. And factors affecting HSCT outcomes.

Methods: A retrospective observational study including all patients who underwent HSCT for SCD at Centre for Bone marrow transplant & cellular therapy at Indraprastha apollo

hospitals, New Delhi, India from June 2014 to November 2025. Required data retrieved from the hospital records and collected in a case record form. Modification of APOLLO protocol since June2024, which includes reduction of dose of thiotepa to 5mg/kg/day and addition of 4Gy Total Body Irradiation(TBI) was done for children >10 years of age.

Results: Total 197 patients were studied. Majority,86.8%(171/197) belong to African ethnicity having multiple comorbities with veno-occlusive crisis(VOC) being most common in 81.2%(160/197) patients. HFD HSCT was done for 53%(105/197) and 46.7%(92/197) underwent matched HSCT [88/92 with MSD/Matched related donor(MRD) and 4/92 with Matched unrelated donor(MUD)]. GCSF + Plerixafor mobilized Peripheral blood stem cell (PBSC) was the major source of stem cells. Pretransplant immunosuppression (PTIS) was given in all except 1 patient, 72%(142/197) received APOLLO protocol based PTIS. Conditioning regimen was myeloablative(Busulfan based) in 13.3%(26/197) and reduced toxicity/Apollo protocol(Fludarabine based) in 86.8%(171/197) patients along with Anti-thymocyte globulin(ATG) and 2Gy/4Gy TBI. Sirolimus, mycofenolate mofetil and Post-transplant cyclophosphamide (PTCY) based GVHD prophylaxis was used predominantly i.e 76.1%(150/197)(Table1).The median duration of follow up in Matched HSCT was 38.7 months(1 to 141months) and HFD HSCT was 32.3 months (1 to 136 months). Matched donor recipients have a significant better OS & acute GVHD free survival as compared to HFD{ 93.1% vs 81.7%(P value: 0.013) & 92.4% vs 75.2%(P value: <0.001)(Figure1A,C) with comparable GF free survival[96.7% vs 95.2%(P value: 0.509)].
Age at HSCT was a significant factor affecting OS irrespective of HSCT type with age <10 years showing best outcomes [91.4% in <10 years vs 78.2% in > 10 years (P value: 0.026)].
Upon evaluation against the type of HSCT, children <10 years of age had comparable OS in both matched and HFD cohort.[95% in matched vs 89.7% in HFD(P value:0.27)](Figure1B). Out of 64, 78.1%(50/64) patients of >10years age were treated on APOLLO protocol and new modified APOLLO protocol was given to 19/50 patients. Those treated on Modified APOLLO protocol had a better trend in OS[89.4% (17/19) vs 70.96%(22/31) P value:0.230](Figure1D) with better tolerability than those on APOLLO protocol, although not statistically significant.

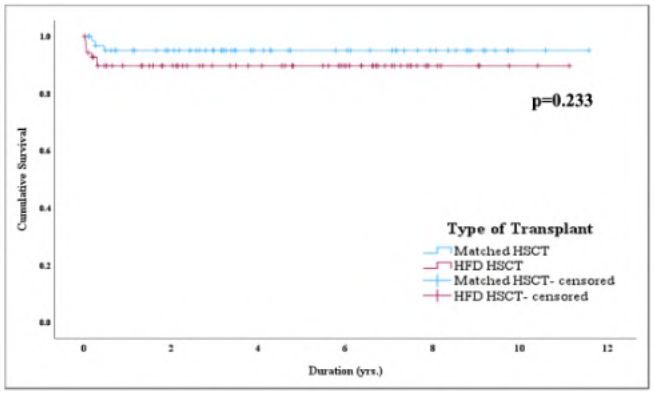
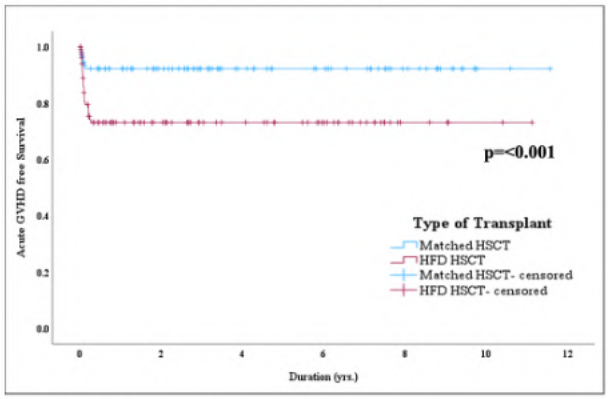
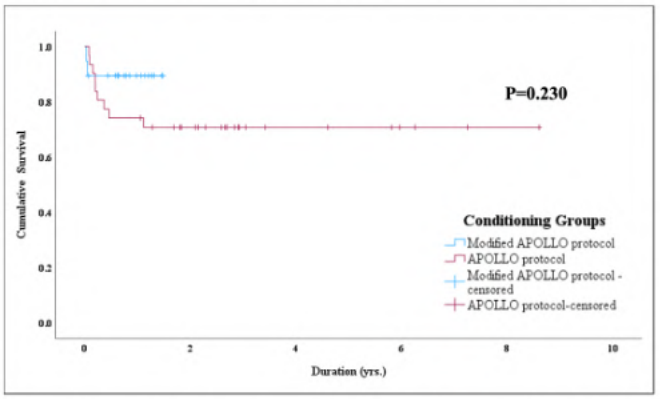
A) Overall survival for Matched vs HFD HSCT patients



B) Overall survival for Matched vs HFD HSCT patients in children < 10 years of



C) Acute GVHD free survival for Matched vs HFD HSCT patients



D) Overall survival in children>10 years on Modified APOLLO vs APOLLO protocol

Figure 1: Showing the survival outcomes for: A) Overall survival (OS) in matched vs HFD HSCT, **B)** OS matched vs HFD HSCT in children <10 years of age, **C)** Acute GVHD free survival in matched vs HFD HSCT, **D)** OS for children >10years treated on Modified APOLLO vs APOLLO protocol
HFD: Haplo-family donor, HSCT: Hematopoietic stem cell transplant, GVHD: Graft vs host disease.

Conclusions: We conclude that SCD children when transplanted below 10 years of age have the best chances of survival even in the setting of HFD HSCT. Children >10 years of age perform poorly, but we report better survival chances and lesser toxicities by using modified APOLLO protocol for this cohort, needing further study to validate.

Disclosure: No conflict of interest.

OS21-06

LOWER GVHD RATES IN MISMATCHED DONORS WITH PTCY AS COMPARED TO MATCHED UNRELATED DONORS WITHOUT PTCY AFTER PEDIATRIC FULL BONE MARROW HSCT FOR HEMOGLOBINOPATHIES

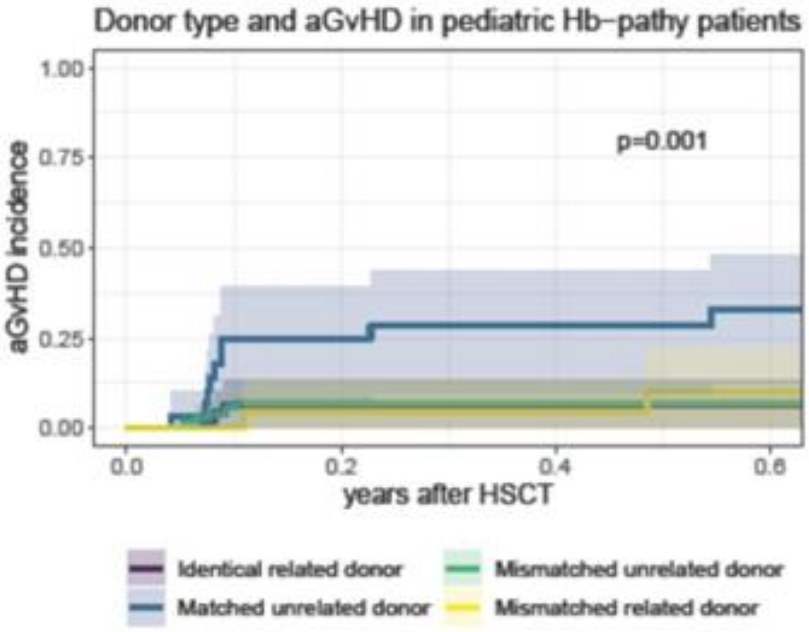
Gertjan Lugthart[1], *Frans J. Smiers*[1], *Federica R. Achini-Gutzwiller*[1], *Dagmar Berghuis*[1], *Robbert GM Bredius*[1], *Emilie P. Buddingh*[1], *Arjan C. Lankester*[1], *Alexander B. Mohseny*[1]
[1]*Leiden University Medical Center, Leiden, Netherlands (the)*

Background: Allogeneic hematopoietic stem-cell transplantation (HSCT) is currently the only available curative therapy for children with hemoglobinopathies. The lack of HLA-matched donors for most patients drove successful HLA-mismatched unrelated and haploidentical HSCT by αβ-depletion or post-transplant cyclophosphamide (PTCy). While PTCy proved effective in preventing graft versus host disease (GvHD) in mismatched HSCT, its additive role in GvHD prevention in HLA-matched unrelated donor bone marrow HSCT needs to be determined and weighted against its potential side effects in pediatric hemoglobinopathy patients.

Methods: We report 171 HSCTs in 154 pediatric hemoglobinopathy patients transplanted in our hospital between 2012 and 2024. Eighty sickle cell disease patients and seventy-four transfusion dependent thalassemia patients were evaluated. Patients received grafts from identical related donors (IRD, n=46), matched unrelated donors (MUD, n=28), mismatched (8/10 or 9/10) unrelated donors (MMUD, n=71) and mismatched (haplo-identical) related donors (MMRD, n=26). Almost all patients (89%) received full BM, 6% PBSC and 5% cord blood. Conditioning was myeloablative, treosulfan-based in 89% and busulfan-based in 11%. Patients received serotherapy with anti-thymocyte globulin (92%) or alemtuzumab (8%). In addition, GvHD prophylaxis for matched patients (IRD and MUD) consisted of ciclosporin A and methotrexate 10mg/m2 on days 1, 3 and 6, whereas mismatched patients (MMUD and MMRD) predominantly received PTCy 50mg/kg on days 3 and 4 followed by ciclosporin A and mycophenolate mofetil. We compared the incidence of overall survival, acute- and chronic GvHD, mixed chimerism, retransplant and viral reactivations between these different donor groups. Log-rank and cox-proportional-hazard models were used for uni- and multivariate comparisons.

Results: Overall survival was 96.5% and did not differ between the donor groups. Strikingly, the incidence of acute and chronic GvHD was the highest in MUD transplants: 9/28 MUD recipients (32%) developed >grade II aGvHD, compared to respectively 6.5%, 7.0% and 7.7% of IRD, MMUD and MMRD recipients ($p<0.001$, Figure 1). In addition, moderate/severe cGvHD occurred in 36% of MUD recipients compared to 2,2%, 4.2 and 3.8% of IRD, MMUD and MMRD recipients, respectively ($p<0.001$). In addition, aGvHD rate was increased in hemoglobinopathy patients with leukocytosis in the three months before conditioning: 7/23 patients (30%) with leukocytes >12*10^9/l developed aGvHD compared to 12/148 patients (8.1%) without leukocytosis. The occurrence of mixed chimerism, graft failure, as well as reactivation of cytomegalovirus, Epstein-Barr virus and adenovirus did not differ between the donor groups. In multivariate analysis, both donor type (MUD: HR 4.7, $p=0.016$) and pre-

HSCT leukocyte count (HR 1.16 per 10^9 leukocytes/l increase, p=0.019) were associated with the development of aGvHD (Table 1).



Multivariate evaluation of risk factors for aGvHD in pediatric hemoglobinopathy patients				
Risk factor	**Event Rate**	**HR[1]**	**95% CI[1]**	**p-value**
Diagnosis				>0.9
Transfusion Dependent Thalassemia	7 / 88 (8.0%)	—	—	
Sickle cell disease	12 / 83 (14%)	1.03	0.36, 2.96	
Donor type				0.016
Identical related donor	3 / 46 (6.5%)	—	—	
Matched unrelated donor	9 / 28 (32%)	4.67	1.18, 18.4	
Mismatched unrelated donor	5 / 71 (7.0%)	1.02	0.23, 4.49	
Mismatched related donor	2 / 26 (7.7%)	1.21	0.19, 7.72	
Leukocytes pre-HSCT (per 10^9/l)		1.16	1.03, 1.32	0.019
[1] HR = Hazard Ratio, CI = Confidence Interval				

Conclusions: In the pediatric hemoglobinopathy patient cohort presented here, PTCy effectively reduced GvHD rates in HLA-mismatched HSCT to the level of HLA-identical HSCT. The significantly higher rate of GvHD in children receiving full bone marrow grafts from MUD donors demonstrates the need for additional GvHD prophylaxis in this group. In addition, pre-HSCT leukocytosis -and possible related systemic inflammation and endovascular activation-provide an interesting base for future studies to further limit HSCT toxicity and substantiate the use of HSCT to cure hemoglobinopathies.

Background: Allogeneic hematopoietic cell transplantation (HCT) is the best established curative option for sickle cell disease (SCD) & transfusion dependent thalassemia (TDT). Primary and particularly secondary graft failure are important risks impacting on event free survival.

Methods: Data on pediatric and adult patients with TDT and SCD receiving a HCT from January 2000 to December 2022 were extracted from the EBMT Hemoglobinopathy registry database. Only first transplants were included.

Results: 2,045 consecutive patients underwent transplanted in centers distributed accross 33 countries in Europe, Asia and Africa: 1,532 were for TDT and 513 for SCD. Median age at transplant was 9 years (IQR 5, 15; range 1-49) with 62% HCT up to the age of 10 years. The median year of HCT was 2012 (IQR 2006, 2017). A total of 1,425 patients received a matched related donor HCT (70%), 435 patients a matched unrelated donor HCT (21%) and 174 patients a haploidentical HCT (8.6%). Bone marrow as a stem cell sourse was used in

74% of HCT and 75% received a cell dose >3 x 10^8 TNC/kg. Half of HCT were donor-recipient gender mismatched: 512 female to male (26%) and 476 male to female (24%). 60% HCT (n=504) were ABO compatible whereas minor ABO incompatibility was present in 15% HCT (n=129), major ABO incompatibiolity in 19% HCT (n=163) and biderictional ABO incompatibility in 4.8% HCT (n=40). CMV donor to patient was as follows: neg/neg 207 HCT (12%), neg/pos 242 HCT (14%), pos/neg 185 HCT (11%), pos/pos 1,076 HCT (63%). 89% HCT received myeloablative conditioning.
134 patients (6.5%) received a second HCT: 111 with TDT (83%, 7.2% of first HCT) and 23 with SCD (17%, 4.4% of first HCT). The time to subsequent HCT was ≤3 months in 20% cases. A second HCT was undertaken for reasons other than graft failure in 9.4% of the cases, including clonal evolution. The age and year at HCT was no different from first HCT. There were no differences in conditioning regimens and use of TBI, and only small reduction in use of serotherapy between first and second HCT.
The estimated incidence of subsequent HCT continues to increase over time with no apparent plateau. With median follow up of 5 years (IC95%, 4.6-5.1) the incidence at 1 year was 2.8% (2.1-3.6), at 2 years 3.9 (3.1-4.9), at 3 years 4.7 (3.7-5.7) and at 5.7 years (4.6-6.9). With median follow up of 4.8 years (IC95%, 3.3-6.7) from a second HCT, the overall survival at 1 years was 70.3% (62.7-76.6), at 2 years 66.7% (58.9-73.4), at 3 years 66.7% (58.9-73.4) and at 5 years 62.6% (54.1-69.9).

Conclusions: Real-world data confirms a small but significant risk of the need for a subsequent HCT in haemoglobinopathies. This, unlike in malignancies, usually is a late event (after day +100) and the incidence does not achieve a plateau over time. The OS following a subsequent HCT is inferior to first HCT and continues to decline over time with no plateau unlike the outcomes of first HCT, highlighting the need for improvement to avoid graft failure.

EARLY DETECTION OF CLONAL HEMATOPOIESIS IN SICKLE CELL DISEASE: RESULTS FROM AN ACTIVELY MONITORED COHORT

Alice Corsia[1], *Lucien Courtois*[2], *Laure Joseph*[2], *Patrick Villarese*[2], *Marina Cavazzana*[1], *Thiago Trovati*[1], *Vahid Asnafi*[2]
[1]*Institut Imagine, Paris, France,* [2]*Necker Hospital, Paris, France*

Background: Clonal hematopoiesis (CH) is increasingly recognized as a frequent, age-related phenomenon associated with adverse outcomes, including hematologic malignancies and cardiovascular disease.
Whether CH occurs more frequently in patients with sickle cell disease (SCD)—who are exposed to chronic inflammation, increased hematopoietic turnover, and repeated therapeutic interventions—remains unclear, as recent studies have reported conflicting results. Clarifying the prevalence and spectrum of CH in SCD patients has become critical since several cases of CH have been reported in the setting of allogenic stem cell transplantation and gene therapy (GT) for SCD, raising concerns about treatment-related

risk. In particular, TP53 mutations detected before transplantation have been linked to hematological malignancies in patients with graft rejection, and several cases of acute leukemia occurred following GT. Together, these observations underscore the need for a better understanding of CH in this population.

Methods: We screened peripheral blood samples from our actively followed cohort of 147 patients with sickle cell disease (SCD) at Necker Hospital. A targeted high-throughput approach was performed using an in-house panel covering 38 CH-associated genes, sequenced on our MiSeq (Illumina) plateform (validated LOD = 0.1%). Variants with an allelic frequency (VAF) above 0.9% and below 40% were considered clonal. Mutations previously identified with Agilent's NGS capture system were confirmed using a Quiagen amplicon-based NGS assay. Both sequencing strategies ensured high sensitivity and confidence for detecting CHIP-related variants down to ~0.9% VAF.

Results: Median age at blood sampling was 27 ± 10.4 years and SCD subtypes included SS or S/β^0 thalassemia (n = 125) and SC (n = 22).
After quality filtering, MiSeq sequencing yielded 20 suspect variants in 17 patients (11.5%), with a median variant allele frequency (VAF) of 1.2% [0.9-21%] (min-max). The most frequently affected genes were *ASXL1* (30%), *PPM1D* (25%), *RUNX1* (25%) and *DNMT3A* (20%). Amplicon-based confirmation reduced this list to 7 true CH mutations in 5 patients (3.4%) of a median age of 34,3 years (18-57 years). This group included 3 SS patients (all receiving hydroxyurea at the time of sampling) and 2 SC patients. Validated variants displayed VAFs ranged from 0.95% to 26%. We identified 4 single nucleotide variants and 3 deletions, classified as coding in *TP53*, *DNMT3A* and *RUNX1*, stop in *PPM1D* and frameshift mutation in *ASXL1*, *DNMT3A* and *PPM1D*. A patient who recently experienced bone marrow transplant failure was found to harbor two clonal hematopoiesis variants in *TP53* and *PPM1D*. Following immunomodulatory therapy and prior to a second bone marrow transplantation, the *TP53* variant was no longer detectable.

Conclusions: Initial sequencing identified numerous low-VAF variants, but amplicon confirmation reduced the true CH prevalence from 11.5% to 3.4%. These findings highlight the necessity of rigorous validation of low-frequency variants and suggest that background CH remains uncommon in this young SCD population. CH was detected in both SS and SC patients, highlighting that CH is not restricted to the most severe SCD genotypes. Given the dynamic behavior observed in a post-transplant setting, longitudinal monitoring of CH may be particularly relevant in patients undergoing transplantation or gene therapy.

TREOSULFAN-BASED CONDITIONING IS ASSOCIATED WITH BETTER OUTCOMES IN ADOLESCENTS AND YOUNG ADULTS UNDERGOING MATCHED RELATED DONOR TRANSPLANTATION FOR THALASSEMIA MAJOR

Mithun Abraham Prakash[1], *Uday Kulkarni*[1], *Sujith Karumuthul*[1], *Sushil Selvarajan*[1], *Sharon Lionel*[1], *Anu Korula*[1], *Fouzia Na*[1], *Kavitha M Lakshmi*[1], *Eunice Sindhuvi*[1], *Aby Abraham*[1], *Vikram Mathews*[1], *Biju George*[1]
[1]*Christian Medical College, Ranipet, India*

Background: Outcomes of allogeneic transplantation for Thalassemia Major (TM) in adolescents and young adults (AYA) remain suboptimal in resource-limited settings due to late referral, iron overload, and high-risk disease biology. Evidence comparing Treosulfan-based regimens with conventional Busulfan-based conditioning in this age group is limited.

Methods: We performed a retrospective analysis of AYA patients (≥12 years) with TM who underwent matched sibling or family donor transplantation at our centre between 1994–2022. Conditioning consisted of either Busulfan–Cyclophosphamide (Bu/Cy ± ATG) or Treosulfan–Fludarabine–Thiotepa (FTT). Standard institutional protocols were followed for GVHD prophylaxis, supportive care, and engraftment monitoring. Overall survival (OS) and thalassemia-free survival (TFS) were estimated using Kaplan–Meier analysis. Multivariable Cox regression was used to assess prognostic factors.

Results:

5-year Thalassemia Free Survival	60.1 + 4.5%	51.1 $\pm$ 7.5%	70.1 $\pm$ 5.5%	0.018

A total of 124 AYA patients underwent MRD transplant. Median age was 15 years (13–25); 88.7% were Lucarelli Class III, and 65.3% belonged to the Vellore high-risk subgroup. The

median ferritin level was 3490 ng/mL (range: 361 – 16761). Conditioning comprised Bu/Cy in 46 (37.1%) and FTT in 73 (58.9%) patients. Peripheral blood stem cells were used in 94.5% of FTT recipients versus 6.5% in the Bu/Cy group.
Engraftment occurred in 111 patients (89.5%); median neutrophil and platelet engraftment times were 16(range: 8 - 43) and 21(range: 10 - 66) days, respectively. Primary graft failure occurred in 3.2% and secondary graft failure in 6.4%. Treatment-related mortality by Day 100 was 26.6% and significantly lower with FTT (15%) compared to Bu/Cy (39.1%, p=0.002).
Sinusoidal obstruction syndrome (SOS) occurred in 38.7%, with significantly lower incidence in the FTT group (31.5% vs 54.3%, p=0.021). Haemorrhagic cystitis was also less frequent with FTT (2.7% vs 19.6%, p=0.003). Grade II–IV acute GVHD occurred in 34.2% of evaluable patients, with similar rates in the FTT and Bu/Cy groups (34.8% vs 35%; p=1.000). Chronic GVHD was higher with Bu/Cy (40% vs 14.2%; p=0.026).
The median duration of follow-up after excluding early deaths was 59 months (range: 1 - 289 months). For the entire cohort, 5-year OS and TFS were 63.6$\pm$ 4.5% and 60.1$\pm$ 4.5% respectively. FTT was associated with superior OS 72.2% vs 54.8% (p=0.017) and TFS 68.7% vs 51.1% (p=0.018). Platelet engraftment was faster, complete chimerism at Day 30 was higher (92.8% vs 78.6%, p=0.023), and regimen-related toxicity was reduced in the FTT cohort.
In Lucarelli Class III patients overall, FTT showed significantly improved survival, with a 5-year OS of 71.9% vs 52.5% for Bu/Cy (p=0.014) and a 5-year TFS of 69.3% vs 52.5% (p=0.029). In the Vellore High-Risk subset, the benefit was even more pronounced, with 5-year OS of 75.2% vs 40.2%

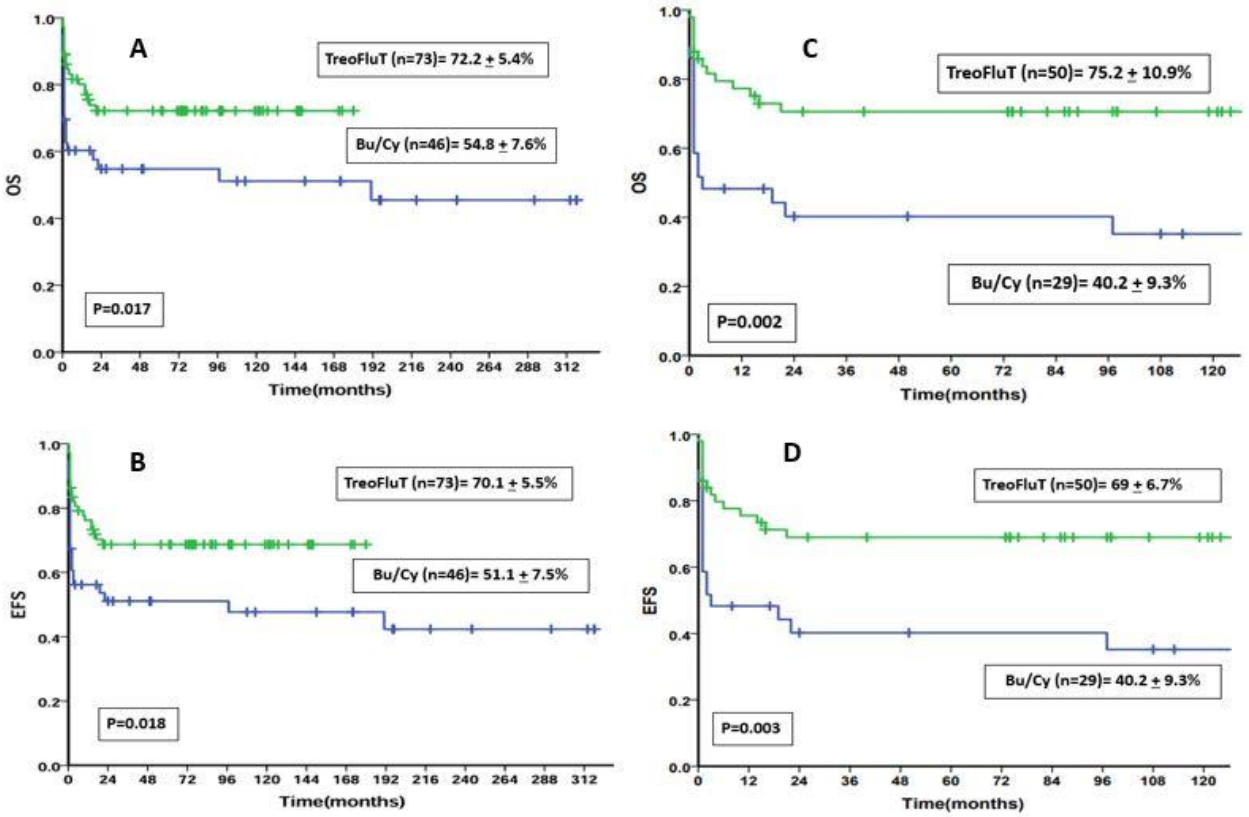

Figure A - 5-year overall survival of Treosulfan and Busulfan based regimens, Figure B- 5-year Thalassemia free survival of Treosulfan and Busulfan based regimens , Figure C 5 year Overall free survival of Treosulfan and Busulfan based regimens for Class III Vellore High Risk patients, Figure D- 5-year Thalassemia free survival of Treosulfan and Busulfan based regimens for Class III Vellore High Risk patients

Conclusions: Treosulfan-based conditioning significantly reduces early toxicity and improves long-term OS and TFS in AYA patients with TM undergoing MRD transplantation, including those in high-risk subgroups. These findings support Treosulfan-based conditioning as the preferred regimen for AYA patients in resource-constrained settings.

[1]Nasser Institute for Research and Treatment, Cairo, Egypt, [2]National Cancer Institute, Cairo, Egypt, [3]Cairo University Hospital, Cairo, Egypt

Background: Hematopoietic stem cell transplantation (HCT) remains a cost-effective curative treatment for transfusion-dependent thalassemia major(TDT).Myeloablative conditioning (BU/CY) and CSA/MTX as GvHD prophylaxis has been the standard of care for decades in Matched Sibling Donor(MSD) HCT. Adding ATG both to mitigate the high rejection rate and minimize GvHD when using peripheral blood(PBSC) for MSD has shown satisfactory results in Thalassemia-Free Survival(TFS).However, in Egypt, the high-cost and irregular availability of ATG has been a major shortcoming.Post-transplant Cyclophosphamide(PT-CY) has emerged as a cost-effective,readily available option in the haplo-setting with favorable graft rejection and GvHD outcomes.

Methods: **Aim:** To evaluate whether PT-Cy can be used(in cost-constrained countries)as an alternative to ATG for GvHD prophylaxis in MSD-PBSC-HCT for TDT, focusing on Engraftment, Thalassemia-Free Survival and GvHD
Study design: In a comparative study, a prospective group of 41 consecutive patients transplanted between August 2023-January 2025(Group A) with TDT who underwent MSD-PBSC-HCT, conditioned with BU/CY and GvHD prophylaxis using PT-CY 40mg/kg/day(Day+3,D+4) plus CSA were compared to a retrospective historical control of 55 consecutive patients transplanted between 2021-2023(Group B),conditioned with BU/CY+rabbit ATG 7mg/kg/day(Day-3-Day-1)and GvHD prophylaxis using CSA/MTX.

Results:

Baseline characteristics were rather balanced,apart from Pesaro class 3 patients being more prevelent in group A.
The median follow-up was 20 months(1-31) vs 44 months(1-61) in Groups A&B respectively(Table.1).
Primary Endpoints: In Group A vs B respectively,
1-yTFS was non-significantly different between the two groups(78%vs83.6%,p=0.59).
Chimerism analysis was available for 28 and 26 patients,respectively. Full donor chimerism(FDC) was significantly lower in Group A(53.5%vs 88.5%, p=0.007). Mixed chimerism(MC) and Primary graft failure(GF) were observed in(28%vs7.7%,p=0.14)and(21.4% vs 3.8%,p=0.1),respectively.Notably, at a median of 6-months post-immunosuppression withdrawal(ISW), four patients(9.8%) with stable mixed chimerism in group A experienced late graft rejection versus non in group B. Hence,TFS showed a clinically relevant drop in group A post-ISW (68%vs83.6%,p=0.09).
Acute and chronic GvHD were significantly lower in groupA, (2.4%vs 38.2%,p=0.001) and (2.4%vs32.7%,p=0.001) for aGvHD II-IV and Moderate-severe cGvHD respectively.Two patients in group B died from aGvHD(3.6%).
CMV reactivation was significantly lower in group A(2.4%vs20%,p=0.01).
Secondary Endpoints:
OS and TRM were similar in both groups(85.5% and 14.5% p=0.99),respectively.
Neutrophil and platelet engraftment were delayed in Group A(mean 20.78vs17.36

days,p=0.001) and(20.31vs18.3 days,p=0.317), respectively.
Bacterial infections were higher in Group A(51.2%vs23.6%,p=0.005) with comparable Infection-related-mortality(4.8%vs7.2%,p=0.97).
Hemorrhagic cystitis was non-significantly higher in Group A(14.6%vs7.3%,p=0.317).
VOD was comparable (14.6%vs12.7%,p=0.787).
Thalassemia-Free,GvHD-Free Survival was 60%vs49.1%,p=0.3

Characteristics	**BU CY/ PT-CY+CSA (Group A) (n=41)**	**BU CY / ATG MTX+CSA (Group B) (n=55)**	**P-value**
Median Age	5 (0.58 -15)	6 (2-18)	0.161
Male, n (%)	23 (56%)	33 (60%)	0.701
Primary Disease BTM Class 1 BTM Class 2 BTM Class 3 BTM/SCD Congenital Dyserythropoietic anemia Sideroblastic anemia	 1 (2.4%) 17 (47.2%) 18 (50%) 1 (2.4%) 2 (4.8%) 2 (4.8%)	 11 (20.4%) 29 (53.7%) 14 (25.9%) 1 (1.8%) 0 0	0.01 0.082
Ferritin >1500 n (%)	22 (53.7%)	26 (47.3%)	0.536
Splenectomy	1 (2.4%)	6 (10.9%)	0.233
Donor (Trait/Normal)	17/23 (42.5%)	21/33 (38.9%)	0.724
Mean CD34 count (x10^6/kg)	6.83 (4-9.6)	7.24 (3.5-10)	0.097
Median follow-up (months)	20 (1-31)	44 (1-61)	0.001
Results	**BU CY/ PT-CY+CSA (Group A) (n=41)**	**BU CY / ATG MTX+CSA (Group B) (n=55)**	**P-value**

OS	85.5%	85.5%	0.99
TFS (1-year)	78%	83.6%	0.59
TFS (6months post-ISW)	68%	83.6%	0.09
Full Donor Chimerism	15/28 (53.3%)	23/26 (88.5%)	0.007
Primary Graft failure	6/28 (21.4%)	1/26 (3.8%)	0.1
aGvHD (Grade II-IV)	2.4%	38.2%	0.001
cGvHD (Moderate-Severe)	2.4%	32.7%	0.001
CMV reactivation	2.4%	20%	0.01

Conclusions: Replacing ATG by PT-CY has significantly reduced aGvHD/cGvHD risks together with reducing CMV reactivation while maintaining comparable OS. However, the higher rates of MC and late graft rejection were observed. The clinically relevant trend toward lower TFS and graft instability in the PT-Cy group warrants caution and further optimization of immunosuppression strategies.
Study limitations: Non-randomized.
Retrospective nature of the control arm(with possible non-identical practice)
The small sample size and shorter follow-up in PT-CY arm.
Recommendations: A larger prospective RCT is recommended to confirm these findings. Augmentation or a slow-tapering of Immunosuppression is probably mandatory in stable MC to suppress residual host immunity with vigilant chimerism monitoring(preferably lineage-specific chimerism to guide ISW).

ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION FOR PEDIATRIC HEMOGLOBINOPATHIES: LONG-TERM OUTCOMES IN A LARGE SINGLE-CENTER COHORT

*Arianna Panigari[1], Michele Massa[1], Francesco Delle Cave[1], Tommaso Mina[1], Annalisa Agostini[1], Veronica Sesenna[1], Gloria Acquafredda[1], Tina Diana Boti Lou[1], Jessica Rotella[1], Francesco Scattaglia[1], Giovanna Giorgiani[1], **Patrizia Comoli**[1], Marco Zecca[1]*
[1]Fondazione I.R.C.C.S. Policlinico San Matteo, Pavia, Italy

Background: Allogeneic hematopoietic stem cell transplantation (HCT) has long represented the only curative therapy for transfusion-dependent thalassemia (TDT) and sickle cell disease (SCD), supported by extensive long-term follow-up. Gene-editing–based therapies have recently broadened the therapeutic landscape for hemoglobinopathies; however, their positioning within current treatment algorithms remains to be defined. In this context, contemporary HCT results from experienced centers remain crucial for patient-specific treatment selection. We report the long-term outcomes of pediatric patients with hemoglobinopathies transplanted at I.R.C.C.S. Policlinico San Matteo, Pavia, Italy.

Methods: We retrospectively analyzed 134 consecutive patients with TDT or SCD who underwent allogeneic HCT between 2009 and 2025. Myeloablative conditioning was based on busulfan or treosulfan. Stem cell sources included bone marrow, peripheral blood stem cells, or combined bone marrow plus cord blood grafts. Donors were matched family (MFD), matched unrelated (MUD), or partially matched family donors (PMFD). Overall survival (OS), event-free survival (EFS), graft-versus-host disease-free/relapse-free survival (GRFS), and thalassemia-free survival (TFS) were estimated using the Kaplan-Meier method. Cumulative incidences of transplant-related mortality (TRM), graft failure (GF), and acute and chronic GVHD were estimated using competing-risk methods. Events included death and graft failure.

Results: A total of 134 patients underwent first allogeneic HCT, including 71 with TDT and 63 with SCD (Table 1). At 5 years, OS was 97% (95%CI: 91-99), EFS 86% (95%CI: 79-91), GRFS 85% (95%CI: 78-90), and TFS 90% (95%CI: 83–94). Donor type significantly affected outcomes: 5-year OS was 100% after MFD HCT, 97% after MUD HCT (95%CI: 90–99), and 79% after PMFD HCT (95%CI: 38–94; p=0.004), with similar trends for EFS (p=0.01).
The cumulative incidence of grade II–IV acute GVHD was 12.7% (95%CI: 8–19). Chronic GVHD was rare (4%, 95%CI: 1.5–9), with moderate to severe forms below 3%. The incidence of acute GVHD (any grade) differed by donor type (p=0.020), being lowest after MFD HCT. Five-year TRM was 3% (95%CI: 1.4–9.5) and was higher in patients aged ≥11 years (p=0.021) and after PMFD HCT (p=0.002). The cumulative incidence of GF was 8.4% (95%CI: 4–14).
At 1-month post-HCT, median donor chimerism was 99% (IQR 93–100). At last follow-up donor chimerism remained stable in 76% of patients, whereas progressive mixed chimerism (defined as ≥10% decline between consecutive timepoints) occurred in 13%. Excluding GF,

6% of patients had donor chimerism <50% at last follow-up, yet remaining transfusion-independent and free from disease-related symptoms. In competing-risk analysis, donor chimerism ≤90% at 1 month was a strong predictor of graft failure (sHR 50, 95%CI:12.5-200; p<0.001).

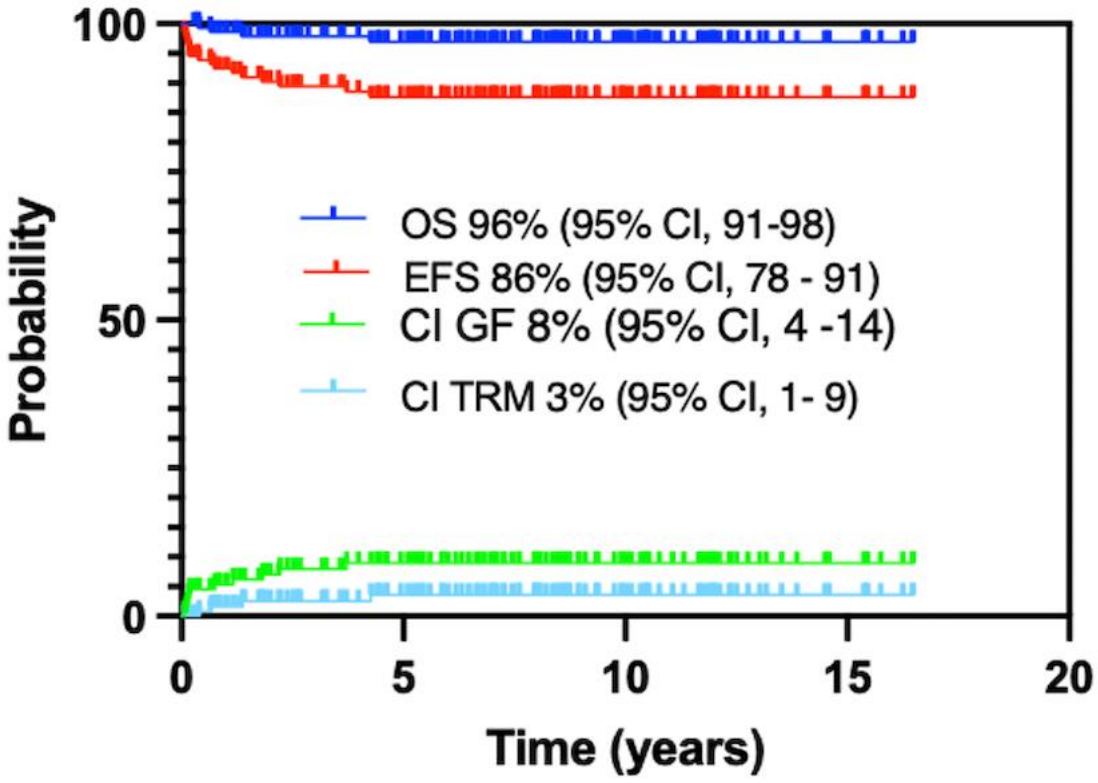
	CD3+ $\times 10^6$/kg (median, IQR)	61.2 (40-118)	65.66 (41.96–148.03)	55.47 (33.35–83.72)	0.23

Figure 1. Survival and graft failure.



Conclusions: Allogeneic HCT for pediatric hemoglobinopathies was associated with excellent long-term survival, low TRM, and low incidence of severe GVHD. Donor type significantly influenced outcomes, with MFD transplantation providing the most favorable results, while age ≥11 years was associated with higher TRM. Early donor chimerism ≤90% at 1 month strongly predicted graft failure; however, patients without GF maintained clinical cure despite mixed chimerism. Even in the era of gene therapy, HCT remains a safe and effective option for selected patients.

Disclosure: No disclosure.

RELIABLE ENGRAFTMENT AND COMPARABLE OUTCOMES ACROSS DONOR SOURCES WITH BUSULFAN65–FLUDARABINE–THIOTEPA CONDITIONING IN PAEDIATRIC SICKLE CELL DISEASE

Anna-Lisa Lanz[1], *Tanja C. Vallée*[1], *Jonas B. Lang*[1], *Vincent D. Gaertner*[1], *Johannes Rädler*[1], *Walther Stamm*[1], *Hannah Bendner*[1], *Anna Eichinger*[1], *Irene Schmid*[1], *Michael H. Albert*[1]
[1]*Dr. von Hauner Children's Hospital, University Hospital, LMU, Munich, Germany*

Background: HSCT is an established and increasingly accessible curative option for children with severe sickle cell disease (SCD) and transplant activity is expanding rapidly. Outcomes with MSD are excellent, whereas data on alternative donors remain limited and often associated with graft failure or GVHD. These are therefore generally reserved for patients with a severe, progressive disease phenotype. Experience from other inborn errors has shown that pre-emptive HSCT, performed before significant comorbidities develop, offers the best chances of survival in conditions with an otherwise poor long-term natural history.

Methods: We report on 35 symptomatic SCD patients aged 1-17 years (median 6) transplanted between 2014 and 2025 on an institutional protocol (including an established psychosocial support framework) with a uniform conditioning: busulfan tAUC 65ng*h/ml, fludarabine 150mg/m² and thiotepa 10mg/kg (plus cyclophosphamide 29mg/kg in MMFD). Donors were haploidentical MMFD (n=11), (M)MUD (10/10: n=3; 9/10: n=4), or MSD/MFD (n=17). All patients received serotherapy depending on donor source and HLA match: alemtuzumab 0.4mg/kg for MMFD, 0.8mg/kg for (M)MUD and ATG Grafalon® 45mg/kg for MSD/MFD. GVHD prophylaxis was post-transplant cyclophosphamide (PTCY), tacrolimus, MMF for MMFD and CSA-MMF for all other donors. One MMFD patient received a TCRa/b depleted PBSC graft because of pre-existing chronic kidney failure. All other but two MUD grafts were unmanipulated bone marrow. The three patient cohorts did not significantly differ with regards to age, disease severity, CMV status, cell source and number, and busulfan AUC (table).

Results: After a median follow-up of 3.3 years (range 0.4-9.1), 34/35 patients are alive (97%) without clinical signs of SCD or active GVHD. One patient in the MMFD group died from severe COVID-19 triggered bronchiolitis obliterans. Neutrophil and platelet engraftment were observed on median days +19 (significantly slower in the MSD/MFD group [p=0.005]), and +20 (not impacted by donor type [p=0.182]), respectively. There were no graft failures, and donor chimerism was >90% in all MMFD and 86% and 88% of (M)MUD and MSD/MFD recipients, respectively (p=0.462). All patients with mixed chimerism had either undetectable HbS levels or in the range of their heterozygote donor. Rates of acute GVHD in the MMFD, (M)MUD and MSD/MFD groups were °III-IV: 9%, 0% and 0% (p=0.325), and °II-IV: 27%, 29% and 0% (p=0.063), respectively. NIH moderate/severe chronic GVHD occurred in 9%, 14%, and 0% (p=0.330), respectively. Infectious complications and immune reconstitution were comparable across donor groups with no significant differences (not shown). There was one mild-moderate VOD case each in the MMFD and the MSD/MFD groups. In summary, overall survival, SCD-free survival and mod./sev. chronic GVHD, SCD-free survival rates were 97%, 97%, 94% for all patients with 91%, 91%, 91% with MMFD, 100%, 100%, 86% with (M)MUD, and 100%, 100%, 100% with MSD/MFD, respectively (p=0.325-0.330; table).

ACS: acute chest syndrome; AUC: area under curve; VOC: vaso-occlusive crisis.
(*chi-square for categorical and ANOVA for grouped variables)

Conclusions: These results, obtained in a relatively young and otherwise healthy pediatric cohort treated with a Bu65–Flu–TT conditioning regimen, demonstrate reliable engraftment and similarly favorable outcomes across MSD/MFD, (M)MUD, and MMFD donors. These findings may pave the way for broader consideration of very early HSCT from alternative donors in children with SCD.

THE IMPACT OF TREOSULPHAN-BASED CONDITIONING AND INTEGRATED FOLLOW UP IMPROVES EVENT FREE SURVIVAL IN CHILDREN UNDERGOING HSCT FOR SICKLE CELL DISEASE

Kavitha Ganesan[1], Amr Abdullah[2], Abdulhakim Al Rawas[2], Indira Jayakumar[1], Ravindra Prasad Thokala[1], Vijayashree Muthukumar[1], Krithika Krishnakumar[1], Ramya Uppuluri[1], ***Revathi Raj***[1]
[1]*Apollo Hospitals, Chennai, India,* [2]*Sultan Qaboos University Hospital, Muscat, Oman*

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) remains as one of the curative therapies for sickle cell disease (SCD). Busulphan-based myeloablative conditioning is effective, is associated with significant immediate and late toxicity in this cohort with pre-existing organ damage due to vasculopathy. We report our experience using uniform Treosulphan-based conditioning in children patients undergoing HSCT for SCD and the outcomes of integrated follow up between SQUH, Muscat and ASH, Chennai.

Methods: We performed a retrospective study conducted at the Apollo Speciality Hospital, Chennai collected data from patient records. We included children with SCD who underwent HSCT at our centre from October 2010 to October 2025 over a fifteen-year period and children from Muscat had an integrated follow up protocol. The conditioning combined Treosulphan with Fludarabine and Thiotepa with or without serotherapy. Children who had a haplo-identical transplant received 2 Gy TBI along with plasma exchange and rituximab based on donor specific antibodies.
We analysed the impact of the Treosulphan based conditioning regimen on the engraftment, graft failure, sinusoidal obstruction syndrome, viral reactivation, PRES, graft versus host disease, and and Overall Survival. The study has been approved by our Institutional Ethics Committee and we performed the statistical analysis using SPSS software.

Results: A total of 74 children with sickle cell disease underwent HSCT, of whom 14 (18.9%) were of Indian ethnicity and 60 (81.1%) were of other ethnicities. The cohort included 47 males (63.5%) and 27 females (36.5%). Forty-six children (62.2%) were aged ≤13 years, while 28 (37.8%) were older than 13 years, with a median age of 10.5 years. The underlying diagnosis was SCD in 64 children (86.4%), S beta thalassemia in 7 (9.5%), and SD disease in 3 (4.1%).The indication for HSCT included recurrent vaso-occlusive crises in 59 (79.7%), acute chest syndrome in 14 (18.9%), stroke in 12 (16.2%), avascular necrosis of the femur or osteomyelitis in 8 (10.8%), and hepatopathy in one child (1.4%). We used peripheral blood stem cells in 50 (67.5%), bone marrow in 23 (31.1%), and cord blood in 1 (1.2%) as stem cell source. Donors were matched family donors in 60 (81%), haploidentical donors in 13 (17.6%), and a matched unrelated donor in one child (1.4%).
We documented acute graft-versus-host disease in 7 children (9.5%), involving the gastrointestinal tract and chronic graft-versus-host disease in 5 children (6.8%), predominantly affecting the skin and musculoskeletal system. We did not document any primary or secondary graft failure but mixed chimerism was observed in 3 children (4.1%)

who remain clinically stable with sickle-free survival on follow-up of up to five years. At last follow-up, 68 children (91.9%) are alive with similar event free survival. The cause of death was graft-versus-host disease in 3 children and overwhelming sepsis in 3 children.

Conclusions: Treosulphan-based conditioning is a safe and effective conditioning regimen for children with sickle cell disease from different ethnic backgrounds. Seamless follow up between two HSCT units has improved event free survival to 91.9%. The combination of reduced gonadotoxicity and hepatotoxicity results in intact survival.

Disclosure: NIL

LONG TERM FOLLOW-UP OF THALASSEMIA PATIENTS SHOWS REASONABLE OUTCOMES AFTER TRANSPLANTATION- A SINGLE CENTER EXPERIENCE FROM INDIA

Rohan Halder[1], *Dravie Bansal*[1], *Mansi Bidla*[1], *Reshmi H Pillai*[1], *Reema Singh*[1], *Garima Sarpal*[1], *Niharika Bhatia*[1], *Swapnil Tripathi*[1], *Mayank Soni*[1], *Aakanksha Singh*[1], *Sakshi Bhatnagar*[1], *Vipul Sheth*[1], *Narendra Agrawal*[1], *Dinesh Bhurani*[1]
[1]*Rajiv Gandhi Cancer Institute and Research Centre, New Delhi, India*

Background: Allogeneic transplantation (ASCT) is the only available curative therapy for a patient with Thalassemia as far as most of the countries are concerned. In India thalassemia continues to be a significant public health problem. Graft failure (GF), Veno-occlusive disease (VOD) or Sinusoidal obstruction syndrome (SOS) and Graft versus Host Disease (GVHD) are some of the unwarranted effects due to ASCT which can lead to Transplant related mortality (TRM). Most of the studies previously have shown a TRM ranging from 5-24% in these children.
We show that TRM can be improved in patients with thalassemia with satisfactory long-term outcomes with pretransplant optimization and improvements in supportive care.

Methods: Patients with a diagnosis of transfusion dependent thalassemia who underwent ASCT (Matched related transplant/Unrelated transplant) using Flu-Bu-Cy-ATG or Flu-Treo-Cy-ATG protocol between 2017 and 2025 were included in the study. No liver biopsies were performed prior to transplantation. Hydroxyurea was used in most of the patients prior to transplantation to decrease the liver size. Baseline demographic information, clinical and laboratory data, and details of transplantation, including donor characteristics, graft characteristics, and clinical outcomes, including graft rejection, TRM, GVHD, and death, were retrieved from the hospital records.

Results: One hundred forty-five patients with transfusion dependent thalassemia underwent transplant during this period with a median age of 8 years (IQR:5-9 years) with 66% being male. Median pre-transplant ferritin was 1720 ng/ml (IQR:1260-2220), median liver size was 2 cm (IQR:2.0-3.5), median hydroxyurea exposure was 9 years (IQR:4.7-14.4 years), median number of blood transfusions before transplant was 94 (IQR: 58-142). Patients were

classified as Lucarelli class 1 in 47(35.5%), class 2 (n=59,44.4%) and class 3 (n=27,20%) out of 133 patients. Eighty-four percent (123) underwent matched sibling donor transplant, and the rest underwent matched unrelated donor transplant. Five patients received treosulfan instead of busulfan as part of conditioning. 64% patients were ABO group matched. Median CD34 dose was 3.7 x 10^6/kg (IQR:2.4-5.0). The median TNC infused was 8 x 10^8 cells/kg available in 73/145 patients. The median time to neutrophil engraftment was 18 (IQR:16-21) days and platelet engraftment was 17 (14-21) days. More than 95% donor chimerism at day +100 was seen in 84.3% patients and in 73.8% patients at the time of stopping immunosuppression. Most common transplant related complications seen were veno-occlusive disease (VOD) in 21.4% (86% mild), infections in 47.6% (bacterial predominant), graft versus host disease (GVHD) in 20.0% (16.6% acute, 8.3% chronic), hypertension in 22.8%, graft rejection in 6.2%. The overall survival of the cohort was 97.9% with a median follow up of 3 years. The thalassemia free and gvhd free survival of the cohort was 82.1%.

Conclusions: Our real-world data shows excellent post-transplant outcomes in Indian children with thalassemia similar to the ones reported in western literature.

Clinical Trial Registry: None.

Disclosure: None.

B361

TREOSULFAN BASED MYELOABLATIVE CONDITIONING IN ADOLESCENT AND ADULT PATIENTS WITH HEMOGLOBINOPATHY

Stephanie Leszczak[1], *Katharina Kleinschmidt*[1], *Anja Tröger*[1], *Tarek Hanafe*[1], *Patrick Schlegel*[1], *Marcus Jakob*[1], *Felix Seyfried*[1], *Sonja Kramer*[1], *Peter Offner*[1], *Andreas Brosig*[1], *Florian Bayer*[1], *Melissa Woller*[1], *Chris Kurzweil*[1], *Daniel Wolff*[1], *Jürgen Föll*[1], *Selim Corbacioglu*[1]
[1]*University of Regensburg, Regensburg, Germany*

Background: Hematopoietic stem cell transplantation (HSCT) is currently the standard curative treatment for transfusion-dependent thalassemia (TDT) and sickle cell disease (SCD), as outcomes remain poor despite optimal supportive care. Busulfan is the traditional alkylator for myeloablative conditioning. Due to a narrow therapeutic window and lack of standardized drug monitoring, busulfan is associated with a high risk of severe toxicity, such as sinusoidal obstruction syndrome (SOS). Treosulfan, an increasingly preferred alternative, has a wider therapeutic window, offering notable advantages. It is not metabolized in the liver, does not cross the blood-brain barrier, and has low endo-/epithelial toxicity, which reduces the need for extensive drug monitoring. However, treosulfan has been linked to graft failure and mixed chimerism (MC). This retrospective analysis summarizes the outcomes for adolescent and young adult (AYA) patients with SCD and TDT- groups at high risk for rejection and MC - who were transplanted with a treosulfan-based conditioning regimen.

Methods: 35 AYA patients (28 SCD/SCD-β-Thal, 7 TDT) (median age: 23 years; range: 16-39) received either a matched sibling donor (MSD) or an aß T cell-depleted haploidentical HSCT (T-haplo-HSCT; n=17, MSD; n=18), indicated by severe transfusion-related iron overload or SCD-related complications. All patients received a conditioning regimen consisting of treosulfan (3 x 14 g/m²), thiotepa (2 x 5 mg/kg BW), fludarabine (4 x 40 mg/m²), and ATG-Grafalon®, with the only difference being in the timing of ATG (upfront 3 x 15 mg/kg BW in T-haplo-HSCT, 3 x 10 mg/kg BW in MSD-HSCT on days -3 to -1). Immunosuppression involved a combination of calcineurin inhibitors and mycophenolate mofetil.

Results: Overall survival (OS) and disease-free survival (DFS) were 94%, respectively. One patient in each group died at 11 and 14 months, respectively, due to acute gastrointestinal bleeding and SCD-related chronic complications. Neutrophil engraftment was achieved at a median of 21 days (range 8-38) and platelet engraftment was achieved at a median of 20 days (range 13-48) post-transplant. Two patients experienced graft failure (GF) in the context of HHV-6 reactivation combined with macrophage activation syndrome and recent EBV infection. All GF cases underwent successful re-transplantation and are now disease-free. Mixed chimerism was observed in 11 patients (median 91%; range 86–94%), with median CD14+ split-chimerism at 99.5%. All TDT patients became transfusion-independent, and all SCD patients were free of vaso-occlusive crises after transplant. Ten patients developed mild aGVHD (grades I–II), all resolving completely with intensified immunosuppressive therapy. No severe acute GVHD (grades III–IV) was observed. There was no moderate or severe cGVHD, and mild cGVHD was not systematically documented. No additional severe infectious complications occurred. Three patients developed mild hepatic SOS, all responding well to defibrotide and fully recovering. No significant differences in all outcome parameters were observed between MSD and T-haplo-HSCT.

Conclusions: Treosulfan-based conditioning proved to be safe, myeloablative, and highly immunosuppressive. It emerges as an excellent alternative to busulfan in this high-risk population, with no cases of conditioning-related graft failure, no significant mixed chimerism, and neither severe GVHD nor SOS.

Disclosure: Nothing to declare.

ESTABLISHING PRE-TRANSPLANT AUTOMATED RED CELL EXCHANGE FOR SICKLE CELL DISEASE: SAFETY AND FEASIBILITY RESULTS FROM A START-UP HSCT PROGRAM IN TANZANIA

Antonella Capasso[1,2], *Julieth Obedi*[3], *Cristina Tassi*[1], *Stella Malanghae*[3], *Merlikiad Mhozya*[3], *Allen Patrick Magoha*[3], *Happiness Igogo*[3], *David Mashala*[3], *Cathey Mhando*[3], *Alessia Orsini*[1,2], *Paola Erminia Ronchi*[1,2], *Irene Mteta*[3], *Zimbwe Bakari*[3], *Shakilu Jumanne*[3], *Francis Ngiliule*[3], *Nunzia Manna*[1], *Pietro Pioltelli*[1], *Alphonce Chandika*[3], *Kessy Charles Shija*[3], *Fabio Ciceri*[2], *Abel Makubi*[3], *Fabio Giglio*[1,2], *Cornelio Uderzo*[1]

[1]HELP3 ODV, Monza, Italy, [2]IRCCS San Raffaele Hospital, Milano, Italy, [3]Benjamin Mkapa Hospital, Dodoma, Tanzania, United Republic of

Background: Automated red blood cell exchange (a-RCE) is a key preparatory intervention before allogeneic hematopoietic stem cell transplantation (allo-HSCT) in patients with sickle cell disease (SCD), as it enables rapid reduction of sickle haemoglobin and minimizes sickling-related toxicity, improving organ protection, engraftment, and transplant outcomes.

Methods: Allo-HSCT represents the only curative therapy for SCD. As part of the first structured start-up transplantation program in Tanzania, we evaluated the feasibility, safety, and operational integration of a-RCE as a pre-transplant intervention intended to reduce sickling-related complications. Tanzanian staff didn't have previous experience in HSCT and procedures such as automatic RCE. From January 2023 to September 2025, 23 patients with severe sickle cell disease underwent allogeneic HSCT. The median patients age was 8 years (IQR 4-12). Overall, median pre-transplant level of HbS and haemoglobin were 78% (IQR 48-97) and 7,5 g/dL (IQR 5,8-10,8), respectively. All donors were HLA-matched siblings and 16 of them had sickle cell trait donor; two donor–recipient pairs exhibited major and minor ABO incompatibility. All patients had a tunneled central venous catheter placed prior to transplant. After dedicated training, Tanzanian clinical and technical staff performed automated red cell exchange using the Spectra Optia Apheresis System prior to conditioning, with fully compatible, irradiated, leukocyte-filtered packed red blood cells, to achieve a pre-transplant HbS level <30%.

Results: Overall, 20 patients underwent a-RCE prior to allo-HSCT , while one patient, presenting with 43% HbS, received two top-up transfusions 15 days before the transplant, having undergone automated RCE three months earlier for recurrent severe vaso-occlusive crises. An additional two patients treated in the first two months of the program received manual exchange transfusions. The median time between automated RCE and transplant was 17 days (IQR 12-24). 45% of patients (9/20) had a prior history of transfusion, with no documented alloimmunization. 70% of patients (14/20) with Hb level < 8 g/dl received top-up transfusions before the procedure. 80% (15/20) of patients required two RCE sessions, while 20% (4/20) underwent a single session and one patient required three. A mean of 3 (range 2–5) RBC units were exchanged per procedure. Median HbS level decreased from 78% (IQR 58-97) pre-RCE to 22% (IQR 12-33) post-RCE. Procedures were well tolerated, with stable post-procedure hemoglobin values. One patient developed transient haemolytic reaction during the second RCE session, despite pre RCE negative cross matches and IAT, leading to procedure interruption with full recovery. All patients reached stable donor engraftment without SCD-related complications.

Conclusions: In low-resource settings, safety and feasibility of a-RCE are strongly influenced by infrastructure, expertise, sustainability and reliable blood supply. Our experience demonstrates that, following targeted capacity building, a-RCE can be effectively incorporated into pre-transplant workflows, achieving the expected reduction in sickle hemoglobin with manageable, adverse effects and reducing allo-HSCT toxicities. a-RCE is now used in the same Centre also for SCD indications outside allo-HSCT. These findings highlight the importance of structured training in expanding access to advanced therapies for patients with SCD in LMIC, while a reliable and economically sustainable supply chain remains essential to ensure their availability.

B363

HIGH PLATELET TRANSFUSION BURDEN FLAGS ENDOTHELIAL RISK BUT NOT GVHD, AFTER PEDIATRIC SICKLE CELL HSCT

Hailey Tinsley[1], *Alonzo Needum*[1], *Kendall Oh*[1], *Erin Doherty*[1], *John Craddock*[1], *Bahey Salem*[1], *Anil George*[1], *Khaled Yassine*[1], *Gabriela Llaurador*[1], *Megha Thakkar*[1], *David Steffin*[1], *Bilal Omer*[1], *Helen Heslop*[1], *Robert Krance*[1], *Caridad Martinez*[1], *Alexander Ngwube*[1]
[1]*Baylor College of Medicine, Houston, United States of America (the)*

Background: Severe thrombocytopenia in the early post-HSCT period carries a risk of life-threatening bleeding, prompting platelet transfusions to maintain counts above 50000/μL in patients with sickle cell disease (SCD). Achieving this threshold often requires substantial platelet support during days 0–30. However, emerging evidence suggests that higher transfusion intensity may not be uniformly beneficial and may contribute to downstream harm. Platelets exert immuno-inflammatory effects that can amplify endothelial injury, and evaluating whether early platelet transfusion burden predicts acute GVHD (aGVHD) or endothelial syndromes could address a knowledge gap and help refine supportive care without implying causation.
Objectives: Primary: Assess whether high early platelet transfusion burden is associated with grade II–IV aGVHD by day +100.
Secondary: Explore associations with endothelial complications, hepatic veno-occlusive disease (VOD), posterior reversible encephalopathy syndrome (PRES), diffuse alveolar hemorrhage (DAH) and characterize severity signals including engraftment kinetics and RBC transfusion needs.

Methods: We retrospectively reviewed 80 pediatric and young adult SCD recipients of myeloablative HLA-identical sibling HSCT (2005–2024). The exposure was cumulative apheresis platelet units transfused during days 0–30 (median 12; IQR 7.8–15.3). "High burden" was defined a priori as the upper quartile (Q3; ≥15.25 units); a median split (≥12 vs <12) served as sensitivity testing. Platelet burden was also evaluated as a continuous variable for descriptive correlations. Outcomes followed standard institutional/EBMT criteria. Fisher's exact test evaluated categorical associations; Spearman correlation and OLS regression summarized trajectories. Given sample size, findings are exploratory.

Results: Primary outcome: Grade II–IV aGVHD occurred in 5.0% of high-burden vs 10.5% of low-burden patients (1/20 vs 6/57; OR 0.45; p = 0.67). Median-split sensitivity analyses were consistent, providing no evidence that higher early platelet burden increases aGVHD risk.
Endothelial complications: VOD occurred only in the high-burden group (3/20 vs 0/57; p≈0.016). Although notable, this small number and the multifactorial nature of VOD (conditioning exposure, iron status, graft source) limit inference. PRES and DAH were rare, and pooled analyses excluding VOD showed no association with platelet burden.
Severity signals (transfusion and engraftment): Platelet burden correlated strongly with RBC

transfusion needs (ρ = 0.66; $p<10^{-10}$). OLS regression estimated +0.19 RBC units per +1 platelet unit (95% CI 0.14–0.24; $R^2 \approx 0.42$). Higher platelet burden was associated with later platelet and ANC recovery ($\rho \approx 0.30$; $p \approx 0.02$ and $p \approx 0.008$, respectively). These relationships likely reflect clinical complexity rather than direct effects of transfusion.

Conclusions: In pediatric SCD HSCT, higher early platelet transfusion burden was not associated with increased grade II–IV aGVHD. A small enrichment of VOD in the high-burden group is hypothesis-generating and warrants validation incorporating factors including busulfan exposure, iron overload, graft source, and infection history. Independently, strong correlations with RBC support and delayed engraftment indicate that early platelet burden may function as a practical marker of early clinical severity, useful for risk stratification and targeted surveillance. Future work should evaluate a risk-adapted, platelet-trajectory anchored model in which day 0–30 platelet burden helps guide CNS-focused surveillance, hepatic monitoring in high-risk windows, and standardized thresholds to minimize unnecessary exposure.

63 HLA-IDENTICAL RELATED HAEMOTOPOIETIC STEM CELL TRANSPLANTS IN SICKLE CELL DISEASE

Eduardo J. Bardón-Cancho[1], *Teresa Martín-Aláez*[1], *María Salvador-Rodríguez*[1], *Jose Manuel Marco-Sanchez*[1], *Elena Cela*[1], *Cristina Belendez*[1], *Alba Gonzalez Guerrero*[1], *Pablo González Navarro*[2], *Marina García-Morin*[1]
[1]*Pediatricas Haematology Unit. Hospital General Universitario Gregorio Marañon, Madrid, Spain,* [2]*Unidad de Metodología y Bioestadistica - Instituto de Investigacion Sanitaria Gregorio Marañon, Madrd, Spain*

Background: Despite the progress in management, sickle cell disease (SCD) still carries high morbimortality. Waiting for gene therapy, allogeneic haematopoietic stem cell transplantation (HSCT) is the only curative treatment.

Methods: A single-center descriptive study was conducted in patients with SCD who underwent HSCT from an HLA-identical sibling donor between May 2010 and May 2025.
Stem cell source: bone marrow.
Transfusion therapy began 3 months before HSCT. Since 2015, hydroxyurea was initiated/intensified 1 month before to keep reticulocytes <100,000/mm³. During transplant, platelets were maintained >50,000/µL, hemoglobin >11 g/dL, and hypertension and hypomagnesemia were prevented to reduce neurological complications. Ovarian tissue is cryopreserved since 2015.
Conditioning regimen:

- Until January 2015: Busulfan, cyclophosphamide, alemtuzumab. Graft versus host disease (GVHD) prophylaxis: cyclosporine A (CsA) and methotrexate.
- After January 2015: Thiotepa, Treosulfan, Fludarabine, anti-thymocyte globulin (myeloablative conditioning but reduced toxicity).GVHD prophylaxis: CsA, mycophenolate mofetil (MMF) (Jan 2015–Feb 2019); tacrolimus, MMF (Feb 2019–May 2024) or tacrolimus, MMF and *post*-transplant cyclophosphamide (PTCy) (January 2025–May 2025).

Epidemiological, clinical, and analytical parameters were collected. Data are presented as percentages and medians (p25–p75).

Results: 63 HSCT were performed in 62 patients, 29 females (46%), median age of 6.45 years (3.07–9.82), 11 patients with the first conditioning, 52 with the second (GVHD prophylaxis: CsA/MMF 10/52, tacrolimus/MMFF 39/52 and tacrolimus/MMF/PTCy 3/52). Donor median age: 6.54 years (4.31–9.54). 48.4% sickle cell trait, 20.6% with major group incompatibility.All patients grafted but 3 patients had autologous reconstitution (AR): one developed recurrent symptoms and underwent a successful second HSCT (same donor); one lost follow up (month +14) with mixed chimerism (MC) and come back in AR with a refractory HLH due to EVB causing decease (month +41); the third is alive but without follow-up (month +4). Complete chimerism (CQ) was achieved in 41/63 (65.1%), mixed in 19/63 (30.1%). Overall survival (OS) and event-free survival (EFS) (death and graft failure) were 96% and 95% respectively, median follow-up of 5 years (2.5–6.7). First conditioning: OS 91% and EFS 90%. Second conditioning: OS 97% and EFS 96%.
Time to neutrophil and platelets engraftment: 19 days (17–22) and 23 (20–28) respectively. Complications of HSCT included: hypertension 52/63 (82.5%), CMV reactivation 43/63 (68.3%), acute renal failure 10/63 (15.9 %) and neurological complications 12/63 (19.4%) all recovered: subarachnoid haemorrhage (n=6), seizures (n=9), posterior reversible encephalopathy syndrome (n=5) or drug-related toxicity (n=4). Acute GVHD in 23/63 (36.5%): 52.2% stage I (n=12), 30.4% stage II (N=7), stage III (n=1) with good response to treatment and two patients developed grade IV causing one death on day +51 (first conditioning), the other with good response. One patient developed skin chronic GVHD score 1 with favorable evolution. One patient developed Hodgkin lymphoma 4.7 years after HSCT (QC, 7 months of immunosuppressive therapy) and, due to progression, he underwent a second HSCT with a favorable outcome.

Conclusions: The results of our study, the largest HSCT series in Spain, is similar to the international cohort and confirms the role of HSCT for children with SCD . Long-term follow-up remains essential to identify late complications.

Disclosure: Nothing to declare.

B365

CORRELATION OF HB S LEVEL WITH CHIMERISM POST BONE MARROW TRANSPLANT IN PATIENT WITH SICKLE CELL DISEASE

Hamza Albrashdi[1], *Mohammed Nasser Al Huneini*[2], *Thuraya Khalaf Al Busaidi*[2], *Abdul Hakim Al Rawas*[2], *Amr Abdalla Dahdouh*[2], *Maryam Al Bakri*[2], *Murtadha Al Khabori*[2]
[1]*Oman Medical Specialty board (OMSB), Muscat, Oman,* [2]*Sultan Qaboos University, Muscat, Oman*

Background: Hematopoietic stem cell transplant is the only curative treatment for sickle cell disorder which is recommended in selective patients in terms of prevent furthers serious complications of the disease and improved the quality of life (Payal Desai, 2022).Chimerism analysis is an crucial molecular test that used for assessment of engraftment after bone marrow transplant in patient with sickle cell disease. In addition to that, HbS level measurement has also been used along with chimerism by many transplant centers. In fact, there is no study that has been done to evaluate the correlation between Hb S level and chimerism in sickle cell disease post-transplant. Therefore, our research will evaluate whether the Hb S level is sufficient to predict the chimerism level and monitor the successful of engraftment or failure in SCD patient post HSCT following at SQUH.

Methods: In this single center retrospective study, we included patients with SCD who underwent HSCT at the transplant unit of Sultan Qaboos University Hospital (SQUH) and those who were transplanted abroad and returned for their post-transplant care to SQUH between January 2006 and December 2023. We included pediatric and adult patients. Clinical, laboratory and epidemiological data of relevance were collected for this cohort from the electronic health records. Patients were excluded if no chimerism or Hb S level results were available. Results were presented as appropriate using medians, means and proportions. The correlation was assessed using univariable and multivariable logistic regression. Scatter plot and linear regression analyses were performed to assess the correlation between hemoglobin S (Hb S) level and donor chimerism at multiple post-transplant intervals (3 months, 6 months, 1 year, and 2 years). All analyses and graphs were performed using R program software.

Results: A total of 117 patients were included in the study, comprising 71 males (60.7%) and 46 females (39.3%), with a mean age of 28.8 years. Most transplants were performed abroad, primarily in India (n = 64), while 53 transplants were carried out at SQUH. The majority of donors were sickle cell trait carriers (n=68,58.1%). Engraftment failure occurred in six patients (5.1%).No statistically significant correlation was observed at 3 months ($p = 0.374$) or 6 months ($p = 0.768$). This lack of correlation may have been influenced by donor sickle cell trait status, as majority of donors were carriers. At one-year post-transplant, a trend toward significance was observed ($p = 0.0573$), and a strong, statistically significant positive correlation emerged at two years ($p < 0.001$).

Conclusions: Hb S monitoring is a valuable indicator for long-term post-transplant follow-up, showing significant correlation with donor chimerism at 1 and 2 years. This relationship is influenced by donor sickle-trait status, underscoring the need for further analyses stratified by donor genotype.

Disclosure: I declare that there are no conflicts of interest in this study.

DIFFERENT APPROACHES TO HSCT IN TRANSFUSION-DEPENDENT B-THALASSEMIA

Gleb Bronin[1], *Feruza Rizaeva*[1], *Djamila Polatova*[1], *Gülüz Öztürk*[2], *Fatma Demir Yenigürbüz*[2], *Nazokat Aripova*[1], *Indira Erimbetova*[1], *Nigora Rustamova*[1]
[1]*Scientific and Practical Medical Center for Pediatric Oncology, Hematology and Immunology, Tashkent, Uzbekistan,* [2]*Medicana International Hospital Beylikdüzü, Istanbul, Turkey*

Background: β-thalassemia is a huge problem for the Central Asian region, causing the death of dozens of patients every year. Allogeneic hematopoietic stem cell transplantation (HSCT) is the only available curative treatment option in the region. The aim of this study is to explore different approaches to HSCT in transfusion-dependent β-thalassemia (TDT).

Methods: We analyzed the results of 50 HSCTs on patients with TDT treated according to different protocols. Patients' ages at the time of HSCT ranged from 2 to 14 years (average 5 years). Retrospective statistical analysis of HSCT results was performed.

Results: All patients received normal transfusion rates and chelation therapy in preparation for HSCT. Myocardial iron overload was detected in 3 cases and hepatic iron overload - in 29 cases before HSCT. 39 children had splenomegaly before HSCT. In 35 cases, long-term pre-transplant immunosuppressive therapy was administered, including fludarabine, dexamethasone, and monoclonal antibodies against CD20 and CD38. 15 patients were transplanted without long-term immunosuppression. 16 patients received transplant from a matched related donor (MRD), 20 patients - from an 10/10-matched unrelated donor (MUD), 10 – from an 9/10 MUD, 4 – from a haploidentical donor (haplo). All patients received a myeloablative conditioning regimen. The source of stem cells was peripheral blood for 42 patients and bone marrow – for 8 ones. 40 children received 100 mg/kg post-transplant cyclophosphamide for graft-versus-host disease (GVHD) prophylaxis. Additionally, 48 children received calcineurin inhibitors, 20 - mycophenolate mofetil, 12 -ruxolitinib. In 47 cases the engraftment was achieved with a median engraftment time of 21 days. Primary non-engraftment was observed in 1 patient, who demonstrated restoration of native hematopoiesis. 5 patients died: 3 due to severe GVHD, 2 – due to infection. Acute GVHD grade 3 was in 5 cases, chronic GVHD was detected in 10 patients. Mixed chimerism was seen in 20 cases, causing complete graft rejection in 5. Therapy with donor lymphocyte infusion was effective in 15 children. Transfusion dependence persisted for median duration of 6 months in 5 cases. In the group of patients received long-term pre-HSCT immunosuppression was significantly lower rate of severe GVHD ($p=0.03$), but significantly higher rate of severe infections ($p=0.04$). The rate of severe GVHD was higher in MUD group in comparison to haplo group ($p=0.04$). There was no difference in severe GVHD between 9/10 MUD and 10/10 MUD ($p=0.2$).

Conclusions: Multivariate statistical analysis shows age, primary organ iron overload, immune hemolysis as the major negative prognostic factors for the results of HSCT for TDT. Long-term immunosuppression can prevent severe GVHD but increases the risk of severe infections. Haplo HSCT is feasible and can be an alternative approach for HSCT strategy.

Clinical Trial Registry: Not applicable.

THIRTY YEARS LATER: UNEXPECTED, UNHERALDED, AND UNEXPLAINED RE-EMERGENCE OF THALASSEMIA FOLLOWING LONG-TERM ALLOGENEIC ENGRAFTMENT

Emanuele Angelucci[1], Stella Santarone[2], Luca Malcovati[3], Massimiliano Gambella[1], Anna Maria Raiola[1], Simona Geroldi[1], ***Valeria Maria Pinto***[1]
[1]IRCCS Policlinico San Martino, Genoa, Italy, [2]Ospedale Civile, Pescara, Italy, [3]Fondazione IRCCS Policlinico San Matteo, Pavia, Italy

Background: Limited data are available on the long-term (30 years) survival of allogeneic hematopoietic engraftment, regardless of the underlying disease. Patients with TDT who underwent transplantation in the 1980s represent a unique natural model to assess the long-term potential of transplanted hematopoietic stem cells to sustain hematopoiesis over several decades.

Methods: We report five patients transplanted in the 1980s and early 1990s who experienced an unexpected, unheralded, and unexplained graft loss and thalassemia recurrence more than 30 years after transplantation.

Results: Case 1: A 16-month-old male underwent transplantation in 1982 after conditioning with dimethyl busulfan and cyclophosphamide from an HLA-identical sister without thalassemia trait. The early post-transplant course was successful. No data were available for decades until 2014, when the patient (age 32) presented with severe anemia (Hb 6.5 g/dL) and 5% donor chimerism by STR. He resumed regular transfusions and was later lost to follow-up.
Case 2: A 3.7-year-old male underwent HCT in 1985 from an HLA-identical brother with thalassemia trait. Engraftment was initially monitored by blood group typing. From 2012 onward, hemoglobin levels progressively declined, reaching 6.5 g/dL by July 2016 (day +11,402), when STR analysis showed 19% donor chimerism. Transfusions were restarted. Donor chimerism further declined to 16% by 2019. He remains on regular transfusions and chelation.
Case 3: A 3.6-year-old female received an HLA-identical sibling transplant in 1994. Full donor chimerism was confirmed in 2010. Subsequently, Hb declined to 9 g/dL, and donor chimerism fell to 25% by 2016. By July 2024 (day +11,046), Hb was 7.5 g/dL with 17% donor cells, prompting resumption of transfusions.

Case 4: A 2.5-year-old female was transplanted in 1994 from an HLA-identical sister, with complete early chimerism. During her second pregnancy in April 2021 (day +9,720), Hb declined and transfusions resumed. Chimerism decreased to 26% in 2022 and 20% in 2023. She underwent a second transplant in October 2023 and is currently well.
Case 5: A 26-year-old male with sickle cell disease/thalassemia underwent transplantation in 1990 from an HLA-identical sister with thalassemia trait. After five years of full donor engraftment, he remained stable until late 2024, when Hb levels fell. In January 2025 (day +12,600), electrophoresis revealed 20% HbS and 7% HbF; FISH showed 61% Y/X metaphases, and blood typing indicated mixed A+/O+ red cells. He is under watchful monitoring.

Conclusions: All patients underwent transplantation in the 1980s or early 1990s, mostly receiving classic oral busulfan–cyclophosphamide myeloablative conditioning and HLA-identical sibling grafts. None received antithymocyte globulin or developed chronic GvHD, and all maintained excellent long-term quality of life. No clear immunologic trigger preceded graft loss.
Where follow-up was available, recurrence manifested as progressive anemia and declining donor chimerism, culminating in re-expansion of autologous hematopoiesis without accompanying leukopenia or thrombocytopenia.
These cases suggest that long-term exhaustion of allogeneic engraftment may occur decades after transplantation and highlight the remarkable durability, and possible "immortality", of autologous thalassemic stem cells, which may remain quiescent yet viable for decades after myeloablation. Systematic evaluation of long-term survivors in this unique cohort is warranted.

HLA-MATCHED RELATED DONOR TRANSPLANTATION IN CHILDREN WITH TRANSFUSION-DEPENDENT THALASSAEMIA: A SINGLE-CENTRE EXPERIENCE IN A RESOURCE-LIMITED SETTING – LADY RIDGEWAY HOSPITAL FOR CHILDREN, SRI LANKA

Shanika Vitharana[1], *Nipunika Senadheera*[1], *Ruwangi Dissanayaka*[1], *Dhammika Vidanagama*[1], *Deepal Perera*[1], *Nihal Gunaratne*[1]
[1]*Lady Ridgeway Hospital for Children, Colombo, Sri Lanka*

Background: Transfusion-dependent thalassaemia (TDT) is a significant health burden in low- and middle-income countries (LMIC) such as Sri Lanka. In LMIC, Haematopoietic stem cell transplant (HSCT) remains the only curative option as it's a low-cost treatment modality compared to gene therapy.

Methods: We present the outcomes of 18 children with confirmed TDT who underwent matched family donor transplants at LRH between December 2021 and Dec 2025. Patients were classified into the Pesaro groups, none of the patients was in class1. 15

children were in class 2, and 3 were in class 3. Class 1 and 2 children received oral Busulfan/Cyclophosphamide either with rabbit or horse Antithymocyte globulin. Class 3 received Thioptepa/Treosulfan/Fludarabin.
All received graft vs host disease prophylaxis with Intravenous Cyclosporin and short course of Methotrexate.

Results: All patients were under the age of 14 years at the time of transplants. and 11%(*n=2*) were under 7 years, while 88% (*n=16*) were over 7 years. The median age of the patients at the transplant was 10 years and 5 month (range 4 years 6 months to 12 years 7 months).
Karnofsky-Lansky score before transplantation was > 90 in all patients. The male-to-female ratio was 1.25:1, and all were 10/10 HLA-matched donor transplants. 55% (*n = 10*) of the patients received stem cells from their brothers, 38% (*n = 7*) from their sisters, and 5 % (*n=1*) from their father. 38% (*n=7*) had sex-matched donors, while 73% (*n=13*) had blood group-matched donors. Of the four group-mismatched donors, three were major mismatches.
72%(*n = 13*) received bone marow graft and 27% received peripharal blood stemcells. The mean CD34 stem cell dose was 7.3 x 10^6 /Kg. All patients engrafted, and the median time to engraftment was 17 days (range,15 -26 days). Platelet engraftment occurred at a median time of 20 days (range, 15 – 27 days). The median duration of follow-up was 539 days (range 51 - 1452 days).
Median donor chimerism was 99% (range 72.07 – 100%) at the last follow-up. Twelve patients achieved sustained full donor chimerism, and four had stable mixed chimerism. Despite being a LMIC, 5% transplant-related mortality (TRM), 95% overall survival (OS) rates, with a 95% thalassaemia-free survival rate and GvHD free thalassaemia free survival (GFGS) being 88.9 % at the time of writing. All 18 children are alive, transfusion-independent, and maintaining excellent quality of life.

Conclusions: This report represents a single-centre experience of HLA-matched sibling donor HSCT in children with TDT in a government-funded transplant centre in Sri Lanka. Our findings confirm that HLA-matched related donor HSCT is a safe, and cost-efficient curative option for children with TDT, even in low-resource settings. Careful patient selection, appropriate conditioning regimens,and experienced multidisciplinary care, enabled excellent outcomes.
Scaling up access to HSCT for thalassaemia in Sri Lanka and similar settings will require increased infrastructure, training, and early identification of suitable patients before irreversible organ damage occurs. Given its curative potential and cost advantage over lifelong transfusion and chelation, HSCT should be prioritised in national thalassaemia management strategies.

Disclosure: No disclosure.

B369

HAPLOIDENTICAL STEM CELL TRANSPLANTATION AS A CURATIVE STRATEGY FOR SEVERE SICKLE CELL DISEASE: A SINGLE-CENTER REPORT

*María Salvador-Rodríguez[1], **Teresa Martín-Aláez**[1], Elena Cela[1], Jose Manuel Marco-Sanchez[1], Cristina Belendez[1], Alba Gonzalez Guerrero[1], Marina García-Morin[1], Pablo González Navarro[2], Eduardo J. Bardón-Cancho[1]*
[1]Pediatricas Haematology Unit. Hospital General Universitario Gregorio Marañon, Madrid, Spain, [2]Unidad de Metodología y Bioestadistica - Instituto de Investigacion Sanitaria Gregorio Marañon, Madrd, Spain

Background: Haploidentical hematopoietic stem cell transplantation (haplo-HSCT) has emerged as a curative option for patients with severe sickle cell disease (SCD) who lack an HLA-matched sibling donor. Improvements in conditioning regimens and graft manipulation have broadened transplant accessibility. We report our single-center experience using post-transplant cyclophosphamide (PTCy) platform.

Methods: Descriptive review on patients with high-risk SCD who underwent haplo-HSCT from related donors between December 2022 and December 2025. Conditioning: thiotepa, fludarabine, rabbit antithymocyte globulin (ATG) and 2 Gy TBI, except for the first patient, who received treosulfan. Graft versus host disease (GVHD) prophylaxis: mycophenolate mofetil with tacrolimus or sirolimus and PTCy, abatacept was added in the last two patients. All patients received hydroxyurea before transplantation and peri-transplant transfusion support. The first patient additionally received azathioprine for two months andrequired rituximab and plasmapheresis due to alloimmunization. Bone marrow was the graft source in all but one. Outcomes analyzed included engraftment, chimerism, GVHD, and toxicities. Data is presented as percentages and medians (p25; p75).

Results: Six haplo-HSCT were performed in five patients, median age at transplantation: 16.9 years (15.7; 17.3), 3 males. Donor median age 39.2 years (14.4; 43.5), no major group incompatibility, 1/6 with CMV mismatch. All patients achieved engraftment, with median neutrophil and platelet recovery of 20 (17.5; 23.3) and 41 days (36; 71), respectively.
The first patient experienced early graft rejection on day +40 following HHV-6 reactivation and secondary hemophagocytic lymphohistiocytosis and successfully underwent a second haplo-HSCT (different related donor; thymoglobulin, thiotepa, and fludarabine conditioning and peripheral blood stem cells source). The remaining patients maintained full donor chimerism. Delayed platelet recovery required thrombopoietin receptor agonists in 3/6. Overall survival (OS) was 100%, and event-free survival (considering death or graft failure) was 83%, with a median follow-up of 2.5 years (1.7–2.8).
Acute GVHD occurred in 66.7% of patients (grade I, n=2; grade III, n=2) with good response to treatment. Three patients developed overlap syndrome with intestinal involvement (no biopsy confirmation in 66.7% cases), treated with photopheresis and ruxolitinib: one is off treatment, one is tapering immunosuppression, and one remains on immunosuppressive therapy. One patient (20%) developed chronic GVHD (liver and ocular

involvement), after photopheresis, he remains without immunosuppressive treatment, only receiving topical treatment. CMV reactivation occurred in 2/6, hypertension (4/6), reversible acute kidney injury (3/6), mucositis (2/6) and neurologic toxicity (2/6): two cases of PRESS, one suffering from subarachnoid hemorrhage, seizures and encephalopathy with rising ammonia levels that required chelation therapy and hyperfiltration with neurological sequelae.

Conclusions: Haplo-HSCT using PTCy was feasible in this small cohort of adolescents with severe SCD, resulting in 100% OS and high rates of sustained donor engraftment. Early transplant-related toxicities were frequent, underscoring the need for careful supportive care. Given that hemoglobinopathies are non-malignant diseases, the risk of chronic GVHD remains a major concern due to its potential long-term impact on quality of life. Despite the limited sample size, these results support haplo-HSCT as a curative alternative for patients lacking an HLA-identical donor and emphasize the need for further optimization of transplant strategies.

Disclosure: Nothing to declare.

P266

HEMATOPOIETIC CELL TRANSPLANTATION IN PEDIATRIC UNSTABLE HEMOGLOBINOPATHIES: TWO RARE CASES WITH SUSTAINED DONOR CHIMERISM AND LONG-TERM FOLLOW-UP

Annie Karoline Feijó Costa[1], Joana Teresa Bisinella de Faria[1], Gabriela Ventura de Almeida Silva[1], Renata Fittipaldi da Costa Guimarães[1], Carlos Eduardo Setanni Grecco[1], Thalita Cristina de Mello Costa[1], Ana Beatriz Pereira Lima Stracieri[1], Maria Carolina de Oliveira Rodrigues[1], Fabíola Traina[1], ***Luiz Guilherme Darrigo Jr***[1]
[1]*Clinical Hospital of Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, Brazil*

Background: Unstable hemoglobinopathies are rare inherited disorders. In severe cases, symptoms may appear early in life. This can include marked hemolytic anemia, fetal hydrops, and a need for transfusions. Currently, hematopoietic cell transplantation (HCT) is considered the only curative treatment available. Reports on HCT, particularly for severe variants, are limited. Existing literature often presents fragmented information and lacks comprehensive details regarding donor chimerism and long-term outcomes. This knowledge gap is especially pronounced in the pediatric population.

Methods:

We describe two pediatric patients with severe unstable hemoglobinopathies. The participants underwent HCT at a tertiary care center in Brazil. We evaluated several factors, including age at transplantation, donor type, and conditioning regimen. Additionally, we assessed hematologic engraftment, donor chimerism, and long-term clinical outcomes.

Results:

Case 1 involved a male patient diagnosed with the hyperunstable hemoglobin variant Zurich–Albisrieden. He presented with fetal hydrops and required transfusions from birth. At age 3 years, he underwent HCT from a matched sibling donor, utilizing a myeloablative conditioning regimen. Neutrophil and platelet engraftment were observed on day +28 and +35, respectively. Mild infections and suspected endothelial toxicity were managed conservatively. Donor chimerism reached > 95% within the first year post-transplant and has been maintained to the present. The patient remains transfusion-independent, with iron overload managed by therapeutic phlebotomy.

Case 2 involved a female patient with severe unstable hemoglobinopathy resulting from the co-inheritance of Hb Bristol-Alesha [β67(E11)Val→Met] and the α212 Patchwork allele. At age 1 year, she underwent haploidentical HCT from her mother after a non-myeloablative conditioning regimen of fludarabine, cyclophosphamide, and low-dose total-body irradiation. However, she experienced secondary graft failure prior to day +100. At 4 years old, she underwent a second haploidentical HCT from her father, with a myeloablative conditioning consisting of fludarabine, busulfan, and antithymocyte globulin. Neutrophil and platelet engraftment were observed on days +12 and +20, respectively, with early and sustained donor chimerism. The patient developed grade II acute cutaneous graft-versus-host disease, which responded effectively to corticosteroid treatment. After more than 8 years of follow-up, she remains transfusion-independent, with preserved cardiopulmonary function.

Table1. Characteristics and outcomes of patients

Variable	Case 1	Case 2
Sex	M	F
Hb variant	Zurich–Albisrieden	Bristol-Alesha + α212
Onset	Fetal hydrops	Congenital HA
HSCT age (y)	3	1 / 4
Donor	MSD	Haplo
Conditioning	MAC	NMAC → MAC
Engraftment	ANC +28	PLT +12; ANC +20
GVHD	No	Acute II
Chimerism	Full	Full
Transfusion-free	Yes	Yes
Follow-up	>8y	>7 y

Abbreviations: HA, hemolytic anemia; HSCT, hematopoietic stem cell transplantation; MSD, matched sibling donor; Haplo, haploidentical donor; MAC, myeloablative conditioning; ANC, absolute neutrophil count; PLT, platelets; GVHD, graft-versus-host disease; Flu, fludarabine; Cy, cyclophosphamide; TBI, total body irradiation; Bu, busulfan; ATG, anti-thymocyte globulin.. Source: Authors' own data.

Conclusions:

Currently, the literature reports few cases of transplantation in patients with unstable hemoglobinopathies. This study describes two pediatric patients exhibiting a severe phenotype. HCT resulted in durable donor chimerism and long-term transfusion independence for both patients. These findings suggest that HCT may serve as a curative treatment for severe unstable hemoglobinopathies. Moreover, myeloablative conditioning has demonstrated greater efficacy, even in the context of haploidentical transplantation.

Disclosure: Nothing to declare.

P268

EVALUATING THE SAFETY, EFFICACY, AND OUTCOMES OF A TARGETED INVASIVE PRENATAL SCREENING PROGRAM FOR HEMOGLOBINOPATHIES IN RURAL AND SEMI-URBAN INDIA

Mohana Reddy D M[1], *Tejashree Sridhar*[1], *Anusha S*[1], *Sundar Periyavan*[1], *Balasubramani Rengaraj*[1], *Sudha K*[1], *George Mani*[1], *Anirudha Dhar*[1], *Vidhi Mayur*[1], *Rajat Agarwal*[1], *Ankita Kumari*[1], *Lawrence Faulkner*[2]
[1]*Sankalp India Foundation, Bengaluru, India,* [2]*Cure2children Foundation, Florence, Italy*

Background: Hemoglobinopathies, such as thalassemia and sickle cell disease, are prevalent genetic disorders in India, disproportionately affecting rural and underserved populations. While there have been advances in prenatal diagnostics in metropolitan areas, access to these services still remains limited in rural regions. This study aims to evaluate the implementation and outcomes of an invasive prenatal diagnostic (IPND) program for prevention of hemoglobinopathies by Sankalp India Foundation across five states in India.

Methods: The program screened gestational women within 20 weeks of gestational age across 82 districts in five states in India, from June -2023 to September -2024. The program followed a targeted screening approach consisting of, a three-step model: HPLC testing, molecular confirmation, and invasive prenatal diagnosis for affected fetus (amniocentesis at >16 weeks and chorionic villus sampling at <14 weeks of gestation) supported by comprehensive counselling at each stage along with robust counselling at every step. Fetal samples were collected at local centers and sent to centralized laboratories for the analysis of causative mutations. Couples with a fetus diagnosed with severe hemoglobinopathy received counselling and were allowed to make informed decisions regarding medical termination of pregnancy (MTP), in accordance with the country's legal and ethical guidelines.

Results:

From June 2023 to September 2024, 81,139 women were screened across 24 centers in five states, identifying 6,323 (7.8%) carriers: 2,181 (34.5%) beta thalassemia, 3,618 (57.2%) sickle cell disease, and 524 (8.3%) other hemoglobinopathies (Hb-D Punjab, Hb-E, Hb-Lepore, etc.). Among 5,983 (94.6%) partners screened, 11 (0.2%) couples had benign variants, while 802 (13.4%) couples were at significant risk of having a fetus with a severe hemoglobinopathy.

A total of 536 (66.8%) couples registered for invasive prenatal diagnosis, and 495 (92.4%) completed the procedure. Among these, 495 singleton and five twin pregnancies were analyzed, with 381 (77%) undergoing amniocentesis at a median gestational age of 18.3 weeks (IQR 16.9–20.3) and 119 (24%) undergoing CVS at 13.1 weeks (IQR 12.3–13.8). Antibiotic prophylaxis was given in 393 (80%) cases. Two spontaneous abortions (0.6%) occurred post-amniocentesis without prophylaxis; Anti-D was administered in only two (0.4%) cases.

Of 500 fetal samples analyzed, 476 (95.2%) met quality standards, with 27 (5.4%) requiring culture or repeat testing due to maternal contamination or insufficient fetal cells; three couples required repeat procedures, with one refusal. Eight (1.6%) couples returned for testing in subsequent pregnancies.

Fetal analysis revealed 251 (50.2%) heterozygous carriers, 112 (22.4%) negative, and 137 (27.4%) affected. Couples received genetic and psychological counseling for medical termination of pregnancy (MTP), resulting in 88 (64.2%) terminations, while 49 chose to continue the pregnancy. Median turnaround time for counseling and MTP was 1.7 weeks (IQR 1.4–2.6).

Conclusions: This initiative demonstrates the feasibility of delivering IPND services in low-resource settings through a decentralized sample-collection model integrated with analysis at centralized laboratories. By integrating genetic counselling, effective sample management, and timely facilitation of informed -MTP facilitation, the program provides a scalable framework for reducing the burden of hemoglobinopathies in India.

OS21-05

PROSPECTIVE MULTICENTRE ANALYSIS OF FLUDARABINE EXPOSURE IN CHILDREN RECEIVING FLUDARABINE-TREOSULFAN-THIOTEPA FOR NON-SCID INBORN ERRORS OF IMMUNITY: PRELIMINARY FINDINGS FROM HAPLO+4KIDS

Emma Barlow[1], *Shelby Barnett*[1], *Ka-Yuk Ko*[2], *Kathryn Poad*[2], *Tom Altmann*[1,2], *Christo Tsilifis*[2], *Gareth Veal*[1], *Kanchan Rao*[3], *Mary Slatter*[1,2], *Sophie Hambleton*[1,2], *Su Han Lum*[1,2]
[1]*Newcastle University, Newcastle upon Tyne, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Newcastle upon Tyne Hospital NHS Foundation Trust, Newcastle upon Tyne, United Kingdom of Great Britain and Northern Ireland (the),* [3]*Great Ormand Street Hospital for Children NHS Foundation Trust, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Fludarabine (FLU) has largely replaced cyclophosphamide in paediatric reduced toxicity conditioning regimens as it provides potent lymphodepletion to prevent immune mediated graft rejection while offering a more favourable toxicity profile. FLU-Treosulfan±Thiotepa is now a recommended conditioning regimen for children with inborn errors of immunity (IEI). Despite widespread use, FLU paediatric dosing practices have been variable, including different dosing strategies using body surface area (BSA) and body weight, resulting in considerable heterogeneity in drug exposure. While reported target exposure ranges for paediatric HSCT vary, cumulative exposure (cAUC) > 25mg.h/L is associated with significantly higher transplant related mortality (TRM) attributed to infection and organ toxicity, while cAUC < 15mg.h/L is associated with graft failure. The Haplo+4Kids trial are conducting the first prospective study to systematically measure drug exposure for FLU-treosulfan-thiotepa within a unified conditioning platform. The preliminary results for FLU will be presented.

Methods: All patients enrolled in the Haplo+4Kids trial received standard conditioning with Thiotepa (5mg/kg BD on day -7), Treosulfan (10-14g/m^2/day on days -6, -5 and -4) and Fludarabine (40mg/m^2/day on days -6, -5, -4 and -3). Serotherapy was alemtuzumab for matched unrelated donor and ATG-Grafalon for TCRab-depleted mismatched family/unrelated donor. FLU was infused over 1 hour, with PK samples collected at 0, 1, 3 and 22 hours post end of infusion. A fully validated liquid chromatography-tandem mass spectrometry assay was used to measure fludarabine concentration. Pharmacokinetic (PK) analysis was conducted using a 3-compartment population PK model using InsightRX. FLU exposure using measured PK data was compared with model-based dosing (MBD) predictions without measured PK data to assess the appropriateness of MBD.

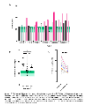
Results: FLU PK analysis has been conducted for 32 non-SCID IEI patients. Median age at HSCT was 2.7 years (0.16 - 16.3 years). All patients except one (25% dose reduction for renal impairment) received standard FLU dosing. The median cAUC was 28.1mg.h/L (16.4-49.3mg.h/L), with 20/32 patients (62%) achieving cAUC >25 mg.h/L, a level which has previously been associated with increased toxicity and transplant related mortality (Figure 1A) (Table 1). All 11 infants (<1 year) achieved exposures >25mg.h/L, with a median of 36mg.h/L (28.1-49.3mg.h/L). Infants also achieved significantly higher cAUCs than older children ($p<0.0001$) (Figure 1B) and demonstrated significantly lower body surface area normalised clearance values ($p<0.0001$).
Model predicted exposures differed significantly from the measured-predicted exposures generated after incorporating concentration-time data into the model (Figure 1C). Measured exposures (median 28.1, 16.4-49.3) were consistently higher and more variable than model predicted exposure alone (median 21.6, 17.1-30.8; $p<0.0.001$). Had model-based dosing alone been utilised, potentially suboptimal achieved exposures would have been missed for 14/32 patients (44%).

Table 1

	Patient Age (Years)		
	< 1 (n= 11)	1-13 (n= 16)	³ 13 (n= 5)

Weight (kg), Median (range)	6.5 (4.2 - 10.7)	14.9 (7.5 - 35)	55.2 (23.8 -72.2)
BSA (m^2), Median (range)	0.36 (0.28 -0.53)	0.65 (0.4 - 1.2)	1.6 (0.9 - 1.9)
Creatinine (pre 1st flu infusion) (mmol/L), Median (range)	21 (12 – 37)	23.5 (17-85)	44 (31 – 76)
cAUC (mg.h/L), Median (range)	36 (28.1 – 49.3)	24.2 (16.4 – 35.6)	30.1 (24.5 - 35.2)
Patients with cAUC 20-25 mg.h/L n (%)	0 (0)	9 (56)	2 (40)
Patients with cAUC <20 mg.h/L n (%)	0 (0)	2 (12.5)	0 (0)
Patients with cAUC >25 mg.h/L n (%)	11 (100)	5 (31)	3 (60)
MBD dosing cAUC (mg.h/L), Median (range)	27.4 (22.2 - 30.8)	18.6 (17.1 - 26.6)	24.2 (20.9 - 25.5)
Percentage difference between measured PK and MBD cAUC, Median (range)	32.2 (6.2 - 101.3)	29.8 (-14.1-87.4)	30.3 (-3.9 - 63.0)

Figure 1



Conclusions: Preliminary data indicate considerable interpatient variability in fludarabine exposure in paediatric HSCT patients. Body surface area-based dosing may lead to overexposure, particularly for infant patients. MBD without measured PK data was inaccurate in estimating individual fludarabine exposure in our study cohort, underscoring the importance of real-time therapeutic drug monitoring to enable personalised dosing to achieve a targeted drug exposure to optimise engraftment whilst minimising the risk of toxicity.

Background: While data on long-term outcomes after haematopoietic stem cell transplantation (HSCT) are growing, existing guidance remains dominated by cohorts with haematological malignancies and often focuses on early follow-up. For patients with inborn errors of immunity (IEI), late effects are uniquely influenced by the underlying immune defect, treatment toxicity, and immune reconstitution, necessitating tailored survivorship care. This project developed the first European, multidisciplinary consensus guidance specifically for late effects post-HSCT in the IEI population. Our objective was to develop and validate the first European, patient-centered, multidisciplinary consensus guidance for the surveillance and management of late effects following HSCT in patients with IEI.

A rigorous, stepwise consensus process was followed: (1) Systematic Literature Review: A comprehensive search of PubMed/Medline and additional databases from April–November 2023 (with updates in March 2024, March 2025, and September 2025) identified 24,768 publications. Inclusion criteria encompassed all study types (including case reports and expert views) involving adult and/or paediatric recipients of HSCT for IEI, with long-term follow-up data (>2 years post-HSCT). Exclusion criteria were *in vitro* or animal studies, non-English language publications, studies with no or few IEI-HSCT patients, and studies reporting only short-term outcomes (<2 years). Following screening and duplicate removal, two independent reviewers applied these criteria for selection and critically appraised the level of evidence, with disagreements resolved by a third reviewer. This resulted in 278 publications for inclusion. (2) Drafting & Grading: Initial recommendations were drafted and graded using the GRADE framework. (3) Internal Consensus: A two-round Delphi process was conducted with a core multidisciplinary panel of 18 internal experts, including 5 junior specialists, 2 nurse specialists, 2 psychologists, 1 patient representative, and 8 senior bone marrow transplant (BMT) and immunology experts. (4) External Validation: A third Delphi round was performed with an independent European validation group of 15 senior BMT and immunology experts (collaborators; figure 1). (5) Integration & Implementation: This included an internal review of external feedback and collaboration with the International Patient Organisation for Primary Immunodeficiencies (IPOPI) to develop a patient leaflet. Consensus was defined *a priori* at ≥80% and further categorized: 100% (unanimous), 90–99% (very strong), and 80–89% (consensus).

Results: The systematic review informed the initial 77 recommendations. The internal Delphi successfully generated consensus on all 77 recommendations across core domains. External validation refined the guidance, with consensus reached on 70/77 recommendations (90.9%). Of these, unanimous consensus was achieved for 29 (37%), very strong consensus for 25 (32%), and consensus for 16 (21%) recommendations. The final guidance is now undergoing internal review, constituting the first part of the implementation step.

Conclusions: This work demonstrates a robust model for guideline development, resulting in the first comprehensive European consensus for post-HSCT survivorship care in IEI. The integration of a parallel patient-resource development process ensures the final guidance will serve as a clinically valid and practical tool to standardize and improve long-term follow-up care for this unique patient population across Europe.

Background: Osteopetrosis (OP) is a group of rare inherited conditions characterized by dysfunctional osteoclasts, leading to hypocalcemia, cytopenia, bone fractures and vision loss. Hematopoietic stem cell transplantation (HSCT) is the only curative approach for most children with OP but is complicated by high incidence of graft failure (GF), veno-occlusive disease (VOD) and transplant-related mortality (TRM). To define prognostic risk factors in this setting, the IEWP of the EBMT performed a large registry study on HSCT in OP.

Methods: We analyzed the outcomes of children with OP receiving HSCT in EBMT centers between 1990 and 2022. Endpoints were overall survival (OS) and event-free survival (EFS) according to year of HSCT, donor type, stem cell source and conditioning regimen.

Results: We studied 752 children affected by OP, with a median age at transplant of 0.7 years (range: 0-15). Genetic results were available for 435 patients: *TCIRG1* 66.4%, *CLCN7* 12.9%, *SNX10* 6.6%, *RANK* 5.9%, and others 8.2%. The median follow-up was 7 years (range 0-33.8 years). Conditioning regimen was Busulfan/Fludarabine (n=316; 43.9%), Busulfan/Cyclophosphamide (n=237; 32.9%), Treosulfan/Fludarabine/Thiotepa (n=131; 18.2%), or other (n=36; 5%). Donors were matched sibling donor (MSD; n=208, 29.2%), matched related (MRD; n=78, 11%), matched unrelated (MUD, 10/10 or 6/6; n=174; 24.4%), mismatched related (MMRD; n= 168; 23.6%), mismatched unrelated (MMUD, n= 84; 11.8%). Stem cell source was bone marrow (BM, n=476; 63.8%), peripheral blood (PB, n=201; 26.9%) or umbilical cord blood (UCB, n=63; 8.4%).
The 3-year Kaplan-Meier estimate of OS was 69% (95% CI, 66-73). Survival improved over time: 3-year OS was 50% (42-59%), 66% (60-73%) and 78% (73-82%) for patients transplanted between 1990-2000, 2001-2011 and 2012-2022, respectively (p<0.001).
Risk factor analysis was performed for patients transplanted between 2007-2022 (n= 497, 66%), reflecting adoption of modern transplant procedures. In this group, the 3-year OS, EFS and CI of graft failure (GF) was 75% (71-79%), 62% (57-66%) and 21% (17-26%), respectively.
In multi-variate analysis (MVA), OS was lower in patients with poor performance status (HR, 1.73; p=0.047), splenomegaly (HR, 2.26; p=0.007). Centre size was associated with OS, with better outcomes in large centers (p<0.001), motivating the inclusion of center in the MVA model.
In MVA, EFS was lower in patients with poor performance score (HR, 2.11; p<0.001), splenomegaly (HR, 2.92; p<0.001), use of HLA mismatched donors (HR, 1.85; p=0.001) and PB as stem cell source (HR, 1.67; p=0.001).
The 30-day CI of VOD was 22% (16-24%). In MVA exposure to Busulfan/Fludarabine (HR, 5.35; p<0.001) was an independent risk factor. Arterial pulmonary hypertension and hypercalcemia were described in 12.1% and 18.5% evaluable patients, respectively.
OP-related clinical phenotype HSCT showed improved cytopenia (p<0.001), growth (p<0.001), and intracranial hypertension (p<0.001). Second HSCT was performed in 104 patients, with a 3-year OS and EFS of 56% (46-66%) and 40% (30-50%), respectively.

Conclusions: This is the largest study to date describing HSCT outcomes in children affected by OP. Survival has significantly improved over the last decade, especially when an HLA matched donor is unavailable. Due to the complexity of OP patients, it is recommended that HSCT is performed in large centers.

Background: Ataxia-telangiectasia (A-T) is a rare DNA-repair disorder characterized by progressive neurodegeneration, immunodeficiency, and a high risk of malignancy. The role of allogeneic hematopoietic stem cell transplantation (alloHSCT) in A-T remains controversial due to concerns regarding toxicity and transplant-related mortality. We report a multicenter experience evaluating feasibility, outcomes, and indications for alloHSCT in patients with A-T.

Methods: We retrospectively analyzed 16 A-T patients undergoing alloHSCT in 8 centers. Indications included malignancy (n=5; EBV+ B-NHL n=1, ALL n=1, T-ALL n=3) and pre-emptive transplantation for immunodeficiency (n=11; CID/SCID phenotypes, severe infections, granuloma, HIGM phenotype, or abnormal newborn screening). Conditioning regimens included reduced-intensity or non-myeloablative fludarabine-based protocols using cyclophosphamide, busulfan or treosulfan, and serotherapy (ATG or alemtuzumab). Overall survival (OS), transplant-related toxicity, graft-versus-host disease (GVHD), and donor chimerism were assessed.

Results: Median age at alloHSCT was significantly lower in the pre-emptive group compared with the malignancy group (2.5 vs 8 years; $P = 0.013$). Median follow-up was 6 years (range 5–9) for pre-emptive HSCT and 11 years (range 2–16) for malignancy-associated HSCT.

Overall survival did not differ significantly between groups (log-rank $P = 0.31$). In the pre-emptive cohort, alloHSCT resulted in sustained correction of immunodeficiency with resolution or improvement of severe infections and granulomatous disease. Peripheral blood donor chimerism at last follow-up was significantly higher in the malignancy cohort, nevertheless both groups achieved high T cell chimerism levels.

Conclusions: Allogeneic HSCT in A-T is feasible when using carefully selected reduced-intensity conditioning regimens. Pre-emptive alloHSCT appears effective in correcting immunodeficiency and may reduce the risk of malignancy. Outcomes in malignancy-associated HSCT were comparable when performed in complete remission. These data support further prospective evaluation of pre-emptive alloHSCT as a disease-modifying strategy in selected A-T patients.

HEMATOPOIETIC CELL TRANSPLANTATION FOR PRIMARY IMMUNODEFICIENCIES IN CHILDREN: THE UKRAINIAN EXPERIENCE (2018–2025)

Oleksandr Istomin[1], *Olha Karpenko*[1], *Andrii Budzyn*[1], *Natalia Stryha*[1], *Natalia Trofimova*[2], *Nataliia Olkhovych*[2], *Oleksandr Lysytsia*[1]
[1]*HCT and Immunotherapy, NSCH "Ohmatdyt", Kyiv, Ukraine,* [2]*Expert Genetics Lab, NSCH "Ohmatdyt", Kyiv, Ukraine*

Background: Hematopoietic cell transplantation (HCT) remains the only curative treatment for many primary immunodeficiencies (PIDs). In Ukraine, although 11 medical centers are involved in transplantation activities, the National Specialized Children's Hospital "Ohmatdyt" (NSCH) is the only institution providing sustained paediatric HCT across haematologic, oncologic, metabolic disorders, and PIDs.
Since 2022, Ukraine has implemented a national expanded newborn screening program, increasing the number of screened conditions from 4 to 21, including severe combined immunodeficiency (SCID). This study summarizes the clinical experience and outcomes of paediatric HCT for PIDs performed at our center between March 2018 and July 2025, with emphasis on early diagnosis and transplant timing.

Methods:

We conducted a retrospective analysis of 25 children with PIDs who underwent allogeneic HCT between 2018 and 2025. Conditioning regimens were based on a modified EBMT/ESID Protocol D with individualized adjustments according to clinical status, infectious burden, donor availability, and transplant-related risk. GVHD prophylaxis was donor-adapted: matched sibling donors (MSD) received cyclosporine A (CsA) and methotrexate (MTX); matched unrelated donors (MUD) received CsA, MTX, and antithymocyte globulin (ATG); haploidentical donors received post-transplant cyclophosphamide (PTCy), CsA, and mycophenolate mofetil (MMF).

Results:

Baseline patient and transplant characteristics are summarized in Table 1. Ten patients (40%) had SCID and 15 (60%) had non-SCID PIDs. The median time from diagnosis to HCT was 3.3 months in SCID and 12.9 months in non-SCID PIDs. Importantly, five SCID cases were identified through the national newborn screening program, enabling pre-symptomatic diagnosis and early referral for transplantation.

Tab 1. Patient and Transplant Characteristics (March 2018 – July 2025)

Characteristic	Value
Patients, n	25
Male, n (%)	21 (84)
Age < 1 year, n (%)	6 (24)
Mean age, years	4
Diagnosis category, n (%) and details, n	**SCID 10 (40);** IL2RG - 3; AK2 - 1; ADA-II deficiency - 1; RAG1 - 1; IL7RA - 1; Artemis - 1; Omenn - 1; CARD11 - 1
	PID 15 (60) WAS - 3; XLP - 2; CGD - 1; STAT1 GOF 1; DOCK8 - 1; GATA2 defficiency - 1; Hyper-IgM (CD40LG) 1; NBS - 1; CID - 1; ADA II 1; CVID - 1; IPEX 1
Median time to HCT, months	SCID 3,3; non-SCID 12,9
Median follow-up, years	2,5
Donor type, n (%)	MSD 8 (32); Haplo 1 (4); MUD 12 (48); MMUD 4 (16)
Graft source, n (%)	PBSC 16 (64); BM 7 (28)

Chimerism, n (%)	Complete 16 (64); Mixed 8 (32)
aGVHD, n (%)	15 (60)

Tab 1. Patient and Transplant Characteristics (March 2018 – July 2025)

Characteristic	Value
cGVHD, n (%)	6 (24)
aGVHD grade, n (%)	I–II 9 (60); III–IV 6 (40)

HCT – hematopoietic stem cell transplantation; **SCID** – severe combined immunodeficiency; **PID** – primary immunodeficiency; **MSD** – matched sibling donor; **Haplo** – haploidentical donor; **MUD** – matched unrelated donor; **MMUD** – mismatched unrelated donor; **PBSC** – peripheral blood stem cells; **BM** – bone marrow; **GVHD** – graft-versus-host disease; **aGVHD** – acute GVHD; **cGVHD** – chronic GVHD; **CsA** – cyclosporine A; **MTX** – methotrexate; **MMF** – mycophenolate mofetil.

WAS – Wiskott–Aldrich syndrome, **XLP** – X-linked lymphoproliferative disease, **CGD** – chronic granulomatous disease, **STAT1 GOF** – STAT1 gain-of-function disease, **NBS** – Nijmegen breakage syndrome, **CID** – combined immunodeficiency, **ADA-II** – adenosine deaminase 2 deficiency, **CVID** – common variable immunodeficiency, **IPEX** – immune dysregulation, polyendocrinopathy, enteropathy, X-linked syndrome

Twenty-two patients received treosulfan-based conditioning; one received melphalan, and two neonatally screened infants underwent HCT without conditioning. Median neutrophil engraftment occurred on day +18. Complete donor chimerism was achieved in 18 patients, while 6 exhibited mixed chimerism.
Acute GVHD occurred in 15 patients (grade I–II: n=9; grade III–IV: n=6), and chronic GVHD was observed in 6 patients, with ongoing immunosuppression required in 2 at last follow-up. Two deaths were recorded: one transplant-related death due to severe grade IV acute GVHD and one early death on day +13 due to acute cardiovascular failure associated with engraftment syndrome. Day +100 transplant-related mortality was 4% (1/25).

With a median follow-up of 2.5 years, **overall survival was 92%**, as shown in **Figure 1**.

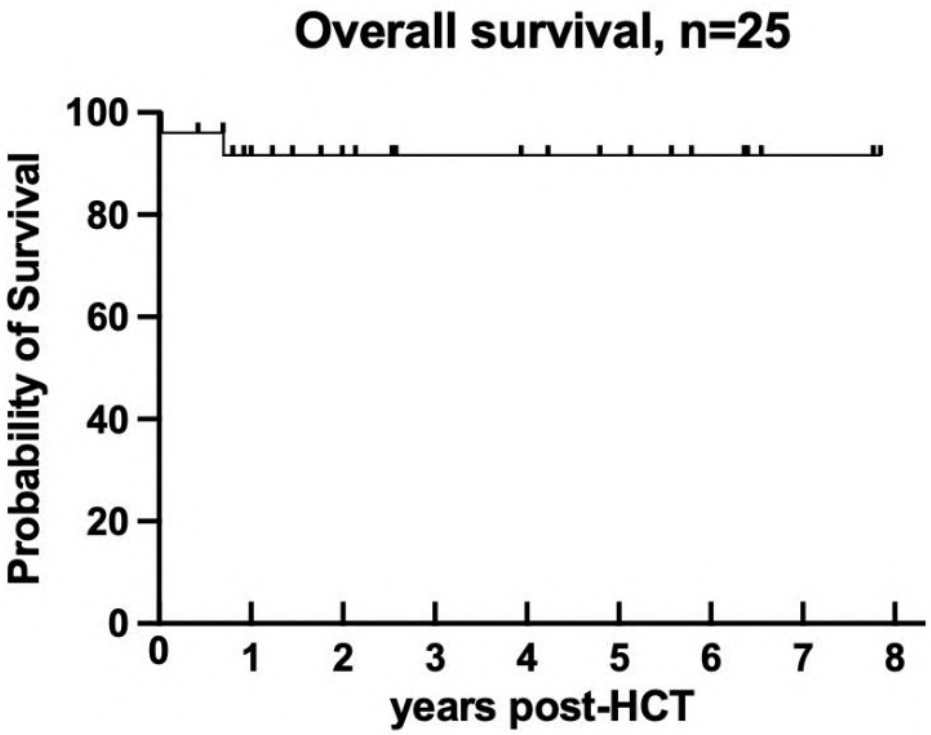

Figure 1. Kaplan–Meier estimate of overall survival after allogeneic HSCT in children with primary immunodeficiencies (n = 25). Tick marks indicate censored observations.

Conclusions: Allogeneic HCT is a feasible and effective curative strategy for children with PIDs in Ukraine, achieving high overall survival and low early transplant-related mortality. The implementation of a national expanded newborn screening program enabled earlier identification of SCID and timely transplantation, contributing to improved outcomes. Notably, 14 of the 25 HCT procedures were performed after the onset of full-scale war, demonstrating sustained and increasing transplant activity despite ongoing conflict. Centralization of paediatric PID transplantation within a single high-volume expert center

allows to optimize resoursces and maintain care quality during wartime conditions. These data reflect the growing capacity and resilience of the Ukrainian paediatric HCT program and highlight the importance of continued expansion of newborn screening and structured referral pathways for children with PIDs.

Disclosure: Nothing to declare

OUTCOMES OF ALLOGENEIC HSCT IN NIJMEGEN BREAKAGE SYNDROME WITH TREOSULFAN-BASED CONDITIONING REGIMEN - A MULTICENTER STUDY

Alexandra Laberko[1,2], *Elena Skorobogatova*[3], *Olga Slesarchuk*[1], *Irina Vlasova*[4], *Larisa Vahonina*[5], *Evgeniy Burtsev*[4], *Larisa Shelikhova*[2], *Yulia Skvortsova*[2], *Evelina Lyudovskikh*[2], *Tatina Bykova*[1], *Larisa Fechina*[5], *Ludmila Zubarovskaya*[1], *Michael Maschan*[2], *Dmitry Balashov*[2]
[1]*RM Gorbacheva Research Institute, Pavlov University, Saint-Petersburg, Russian Federation (the),* [2]*Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation (the),* [3]*Russian Children's Clinical Hospital of the N.I.Pirogov Russian National Research Medical University, Moscow, Russian Federation (the),* [4]*Morozov Children's Hospital, Moscow, Russian Federation (the),* [5]*Sverdlovsk Regional Children's Hospital #1, Institute of Medical Cell Techonogies, Yekaterinburg, Russian Federation (the)*

Background: Nijmegen breakage syndrome (NBS) is a DNA repair disorder characterised by combined immunodeficiency and susceptibility to lymphoid malignancies. Currently HSCT is considered in NBS to prevent malignancy. Minimal-intensity regimens are used in NBS due to risks of toxicity. We recently demonstrated experience of treosulfan 30g/m^2 versus low doses of busulfan. The aim of the current study was to compare efficacy of treosulfan dose 30g/m^2 versus 21g/m^2.

Methods: From 2017 to 2025, 40 NBS patients received allogeneic HSCT with treosulfan-containing conditioning in 5 Russian centers. The median age at NBS diagnosis was 5 years (0.05-15.7), at HSCT 7.4 years (0.5-16.2). Fifteen patients had leukemia/ lymphoma before HSCT (median time of remission to HSCT 10 months (1.4-74)). To 2020, treosulfan 30g/m^2 was used in 16 (Treo30 group) and after 2020 treosulfan 21g/m^2 in 24 patients (Treo21 group). All received fludarabine 150mg/m^2, 24 cyclophosphamide (22–40mg/kg, 1–30mg/kg, 1–20mg/kg). In 37 patients, rabbit ATG (thymoglobulin, Genzyme) 3-7,5mg/kg, in 1 patient horse ATG (ATGAM) 100mg/kg, and in 2 patients no serotherapy was used.
In 25 patients matched unrelated (19–10/10, 6–9/10 HLA-matched), in 9 mismatched related, in 6 matched sibling donor was used. In 19 TCRab/CD19 depletion, in 14 post-transplant cyclophosphamide (25-80 mg/kg), and in 7 patients (4 MSD, 3 MUD) no T-cell depletion was used. 29 patients received various regimens of immunosuppression (16 calcineurin inhibitor-based, 13-other) and 11 patients no immunosuppression (10 after TCRab/CD19 depletion, 1 after Pt-Cy in MSD).

Results: The median follow-up time in survivors was 8,0 years (4,7-8,8) and 2,7 (0,8-5,3) in Treo30 and Treo21 groups, respectively, p<0,001. Overall survival was 0,81 (95%CI 0,62-1,0) after Treo30 and 0,76 (95%CI 0,56-0,95) after Treo21, p=0,7.
All patients reached primary engraftment. The median time of neutrophil engraftment was 13,5 days (10-21) in Treo30 and 19 days (11-28) in Treo21 groups, p=0,009, which was due to higher proportion of TCRab/CD19 depletion in Treo30. The median time of engraftment after TCRab/CD19 depletion was 13 days (10-21) versus 19 days (13-28) after non-depleted grafts, p=0,0003. No patients developed graft rejection.
Severe organ toxicity was seen in 14 patients, 6 received Treo30 and 8 Treo21. Incidence of acute GVHD was 0,5 (95%CI 0,31-0,82) in Treo30 and 0,63 (95%CI 0,46-0,85) in Treo21 (p=0,88), of chronic GVHD 0,31 (95% CI 0,15-0,65) in Treo30 and 0,25 (95% CI 0,13-0,5) in Treo21 groups (p=0,79). The incidence of significant viral infections was 0,38 (95%CI 0,2-0,71) after Treo30 and 0,38 (95%CI 0,22-0,63) after Treo21 (p=0,94).
Two patients (both after Treo30) developed rhabdomyosarcoma (in 7 and 37 months post-HSCT, 1 of them died). Four patients (all after Treo21) developed leukemia relapse (2 received CAR-T therapy and alive, 2 died).
At last follow-up, 8 patients had mixed chimerism, 5 after Treo21 and 3 Treo30, p=0,22. Six of them had hypogammaglobulinemia requiring regular immunoglobulin replacement.

Conclusions: Both doses of treosulfan 21g/m^2 and 30g/m^2 were well tolerated by NBS patients. However, lower dose of 21g/m^2 was associated with higher risk of mixed chimerism and leukemia relapse versus increased incidence of secondary malignancy after higher dose of 30g/m^2.

Disclosure: The authors declare no conflict of interest.

FACTORS ASSOCIATED WITH MIXED CHIMERISM IN CHILDREN WITH NON-MALIGNANT DISEASES TRANSPLANTED WITH A TREOSULFAN-BASED REGIMEN

Etai Adam[1], *Elad Jacoby*[1], *Hana Golan*[1], *Sara Malkiel*[1], *Daphna Hutt*[1], *Amos Toren*[1], *Bella Bielorai*[1]
[1]*Tel Aviv University, Tel Aviv, Israel*

Background: Treosulfan is an alkylating agent used for conditioning for hematopoietic stem cell transplant (HSCT). Children with non-malignant diseases have been shown to have increasing incidence of mixed chimerism when undergoing HSCT at a younger age with melphalan-based (Fitch, et al, 2024) and with busulfan-based conditioning (Dvorak, et al, 2025). This has not yet been evaluated in the context of Treosulfan-based conditioning. Our group has previously published that, conditioning with treosulfan and fludarabine is insufficient for achieving long term donor chimerism in patients with diseases of neutrophil function (Jacoby, et al, 2023).

Methods: We retrospectively reviewed charts of patients undergoing first HSCT for non-malignant disease from 2008 – 2024. In order to isolate the effects of age and conditioning on our ability to myeloablate these patients, we excluded patients with immunologic graft failure and patients with recent chemotherapy for malignancy. Parameters evaluated included diagnosis, age at transplant, cell dose, thiotepa administration, serotherapy administration, and the main outcome was chimerism status at 12 months from HSCT.
All patients received treosulfan and fludarabine, some patients received additional serotherapy (either ATG or alemtuzumab) and/or thiotepa (10 mg/kg on day -2 before HSCT).
Comparison of categorical variables was analyzed using the Fisher exact test, multiple categorical variables together were compared using multiple logistic regression. Mixed chimerism was defined as <95% donor chimerism in whole blood. Immunologic graft rejection was defined as either primary or secondary graft failure with subsequent pancytopenia.

Results: We reviewed 111 consecutive transplants that met inclusion criteria. Patient characteristics are shown in Table 1. Patients undergoing HSCT at an age younger than 6 years had a significantly higher mixed chimerism than patients older than 6 years (52.8% vs 20.8%, p = 0.0057). Similarly, patients not receiving thiotepa had higher incidence of mixed chimerism than patients who received thiotepa (66.1% vs 20.4%, p <0.0001). On multivariate logistic regression lack of thiotepa administration was strongly correlated with mixed chimerism while age <6 and serotherapy administration were not.
Subgroup analysis confirms that thiotepa addition for treosulfan-based conditioning is necessary for durable engraftment in disorders of neutrophil function - of 13 patients transplanted without thiotepa the average 12 month donor chimerism was 25.5% (range 0-64%), whereas the three patients transplanted with thiotepa had 12 month donor chimerism of 90, 100, and 100%.

	Total	Mixed Chimerism (n = 51)	Full Donor Chimerism (n = 60)
Age < 6 years	87	46	41
Age > 6 years	24	5	19
IEI	82	43	39
Red Cell/Platelet	16	5	11
Metabolic	13	6	7
Serotherapy +	89	42	47
Serotherapy -	22	9	13
Thiotepa +	49	10	39

Thiotepa -	62	41	21

Conclusions: Treosulfan and fludarabine conditioning does not ensure durable engraftment in patients with non-malignant diseases especially in disorders of neutrophil dysfunction. Increased mixed chimerism is associated with age <6 years old, suggesting the previous observations of Fitch and Dvorak may be more universal. Still, the addition of thiotepa to conditioning was the most consistent predictor of full donor chimerism.

Disclosure: I have received consultation honoraria/speaker fees from Sanofi, related to belumosudil

MULTICENTER EXPERIENCE OF HSCT IN RAS-ASSOCIATED AUTOIMMUNE LEUKOPROLIFERATIVE DISEASE (RALD) – IEWP EBMT STUDY

Alexandra Laberko[1,2], *Srividhya Senthil*[3], *Eleri Williams*[4], *Anna Osipova*[1], *Ludmila Zubarovskaya*[1], *Peter Arkwright*[3], *Robert Wynn*[3], *Alexei Maschan*[2], *Dmitry Balashov*[2], *Andrew Gennery*[4,5]
[1]*RM Gorbacheva Research Institute, Pavlov University, Saint-Petersburg, Russian Federation (the),* [2]*Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation (the),* [3]*Royal Manchester Children's Hospital, Manchester, United Kingdom of Great Britain and Northern Ireland (the),* [4]*Great North Children's Hospital, Newcastle upon Tyne, United Kingdom of Great Britain and Northern Ireland (the),* [5]*Newcastle University, Newcastle upon Tyne, United Kingdom of Great Britain and Northern Ireland (the)*

Background: RALD – is a rare phenocopy of inborn error of immunity, caused by somatic gain-of-function mutations in KRAS/NRAS genes. The main clinical features are autoimmunity (mainly immune cytopenia) and lymphoproliferation. Case descriptions of RALD are limited and only few cases of HSCT have been reported to date. The aim of the current study was to estimate efficacy of HSCT in RALD.

Methods: Through IEWP EBMT, 7 RALD patients who received HSCT were identified: 4 in Russia and 3 in the UK. The median age at diagnosis was 1.7 years (range 0.8-9.4). In four patients, KRAS c.37G>T and in three, NRAS c.38G>A mutations were identified. All patients had immune cytopenia (hemolytic anemia (AIHA) (n=7), thrombocytopenia (n=5)) and lymphoproliferative syndrome, 3 severe/recurrent infections, 2 neutropenia, 2 systemic lupus erythematosus, 1 ulcerative colitis and osteomyelitis with myeloid cell infiltration, and 1 erythroid myelodysplasia. All had peripheral blood monocytosis (median 4x10*9/L) and hypergammaglobulinemia (median IgG 20g/L). All patients received 2 or more lines of immunosuppression, 4 required regular antibiotics, 2 regular IVIG with no complete remission achieved in any.

Results: The median age at HSCT was 4.8 years (range 2.3-10.2). Six patients received treosulfan/thiotepa-based myeloablative conditioning (MAC) and one busulfan-based MAC. Serotherapy included rabbit ATG in 4, alemtuzumab in 2 and none in 1. Four patients additionally received rituximab. The donor source included haploidentical parents in 4, matched sibling in 1, matched unrelated donor in 1, and 6/8 unrelated cord blood in 1. For graft-versus-host disease (GVHD) prophylaxis, in haploidentitcal grafts TCRab/CD19 depletion was used in 3 and posttranspant cyclophosphamide with ruxolitinib in 1. In the remaining, ciclosporin alone and in combination with prednisolone/mycophenolate mofetil was used.
Neutrophil engraftment occurred in 5 patients (median 16 days, range 11-24 days). One patient developed primary graft rejection and three early secondary rejection. All patients with graft failure received second HSCT (in 2.5, 3, 5.3 and 9 months), 2 from the same donors and 2 with donor change. In second HSCT, conditioning regimens were switched to melphalan/cyclophosphamide and irradiation in two and to busulfan in 1 (after treosulfan) and to treosulfan in one (after busulfan). No patients had severe acute or chronic GVHD. Four patients after the first HSCT and four patients after the second HSCT developed viral reactivation requiring therapy.
All patients are alive with median follow-up after the last HSCT of 5.5 years (range 1-7.4). At last follow-up, 3 patients had 100% donor and 3 82-94% donor chimerism, (mixed T cell with full donor myeloid chimerism in 2). One patient with mixed chimerism has lupus nephritis, and one AIHA. No other patients have disease symptoms, one has hypogammaglobulinemia (after post-HSCT rituximab).

Conclusions: HSCT is a feasible option to control symptoms of RALD. Our case series demonstrate a very high risk of graft failure, however, salvage HSCT is a viable option in these patients. Mixed chimerism may lead to uncomplete disease control. Larger series are needed to elaborate optimal timing and HSCT regimens in this condition.

Disclosure: The authors declare no conflict of interest.

OUTCOMES OF LATE-ONSET KRABBE DISEASE TREATED WITH HAEMATOPOIETIC STEM CELL TRANSPLANTATION: SINGLE-CENTRE EXPERIENCE

Callum Fernando[1], *Divij Sachdeva*[1], *Evangeline Wassmer*[1], *Sarah Lawson*[1], *Olya Oconnor*[1]
[1]*Birmingham Children's Hospital, Birmingham, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Krabbe disease is a rare lysosomal storage disorder caused by deficiency of the galactocerebrosidase (GALC) enzyme, resulting in psychosine accumulation, progressive demyelination, and neuronal loss. The late-onset form presents with variable combinations of spasticity, ataxia, and cognitive decline. Haematopoietic stem cell transplantation (HSCT) may modify disease progression by providing donor-derived microglial enzyme activity that helps clear psychosine and preserve myelin integrity. However, HSCT carries significant

morbidity and mortality, and published outcomes in late-onset Krabbe disease are limited and heterogeneous. We report survival, neurodevelopmental, radiological, and HSCT outcomes of children with late-onset Krabbe disease, including the first patient to receive transplant for the attenuated form in the UK.

Methods: We performed a retrospective review of all patients with juvenile-onset Krabbe disease who received HSCT at Birmingham Children's Hospital between 2015 and 2025. Clinical, biochemical and genetic data were collected. Transplant details included donor type, stem-cell source and dose, conditioning regimen and engraftment kinetics. Neurological function was assessed using serial clinical examinations. Brain MRI scans were reviewed pre- and post-transplant, and white matter changes were scored using a semi-quantitative system of disease burden. Electrophysiological studies were analysed longitudinally where available. Survival, transplant-related toxicity, and neurological trajectory were evaluated up to the last follow-up.

Results: Six patients underwent HSCT for late-onset Krabbe disease during the study period. Four were symptomatic and two presymptomatic at the time of transplantation. The median age at HSCT was seven years (range 2–12). Conditioning regimens included Fludarabine/Busulfan and Busulfan/Cyclophosphamide with serotherapy. Donor sources were mismatched cord (3/6) and MUD (3/6). Notably, two patients had graft failure and required rescue with a second graft using a haploidentical donor. At a median follow-up of 87.5 months post-transplant, five patients were alive, and one died from CMV pneumonitis at day +147. Transplant-related complications included viral reactivation in three patients and acute skin graft-versus-host disease (GvHD) in two patients. None of the surviving patients developed chronic GvHD. Four surviving patients had full donor chimerism at most recent assessment. One patient developed mixed chimerism, stabilising at 94% six years post-HSCT. All surviving patients demonstrated neurological stabilisation, with improvement or preservation of motor and cognitive function compared to their pre-transplant course. Post-HSCT galactocerebrosidase levels normalised within 3 months of transplant, while MRI showed stabilisation of white matter abnormalities in all survivors. Electrophysiological studies showed stable conduction velocities over time.

Conclusions: Our review of a single – centre cohort of patients with late-onset Krabbe disease demonstrated that HSCT appears to modify the natural history of the disease, resulting in prolonged survival and stabilisation of neurodegenerative progression when performed in appropriately selected patients. Transplant was generally well tolerated without a significant morbidity however graft failure remains a significant problem in this group of patients, with two out of six patients in our cohort requiring a second graft. Larger, collaborative studies are required to refine prognostic markers, optimise donor and conditioning strategies, and establish standardised pre-HSCT evaluation and follow-up protocols to maximise the benefits of HSCT in this leukodystrophy.

HAEMATOPOIETIC STEM CELL TRANSPLANT (HSCT) IN NEUROPATHIC MUCOPOLYSACCHARIDOSIS TYPE-II (MPS-II) PRESERVES NEURODEVELOPMENT AND SHOULD BE ROUTINE PRACTICE

Osama Mansour[1], *Simon Jones*[2], *Claire Horgan*[1], *Arunabha Ghosh*[2], *Heather Church*[2], *Denise Bonney*[1], *Robert Wynn*[1]
[1]*BMT Program, Royal Manchester Children's Hospital, Manchester, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Willink Unit, Biochemical Genetics, St Mary's Hospital, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: MPS-II (Hunter Syndrome) is a rare X-linked lysosomal storage disease resulting in multi-system accumulation of heparan and dermatan sulfate with genetic deficiency of iduronate-2-sulfatase enzyme. In its more common "neuropathic or severe" form, it causes progressive neurodegeneration, severe functional limitations, and early death. It is often thought that enzyme replacement therapy (ERT) is the treatment of choice, and that allogeneic HSCT isn't indicated and is less effective than it is in MPSIH (Hurler Syndrome).
ERT has many limitations in controlling disease progression including attenuating antibodies, and that it doesn't penetrate the BBB and affect CNS correction. However, Graft-derived leukocytes cross the BBB and deliver enzyme to the brain as microglia, with no immune response against the deficient enzyme protein, since it is not foreign to the graft source. Despite some evidence supporting early HSCT, there is still very little systemically reviewed data available to support a paradigm shift in guidance towards early diagnosis and treatment with HSCT rather than ERT.

Methods: We report dramatic outcome differences between 2 siblings, one treated with ERT, and another with HSCT, emphasising the importance of early intervention, and cellular therapy in optimising patient outcomes.
The older sibling (Sibling-A) was diagnosed at 4 years of age (post-symptom onset) and received weekly ERT.
The younger sibling (Sibling-B) was diagnosed at birth via newborn biochemical and genetic testing showing same diagnosis. He underwent a 10/10 HLA MUD HSCT (BM source) at the age of 3 months. He was conditioned with Busulfan and Fludarabine following the standard European Guidelines. Alemtuzumab Serotherapy and GVHD prophylaxis with Ciclosporin-A were used. A second transplant at the age of 1 year was required after secondary engraftment failure (myeloid chimerism falling below 17% after 6 months). The same donor donated PBSC and conditioning was with Fludarabine, Thiotepa and Treosulfan. Alemtuzumab serotherapy, Cyclosporin-A and mycophenolate mofetil used as GVHD prophylaxis.
Defibrotide was used for VOD prophylaxis in second transplant due to experiencing mild VOD during first transplant.
Multisystem evaluation including neurodevelopmental assessments were recorded over 6–7 follow-up-years.

Results: Despite sharing the same biochemical and molecular diagnosis, the siblings experienced significantly divergent developmental and multisystem outcomes.

Sibling-A showed some early somatic improvements but has expectedly experienced severe irreversible neurocognitive decline. He initially plateaued then progressively lost most of the acquired developmental and language skills.
Sibling-B achieved stable 100% donor chimerism after the second HSCT with mild transplant related acute complications including mild skin GVHD resolving with short-course of systemic steroids, and with no chronic complications. Circulating mixed leukocytes measured normal levels of iduronate-2-sulphatase activity. He has been showing highly preserved neuro-cognitive development within normal limits for age.

Comparison of Developmental Milestones and Functional Status of both Siblings

Milestone / Skill	Sibling A – Older Sibling (Late ERT)	Sibling B – Younger Sibling (Early HSCT)
Sitting unsupported	Initially no delay but later requiring supportive chair most of the time.	Achieved at 10 months (mild delay due to transplant period). Currently sits independently without issues (normal balance).
Crawling	Achieved on time.	Achieved at 12 months.
Walking independently	Initially no delay, but toe-walker. Later becoming very stiff, walking like "an old man" for short distances and requiring constant support.	Delayed – achieved at 2 years old (24 months) after recovery from transplants. Currently walks and runs normally for age with no gait abnormality or fatigue.
First words	Delayed – only began saying a few single words around 3–4 years old.	Slightly delayed – spoke first words around 18–24 months.
Combining words	Never achieved meaningful phrases; at best had <5 single words, which were later lost (no phrase speech).	Achieved by 3 years old, speaking in 3-4-word sentences.
Later speech and communication abilities	No functional speech at 10 years old; non-verbal aside from occasional sounds. Uses some signs or gestures but largely unable to communicate needs.	Age-appropriate speech at 7 years; fluent in communicating wants and needs. Mild word-finding difficulty at times but essentially normal language for age.
Hearing	Newborn hearing screen failed; diagnosed bilateral moderate SNHL in early childhood. Uses hearing aids since toddlerhood but hearing progressively deteriorated to	Newborn hearing screen failed with mild conductive loss in infancy. Developed mild bilateral SNHL by age 5 (≈30 dB). Uses bilateral hearing aids

Comparison of Developmental Milestones and Functional Status of both Siblings		
	severe mixed loss by age 8–10 (requires loud prompts even with aids).	consistently with good benefit; hearing is stable and mild with aids.
Vision	Mild corneal clouding and mild hyperopia. Refusing corrective glasses due to cognitive delay.	Clear corneas and normal vision with very mild hyperopia effectively corrected with glasses.
Cardiac	No cardiomyopathy, mild mitral valve thickening by age 8 (trace prolapse) but normal function.	Normal cardiac exams and echocardiograms to date; no valvular disease or cardiac dysfunction.
Airway/Sleep	Chronic rhinorrhea and loud snoring from infancy. Developed obstructive sleep apnoea by age 9 (AHI 14) requiring invasive interventions.	No chronic upper airway obstruction. No sleep apnoea on studies post-HSCT; normal sleep quality without intervention.
Continence (Toilet training)	Never achieved; remains fully incontinent (doubly) and in diapers at age of 10 years. No awareness of toileting needs.	Daytime toilet trained by ~4 years old; reliably dry and clean during day. Achieved night-time dryness by ~5–6 years old.
Fine motor skills	Markedly impaired; cannot perform purposeful drawing or writing. Has clawed hands with joint contractures and carpal tunnel syndrome, requiring surgical release. Cannot use utensils well – eats with assistance.	Age-appropriate fine motor skills; able to draw shapes, use utensils, and manipulate objects. No hand deformities or carpal tunnel signs.
Gross motor skills / Mobility	Frequently uses wheelchair due to fatigue and poor safety awareness. At risk of falls due to inattentiveness and joint stiffness.	Runs, jumps, and climbs like an ordinary child. Enjoys physical play (e.g. trampoline). No mobility aids needed. Good endurance for age-appropriate activities.
Behaviour	Severe hyperactivity, impulsivity, and aggressive behaviours. Episodes of hitting, kicking, and head-banging daily. Requires behavioural medication (risperidone) and constant supervision. Unable to follow	Generally good behaviour for age. Mildly impulsive or "silly" at times but no abnormal aggression. Follows instructions appropriate for age, though can be shy in new environments. No special supervision needed beyond normal parenting.

Comparison of Developmental Milestones and Functional Status of both Siblings		
	instructions or understand discipline due to cognitive level.	
Educational placement	Enrolled in a special needs school with one-on-one support. Curriculum focused on life skills and sensory activities. Not engaged in academic learning due to cognitive impairment.	Enrolled in mainstream primary school at the appropriate age. Requires no classroom aid, performing at or only slightly below grade level in academic skills. Interacts well with classmates.
Current age and status	10 years old – **Severely affected.** Profound cognitive impairment (functioning at <3-year-old level). Fully dependent on caregivers for all aspects of care. Quality of life is poor due to behavioral issues and loss of skills, despite ongoing ERT.	7 years old – **Minimally affected.** Mild developmental delays but essentially functional in an age-appropriate range. Independent in ADLs for age, with good quality of life and participation in normal activities.

Conclusions: In neuropathic MPS-II, definitive therapy with HSCT in early infancy preserves neurodevelopment and significantly reduces the multi-system disease burden compared with initiating ERT in later childhood. This sibling case-comparison supports the rationale for the need of newborn screening and prompt referral for HSCT. We have separately developed a gene therapy programme to further improve outcomes of cellular therapy in MPS-II and are reporting those outcomes at this meeting.

Clinical Trial Registry: Not applicable

IMPAIRED P53-MEDIATED DNA DAMAGE RESPONSE IN A HUMAN *ETV6::RUNX1* IPSC MODEL SHOWS GENOMIC INSTABILITY IN PRE-LEUKEMIC CELLS

Rigveda Bhave[1], Vera H. Jepsen[1], Ersen Kameri[1], Ute Fischer[1], ***Gesine Kögler[1]***
[1]Universitätsklinikum Düsseldorf, Heinrich Heine University, Düsseldorf, Germany

Background: The *ETV6::RUNX1* (*E::R*) fusion gene is a prevalent pre-leukemic state in childhood B-cell precursor acute lymphoblastic leukemia that requires secondary somatic mutations for leukemic transformation. We utilized a human iPSC model to investigate whether *E::R* intrinsically impairs DNA damage repair (DDR) pathways, thereby creating a permissive environment for the accumulation of these secondary genomic hits.

Methods: We utilized a previously described human iPSC model (Jepsen *et al*., HemaSphere 2025) comparing wind-type (WT) iPSCs against CRISPR/Cas9-generated *E::R* knock-in clones. To simulate genotoxic stress, cells were treated with the topoisomerase II inhibitor etoposide (1-40 nM) or vehicle control, and DDR activation was assessed via immunoblotting for phosphorylated p53 (Ser15) and PARP cleavage (n=3). To validate the findings in a hematopoietic context, iPSCs were differentiated into hematopoietic stem and progenitor cells (HSPCs; Terheyden-Keighley *et al*., Stem Cells Transl Med 2024) and characterized via multiparameter flow cytometry. Additionally, we employed a newly established serum-free differentiation protocol to direct HSPCs towards the B lineage to further study these pathways in B-cell progenitors (Bhave *et al*., Sci Rep 2025).

Results: Western blot analysis confirmed robust expression of the E::R fusion protein in knock-in clones. Upon induction of DNA damage with etoposide, WT iPSCs exhibited a strong, dose-dependent activation of the p53 pathway, evidenced by high levels of p-p53 (Ser15) and significant PARP cleavage. In sharp contrast, *E::R* iPSC clones displayed attenuated phosphorylation of p53 at Ser15 and reduced PARP cleavage across all tested concentrations. Notably, preliminary data suggests that this suppression occurs independently of the canonical MDM2 upregulation pathway often cited in murine models. Furthermore, we successfully differentiated these lines into hematopoietic progenitors with a CD34+CD38-CD90+CD45RA+/- phenotype (HSC/MPP/MLP), demonstrating that this model accurately recapitulates the early hematopoietic hierarchy required to study these defects in the lineage of origin. We have further validated a protocol to differentiate these HSPCs into the B-lineage, providing a physiologically relevant system to confirm these defects in committed B-progenitors.

Conclusions: Our findings demonstrate that pre-leukemic *ETV6::RUNX1* expression leads to significant impairment of the p53-mediated response to DNA damage in a human model system. This "dampened" DDR may allow pre-leukemic cells to evade apoptosis following genotoxic stress, facilitating the survival of clones carrying secondary mutations. By extending our model to include HSPCs and B-lineage progenitors, we are now positioned to characterize the precise impact of this repair defect on genomic stability during the vulnerable stages of B-cell development.

GLOBALISING HAEMATOPOIETIC STEM CELL TRANSPLANTATION FOR CEREBRAL X-LINKED ADRENOLEUKODYSTROPHY: A UK–INDIA MULTICENTRE EXPERIENCE

Divij Sachdeva[1], *Evangeline Wassmer*[1], *Callum Fernando*[1], *Shaswati Dey*[1], *Katharine Foster*[1], *Anupam Sachdeva*[2], *Manas Kalra*[2], *Olya Oconnor*[1], *Sarah Lawson*[1]
[1]*Birmingham Children's Hospital, Birmingham, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Sir Ganga Ram Hospital, New Delhi, India*

Background: X-Linked Adrenoleukodystrophy (X-ALD) is a rare genetic disorder (1:20,000–50,000) caused by ABCD1 gene mutations which encodes a peroxisomal membrane protein responsible for transporting very long chain fatty acids (VLCFAs). Impaired metabolism leads to VLCFA accumulation in the CNS/PNS and adrenal cortex, resulting in a spectrum of presentations including Cerebral ALD (CALD), axonopathy, and adrenal insufficiency. Haematopoietic stem cell transplant (HSCT) can halt disease progression in early CALD, when the patients have no significant neurology deficits (Neurology Function Score (NFS) ≤1) and limited demyelinating lesions in the brain (Loes score ≤9).

Methods: We retrospectively reviewed survival, neurological, and radiological outcomes following HSCT for CALD at UK and Indian centres, comparing results to a contemporary non-HSCT cohort. This included all patients transplanted at Birmingham Children's Hospital between 2005 and 2025 and the first patient transplanted at Sir Ganga Ram Hospital. Clinical, biochemical, and genetic data were collected. Donor type, graft source, conditioning regimen, and engraftment kinetics were collected. Neurological function was assessed using serial MRI and neurocognitive testing. Survival, transplant morbidity, and neurological trajectory were analysed to last follow-up.
A non-HSCT comparator cohort (n=6) was analysed for outcome comparison.

Results: Five patients underwent six HSCTs (median age 11 years, range 5-13). Lesions included fronto-pontine (n=2), posterior (n=2), and midbrain/pons/medulla (n=1). Donors included HLA-mismatched unrelated (n=2), matched unrelated (n=2), HLA-identical sibling (n=1) and haploidentical parent (n=1). Graft sources were PBSC (n=3), marrow (n=2), and cord (n=1). All patients received myeloablative conditioning with Fludarabine and Busulfan or Fludarabine/Treosulfan/Thiotepa plus ATG/Alemtuzumab. Neutrophil and platelet engraftment was achieved in all (median day +20 and +16). One patient required a second HSCT for secondary graft failure. No significant toxicity was observed in the first five patients. Patient transplanted from the haploidentical donor experienced viral reactivation and acute skin and gut GVHD. One patient had mild chronic skin GVHD. All patients achieved full donor chimerism at 3-year median follow-up.
Loes scores at HSCT were 2, 2, 2.5, 7.5 and 6. Imaging post HSCT remained stable at median follow up of 2,5 years. Neurological function scores stayed at 0 at 3 years and IQ scores remained stable.
The six non-HSCT CALD patient presented with neurology symptoms (NFS 1-6) and abnormal radiology (median Loes 14). Three died 2, 11 and 26 years after presentation. Two have severe cognitive and motor impairment 3 years post presentation, while one remains ambulant (NFS 4) 1 year post presentation.

Conclusions: Allogeneic HSCT provided robust outcomes for CALD patients, demonstrating excellent engraftment, acceptable toxicity, and 100% survival. Neurological and radiological stability was maintained in all transplant recipients, contrasting sharply with the rapid decline and 50% mortality observed in the non-HSCT comparator cohort. Our multi-center experience reinforces HSCT as an effective, disease-modifying therapy. Crucially, the successful haploidentical transplant, performed as the first in a resource-limited centre, broadens the feasibility of HSCT for CALD globally, proving successful outcomes with alternative donor sources. These findings reinforce HSCT as an effective disease-modifying therapy for CALD when performed early in the disease course.

Disclosure: Nothing to declare

FIRST REPORTED ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (ALLO-HSCT) FOR RAD50 DEFICIENCY: INITIAL CLINICAL EXPERIENCE IN TWO PEDIATRIC PATIENTS

Alexandra Shutova[1], *Yulia Skvortsova*[1], *Evelina Lyudovskikh*[1], *Svetlana Kozlovskaya*[1], *Irina Shipitsyna*[1], *Maria Ilushina*[1], *Larisa Shelikhova*[1], *Asmik Avedova*[1], *Yulia Rodina*[1], *Alexey Pshonkin*[1], *Anna Pavlova*[1], *Alibey Gadzhiev*[1], *Elena Raykina*[1], *Anna Scherbina*[1], *Michael Maschan*[1], *Dmitry Balashov*[1]
[1]*Dmitry Rogachev National Medical Research Center Of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation (the)*

Background: Biallelic loss-of-function variants in RAD50 is an extremely rare DNA double-strand break repair disorder characterized by genomic instability, impaired ATM signaling and defects in lymphocyte development. Published reports of RAD50 deficiency are scarce and describe a heterogeneous phenotype including microcephaly, growth delay, variable immune dysfunction and sometimes progressive bone marrow failure. Unlike other DNA repair disorders such as Nijmegen breakage syndrome or LIG4 deficiency, no allo-HSCT cases have been reported in RAD50-deficient patients, and transplant-related biological risks, particularly sensitivity to alkylating agents, remain undefined. This lack of clinical experience leaves a critical gap in understanding HSCT feasibility, conditioning tolerability, immune reconstitution and genomic stability under transplant-related stress.

Methods: We report two pediatric patients with compound heterozygous mutation in RAD50 gene confirmed by whole-genome sequencing who underwent allo-HSCT.
Case #1. An 8-year-old girl presented with progressive trilineage cytopenia and bone marrow hypoplasia, DEB testing and telomere length were normal. Within one year, bone marrow dysplasia with a del(5q) clone and blasts up to 6–7% evolved, consistent with MDS on the background of inborn error of immunity.
Unrelated-donor allo-HSCT (conditioning regimen: fludarabine 150 mg/m², busulfan 4 mg/kg, ATG 5 mg/kg and rituximab 375 mg/m², with PTCy-based GVHD prophylaxis) was complicated by HHV-6 infection, severe infusion-associated rash, and subsequent graft rejection by day +60. Six months later a second haploidentical HSCT from the mother (conditioning regimen: fludarabine 150 mg/m², treosulfan 21 g/m², rituximab 375 mg/m² and alemtuzumab 0.4 mg/kg with PTCy-based GVHD prophylaxis) resulted in timely engraftment and was complicated by megakaryocytic lineage hypofunction, viral reactivation, COVID-19 infection, and mild skin GVHD.
Case #2. A 10-year-old girl with syndromic features (microcephaly, reticular skin hyperpigmentation, oral leukoplakia and onychodystrophy) developed severe pancytopenia with markedly hypocellular marrow and pathologically shortened telomeres, consistent with telomere biology disorder. The course was marked by transfusion dependence, recurrent infections and refractory thrombocytopenia despite romiplostim and eltrombopag therapy.

At the age of 13, haploidentical HSCT from the mother (conditioning regimen: fludarabine 150 mg/m², treosulfan 30 g/m², ATG 5 mg/kg, cyclophosphamide 40 mg/kg and rituximab 375 mg/m² with a CD3-depleted graft) was performed and resulted in primary graft failure by day +20. Three months later a second haploidentical HSCT from the father (conditioning regimen: TLI 4 Gy, fludarabine 150 mg/m², thiotepa 8 mg/kg, ATG 5 mg/kg and rituximab 375 mg/m² with PTCy-based GVHD prophylaxis) resulted in timely engraftment and was complicated by severe generalized HSV infection, engraftment syndrome, acute kidney injury and toxic encephalopathy.

Results: At last follow-up (+16 and +10 months after HSCT, respectively), both patients demonstrated complete donor chimerism with stable graft function.

Conclusions: These cases represent the first reported allo-HSCT procedures in patients with RAD50 deficiency, demonstrating that transplantation is feasible. However, an attempt to reduce the conditioning intensity, by analogy with other DNA repair disorders, resulted in severe graft dysfunction. We believe our experience should be taken into account when selecting a treatment strategy for this ultra-rare DNA repair disorder.

Disclosure: Nothing to declare.

SUCCESSFUL HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A CHILD WITH WOLMAN DISEASE REFRACTORY TO HIGH-DOSE ENZYME REPLACEMENT THERAPY: COMPLETE DONOR CHIMERISM AND SUSTAINED METABOLIC RECOVERY

*Suleimen Zhumatayev[1], **Burcu Akıncı**[1], Hayriye Daloğlu[1], Koray Yalçın[2], Gülsün Karasu[1], Vedat Uygun[3], Mehmet Akif Yeşilipek[1,3]*
[1]Medical Park Pendik Hospital, Istanbul, Turkey, [2]Acıbadem Altunizade Hospital, İstanbul, Turkey, [3]Medical Park Antalya Hospital, Antalya, Turkey

Background: Wolman disease is a severe lysosomal storage disorder caused by biallelic mutations in the LIPA gene, resulting in markedly reduced lysosomal acid lipase (LAL) activity. Affected infants develop malabsorption, hepatosplenomegaly, dyslipidemia, and growth failure, and the condition is typically fatal without treatment. Enzyme replacement therapy (ERT) improves early survival; however, many patients continue to exhibit clinical progression despite receiving high-dose, long-term therapy. Hematopoietic stem cell transplantation (HSCT), by providing donor-derived enzyme production, offers a potential curative option, although real-world experience remains limited. We report the transplant course and 18-month outcome of a 29-month-old child whose symptoms persisted despite prolonged high-dose ERT.

Methods: The patient was a 29-month-old male with genetically confirmed homozygous *LIPA* mutation and severe LAL deficiency (<0.03 nmol/punch/h). Despite high-dose ERT initiated at 6 months of age, he continued to exhibit hepatosplenomegaly, malabsorption,

hypertriglyceridemia, and significant growth delay. Pre-HSCT evaluation also showed mild elevation in liver enzymes and poor nutritional status.
HSCT was performed using bone marrow from his fully matched (6/6) mother. Conditioning Regimen (with editable doses): Treosulfan 42 g/m² (Days −6 to −4), Fludarabine 150 mg/m² (Days −6 to −2), Thiotepa 10 mg/kg (Day −2), Anti-thymocyte globulin (ATG) 20 mg/kg total dose (Days −6 to −5). GVHD Prophylaxis: Tacrolimus (target trough 6-15 ng/mL), Methotrexate (Days +1, +3).
Supportive care included nutritional optimization and standard antimicrobial prophylaxis. No transplant-related toxicity, organ dysfunction, or infectious complications were observed.

Results: **Table 1. Clinical and Metabolic Parameters Before and After HSCT**

Parameter	Before HSCT	After HSCT (12 months)
LAL enzyme (nmol/punch/h)	<0.03	4.73
Weight (kg)	10	16.2
Height (cm)	78	91
Triglycerides (mg/dL)	223	84
Cholesterol (mg/dL)	203	161

Table comparing key metabolic and growth parameters before and 18 months after HSCT, showing normalization of LAL enzyme activity, improved triglyceride and cholesterol levels, and significant gains in weight and height.

Both neutrophil and platelet engraftment occurred on Day +14. Donor chimerism reached 85% on post-transplant Day +30 and increased to 100% by post-transplant Day +60, remaining fully donor-derived at post-transplant Months +3, +6, and +12. LAL enzyme activity normalized by post-transplant Month +3 (4.73 nmol/punch/h) and remained stable at post-transplant Months +6 and +12.
Metabolic parameters improved consistently: triglycerides decreased from 223 mg/dL to 84 mg/dL, cholesterol from 203 mg/dL to 161 mg/dL, and liver enzymes normalized. Clinically, the patient showed clear resolution of malabsorption, with improved appetite and energy level, and demonstrated substantial catch-up growth by the end of the first post-transplant year (weight increased from 10 to 16.2 kg; height from 78 to 91 cm) *(Table 1)*.
Hepatosplenomegaly regressed markedly on follow-up, and no acute or chronic GVHD was observed throughout the 18 months.

Conclusions: This case shows that HSCT can provide rapid engraftment, durable full donor chimerism, and sustained metabolic correction in a child with Wolman disease unresponsive to high-dose ERT. Despite pre-transplant clinical morbidities, the absence of toxicity or GVHD and remarkable clinical improvement highlight HSCT as a viable treatment option with a case-specific conditioning regimen. These findings support the evaluation of HSCT in patients who do not benefit adequately from ERT and add longer-term outcome data to the limited global experience in Wolman's disease.

Disclosure: Nothing to declare.

B380

HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR INBORN ERRORS OF IMMUNITY: IMPACT OF CONDITIONING REGIMENS

*Suar Caki Kilic[1], Hayrunnisa Bozkurt[1], **Gizem Zengin Ersoy**[1], Begum Sirin Koc[1], Funda Tekkesin[1], Murat Elli[1]*
[1]Health Sciences University Umraniye Research and Training Hospital, İstanbul, Turkey

Background: Inborn errors of immunity (IEIs) are genetically inherited diseases characterized by susceptibility to severe and opportunistic infections, malignancy, and immune dysregulation. Early diagnosis during childhood and timely referral for hematopoietic stem cell transplantation (HSCT) are critical for improving survival and long-term immune reconstitution. HSCT represents the only curative treatment for many severe forms of IEI; however, graft failure and loss of donor chimerism remain major challenges.
The aim of this study was to evaluate the demographic and clinical characteristics, transplant-related features, chimerism outcomes, graft failure, and survival of pediatric patients with IEI undergoing HSCT, with particular focus on the impact of conditioning regimens.

Methods: We retrospectively reviewed pediatric patients diagnosed with IEI who underwent HSCT between February 2019 and August 2024 at our Pediatric Bone Marrow Transplantation Center. Data were extracted from medical records. Transplant indications, donor and graft characteristics, conditioning regimens, chimerism status, graft-versus-host disease (GVHD), and outcomes were analyzed. Conditioning protocols were applied according to the 2021 EBMT/ESID Guidelines for HSCT in Primary Immunodeficiencies.

Results: A total of 36 patients (25 males, 69.4%) underwent 40 HSCT procedures; four patients required a second transplant. Median age at diagnosis was 40 months (range: 14–121 months), and median age at transplantation was 12 months (range: 2–94 months). Underlying diagnoses included combined immunodeficiency in 16 patients (44%; SCID n=15, DOCK8 deficiency n=1), immune dysregulation syndromes in 11 patients (30%; primary HLH n=9, IL-10 receptor deficiency n=1, RASGRP1 deficiency n=1), phagocytic system defects in 7 patients (19%; congenital neutropenia n=3, LAD n=2, chronic granulomatous disease n=2), and syndromic bone marrow failure in 2 patients (5%; Wiskott–Aldrich syndrome n=1, cartilage–hair hypoplasia n=1).
Chimerism analysis revealed full donor chimerism at engraftment in 22 patients. At 6 months post-transplant, 13 patients maintained full chimerism, while 9 patients who reached one-year follow-up remained fully chimeric. Among four patients with chimerism levels <10%, one experienced primary graft failure, and three required a second HSCT following recurrence of disease-related symptoms. At one-year follow-up, 10 patients exhibited chimerism <10%. Loss of chimerism was significantly less frequent in patients receiving busulfan-containing conditioning regimens.
GVHD occurred in 10 patients (25%); no grade IV GVHD was observed. GVHD incidence was

significantly higher in patients receiving busulfan-based conditioning. Overall survival was 88.8%, with 32 patients alive at last follow-up.

Conclusions: HSCT provides excellent survival outcomes in pediatric patients with IEI when performed early and according to guideline-based protocols. Conditioning regimens play a pivotal role in stable donor chimerism and long-term graft sustainability. Our findings highlight treosulfan- and busulfan-based conditioning as key determinants of chimerism outcomes, emphasizing the importance of individualized transplant strategies to optimize long-term success in IEI patients.

Disclosure: None.

ALLOGENEIC STEM CELL TRANSPLANTATION AS A CURATIVE STRATEGY FOR PYRUVATE KINASE DEFICIENCY: A SINGLE-CENTER EXPERIENCE

Anna Osipova[1], *Tatiana Bykova*[1], *Olga Slesarchuk*[1], *Ekaterina Dolgushina*[1], *Polina Sheveleva*[1], *Kristina Borisenko*[1], *Egor Zakharov*[1], *Alexander Kulagin*[1], *Ludmila Zubarovskaya*[1]
[1]*RM Gorbacheva Research Institute, Pavlov University, Saint-Peresburg, Russian Federation (the)*

Background: Pyruvate kinase deficiency (PKD) is an autosomal recessive enzymatic defect that causes congenital chronic hemolytic anemia with complications such as iron overload, bilirubin gallstones, extramedullary hematopoiesis, pulmonary hypertension, thrombosis, and others. The heterogeneous clinical manifestations lead to significant morbidity and reduced quality of life. The long-term effect of disease-modifying therapy in PKD requires further evaluation. Allogeneic hematopoietic cell transplantation (allo-HCT) is the only potentially curative treatment for patients with PKD.

Methods: We present 4 patients with PKD who underwent allo-HCT at RM Gorbacheva Research Institute over two years (Table 1). The diagnosis was confirmed by mutations in the *PKLR* gene in all children. Patients had a high degree of dependence on blood transfusions from an early age. Three patients had secondary cardiomyopathy, NYHA class 0, 1 patient underwent cholecystectomy for calculous cholecystitis. The median ferritin level before transplantation was 1032 µg/L (range 245-2440). The median age was 4.8 years (range 1.5-14.6), and the median time from diagnosis to HCT was 52 months (13.6-177.8). All patients received a myeloablative conditioning regimen based on treosulfan, fludarabine, and thiotepa. The sources of hematopoietic cells were bone marrow from matched sibling donor (MSD) – 1, matched unrelated donor (MUD) – 3 with median CD34+ cell dose of 4.2 x 10^6/kg (range 2.4-6). Prophylaxis of graft-versus-host disease (GVHD) included post-transplant cyclophosphamide (PTCy, 50 mg/kg on days 3 and 4) with ruxolitinib at a dose of 0,3 mg/kg; abatacept was added at a dose of 10 mg/kg (4 doses on days −1, 5, 14, and 28) in 1 patient.

Table 1. Patients characteristics

	Case 1	Case 2	Case 3	Case 4
Patient sex	female	male	female	male
PKLR genotype	*PKLR*: c.1529G>A; c.1079G>A	*PKLR*: c.1529G>A, c.994G>A	*PKLR*: c.1+C4529G>A c.1318G>T	PKLR: c.948C>A c.848T>A
Splenomegaly	12,8*5,4	17,1*7,7	8,2*4,0	7,1*3,4 -N
Liver elastography	6,43 kPascal (F2 - F3)	4,8 kPascal (F0-F1)	7,49 kPascal (F2 - F3)	5,64 kPascal (F0-F1)
Number of transfusions	63	>100	18	19
Ejection fraction (EF), %	68%	58%	65%	65,9%
Age at allo-HCT, years	7	14	1,7	3
Ferritin before allo-HCT	245	614	2440	1450
Donor sex	male	female	male	female
Type donor	MUD	MUD	MUD	MSD
Conditioning regimen	Treo42Flu150Tio8	Treo42Flu150Tio8	Treo30Flu150Tio8	Treo42Flu150Tio8
GVHD prophylaxis	PTCyRuxoAba	PTCyRuxo	PTCyRuxo	PTCyRuxo
Hematopoietic cell transplant source	BM	BM	BM	BM
Complications	Oral mucositis grade1; bloodstream infection	Oral mucositis grade1; infections skin, anal fissure;	Febrile neutropenia Macrophage	Febrile neutropenia

		hepatotoxicity grade 2	Activation Syndrome	
GVHD	No	No	No	No
Outcome	alive	alive	alive	alive
Follow-up time (months)	1	8	13	22

Results: With follow-up time of 10 months (range 0.8-22.5) all patients are alive. Primary engraftment was achieved in all patients with median time of 20 days (14-23) for neutrophils. Despite this, one patient experienced secondary graft rejection on day +141, and still requiring blood transfusions and continued chelation therapy. One patient has 100% chimerism, two patients have stable mixed chimerism that does not require any further therapy.

Conclusions: Allo-HSCT is a therapeutic alternative to long-term transfusion therapy and allows for definitive correction of PKD in certain severe cases.

Disclosure: Nothing to declare.

B383

SUCCESSFUL ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A CHILD WITH IMMUNODEFICIENCY ASSOCIATED WITH ITGB4 MUTATION: EXPANDING THE PHENOTYPE

Neeraj Teotia[1], *Meet Kumar*[1], *Umesh Kumar*[1]
[1]*Marengoasia Hospital, Gurugram, India*

Background: ITGB4 mutations are classically linked to junctional epidermolysis bullosa with pyloric atresia (JEB-PA), reflecting the integrin's essential role in epithelial adhesion. Increasing evidence suggests broader immunological functions of integrins in leukocyte adhesion, migration, and epithelial–immune signaling. Immunodeficiency associated with *ITGB4* variants is exceedingly rare, and HSCT experience is limited. We report what appears to be the first successful allogeneic HSCT performed for ITGB4-associated combined immunodeficiency in a child with syndromic features of JEB-PA.

Methods: An 18-month-old male presented with recurrent severe infections, chronic diarrhea, growth failure, and extensive blistering since birth. Immunological evaluation showed reduced CD3+, CD4+, and CD19+ lymphocytes, low serum IgA, and markedly elevated IgE. Whole exome sequencing identified a homozygous *ITGB4* missense variant (p.Pro305Leu), confirming JEB-PA with combined immunodeficiency. Despite IVIG and antimicrobial prophylaxis, infections persisted, warranting HSCT.
A fully HLA-matched (10/10) paternal donor was selected. Reduced-intensity conditioning

consisted of fludarabine (30 mg/m²/day × 5) and treosulfan (12 g/m²/day × 3). Peripheral blood stem cells (CD34+ dose 8.0 × 10⁶/kg) were infused. GVHD prophylaxis included cyclosporine and mycophenolate mofetil. Chimerism, immune reconstitution, and clinical recovery were monitored serially.

Results: Neutrophil engraftment occurred on day +14 and platelet engraftment on day +20. Donor chimerism was 82 percent at day +28, 70 percent at day +100, and 72 percent at day +180. No acute or chronic GVHD developed. At 6 months, T- and B-cell subsets normalized, allowing discontinuation of IVIG. Clinically, infections resolved, chronic diarrhea improved, and significant amelioration of blistering and wound healing was observed. By 12 months, the child showed catch-up growth to the 25th percentile. No transplant-related epithelial or gastrointestinal toxicity occurred.

Conclusions: This case broadens the recognized phenotype of *ITGB4*-related disorders, supporting a pathogenic role of β4 integrin in immune homeostasis. Allogeneic HSCT resulted in stable engraftment, full immune reconstitution, and substantial clinical improvement, indicating its curative potential for ITGB4-associated immunodeficiency even in the presence of JEB-PA. Early genomic diagnosis is essential for identifying these rare immuno-epithelial syndromes and enabling timely HSCT before irreversible complications occur.

Clinical Trial Registry: Not applicable

Disclosure: None

B384

SINGLE CENTER EXPERIENCE OF ALLOGENEIC HSCT WITH POSTTRANPLANT CYCLOPHOSPHAMIDE IN INBORN ERRORS OF IMMUNITY

Alexandra Laberko[1], *Tatiana Bykova*[1], *Olga Slesarchuk*[1], *Anna Osipova*[1], *Yulia Vlasova*[1], *Yuriy Kuznetsov*[1], *Vera Yasnitskaya*[1], *Ekaterina Dolgushina*[1], *Polina Sheveleva*[1], *Egor Zakharov*[1], *Alexander Kulagin*[1], *Ludmila Zubarovskaya*[1]
[1]*RM Gorbacheva Research Institute, Pavlov University, Saint-Petersburg, Russian Federation (the)*

Background: Inborn errors of immunity (IEI, or primary immunodeficiency) is a big group of genetic disorders of immune system. Better diagnostics, improving survival and decreasing morbidity post-HSCT over the past decade have led to significant expansion of indications for HSCT in IEI. Posttransplant cyclophospamide (Pt-Cy) has been becoming a standard of GVHD prophylaxis for HLA-mismatched transplantations. The aim of the study was to analyze HSCT results after Pt-Cy in IEI.

Methods: From 2015 t0 2025, 59 patients with IEI received allogeneic HSCT with Pt-Cy in our center. The median age at diagnosis was 2.2 years (at birth-28.7), at HSCT 2.6 (0.2-29.4). 18 patients had severe combined immunodeficiency (SCID), and 41 other IEI (19 of them developed malignancy before HSCT). Treosulfan-based conditioning was used in 48

patients (31 with thiotepa/melphalan), busulfan-based regimen in 10 (all older than 13), 1 received thiotepa/melphalan regimen. In 36 ATG and in 10 rituximab was used. In 5 patients matched sibling (MSD), in 22 matched unrelated (MUD)(12-10/10, 10-9/10 HLA-matched), in 32 mismatched related (MMRD) donor was used. In MMRD group 17 patients were SCID, 12 of them had active infections at HSCT. Graft source in 49 patients was bone marrow and in 10 patients peripheral blood stem cells. The median of CD34 cells in graft was 5.2 (range 1.8-15.6). In addition to Pt-Cy, GVHD prophylaxis included: in 26 calcineurin or mTOR inhibitor-based, in 30 ruxolitinib-based regimens, and in 3 (MSD) no prophylaxis was used.

Results: The median follow-up in survivors was 2.3 years (range 0.3-10.1). The overall survival (OS) was 0.79 (95%CI 0.69-0.9). OS was 0.96 (95%CI 0.87-1.0) in MUD and 0.65 (95%CI 0.48-0.82) in MMRD, and all 5 patients survived after MSD, p=0.035. Neutrophil engraftment occurred in 53 patients (median 22, range 13-33 days), 3 patients had severe infections early after HSCT before engraftment, and 3 had non-engraftment and received second HSCT (all died after second HSCT).
The incidence of acute GVHD was 0.26 (95%CI 0.17-0.4).Of 16 patients, acute GVHD was of grade 3 in 5 of grade 4 in 1 (was associated with CMV disease). The incidence if chronic GVHD was 0.13 (95%CI 0.07-0.27). No significant differences in acute and chronic GVHD rate were seen between the donor groups, p=0.94 and 0.86, respectively. The incidence of viral infection requiring therapy was 0.35 (95%CI 0.24-0.49), without differences between the donor groups, p=0.12. One SCID patient developed EBV-posttransplant lymphoproliferative disease transformed to lymphoma and died. The causes of death in all patients were infections.

Conclusions: Pt-Cy is a feasible option for GVHD prophylaxis in allogeneic HSCT for IEI. Decreased survival in MMRD group is related to high amount of patients undergoing HSCT with active infections (mainly SCID) or no complete control of inflammatory complications (like hemophagocytic lymphohistiocytosis), as no increased risks of development of acute and chronic GVHD, and viral infections is seen in this group.

Disclosure: The authors declare no conflict of interest.

B385

CLINICAL PICTURE AND IMMUNE RECONSTITUTION POST-HAEMATOPOIETIC CELL TRANSPLANTATION IN PAEDIARIC PATIENTS WITH CHRONIC GRANULOMATOUS DISEASE – LATIN AMERICAN SINGLE EXPERIENCE

Maria Pilar Tejada[1,2], *Maria Paula Martinez*[1], *Maria Isabel Gaillard*[1], *Daniela Di Giovanni*[1], *Danila Labonia*[3], *Magdalena Schelotto*[4], *Yasmin Espinosa Vielma*[5], *Rosa Maria Nideshda Ramirez Uribe*[6], *Maria Natalia Gonzalez Gonzalez*[7], *Natalia Builes Restrepo*[8], *Maria Emilia Mas*[9], *Nicolas Fernandez Escobar*[1], *Cristián Sotomayor*[10]

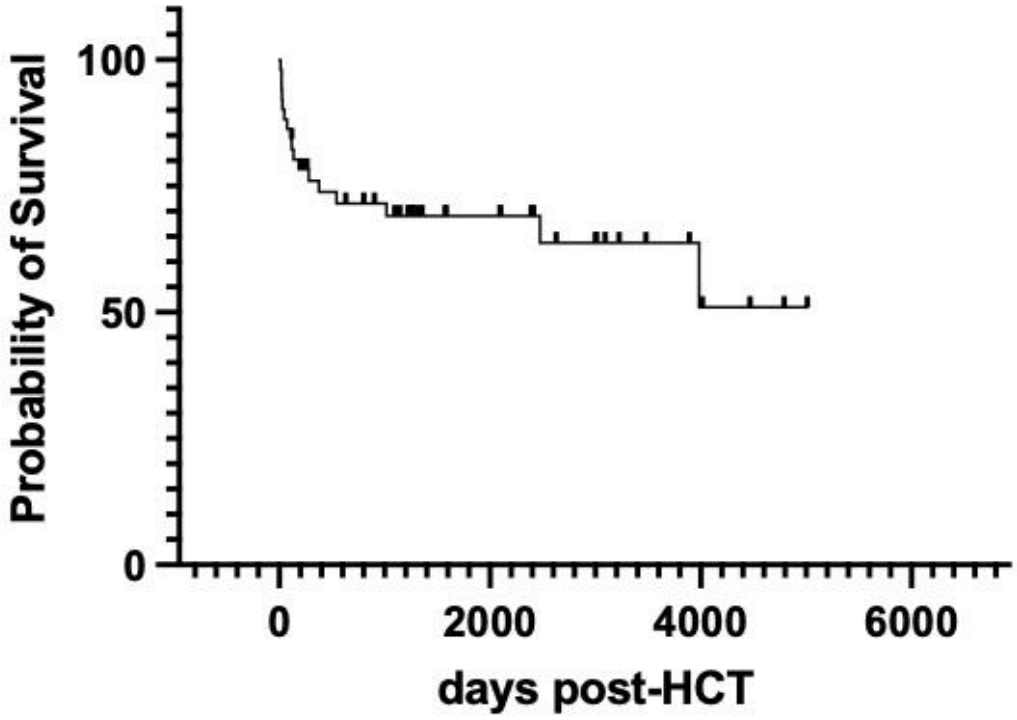
Rossell - Fundacion Perez Scremini, Montevideo, Uruguay, [5]Hospital Roberto del Río , Santiago, Chile, [6]Instituto Nacional de Pediatría, Ciudad de Mexico, Mexico, [7]Clínica Santa María, Santiago, Chile, [8]Hospital Pablo Tobón Uribe, Medellin, Colombia, [9]Hospital Privado Universitario de Córdoba, Cordoba, Argentina, [10]Red UC Christus, Departamento de Pediatría Pontificia Universidad Católica de Chile, Santiago, Chile

Background: Haematopoietic cell transplantation (HCT) is a curative treatment option for Chronic Granulomatous Disease (CGD). Post-HCT clinical features and immune reconstitution of patients from Latin America remain poorly described.
On behalf of the LASID Working Group of HCT**,** we aim to report the outcomes of CGD patients who received HCT at 8 different centers from Latin America: Argentina (3), Chile (2), Colombia (1), Mexico (1), Uruguay (1).

Methods: Retrospective data collection from 58 clinical records from post-HCT CGD patients (p).
2p were excluded due to insufficient information.

Results: Of 56p included, 54p (96.4%) were male and 51p (91.1%) X-linked CGD. Median age at diagnosis 27.9 months [0-164].Median follow-up 3.6 years [0-13], median age at transplant 43 months [1-197]. 8p (14.3%) required a second conditioned HCT and 1p (1.8%) a third procedure. The main reason was primary graft failure (5p, 55.6%).
Pre-HCT patients had: 47 (84%) at least one severe infection, 38 (67.9%) lung disease, 27 (48.2%) growth failure, and 14 (25%) CGD colitis. Of the 51p (91.1%) who received BCG vaccine, 23p (45.1%) developed associated complications (13p BCGitis, 10p BCGosis).
Regarding HCT, patients received bone marrow stem cells (n=19), peripheral blood (n=25) or cord (n=12) from matched (n=20) or mismatched (n=11) unrelated donors, matched sibling donor (n=10), haploidentical (n=9) or mismatched family donors (n=6).
47p (83.9%) received myeloablative conditioning, with busulfan-fludarabine being the most commonly used regimen (39p, 83%). Only 9p (16.1%) received a reduced toxicity conditioning regimen. 43p (76.8%) received serotherapy with Anti-Thymocyte Globulin. Cyclosporine and MMF as GvHD prophylaxis in most patients (20p, 35.7%).
In the post-HCT evolution, 17p (30.4%) developed acute, and 9 (16.1%) chronic GvHD. 14p (25%) had CMV, 6 (10.7%) EBV, 2 (3.6%) HHV6, and 1 (1.8%) ADV viremia. 1 (1.8%) developed EBV-PTLD.
At last follow-up, 34 patients were certified to be alive, resulting in a 14-year OS of 51%. Of the 17p that passed away, an infectious complication was the reason in 12. During the follow-up: 21/47 (44.7%) had significant infections, 21/38p (55.3%) stabilized lung disease, 11/27 (40.1%) improved growth and 13/14 (92.9%) resolved colitis.
Among the 37 patients who underwent both donor chimerism and DHR testing, a statistically significant correlation was observed between DHR results and chimerism ($r = 0.5630$; $p < 0.003$).



Conclusions: This study provides valuable insights into outcomes after HCT in patients with CGD at different centers of Latin America.
In our cohort, most patients had multiple severe pre-HCT complications. Despite high mortality, HCT led to myeloid reconstitution with improvement in infection rate, growth, lung disease and colitis.
These results support HCT as a curative option for CGD and highlight the need for earlier referral and better transplant strategies in Latin America.

Disclosure: Nothing to declare.

SUCCESSFUL CORD BLOOD TRANSPLANTATION IN AN INFANT WITH LEUKOCYTE ADHESION DEFICIENCY TYPE III: A CASE REPORT AND 1 YEAR FOLLOW-UP

*Beatrice Gregorio[1], Stefano Rossi[1], **Marianna Maffeis**[1], Giulia Baresi[1], Arnalda Lanfranchi[2], Fulvio Porta[1], Elena Soncini[1]*
[1]ASST Spedali Civili / Pediatric Oncohematology Unit and Pediatric Bone Marrow Transplant Center, Brescia, Italy, [2]ASST Spedali Civili / Stem Cell Laboratory, Section of Hematology and Blood Coagulation, Clinical Chemistry, Brescia, Italy

Background: Leukocyte Adhesion Deficiency type III (LAD-III) is the rarest form of leukocyte adhesion defects and is caused by biallelic mutations in *FERMT3*, leading to impaired integrin activation in leukocytes and platelets. Patients present with severe immunodeficiency and a Glanzmann-like bleeding phenotype due to dysfunctional GPIIb/IIIa. Diagnosis typically occurs in infancy following evaluation for recurrent infections, mucocutaneous bleeding, and abnormal platelet function. Hematopoietic stem cell transplantation (HSCT) is considered the only curative treatment. We describe the clinical course and post-transplant outcome of a female infant with genetically confirmed LAD-III who underwent allogeneic cord blood transplantation.

Methods: The patient presented at four days of life with petechiae, gross hematuria, hematomas, leukocytosis, anemia, and mild thrombocytopenia. Platelet aggregation testing revealed absent aggregation to all agonists. Whole-genome sequencing identified a homozygous *FERMT3* p.(Arg573*) nonsense mutation, confirming LAD-III. Comprehensive hematologic, immunologic, and genetic evaluations excluded alternative causes. Due to the absence of an HLA-identical related or unrelated donor, an HLA-compatible cord blood unit (CBU) was selected from international registries. The patient underwent a stem cell transplant from an unrelated CBU at 4 months old, following Treosulfan, Fludarabine, Thiotepa, and Alemtuzumab conditioning. Standard antimicrobial prophylaxis, immunoglobulin supplementation, and post-transplant monitoring were performed according to institutional protocols.

Results: Neutrophil engraftment occurred on day +19 and platelet engraftment on day +41. Only complication registered during the HSC infusion was a blood pressure spike due to hemodinamic imbalance which quickly resolved with medical treatment. The patient did not develop any infectious complications. Cystoscopy performed during hospitalization showed complete resolution of previously documented hemangioma-like submucosal bladder lesions, with residual hemosiderin deposits and no active bleeding. Patient showed no evidence of acute GvHD. Immunosuppression with cyclosporine was discontinued in September 2025. Donor chimerism progressively improved: 85% in T cells and 100% in B cells and PMN 4 months post transplant, rising to 98.3% T-cell donor chimerism by 6 months post HSCT. Immune reconstitution was robust, with adequate lymphocyte subpopulations: RTEs were 2920 cell/uL 6 months post transplant; CD3+ 7180 cell/uL and CD4+ 5032 cell/uL 1 year post transplant. Patient showed normal mitogen responses, and serum IgG levels within acceptable range. TRECs/KRECs were >100,000/mL 6 months post transplant. The patient started routine vaccinations 6 months post HSCT. At the 1-year follow up evaluation the patient is clinically well, with appropriate growth, normal psychomotor development, no evidence of GvHD and no ongoing treatment.

Conclusions: This case highlights the effectiveness of cord blood transplantation as a curative option for LAD-III in the absence of matched donors. The patient achieved timely engraftment, full donor chimerism, resolution of bleeding manifestations, and robust immune recovery with an excellent clinical outcome. We believe CBUs represent a viable and potentially lifesaving strategy for patients with ultra-rare immunodeficiencies such as LAD-III.

HEMATOPOIETIC STEM CELL TRANSPLANTATION WITHOUT CONDITIONING IN IL2RG-MUTATED SCID AND SEVERE ACTIVE CMV INFECTION: RAPID IMMUNE RECONSTITUTION AND INFECTION CONTROL

Peter Svec[1,2], *Veronika Dobsinska*[1], *Julia Horakova*[1], *Robert Ostro*[3], *Ivana Bodova*[1], *Jaroslava Adamcakova*[1], *Maria Fussiova*[1], *Tomas Sykora*[1], *Dominika Doczyova*[1], *Miroslava Pozdechova*[1], *Kristina Polakova*[1], *Anna Panikova*[1], *Alexandra Kolenova*[1,2]
[1]*National Institute of Children's Diseases, Bratislava, Slovakia,* [2]*Comenius University, Bratislava, Slovakia,* [3]*University Children's Hospital Kosice, Košice, Slovakia*

Background: In severe combined immunodeficiency (SCID), early hematopoietic stem cell transplantation (SCT) is curative, but active infections prior to SCT such as cytomegalovirus (CMV) are associated with increased morbidity and mortality. Considerations of optimal transplant approach in these infants with active infection include omitting conditioning regimen, even with increasing the risk for necessity of a second procedure due to incomplete B-cell recovery and the need for ongoing immunoglobulin replacement.

Methods: Retrospective review of clinical charts was used to report on a 4-month-old male with genetically confirmed interleukin-2 receptor gamma (IL2RG)-mutated SCID (T−B+NK−) presenting with severe CMV infection, including severe encephalitis with multiple brain calcifications and CMV retinitis. Pre-transplant management included intense combined antiviral therapy with foscarnet and ganciclovir. At 6 months of age, the patient received an unmanipulated bone marrow graft from a matched sibling donor, without conditioning or serotherapy; immunosuppression was limited to cyclosporine A. Immune reconstitution and clinical outcomes were monitored longitudinally.

Results: Despite intensive antiviral therapy pre-transplant, the SCT was performed while CMV was actively replicating - CMV DNA in CSF was still high positive (350 000 copies of CMV /ml. We noted fast immune reconstitution, with first naive CD4+ T cells in peripheral blood as early as day +8 (30/uL). The patient encountered engraftment syndrome on day +11, treated with short course of steroids. Despite steroids, CMV PCR became negative in blood since D+24. Additional virus specific T cell therapies were not needed. At D+21 the donor chimerism was already dominant (62%), patient was discharged at D+31 and remained free of GvHD, severe infections and demonstrated stable donor chimerism through 24 months of follow-up post-transplant. The immune reconstitution continued well (at 6months post SCT, naïve CD4 were 480/ul, with complete donor chimerism also in CD19 and IgG substitution independence at 10 months).

Conclusions: The case supports the preference for unconditioned SCT in T−B+NK− IL2RG SCID with severe active CMV or other severe infection, especially with available matched sibling donor – an option included in recent ESID/IEWP EBMT recommendations (1). SCT without conditioning can achieve rapid T-cell reconstitution and infection control and spare

the patient from dangerous organ toxicity, in the presented case also with adequate B cell reconstitution without the need for a second procedure.

SUCCESSFUL HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR DIAPH1 MUTATION: A CASE REPORT

Burcu Akıncı[1], *Hayriye Daloglu*[1], *Suleimen Zhumatayev*[1], *Gülsün Karasu*[1], *Akif Yesilipek*[1]
[1]*Medicalpark Pendik Hospital, İstanbul, Turkey*

Background: Loss of function mutations in Diaphanous related formin 1 (*DIAPH1)* are associated with seizures, cortical blindness, and microcephaly syndrome (SCBMS). It is rare entity which has an autosomal recessive inheritance. The affected children mostly have microcephaly, early-onset epilepsy, severe visual impairment and hearing loss. Also, it causes combined immune deficiency which is associated with major T, natural killer (NK), and innate lymphoid cells (ILCs) defects. Consequently, recurrent pulmonary infections and bronchiectasis are frequently observed in association with this. For today, there is no specific treatment for DIAPH1 deficiency and hematopoietic stem cell transplantation (HSCT) may be an option.

Methods: We report a 5 years-old female patient with DIAPH1 mutation who received HSCT at the Bone Marrow Transplantation Unit at Medicalpark Pendik Hospital, Istanbul.

Results: The patient had been presented with microcephaly, cortical blindness, and seizures starting in first month postnatally. She had been operated because of ventricular septal defect. Also, she had recurrent pulmonary infections requiring hospitalization many times and mouth sores. Pediatric immunology tests revealed low CD4 and CD8 T lymphocyte counts, leading to a diagnosis of T-B+NK+ combined immunodeficiency. Whole exome sequencing test identified homozygous pathogenic variant p.(Arg351Ter) in DIAPH1 gene. The patient, whose signs of infection persisted despite antibacterial prophylaxis and regular intravenous immunoglobulin (IVIG) replacement, was referred for HSCT.
The conditioning regimen consisted of; fludarabine 180 mg/m^2 on days -7 to -2, treosulfan 36 gr/m^2 on days -6 to -4, rabbit anti-thymocyte globulin (rATG) 15 mg/kg on days -2 to -1. Because, EBV-DNA level was 1993 copies/ml in the pre-transplantation tests, rituximab at a dose of 375 mg/m^2 was administered before starting the conditioning regimen. HSCT was performed from a fully matched unrelated male donor. Peripheral blood stem cells with a dose of 4.4x10^6 CD34/kg were infused. For graft versus host disease (GVHD) prophylaxis, she received methotrexate on days +1, +3, +6 along with tacrolimus starting on day -2. Neutrophilic engraftment was achieved on day +14, while platelets were engrafted on day +15 post-HSCT. The post-transplant period was uneventful apart from having seizures. GVHD

did not develop. Chimerism test performed one month after transplantation was %100 donor cells. At 6 months follow up, no complications occurred. Peripheral blood cell counts and immunoglobulin levels are normal, and there is no need for IVIG.

Conclusions: This rare combined immunodeficiency can be fatal due to pulmonary infections. HSCT can be a curative treatment for immune deficiency component of this syndrome. However, prospective studies involving a larger patient population are needed on this subject.

Disclosure: The Authors declare no conflict of interest.

CLINICAL CONSIDERATIONS FOR HEMATOPOIETIC CELL TRANSPLANTATION IN PATIENT WITH CONCOMITANT CHRONIC GRANULOMATOUS DISEASE AND MCLEOD SYNDROME

Kentaro Fujimori[1], *Soichiro Shimizu*[1], *Takashi Ishikawa*[1], *Yoshihiro Gocho*[1], *Hirotoshi Sakaguchi*[1], *Toru Uchiyama*[1], *Kazuhiko Nakabayashi*[1], *Daisuke Tomizawa*[1], *Masafumi Onodera*[1], *Kimikazu Matsumoto*[1], *Toshinao Kawai*[1], *Akihiro Iguchi*[1]
[1]*National Center for Child Health and Development, Setagaya, Japan*

Background: The CYBB gene, responsible for X-linked chronic granulomatous disease (X-CGD), is located adjacent to the XK gene, which is responsible for McLeod syndrome (MLS). A contiguous deletion of both genes results in a phenotype exhibiting both X-CGD and MLS. MLS is a genetic disorder that causes neuroacanthocytosis. It is characterized by the loss of XK protein along with Kx antigen on red blood cell (RBC) surfaces and late-onset neurocognitive symptoms.
The absence of XK protein leads to a high risk of sensitization from allogenic RBC transfusions, producing anti-Kx or anti-Km antibodies. This makes subsequent transfusions difficult because of the risk of acute hemolytic transfusion reactions. Therefore, performing hematopoietic cell transplantation (HCT) -the only radical cure for X-CGD, which often requires several transfusions- is challenging.
Here, we report a case of X-CGD with MLS who underwent HCT and experienced a stable mid-term clinical course.

Methods: A retrospective chart review was completed for a case of X-CGD associated with MLS who underwent HCT.

Results: A Japanese boy was diagnosed with X-CGD and MLS in his infancy base on a family history. Genetic testing confirmed a deletion of both CYBB and XK genes. The patient suffered from recurrent infections and refractory inflammatory bowel disease due to X-CGD. He required an RBC transfusion from a random donor at age 6, but fortunately, pre-HCT testing confirmed he was not sensitized to the Kx antigen.
At age 7, he underwent HCT from a matched unrelated donor. He received a reduced intensity conditioning regimen composed of targeted busulfan, fludarabine, anti-thymocyte

globulin, and total body irradiation (3 Gy). To specifically prevent Kx sensitization, rituximab was added to this regimen, and RBCs were depleted from the donor bone marrow graft prior to infusion.
The post-HCT course was successful. The patient received 7 units of RBCs from random donors without any hemolytic events. Neutrophil engraftment occurred on day +19 with full donor chimerism. Every immunosuppressants, were successfully tapered and discontinued one year after HCT. Three years have passed since HCT, and the patient is living well without SCT-related complications such as chronic GVHD, severe infections and neurological complications associated with MLS.

Conclusions: We successfully performed HCT in a patient with X-CGD and MLS. Our strategy was based on using rituximab and RBC depletion from the graft, and conditioning including low-dose total body irradiation may also have contributed to preventing sensitization.
Past reports have shown that inadequate measures can lead to severe hemolysis. Thus, HCT for X-CGD with MLS requires additional interventions to prevent hemolysis and a meticulous transfusion plan. Although, a fully established, standard method does not yet exist, our approach may be considered a promising optimal method.
Fortunately, no neurological complications associated with MLS have developed after three years of follow-up.
In conclusion, while this HCT method can safely cure X-CGD, improving prognosis and quality of life by eliminating recurrent infections, the long-term impact of HCT on the late-onset neurocognitive symptoms of MLS remains unclear. Further studies involving more cases and vigilant long-term follow-up are essential.

P273

EXPERIENCE IN PREPARING FOR ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A PATIENT WITH WISKOTT-ALDRICH SYNDROME

*Liubou Zherko[1], **Volha Mishkova**[1], Maryia Navumovich[1], Yuliya Mareika[1], Natalia Kirsanava[1], Dmitry Prudnikau[1], Nina Minakovskaya[1], Anzhalika Solntsava[1]*
[1]Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Minsk, Belarus

Background: Grafts from unrelated donors in patients with Wiskott-Aldrich syndrome (WAS) carry a high risk of severe complications, particularly graft-versus-host disease (GVHD). Allogeneic hematopoietic stem cell transplantation (HSCT) in WAS patients is also associated with a significant risk of graft dysfunction, such as failure, rejection, or persistent mixed chimerism in the myeloid compartment. These outcomes have been consistently reported in large clinical studies.

Methods: A patient with a genetically confirmed diagnosis of WAS received treatment at the Belarusian Research Center for Pediatric Oncology, Hematology, and Immunology, where he later underwent allogeneic HSCT from an HLA-compatible unrelated donor.

Results: The patient was born from the third pregnancy and second delivery. He has a five-year-old half-brother with a genetically confirmed diagnosis of WAS, who underwent umbilical cord blood HSCT at the Center at eight months of age.
On the second day after birth, the patient was transferred to the intensive care unit due to thrombocytopenia ($15*10^9$/L). Given his complex medical history, he was first seen at the Center for Pediatric Oncology, Hematology, and Immunology at 20 days old. Genetic testing identified a WAS gene mutation (c.631C>T, p.Arg211Ter (rs1602178165)). Standard immunological tests showed reduced T-lymphocytes ($0.225*10^9$/L) and B-lymphocytes ($0.517*10^9$/L).
At admission, the patient had loose stools, blood in every bowel movement, rotavirus enterocolitis, poor weight gain, aphthous stomatitis, and congenital pneumonia. After treating the rotavirus infection, he began preparation for hematopoietic stem cell transplantation (HSCT). He was admitted to the transplantation unit with enterocolitis and pneumonitis, likely of immunological origin.
Both the Center's experience and global data indicate a high incidence of intestinal graft-versus-host disease (GVHD) in WAS patients after transplantation. Due to persistent gastroenteritis and malabsorption, with no evidence of infection and negative viral tests (including CMV and EBV), the patient began conditioning with infliximab 10 mg/kg on days -10 and -2, ATG (Genzyme), treosulfan, fludarabine, thiotepa, and rituximab.
The patient underwent allogeneic bone marrow HSCT from an unrelated HLA-compatible donor. GVHD prophylaxis included cyclosporine and methylprednisolone. Two mesenchymal stem cell transplants were also administered to prevent GVHD.
In the early post-transplant period, the patient developed grade I GVHD (skin 2) on day +14. Engraftment was confirmed on day 11, with cytopenia lasting 18 days. On day +13, 100% PCR chimerism was achieved. Enterocolitis and pneumonitis resolved after the initial infliximab administration but recurred following enterovirus infection on day +8 after HSCT. The patient's condition stabilized after the infection was cleared.
As of day +85 post-transplant, the patient shows no signs of graft-versus-host disease (GVHD) and maintains 100% donor chimerism.

Conclusions: Based on our Center's experience and global data, patients with Wiskott-Aldrich syndrome require thorough preparation for HSCT to minimize post-transplant complications, with the intestine being the most vulnerable organ. Due to early signs of enterocolitis, persistent malabsorption, hemorrhagic colitis, and previous intestinal infections, the medical team determined that additional pre-transplant preparation was necessary. Two infliximab administrations were performed, resulting in stabilization of the patient's enterocolitis and pneumonitis.

Disclosure: No conflict of interests.

HEMOPHAGOCYTING LYMPHOHISTIOCYTOSIS – ISOLATED CNS MANIFESTATION

Kristína Poláková[1], *Peter Švec*[1,2], *Veronika Dobšinská*[1,2], *Miroslava Pozdechová*[1], *Júlia Horáková*[1], *Ivana Boďová*[1], *Jaroslava Adamčáková*[1], *Marika Fussiová*[1], *Dominika Dóczyová*[1], *Tomáš Sýkora*[1,2], *Alexandra Kolenová*[1,2]
[1]*National Institute of Children's Diseases, Bratislava, Slovakia,* [2]*Comenius University, Faculty of Medicine, Bratislava, Slovakia*

Background: Hemophagocyting lymphohistiocytosis (HLH) is an aggressive life-threatening syndrome of excessive immune activation. The familial form typically presents in early childhood as a sepsis-like condition. However, HLH can have diverse clinical presentations, which are even more diagnostically challenging, especially in atypical or isolated manifestations. Isolated central nervous system HLH (CNS-HLH) is a rare and difficult to diagnose due to nonspecific symptomatology and absence of systemic manifestations.

Methods: Case report:

Results: A 4-year-old patient with genetically confirmed familial HLH (UNC13D) underwent allogeneic hematopoietic stem cell transplantation (HSCT) from matched unrelated donor at the age of 8 months. In the post-transplant period, a gradual decrease in donor T cell chimerism was observed. We have been using a „watch and wait" strategy for a long period of time with stable mixed CD3+ T Ly chimerism of 30 % donor which is generally compatible with long term HLH control and our patient was without signs of disease reactivation. Before relapse, 3.5 years after 1st HSCT, chimerism was 28% of donor in CD3+ T ly. Neurological symptomatology slowly developed in the absence of systemic manifestations of HLH: ataxia, tremor, later convulsions up to refractory status epilepticus requiring intensive care. Based on the examination of the cerebrospinal fluid (proteinuria, pleocytosis) and MRI findings (diffuse/multifocal white matter lesions) isolated CNS HLH was diagnosed. At relapse, the detected donor chimerism 16 % in CD3 T cells – the drop happened unrecognized within 3 months. Intensive immunosuppressive treatment with alemtuzumab was indicated and subsequently 2nd allogeneic HSCT. After complicated HSCT, the patient is without signs of active CNS HLH, but with severe neurological impairment with progression.

Conclusions: Isolated CNS HLH is a rare form of HLH and CNS damage by the HLH process is largely irreversible. By clinical and MRI findings it mimics other, more common neurological diseases of childhood and thus represents a significant diagnostic challenge. It should be considered in a patient with neurological symptoms, especially with concurrent pleocytosis, proteinuria and abnormalities on brain MRI associated with HLH. Our patient shows that relying on disease control at lower level of mixed chimerism to spare the patient a second HSCT maybe a risky approach and challenge to monitoring even longterm after 1st HSCT.

Hodgkin Lymphoma and T cell Lymphoma

OS02-06

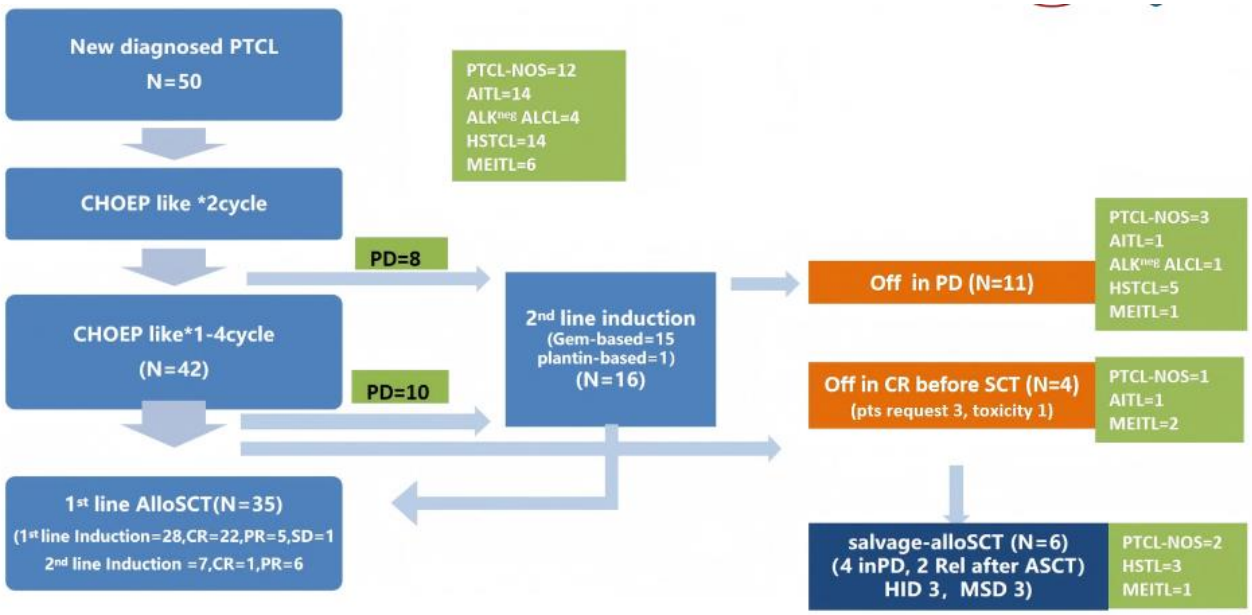
EARLY ALLOGENEIC TRANSPLANTATION AS PART OF FIRST-LINE THERAPY IN HIGH-RISK T-CELL LYMPHOMA: RESULTS OF A PROSPECTIVE PHASE 2 STUDY

FengRong Wang[1], *ShenMiao Yang*[1], *Yang Liu*[1], *XiaoDong Mo*[1], *Yu Wang*[1], *Jin Lu*[1], *KaiYan Liu*[1], *XiaoHui Zhang*[1], *XiaoJun Huang*[1]
[1]*Peking University Institue of Hematology,People's Hospital, Beijing, China*

Background: Allogeneic stem cell transplantation (alloSCT) cures about 50% of patients (pts) with T-cell lymphoma (PTCL). However, more than one-third of pts progress or relapse early failing to reach alloSCT (Schmitz et al. BLOOD 2021). We shortened conventional therapy and followed by alloSCT to prevent early progression (PD).

Methods: This was a prospective phase 2 study conducted in high-risk PTCL pts (no ALK+ ALCL, no stage 1 with aaIPI 0). Pts with PET-neg CR or PR after 3 cycles of CHOEP(or variant) underwent alloSCT, in pts with early PD salvage therapy followed by alloSCT was planned. Pts received myeloablative conditioning with BuCy, MeCCNU, and Ara-C or TBI (8 Gy). GVHD prophylaxis consisted of cyclosporine A, MMF, and short-term MTX, plus ATG (10mg/kg) for unrelated or haplo-transplants. The study was planned according to Simon’s optimal two-stage study design with a total of 47 pts to be included (Clinicaltrials.gov, NCT03672084).

Results:



Fifty newly diagnosed patients were enrolled: 12 pts with PTCL-NOS, 4 ALK-neg. ALCL, 14 AITL, 6 MEITL, and 14 pts (28%) with hepatosplenic T-cell lymphoma (HSTL) (see flowchart). Thirty-five pts responded (28 to first-, 7 to second-line therapy) and proceeded to alloSCT(On-study). 15 pts went off-study due to PD (n=11), patient request for autoSCT (n=3), and heart toxicity (n=1); 6 of these pts finally underwent alloSCT. Until Nov 30, 2025, with a median follow-up of survivors of 1259 days two-year overall survival (OS) and progression-free survival (PFS) was 74.7% and 56.7%, respectively. Incidence of PD or relapse(RI) was 40%, NRM was 2%.

On-study pts: 26/32 pts had durable CR post alloSCT, six pts relapsed (3 HSTCL, and 1 MEITL,ALK-neg ALCL, PTCL NOS each). Four responded to salvage therapy including donor stem cell infusion. Two-year-PFS and -OS were 77.6% and 90.7%. The D100 and 1y transplant-related mortality (TRM) were 0% and 3%, respectively. The cumulative incidences of acute and chronic GVHD were 45.7% and 62.8%.

Off-study pts: Eight of 9(no alloSCT) died of lymphoma, 1 keep CR with chidamide maitaining. Six pts (4 PD, 2 failing autoSCT) received salvage alloSCT and 4 are alive (3 CR, 1 with lymphoma). Their 2y-PFS and -OS were 20% and 33.9%.

Twenty pts (40%) diagnosed with HSTCL or MEITL had a significantly worse survival compared to other subtypes, with the 2y PFS of 31.3% vs 65.2% (p=.088), and 2y OS 59.8% vs 82.1% (p=.048), this probally due to the higher RI (55% vs 27%, p=0.018). None of these pts survived without alloSCT.

Table1 Patient Characteristics

	On-Study Group(n=35)	**Off-Study Group(n=15)**	**Total(N=50)**

MNC, median (range) x108/kg	8.7 (5.4-29.2)	8.98 (7.4-12.1)	8.7 (5.4-29.2)
CD34+ median (range) x106/kg	2.83 (0.47-7.2)	2.32 (1.9-6.4)	2.7 (0.47-7.2)
Engraftment of WBC (day)	12 (10-25)	14.5 (11-27)	12 (10-27)
Engraftment of PLT (day)	14(10-159)	17(10-100)	14(10-159)

Conclusions: *Early* alloSCT as 1st line consolidation was feasible in two-thirds of pts with low TRM resulting in excellent survival. All but one pts without alloSCT died of lymphoma. Notably, 40% of study pts suffered from HSTCL or MEITL. For these pts, underrepresented in other studies, alloSCT is the only curative option although outcomes were worse than in major T-cell entities (2-yr OS 60% vs 82%).

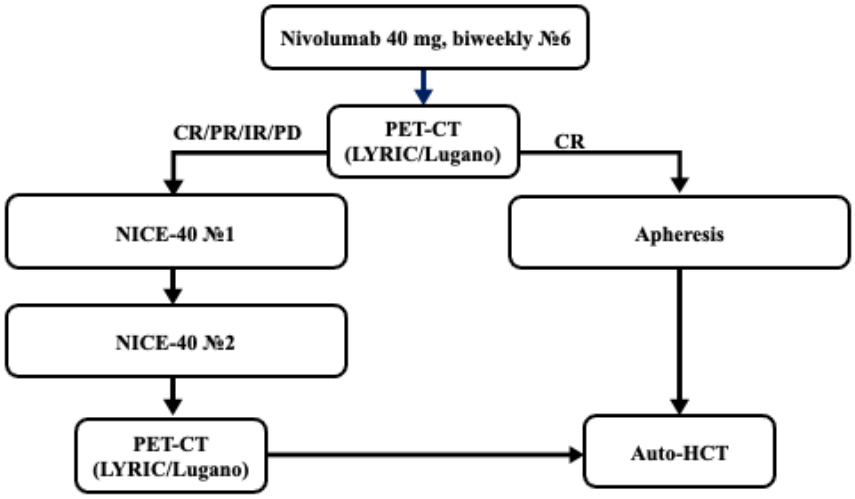
AVOIDING SALVAGE CHEMOTHERAPY IN EARLY PD-1 INHIBITOR RESPONDERS: OUTCOMES OF LOW-DOSE NIVOLUMAB-BASED SECOND-LINE THERAPY (NICE-40) FOR HODGKIN LYMPHOMA

Polina Kotselyabina[1], *Andrey Chekalov*[1], *Aminat Balaeva*[1], *Kirill Lepik*[1], *Liudmila Fedorova*[1], *Stanislav Volchenkov*[2], *Sergey Shalaev*[2], *Ilya Zyuzgin*[2], *Diana Ivanova*[3], *Elena Baryakh*[3], *Maria Grigoreva*[4], *Marina Demchenkova*[4], *Natalia Mikhailova*[1], *Ivan Moiseev*[1], *Alexander Kulagin*[1]
[1]*RM Gorbacheva Research Institute, Pavlov University, Saint Petersburg, Russian Federation (the),* [2]*N.N. Petrov National Medical Research Center of Oncology, Saint Peterburg, Russian Federation (the),* [3]*Moscow Clinical Research Center Hospital 52 of the Moscow City Health Department, Moscow, Russian Federation (the),* [4]*Irkutsk Regional Cancer Center, Irkutsk, Russian Federation (the)*

Background: PD-1 inhibitors enable high response rates in relapsed/refractory classical Hodgkin lymphoma (r/r cHL), prompting investigation of PET-adapted strategy. In this approach, responders to PD-1 monotherapy may potentially avoid salvage chemotherapy before auto-HCT, reducing overall toxicity. For non-responders, adding PD-1 inhibitors to chemotherapy improves efficacy, allowing a significant proportion of patients to achieve an optimal pre-transplant status. However, widespread use of PD-1 inhibitors raises financial toxicity concerns. Pharmacologically supported low-dose regimens represent a viable strategy to reduce costs and expand patient access.

Methods: This prospective, multicenter clinical trial enrolled adults with r/r cHL (NCT04981899) after first-line therapy failure. Patients (pts) received 6 nivo-40 cycles

(biweekly), followed by response-adapted therapy (LYRIC/Lugano): pts achieving early CR (CR) after 6 cycles proceeded directly to auto-HCT, while those with less than CR received combined chemoimmunotherapy (nivo-40 plus ICE, NICE-40) followed by auto-HCT. The primary endpoint was objective response rate (ORR); secondary endpoints included 3-year overall survival (OS) and progression-free survival (PFS).



Results: In total, 33 pts (median age 38 [20–66]) were enrolled across three sites (Dec 2020–Nov 2025). Primary refractory/early relapse occurred in 58% (n=19)/24% (n=8); B-symptoms in 27% (n=9), extranodal disease in 39% (n=13) at the time of enrollment. Post nivo-40 monotherapy: CR - 46% (n=15), partial response (PR) - 21% (n=7), indeterminate response (IR) - 30% (n=10), and progression - 3% (n=1) pts. Among non-CR, 1 continued nivo-40 due to patient/physician decision, 17 proceeded to NICE-40: ORR 76% (13/17) with CR 41% (n=7), PR 35% (n=6), IR 24% (n=4). Auto-HCT was performed in 88% (n=29): 45% (13/29) post nivo-40, 52% (15/29) post NICE-40, 1 post third-line.Post-HCT maintenance was given to 55% (n=16): brentuximab vedotin (n=9, 31%) and nivo-40 (n=7, 24%). With a median follow-up of 37 months (range 4–57), the 3-year OS was 92% (95% CI 72–98%), PFS - 79% (95% CI 59–90%). A trend toward superior PFS was observed in pts achieving CR after nivo monotherapy (93% [95% CI 61–99%] vs. 67% [95% CI 37–85%], p=0.11). Pre-HCT PET status (CR vs. non-CR) did not affect PFS (81% [51–94%] vs. 74% [39–91%], p=0.8). In the safety analysis performed for study treatment, the rate of adverse events (AEs) of any grade occurred in 42% (n=14), including 42% (n=14) of grade 1-2 AEs and 12% (n=4) of grade 3-4 AEs (related to hematological toxicity).

Conclusions: NICE-40 is an effective second-line regimen prior to auto-HCT in r/r cHL. Using a PET-adapted strategy, we identified that 45% of patients can successfully avoid

salvage chemotherapy and proceed directly to auto-HCT after nivo-40 monotherapy, achieving favorable outcomes while reducing toxicity and financial burden.

Blokhin National Medical Research Center of Oncology, Moscow, Russian Federation (the),* [3]*National Medical Research Cancer Center N.A Petrov N.N, St. Petersburg, Russian Federation (the),* [4]*N. N. Alexandrov National Cancer Center of Belarus, Minsk, Belarus*

Background: The introduction of PD-1 inhibitors into the second-line treatment for classic Hodgkin lymphoma (cHL) has raised question about the role of autologous hematopoietic cell transplantation (auto-HCT). It remains unclear whether patients achieving deep responses to PD-1 blockade can safely omit transplantation. Given the early and late complications associated with auto-HCT, clarifying this question in immunotherapy era is clinically important. This study aims to determine if auto-HCT may be omitted in patients who achieved an early complete response (CR) with PD-1 inhibitor prologolimab (Prolgo) monotherapy in second-line treatment of cHL.

Methods: This prospective, multicenter, single-arm, phase 2 clinical trial includes adult patients with histologically confirmed relapsed/refractory (r/r) cHL after first-line therapy (NCT05757466). All patients were naïve to PD-1 inhibitors. According to study protocol (Fig.1) patients with CR after 6 cycles of Prolgo (1 mg/kg every 2 weeks) continue monotherapy for up to 24 cycles. If CR is not achieved pts are switched to combination therapy (Prolgo 1 mg/kg D1,15; Bendamustine 90 mg/m2 D1,2, 28-day cycle, for up to 3 cycles). Response assessments are performed every 3 months by PET-CT using LYRIC criteria. The primary endpoint was overall response rate (ORR). Secondary endpoints included overall (OS), progression-free survival (PFS), duration of response (DOR), and adverse events (AE). The intention-to-treat (ITT) population was used for the safety analysis, and the per-protocol (PP) population - for the efficacy analysis. Four patients were excluded from the PP analysis for the following reasons: significant protocol deviation (n=2), early withdrawal of consent (n=1), and grade 3 AE (n=1).

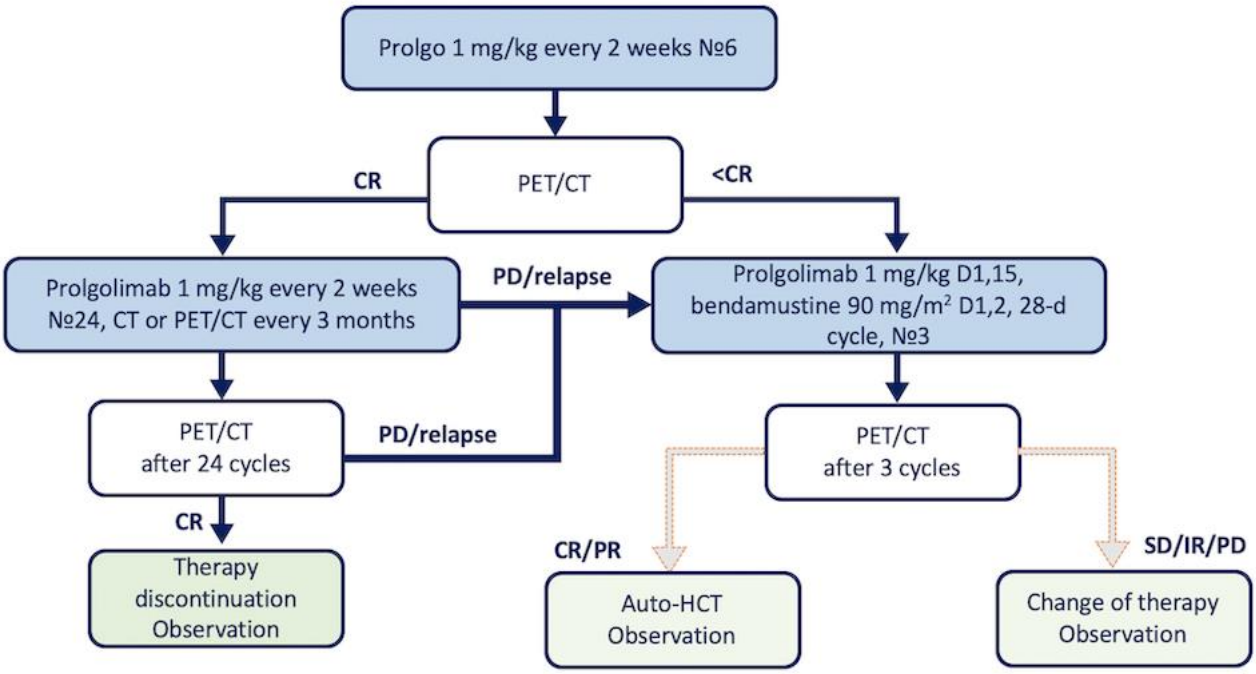

Figure 1 Study protocol

Results: 32 pts with r/r cHL were enrolled in the study from 04.2023 to 11.2025. Median follow-up was 19 months (range,2-31).
In the PP analysis all patients (n=28) completed 6 cycles of Prolgo: 9 pts (32%) achieved CR, 8 (29%) – partial response (PR), 1 (4%) – stabilization, 9 (32%) – indeterminate response, 1 (4%) – disease progression. Among patients who achieved CR after 6 cycles (n=9), 7 pts (78%) had already completed 24 cycles of therapy. Relapse was occurred in 4 pts (44%). Median DOR was 23.3 months (95%CI 20.3-NA). 17/19 pts without CR were switched to the Prolgo-bendamustine arm. Fourteen pts completed combination therapy, among which CR was achieved in 11 (79%) pts and PR in 1 (7%). Auto-HCT was performed at 8 pts (57%).
At the end of therapy per protocol, 19/21 (90%) pts achieved an objective response. Median PFS was 24.1 (95%CI 22.5-NA) and 1-year PFS was 87% (95%CI 74-100%). One patient in CR died of an infectious AE on D+88 after auto-HCT.
In the safety ITT analysis (n=32), the rate of grade 1-2 AE was 63%, grade 3 - 16%. Therapy was discontinued due to AE in 2 pts.

Conclusions: This real-world study demonstrates high response rate within the Prolgo-HL protocol in patients with r/r cHL. However, significant relapse rate in early CR maintenance arm bring into question the benefit of omitting auto-HCT in unselected group of patients with r/r cHL. Further stratification of low risk patients needed to identify population for whom forgoing auto-HCT is feasible.

Clinical Trial Registry: NCT05757466

Disclosure: The investigational drug (prolgolimab) was provided by BIOCAD. The sponsor had no role in the study design, data collection, analysis, interpretation, or decision to submit the manuscript for publication.

B388

FIVE-YEAR FOLLOW-UP OF NIVOLUMAB-BASED COMBINATIONS AND TRANSPLANT STRATEGY AFTER PD-1 INHIBITOR FAILURE IN RELAPSED/REFRACTORY CLASSIC HODGKIN LYMPHOMA

Liudmila Fedorova[1], *Kirill Lepik*[1], *Polina Kotselyabina*[1], *Andrey Chekalov*[1], *Aminat Balaeva*[1], *Anastasia Beinarovich*[1], *Elena Kondakova*[1], *Ivan Moiseev*[1], *Natalia Mikhailova*[1], *Alexander Kulagin*[1]
[1]*RM Gorbacheva Research Institute, Pavlov University, St. Petersburg, Russian Federation (the)*

Background: The optimal management of relapsed/refractory classic Hodgkin lymphoma (r/r cHL) after checkpoint inhibitors (CPI) failure remains an unmet need. While combination regimens with CPI show promise, their long-term outcomes are not systematically described. The role of allo-HCT and alternative strategies for ineligible patients are undefined. Thus, the aim of this study was to assess long-term outcomes of nivolumab (nivo) combined with chemo- or targeted therapy after mono-CPI failure, and to evaluate the prognosis of patients consolidated with allo-HCT versus those continuing conservative therapy.

Methods: The retrospective study included 123 patients with r/r cHL after mono-CPI failure. All patients were treated with combination of nivo (3 mg/kg or 40 mg every 2 weeks) and chemo- or targeted therapy: bendamustine 90 mg/m² D1,2 of a 28-day cycle (n=55), vinblastine 10 mg every 2 weeks (n=42), brentuximab vedotin (BV) 1.8 mg/kg every 3 weeks (n=20), or gemcitabine 800-1000 mg every 2 weeks (n=6). The response was evaluated every 3 months by PET-CT using LYRIC criteria. The survival outcomes and adverse events (AE) were analyzed.

Results: Baseline characteristics are listed in Table 1. Median follow-up was 65 months (2–103). The ORR was 54% (n=67): complete response (CR) 29%, partial response (PR) 25%, stabilization 14%, progression 14% and indeterminate response 18%. 5-year OS was 82.6% (95% CI: 75.5–90.3). Median PFS was 11.5 months (95% CI: 9.4–13.7 mo) with 5-year PFS of 13.1% (95% CI: 6.6–26.3). Median TTNT was 7.1 months (95% CI: 5.9–8.7), 5-year TTNT was 5.5% (95% CI: 2.6–11.7). AE occurred in 81 patients (66%), including grade 3-4 in 17 (14%).
Additional therapy was required in 116 patients (94%), which included: another combination regimen with CPI (51%), chemotherapy (15%), mono-CPI (25%), auto-HCT (3%) or allo-HCT consolidation (7%). Median number of therapy lines following the first combination regimen was 4 (range, 0-10).
29 patients (24%) underwent allo-HCT at any timepoint after combination. Disease status at allo-HCT was CR in 8 (28%), PR in 7 (24%), SD in 1 (3%), IR in 3 (10%), PD in 10 (34%) patients. No significant difference in OS was found between patients receiving only

conservative therapy (n=94) and those undergoing allo-HCT consolidation: 5-year OS: 84.9% vs. 74.8%, p=0.58.
We also analyzed whether performing allo-HCT as consolidation after first combination therapy affected subsequent survival outcomes. Comparing OS and TTNT between the group of patients with allo-HCT consolidation (n=8) and those who continued with other treatment options (n=115), we found no difference in OS (5-year OS 87.5% vs 85.9% respectively, p=0.51); however, a statistically significant difference in TTNT was demonstrated (5-year TTNT 87.5% vs 15%, p<0.001).

Table 1. Patient's characteristics

Patient's characteristics	n=123
Age, years (range)	33 (17-69)
Female/Male, n (%)	59/64 (48/52)
Primary refractory/early relapse, n (%)	77/17 (63/14)
Prior brentuximab vedotin, n (%)	61 (50)
Prior autologous hematopoietic cell transplantation, n (%)	45 (37)
Prior allogeneic hematopoietic cell transplantation, n (%)	3 (2)
Prior exposure to the combination agent, n (%)	54 (44)
Prior lines of therapy, median (range)	5 (2-11)
Median time from last nivolumab infusion, months (range)	1 (0-25)

Conclusions: The use of combination regimens with CPI represents an effective and safe strategy. This approach is beneficial for patients who have failed multiple therapy lines including CPI, including its use as a bridge to allo-HCT, as well as for patients who are not candidates for transplantation.

Disclosure: None.

AUTOLOGOUS TRANSPLANT IN T-CELL LYMPHOMAS

Cristian Rodriguez[1,2], *Gonzalo Bentolila*[3], *Florencia Moreno*[4], *Verónica Oro*[5], *Lucrecia Oses*[6], *Jose Trucco*[7], *Adriana Vitriu*[8], *Jorge Arbelbide*[6], *Alejandra Banchieri*[9], *Mariano Berro*[7], *Martin Castro*[10], *Gregorio Jaimovich*[4], *Ana Lisa Basquiera*[1,2]
[1]*Hospital Privado Universitario de Córdoba, Córdoba, Argentina,* [2]*Instituto Universitario de Ciencias Biomédicas de Córdoba (IUCBC), Córdoba, Argentina,* [3]*FUNDALEU, Ciudad Autónoma de Buenos Aires, Argentina,* [4]*Fundación Favaloro, Ciudad Autónoma de Buenos Aires, Argentina,* [5]*Hospital Central de Mendoza, Mendoza, Argentina,* [6]*Hospital Italiano de Buenos Aires, Ciudad Autónoma de Buenos Aires, Argentina,* [7]*Hospital Universitario Austral, Pilar, Argentina,* [8]*Instituto Alexander Fleming, Ciudad Autónoma de Buenos Aires, Argentina,* [9]*Hospital de Clínicas José de San Martin, Ciudad Autónoma de Buenos Aires, Argentina,* [10]*Sanatorio Anchorena, Ciudad Autónoma de Buenos Aires, Argentina*

Background: For certain T-cell lymphomas, consolidation with autologous transplant in first-line treatment represents an important alternative to improve survival. The optimal conditioning regimen in these lymphomas is not well established.

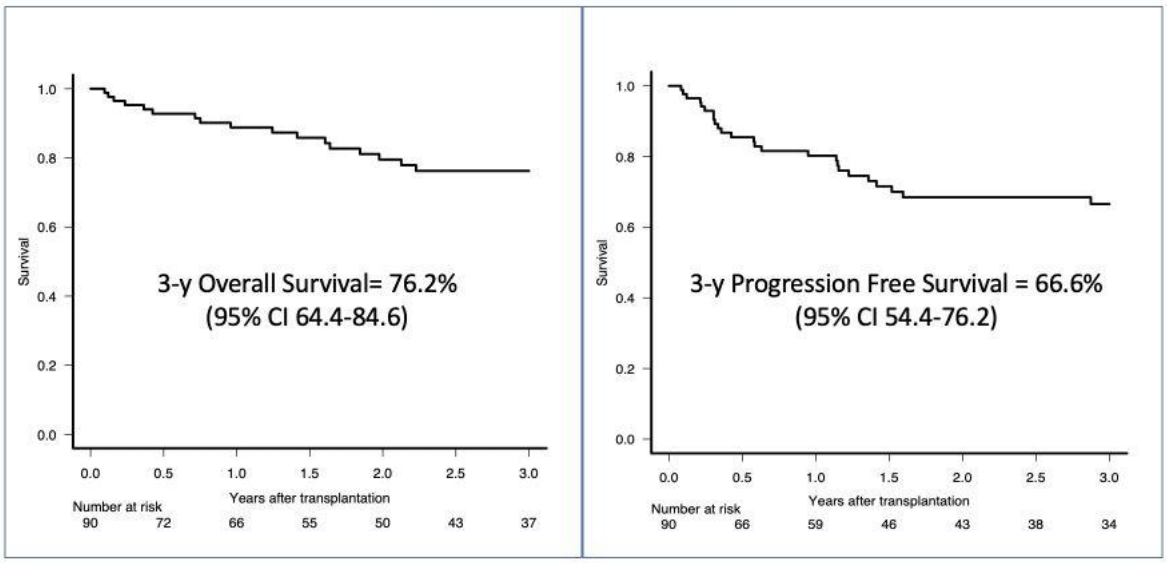
Methods: This is a retrospective study of patients with newly diagnosed T-cell lymphoma who received an autologous transplant as consolidation between 2015 and 2025. The following entities were included: Peripheral T-cell Lymphoma (PTCL-NOS), Anaplastic Large Cell Lymphoma ALK-negative (ALCL ALK-), Anaplastic Large Cell Lymphoma ALK-positive (ALCL ALK+), and Angioimmunoblastic T-cell Lymphoma (AITL). Centers were invited to participate through the Argentine Group for Bone Marrow Transplant and Cellular Therapy (GATMO-TC). Overall survival (OS) and progression-free survival (PFS) were evaluated.

Results: A total of 90 patients were included (median age 49.1 years; range 18.0–70.9; 54 males, 60.0%). Lymphoma subtypes were: PTCL-NOS n = 43 (47.8%), ALCL ALK- n = 27 (30.0%), AITL n = 15 (16.7%), and ALCL ALK+ n = 5 (5.6%). At diagnosis, 26 cases were stage I–II (28.9%) and 64 (71.1%) stage III–IV; 20 (22.5%) had bone marrow involvement; and 40 cases (49.9%) had extranodal involvement. Other pre-transplant characteristics are shown in the table. Median infused CD34+ cells were 4.49 (range 1.6–17.4). Conditioning regimens were BEAM n = 35 (38.9%), CBV n = 26 (28.9%), bendamustine-based n = 24 (26.7%) and others n = 5 (5.5%). All patients achieved myeloid reconstitution. Transplant-related mortality at one year was 2.4% (95% CI 0.5–7.7). Three-year overall survival was 76.2% (95%CI 64.4-84.6) and three-year progression-free survival was 66.6% (95% CI 54.4-76.2) (Figure). Considering the three main conditioning regimens (BEAM, CBV and bendamustine-based), no differences in OS or PFS were observed. Four patients had a prior diagnosis of HIV; in this subgroup, PFS and OS were both 100%.
Variables associated with better 3-year PFS were: Ann Arbor stage I–II vs III–IV at diagnosis (86.1% vs 59.3%; p = 0.015); ECOG 0 vs 1 vs 2 (74.0%, 66.6%, 14.6%; p < 0.001); and best pre-transplant response CR vs PR (72.4% vs 33.3%; p = 0.003). On multivariate analysis, ECOG performance status remained statistically significant.
Variables associated with better 3-year OS were: ECOG 0 vs 1 vs 2 (82.0% vs 82.5% vs 21.4%; p < 0.001); best pre-transplant response CR vs PR (82.1% vs 33.3%; p < 0.001); lymphoma subtype ALCL ALK- vs PTCL-NOS vs ALCL ALK+ vs AITL (92.1% vs 75.6% vs

66.7% vs 50.3%; p = 0.034); and number of prior lines 1 vs 2 vs 3 (78.6% vs 72.3% vs 33.3%; p = 0.021). All four variables remained significant in the multivariate model.

Table. Baseline pre-transplant characteristics of patients with T-cell lymphoma (n=90)

Variable	Results
Age at transplant, median (range)	49.1 (18.0–70.9)
Gender, female/ male, n (%)	36 (40.0)/ 54 (60.0)
ECOG performance status, n (%) 0 1 2	 64 (72.7) 15 (17.0) 9 (10.2)
Lines of therapy, n (%) 1 2 3	 77 (85.6) 10 (11.1) 3 (3.3)
Previous Brentuximab, n (%)	15 (16.7)
Better response, n (%) Complete response Partial response Unknown	 80 (88.9) 9 (10.0) 1 (1.1)



Conclusions:

Consolidation with autologous transplant in patients with T-cell lymphoma offers survival rates above 70%. Carmustine based regimens like BEAM or, CBV, and bendamustine-based regimens were all equally effective. Achieving complete response prior to transplant and requiring fewer lines of therapy to achieve it are the most important variables for clinical decision-making.

Disclosure: Nothing to declare.

THE ROLE OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ADVANCED PRIMARY CUTANEOUS T-CELL LYMPHOMA - A MULTICENTER RETROSPECTIVE ANALYSIS

Moritz Schmidt[1], *Inga Hansen-Abeck*[2], *Elena Stauffer*[1], *Alessia Fraccaroli*[1], *Heidrun Drolle*[1], *Franziska Schümann*[3], *Thomas Weber*[3], *Catrin Theuser*[4], *Johannes Schetelig*[4], *Philipp Nakov*[5], *Friedrich Stölzel*[5], *Barbara Zartner*[6], *Daniel Wolff*[6], *Christina Rautenberg*[7], *Thomas Schroeder*[7], *Elisabeth Livingstone*[7], *Michael von Bergwelt*[1], *Sebastian Theurich*[1], *Nina Booken*[2], *Johanna Tischer*[1]
[1]*LMU University Hospital, Munich, Germany,* [2]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [3]*Martin-Luther-University, Halle, Germany,* [4]*University Hospital TU Dresden, Dresden, Germany,* [5]*University Hospital Schleswig-Holstein, Kiel, Germany,* [6]*University Hospital Regensburg, Regensburg, Germany,* [7]*University Hospital of Essen, Essen, Germany*

Background: Primary cutaneous T-cell lymphomas (CTCL) comprise a rare and heterogeneous group within non-Hodgkin lymphomas which have their primary mostly indolent manifestation in the skin. In advanced stages, these lymphomas can advance to an aggressive course and are associated with a poor overall prognosis and a high recurrence rate. For this reason, the treatment of these patients is particularly challenging. In this context, allogeneic hematopoietic stem cell transplantation (allo-HSCT) can lead to long-lasting remissions by inducing a graft-versus-lymphoma effect and thus represents a potentially curative treatment option. Due to the rarity of the disease spectrum, there is still very limited data on the role of allo-HSCT in primary CTCL.

Methods: We investigated long-term efficacy and safety of allo-HSCT in patients with advanced primary CTCL by means of a multicentric retrospective study analyzing patient data from six German transplant centers to determine overall survival (OS), relapse-free survival (RFS) and the incidence of relapse (RI) following allo-HSCT. In addition, the remission status of the disease prior to allo-HSCT, the intensity of the conditioning regimen, the occurrence of graft-versus-host disease (GvHD) and the clinical impact of different post-transplant strategies were considered.

Results: A total of 28 patients with advanced primary CTCL were included, the majority suffering from Mycosis Fungoides (MF) (*n=12*, 42%). Half of the patients with MF and Sézary Syndrome (SS) had stage IV disease. In addition, patients had received extensive prior treatment, with a median of four previous lines of therapy. On average, 65.5 months passed between the initial diagnosis and transplantation. 23 patients (82%) were in partial (*n=19*, 68%) or complete remission (*n=4*, 14%) at the time of transplantation. 18 patients (64%) underwent myeloablative conditioning and in-vivo T-cell depletion was performed in 16 patients (57%; antithymocyte globulin: *n=6*; post-transplant cyclophosphamide: *n=9*; alemtuzumab: *n=1*). With a median follow-up of 58 months, 17 patients (60%) had died, with infections (*n=8*, 47%) followed by disease relapse (*n=7*, 41%) being the most common causes of death. The median OS after allo-HSCT was 15 months with an estimated one-year OS of 55%. The RI was 64% *(n=18)* after transplantation with a median RFS of 14 weeks and an estimated one-year RFS of 36%. Acute GvHD was seen in 15 patients (53%), with most cases being mild (*n=10* for grade I and II, 66%) and mainly affecting the skin (*n=13*, 86%). Chronic GvHD subsequently developed in 13 patients (46%). In patients suffering from relapse a partial or even complete short- to medium-term therapeutic response was achieved in 7 patients (38%) with the use of various post-transplant strategies (donor lymphocyte infusions (*n=5*), antibody therapy (*n=2*), radiotherapy (*n=2*)).

Conclusions: Although allo-HSCT can prolong RFS compared to conventional therapies, the durability of response is limited. Standardized transplant and post-transplant strategies to maintain disease remission are currently lacking and may be essential to fully exploit the curative potential of allo-HSCT in advanced CTCL.

Disclosure: Daniel Wolff received research funds from Novartis and honoraria from Novartis, Sanofi, Incyte, Therakos, Neovii, Behring.

A COMPARATIVE ANALYSIS OF TRANSFORMED HODGKIN'S LYMPHOMAS FROM MARGINAL ZONE LYMPHOMA: A POPULATION-BASED COHORT STUDY

*Mengyu Zhao[1,2], **Rongrong Chen**[3], Shan Zheng[4], Yamin Tan[5,1]*
[1]Department of Hematology, Zhejiang Cancer Hospital, Hangzhou, China, [2]Hangzhou Institute of Medicine (HIM), Chinese Academy of Sciences, Hangzhou, China, [3]Bone Marrow Transplantation Center of The First Affiliated Hospital & Liangzhu Laboratory, Zhejiang University School of Medicine, Hangzhou, China, [4]The First Affiliated Hospital of Soochow University, Suzhou, China, [5]Postgraduate Training Base Alliance of Wenzhou Medical University (Zhejiang Cancer Hospital), Hangzhou, China

Background: Histological transformation of marginal zone lymphoma (MZL) to Hodgkin's lymphoma (HL) is a rare but clinically significant event, with its risk factors and outcomes remaining poorly characterized. Our study represents the largest comparative analysis to date, aiming to elucidate the distinct clinical features and outcomes associated with this transformation.

Methods: Our study retrospectively analyzed 23,609 MZL patients diagnosed between 2000 and 2021 from the SEER17 registry database. Competing risk and Cox regression analyses were employed to evaluate transformation rates and outcomes, respectively. Additionally, we investigated the prognostic impact of time-to-transformation on outcomes in t-HL patients and conducted a comparative analysis of clinical characteristics and survival profiles between *de novo* HL and t-HL (transformed HL) cases.

Results: Our cohort comprised 23 609 MZL patients, of whom 38 (0.16%) developed t-HL. The median follow-up duration was 112 months (95% CI 110-113) for the overall cohort, 112 months (95% CI 110-113) for non-transformed MZL (nt-MZL) patients, and 148 months (95% CI 107-198) for t-HL patients. Compared to patients with nt-MZL, those with t-HL exhibited younger age at the time of MZL diagnosis and advanced Ann Arbor Stage. By competing risk analysis and Gray's test, the overall cumulative transformation rates (CTRs) at 5, 10 and 20 years were estimated to be 0.09% (95% CI 0.05%–0.13%), and 0.16% (95% CI 0.10%–0.22%) and 0.27% (95% CI 0.17%–0.37%), respectively. The transformation occurred within 10 years in most patients (76%, 29/38) at a median time of 57.5 months. Multivariate analysis further indicated that splenic MZL subtype ($P < 0.001$) and younger age (HR 0.966, 95% CI 0.948-0.984, $P < 0.001$) were associated with an increased risk of developing t-HL, whereas receipt of radiotherapy for MZL was linked to a reduced risk (HR 0.109, 95% CI 0.016-0.752, $P = 0.025$). Late transformation (transformation after 38 months of MZL diagnosis [T38]) was identified as an independent predictor of adverse outcomes in t-HL patients. Lastly, comparative survival analysis revealed a significantly worse prognosis for t-HL patients compared to those with *de novo* HL.

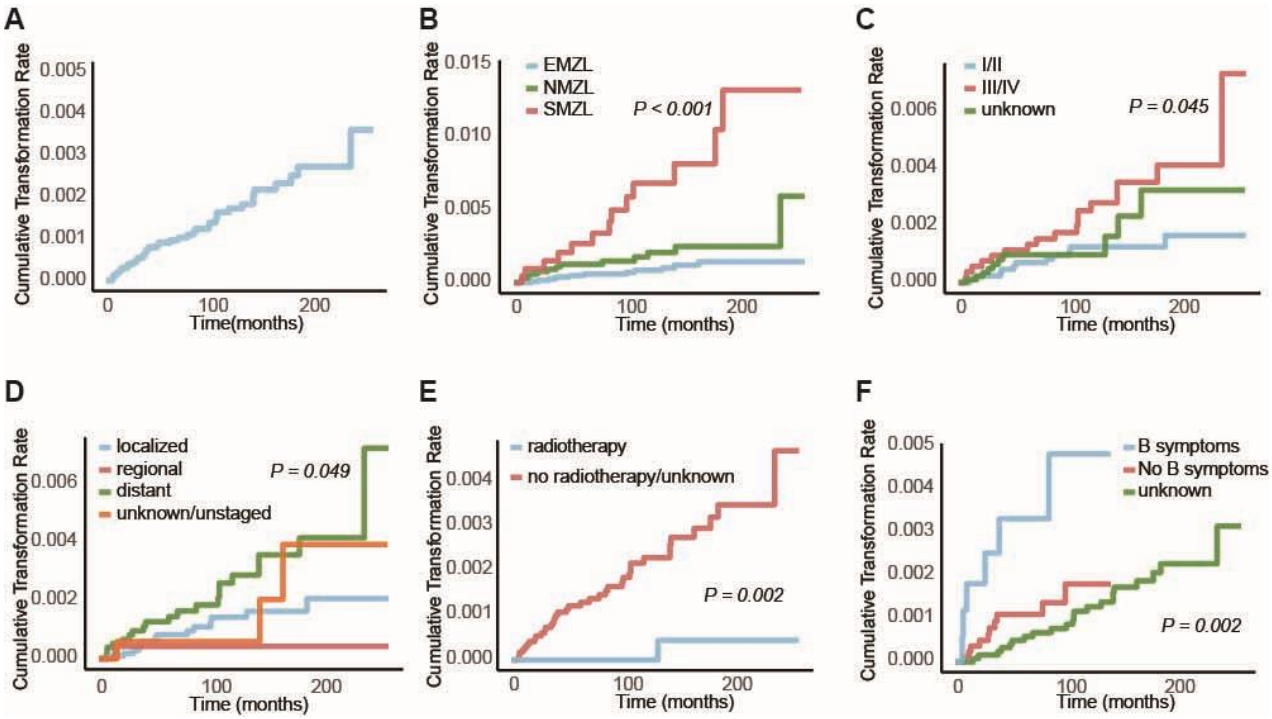

Figure 1. The cumulative incidence of histological transformation in MZL were statistically different among subgroups. (A) Estimated cumulative transformation rates by Fine–Gray's competing risks model. Comparisons of estimated cumulative transformation rate by competing risks model in the SEER database based on MZL subtype (B), Ann Arbor stage (C), disease stage (D), receipt of radiotherapy (E) and B symptoms (F). SEER indicates the Surveillance, Epidemiology, and End Results.

Conclusions: Our study provides comprehensive insights into the characteristics and survival of t-HL patients. We identified MZL subtype and younger age as risk factors for t-HL development, while radiotherapy for MZL was associated with a reduced risk. Importantly, late transformation emerged as an independent predictor of adverse outcomes. Furthermore, we demonstrated significantly worse survival in t-HL compared to *de novo* Hodgkin Lymphoma. These findings highlight critical prognostic factors and underscore the need for tailored management strategies in t-HL.

Disclosure: Nothing to declare

B393

ROLE OF TARGETED IMMUNE THERAPIES IN RELAPSED/REFRACTORY LYMPHOMA (HODGKINS): A MULTICENTER EXPERIENCE FROM VARIOUS TRANSPLANT CENTERS IN PAKISTAN. A LOWER MIDDLE INCOME COUNTRY PERSPECTIVE

Muhammad Sher Ali[1], Saima Humayun Toor[2], Raheel Iftikhar[2], Usman Ahmad[1], Syed Waqas Imam Bokhari[1], ***Bushra Ahsan***[1]
[1]Shaukat Khanum Memorial Cancer Hospital and Research Center, Lahore, Pakistan, [2]Armed Forces Institute of bone Marrow and Transplant center, Rawalpindi, Pakistan

Background: Relapsed/refractory lymphoma (RR-HL) remains a therapeutic challenge, with limited durable responses to conventional salvage chemotherapy. Immunotherapy, particularly CD30-targeted antibody drug conjugates, has emerged as a promising option. This study aimed to evaluate the role, safety and efficacy of targeted immunotherapy in RR-HL patients treated at various bone marrow transplant centers in Pakistan, with focus on clinical responses, transplant outcomes, and treatment-related adverse events.

Methods: We conducted a retrospective review of 63 patients with RR-HL treated cases. All patients had received first-line ABVD followed by salvage ICE/GDP before immunotherapy (brentuximab vedotin ± bendamustine or alternative agents). Safety endpoints included adverse events graded by CTCAE, while efficacy endpoints were response rates, progression to autologous stem cell transplant (ASCT), and post-ASCT PET outcomes as over all survival and progression free survival.

Results: The median age was 38.6 years (range 23–65) and was 64% men. These patients received 3 to 5 cycles of Brentuximab vedotinb+bendamustine. The majority of patients had stage IV disease (72%). Pre-treatment labs were commonly abnormal: ESR >20 was found in 80%, anemia in 60%), and LDH in 72%. All patients relapsed after first-line ABVD, 1/3 achieved CR to salvage ICE, 0/1 to GDP. Immunotherapy Toxicities were diarrhea (28%), nausea/vomiting (20%), rash/mucositis (16%), cytopenias (24%), respiratory (32%), and infections (24%). One death of treatment related was recorded. ASCT was completed in 60 patients (95%); 100-day PET confirmed CMR in 56%, PR in 12%, and progression in 16%. Over all survival and progression free survival results will be shared at time of poster/oral presentation.

Conclusions: Immunotherapy/ targeted therapy showed clinically relevant activity in heavily-pretreated RR-HL patients, allowing many patients to proceed to ASCT with a high remission rate. Toxicities were frequent, but overall manageable and with one death. Our results reiterate the feasibility of immunotherapy in RR-HL as a bridge to transplant in keeping with international experience, although more extensive prospective studies are required in South Asian cohorts.

Disclosure: Nothing to declare.

P275

SAFETY AND EFFICACY OF LENALIDOMIDE IN PATIENTS WITH RELAPSED OR REFRACTORY ADULT T-CELL LEUKEMIA/LYMPHOMA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A MULTICENTER PROSPECTIVE OBSERVATIONAL STUDY

Makoto Yoshimitsu[1], *Yoshitaka Imaizumi*[2], *Nobuaki Nakano*[3], *Mototsugu Shimokawa*[4], *Kisato Nosaka*[5], *Shigeru Kusumoto*[6,7], *Tomoko Narita*[6], *Youko Suehiro*[8], *Masao Ogata*[9], *Toshiro Kawakita*[10], *Kazuya Shimoda*[11], *Shigeo Fuji*[12], *Takashi Ishida*[6], *Kenji Ishitsuka*[1]
[1]*Kagoshima University, Kagoshima, Japan,* [2]*Nagasaki University, Nagasaki, Japan,* [3]*Imamura General Hospital, Kagoshima, Japan,* [4]*Yamaguchi University, Ube, Japan,* [5]*Kumamoto University, Kumamoto, Japan,* [6]*Nagoya City University, Nagoya, Japan,* [7]*Aichi Cancer Center, Nagoya, Japan,* [8]*Kyushu Cancer Center, Fukuoka, Japan,* [9]*Oita University, Yufu, Japan,* [10]*Kumamoto Medical Center, Kumamoto, Japan,* [11]*University of Miyazaki, Miyazaki, Japan,* [12]*Osaka International Cancer Center, Osaka, Japan*

Background: Relapse of adult T-cell leukemia/lymphoma (ATL) after allogeneic hematopoietic stem cell transplantation (allo-HCT) remains associated with extremely poor outcomes, and effective salvage therapies are limited. Lenalidomide, approved in Japan for relapsed or refractory (r/r) ATL, has immunologic activity but may exacerbate graft-versus-host disease (GVHD) after transplantation. This multicenter prospective observational study evaluated the efficacy, safety, tolerability, and immunologic effects of lenalidomide in patients with r/r ATL following allo-HCT.

Methods: The primary endpoint was 1-year overall survival (OS) from relapse. Secondary endpoints included clinical response, 1-year OS from lenalidomide initiation, safety, tolerability, and GVHD incidence. Immune profiling was performed at baseline and at weeks 2, 4, and 12.

Results: Twenty-seven patients from 10 institutions received lenalidomide post-allo-HCT at physician-determined doses and schedules. The median age at registration was 62 years (interquartile range [IQR], 58–65), and 14 patients (51.9%) were female. The median time from relapse to lenalidomide initiation was 30 days (IQR, 10–52), and the median time from transplantation to initiation was 171 days (IQR, 77–418). The 1-year OS from relapse was 48.1% (95% CI, 28.7–65.2), with a median OS of 0.92 years (95% CI, 0.43–1.60). From the start of lenalidomide, the 1-year OS was 33.3% (95% CI, 16.8–50.9), and the median OS was 0.47 years (95% CI, 0.19–1.08).
Regarding clinical response, the best overall response included complete response in 3 patients (11.1%), partial response in 4 (14.8%), stable disease in 10 (37.0%), and progressive disease in 10 (37.0%). The median starting dose was 5 mg (IQR, 5–10), and the median maximum dose was 10 mg (IQR, 5–15). The median duration of lenalidomide therapy was 33 days, and only 22.2% of patients remained on treatment at week 12, indicating limited tolerability. Discontinuation was primarily due to disease progression or adverse events. Grade ≥3 adverse events were common, including neutropenia (33.3%), thrombocytopenia (29.6%), and febrile neutropenia (18.5%). Worsening of acute GVHD occurred in 5 patients and exacerbation of chronic GVHD in 3. Transplant-related mortality 12

months after relapse was 11.1% (95% CI, 2.7–26.3).
Immune profiling demonstrated increases in activated CD8+ T cells, effector regulatory T cells, and NK cells in clinical responders between weeks 2 and 4, indicating pharmacodynamic immunomodulatory activity of lenalidomide.

Conclusions: Lenalidomide showed immunologic activity and clinical benefit in a subset of patients with r/r ATL after allo-HCT; however, its broader use was limited by substantial toxicity, GVHD exacerbation, and short treatment duration. These findings underscore the importance of individualized patient selection and warrant further clinical trials to optimize the post-transplant use of lenalidomide for r/r ATL.

Clinical Trial Registry: UMIN 000029635

Disclosure: This study was supported by a research grant provided under a clinical trial support agreement with Celgene K.K., the manufacturer of lenalidomide (Revlimid®), which later became a part of Bristol Myers Squibb.

P276

HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR T-CELL LYMPHOMAS IN A MIDDLE-INCOME COUNTRY: FEASIBILITY, DELAYS, AND REAL-WORLD OUTCOMES FROM A NATIONAL REFERRAL CENTER IN MEXICO

Mistral Castellanos-Mares[1], *Amaya Llorente-Chávez*[1], *Rodrigo Figueroa-Méndez*[2], *Luis Manuel Valero-Saldaña*[1], *Victor Iván Salinas-Herrera*[1], *Andres Yesid Bonilla-Salcedo*[1], *Rosa Adriana Alvidrez-González*[1], *Vicky Margarita Moncada-Gadea*[1], *Raquel Andrea Martínez-López*[1], *Grecia Pamela Martínez-Vázquez*[1], *Irma Karen Pellón-Téllez*[1]
[1]*Instituto Nacional de Cancerología, Ciudad de Mexico, Mexico,* [2]*Instituto Nacional de Ciencias Médicas y Nutrición, Ciudad de Mexico, Mexico*

Background: Despite its established role in T-cell lymphomas, the feasibility and real-world use of hematopoietic stem cell transplantation (HSCT) in middle-income settings remain poorly defined, particularly regarding delayed access.

Methods: We conducted a retrospective cohort study including 40 adult patients with confirmed T-cell lymphomas who underwent HSCT at a national referral cancer center. Demographic characteristics, disease subtype, timing and type of HSCT, early post-transplant outcomes, and survival were analyzed. Primary outcomes included overall survival (OS), progression-free survival (PFS), and post-HSCT PFS. Secondary variables included time from diagnosis to HSCT, transplant indication (CR1 vs relapsed/refractory [R/R]), and feasibility indicators such as day +100 response, infectious complications, and transplant-related mortality (TRM).

Results: The cohort primarily included young adults (median age 36 years), with extranodal NK/T-cell lymphoma being the most frequent subtype (52.5%). Marked delays in access to HSCT were observed, with a median interval of 22 months from diagnosis to transplantation.

As a result, 57.5% of patients underwent HSCT in the R/R setting, whereas only 42.5% were transplanted in CR1. Most patients received autologous HSCT (87.5%), while 12.5% underwent allogeneic HSCT.
Early post-transplant outcomes demonstrated high feasibility despite resource limitations: day +100 complete response was achieved in 90% of patients, and no transplant-related mortality occurred. Infectious complications were observed in 57.5% of all patients and in all allogeneic recipients.
Median OS and PFS for the entire cohort were 60 and 48 months, respectively. Survival outcomes differed by lymphoma subtype: PTCL-NOS/AITL showed the most favorable results, with median OS and PFS of 60 months; ALCL had a median OS of 60 months and median PFS of 48 months; whereas extranodal NK/T-cell lymphoma exhibited poorer outcomes, with a median OS of 44 months and median PFS of 43 months. Post-HSCT PFS varied significantly by subtype, with the poorest outcomes observed in ENKTL (10 months), compared with ALCL (27 months) and PTCL-NOS/AITL (60 months). Patients transplanted in the relapsed/refractory (R/R) setting exhibited approximately twice the risk of post-transplant progression compared with those transplanted in CR1, although differences in OS and PFS did not reach statistical significance.

	Years								
No. at risk	1	2	3	4	5	6	7	8	9
PTCL-NOS	6	4	4	4	4	4	2	2	1
AITL	1	1	1	1	1	1			
ALCL	8	5	4	3	3	2	2	2	
ENKTL	10	8	8	8	6	3	3	2	
T-LBL	2								

Metric	Value
Median time from diagnosis to HSCT	22 months
HSCT performed in CR1	42.5%

HSCT performed in relapsed/refractory setting	57.5%
Autologous HSCT	87.5%
Allogeneic HSCT	12.5%
Most frequent subtype	ENKTL (52.5%)
Day +100 complete response	90%
Transplant-related mortality	0%

Conclusions: HSCT was feasible, safe, and effective in this middle-income setting, achieving high early response rates and no TRM. However, substantial delays in access to transplantation resulted in a majority of patients undergoing HSCT in the R/R setting, which was associated with increased post-transplant progression. The predominance of aggressive ENKTL and delayed referral likely contributed to shortened post-HSCT PFS. These findings highlight the need to improve timely access to HSCT and address system-level barriers that disproportionately affect patients with high-risk T-cell lymphomas in resource-limited environments.

PEMBROLIZUMAB PLUS GEMCITABINE, VINORELBINE, AND DOXORUBICIN FOLLOWED BY AUTOLOGOUS STEM CELL TRANSPLANTATION IN 24 RELAPSED/REFRACTORY CLASSICAL HODGKIN LYMPHOMA PATIENTS

Hanane Bouarab[1], Sabrina Akhrouf[1], Fatiha Silem[1], Soumia Rahali[1], Amira Madani[1], Mounira Bitam[1], Farih Mehdid[1], Mounira Baazizi[1], Nadia Rahmoune[1], Dina Ait Ouali[1], Hanane Moussaoui[1], Belkis Dekhili[1], Fateh Boukhemia[1], Naima Abdennebi[1], Farida Harieche[1], Rose-Marie Hamladji[1], Redhouane Ahmed Nacer[1], ***Malek Benakli***[1]
[1]*Department of Hematology-Bone Marrow Transplantation, Pierre and Marie Curie Center, Algiers, Algeria*

Background: Relapsed/refractory (R/R) classical Hodgkin lymphoma (cHL) remains challenging, particularly in patients failing multiple therapy lines. PD1-inhibitor based salvage regimens before autologous stem cell transplantation (ASCT) are associated with significantly higher PFS. Previously reported results with pembrolizumab, gemcitabine, vinorelbine, and doxorubicin (P-GVD) followed by ASCT (Moskowitz, et al. JCO 2021) achieved better outcomes.

Methods: We retrospectively analyzed 24 consecutive patients (pts) with R/R cHL treated with P-GVD followed by ASCT between Dec 2023 and Aug 2025. Median age was 36 years (22–57); sex ratio M/F: 0.4. Patients received the regimen after ≥2 prior lines (range 2–5); 4 relapsed and 20 were refractory. The status of the pts at transplantation was: coplete remission (CR) in 13 patients (11 metabolic CR, mCR), and partial remission (PR) in 11 pts (with metabolic assessment in 2). Conditioning regimen was BeEAM (Bendamustine: 300 mg/m², Aracytine: 800 mg/m², Etoposide: 800 mg/m² and Melphalan: 140 mg/m²). Peripheral HSC was collected by cytapheresis after mobilization with G-CSF alone. The median CD34+ cells dose was 2.66×10⁶/kg (1.05–9.19). Brentuximab-vedotin maintenance was given in 9 pts (39%). The median follow-up at 31/10/2025 is 18 months (4-24).

Results: Median duration of aplasia was 8 days (6–14); neutrophil recovery occurred at day +11 (9–15). One patient died at 3 months from a metabolic complication. At 3-month post-ASCT evaluation, 16 pts were in CR (15 mCR) and 7 in PR. Two progressed at a median time of 3 months (1-6); one achieved CR after geno-identical allo-HSCT (full donor chimerism), and one remains under assessment. At a median follow-up of 18 months (4–24), 23 pts (95.8%) were alive: 16 in CR, 6 in PR, and 1 under evaluation. The overall survival (OS) at 2 years is 95,8% and the event-free survival (EFS) is 87,5%.

Conclusions: Currently, patients with R/R cHL receive salvage therapy with immune checkpoint inhibitors. Pembrolizumab-GVD prior to ASCT provides deep pre-transplant responses and excellent post-ASCT outcomes. This strategy increases transplant eligibility and supports a tailored approach incorporating post-ASCT consolidation.

P278

IMMUNE RECONSTITUTION AND LONG-TERM OUTCOMES AFTER ALLOGENEIC STEM CELL TRANSPLANTATION IN RELAPSED AND REFRACTORY T-CELL LYMPHOMAS

Quentin Fichaux[1], *Alessia Fraccaroli*[1], *Heidrun Drolle*[1], *Moritz Schmidt*[1], *Elena Stauffer*[1], *Johanna Tischer*[1], *Sarah Haebe*[1]
[1]*Ludwig-Maximilians-University Hospital, Munich, Germany*

Background: Refractory and relapsed T-cell lymphomas represent a rare and biologically heterogeneous group of non-Hodgkin lymphomas associated with poor prognosis and limited therapeutic options. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) remains

a potentially curative approach in this setting. However, post-transplant outcomes are frequently compromised by high rates of severe infections and systemic inflammatory response, with the underlying mechanisms remaining incompletely understood. In particular, the dynamics of immune reconstitution (IR) after allo-HSCT and their impact to post-transplant complications and survival remain poorly defined. We therefore analyzed IR and its association with post-transplant outcomes in patients with T-cell lymphoma undergoing allo-HSCT.

Methods: We performed a retrospective analysis of patients with relapsed or refractory T-cell non-Hodgkin lymphoma (AITL, n=9; ALCL, n=5; PTCL-NOS, n=5; MF, n=2; NKTL, n=1; EATL, n=1; MEITL, n=1; SPTCL, n=1) who underwent allo-HSCT at our institution. Clinical and transplant-related data were collected. Immune reconstitution markers were assessed prior to transplantation and serially up to one-year post-transplant. Associations between immune recovery, transplant-related complications, and clinical outcomes were analyzed.

Results: In total, 25 patients were analyzed. The median age was 50 years, and 15 patients were male. Donors were matched related (n=4), matched unrelated (n=8), or haploidentical (n=13). 75% of patients presented with active disease at the time of conditioning. After a median follow-up of >6 years, 1-, 3-, and 5-year overall survival rates were 60%, 50%, and 50%, and progression-free survival rates were 48%, 48%, and 41%, respectively. Severe non-hematological toxicities (grade III–IV) were observed in 50% of patients. The 1-year cumulative incidence of non-relapse mortality was 36%, most commonly due to septic shock (n=4). Grade III–IV acute GvHD occurred in 16% of patients. Comprehensive IR data are already collected longitudinally, and analyses evaluating their impact on treatment outcomes, including comparisons with B-cell non-Hodgkin lymphoma cohorts undergoing allo-HSCT, are ongoing.

Conclusions: Our study shows that allo-HSCT can provide durable responses in patients with T-cell lymphoma, although severe infections remain a major challenge. Through a detailed and comprehensive analysis of IR and its impact on clinical outcomes, our findings offer the opportunity to gain insights into the interplay between immune recovery, infection, and relapse, which may help guide strategies to improve post-transplant outcomes.

NURSING MANAGEMENT OF A CHEMOTHERAPY PATIENT WITH ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA AND AN INFECTED LOWER-LIMB WOUND: A CASE STUDY

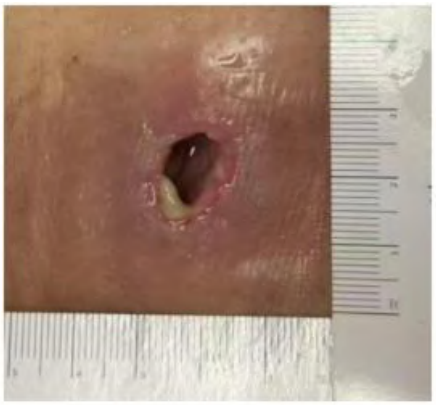
Jing Liu[1], *Na Zhang*[1], *Rui Liu*[1], *Fan Yang*[1], *Menglu Pei*[1], *Yanhong Zhang*[1], *Kai Hu*[1]
[1]*Beijing GoBroad Hospital, Beijing, China*

Background: To share the nursing experience of a patient with angioimmunoblastic T-cell lymphoma (AITL) who developed a lower-limb infected wound during chemotherapy.

Methods: A 71-year-old male was admitted on 14 July 2025 with a diagnosis of AITL and nephrotic syndrome. Physical examination on admission revealed multiple palpable enlarged lymph nodes throughout the body; marked abdominal distension; moderate pitting edema of the lower limbs; and an ulcerated wound located below the left inguinal region, measuring approximately 2 cm × 1.5 cm with a depth of about 1.5 cm. The wound showed yellow purulent discharge. Wound secretion culture indicated *Acinetobacter baumannii* complex infection. Pain assessment showed an NRS score of 0; NRS-2002 score was 6; and ADL indicated mild dependence. Serum albumin was 19.3 g/L. The chemotherapy regimen consisted of CHP + VP16 (cyclophosphamide, vincristine, dexamethasone, and etoposide). Wound care focused on infection control and local management, following the principles of "debridement – infection control – moist wound healing." Nursing interventions were adjusted according to the wound-healing stage, with strict aseptic technique throughout.
Infection Phase (Day 1–Day 5): Debridement and dressing changes combined with anti-infective therapy: normal saline irrigation, povidone-iodine disinfection, removal of necrotic tissue, repeated saline irrigation; application of a mixture of mupirocin, growth-factor gel, and zinc sulfadiazine in a thick layer; silver-containing dressings, covered with gauze and secured with an elastic bandage.
Exudation Phase (Day 6–Day 14): Continued anti-infection treatment with exudate management: saline irrigation → povidone-iodine disinfection → saline irrigation; thick application of a mixture of growth-factor gel, detoxifying-promoting-tissue-regeneration ointment, and zinc sulfadiazine; povidone-iodine gauze packing for drainage; gauze coverage and elastic bandage fixation.
Repair Phase (Day 15–Day 23): Promotion of wound healing: saline irrigation, povidone-iodine disinfection, saline wiping; thick application of the growth-factor gel + detoxifying-regeneration ointment + zinc sulfadiazine mixture; gauze coverage and elastic bandage fixation.
In addition, close monitoring of blood counts and biochemical indicators, vital-sign surveillance, accurate recording of fluid intake and output, medication administration per medical orders, as well as dietary guidance, activity recommendations, and psychological support were provided.

Results: After 23 days of systematic and targeted nursing interventions, the patient's clinical indicators and symptoms improved markedly, meeting all expected nursing goals. The wound achieved complete healing.

Wound Infection Phase



Wound Exudation Phase

Wound Repair Phase

Conclusions: Patients with AITL are prone to skin infections and wound ulceration due to impaired immunity. In this case, nephrotic-syndrome–associated hypoalbuminemia and generalized edema further increased infection risk and hindered wound healing, making nursing care more challenging. Comprehensive management and precise, stage-based wound care—including aseptic dressing changes, debridement, and the targeted use of advanced wound dressings and topical agents—can effectively promote wound healing in such high-risk patients.

Disclosure: Nothing to Disclosure

P280

AUTOLOGOUS STEM CELL TRANSPLANTATION IN 175 PATIENTS WITH RELAPSED OR REFRACTORY CLASSICAL HODGKIN LYMPHOMA; LONG-TERM FOLLOW UP IN A SINGLE-CENTRE SERIES

Sabrina Akhrouf[1], Hanane Bouarab[1], Fatiha Silem[1], Farih Mehdid[1], Mounira Baazizi[1], Dina Ait Ouali[1], Fouzia Louar[1], Fateh Boukhemia[1], Naima Abdennebi[1], Hanane Moussaoui[1], Amira Fahem[1], Aicha Yassa[1], Mounira Bitam[1], Nawel Ait kaci[1], Nacera Ait amer[1], Farida Tensaout[1], Rose-Marie Hamladji[1], Redhouane Ahmed Nacer[1], ***Malek Benakli***[1]
[1]Pierre and Marie Curie Center, Algiers, Algeria*

Background: Classical Hodgkin lymphoma (cHL) has high rates of cure, but in 15% to 20% of general patients (pts) and between 35% and 40% of those in advanced stages, the disease will progress or will relapse after initial treatment. For pts refractory to first-line chemotherapy or who relapse after initial treatment, outcomes are considerably worse. Salvage high-dose chemotherapy (HDT) followed by autologous stem cell transplant (ASCT) is the standard of care.

Methods: A retrospective study was performed with data collected from pts charts. The analysis involved 175 cHL pts who were consecutively submitted to HDT followed by ASCT in a single institution from April 1998 to December 2024 (27 years). The median age is 28 years (13-64) and a sex-ratio of 0,88 (82M /93F). It is cHL refractory and early relapse (120 pts), and late relapse (55 pts). Immunotherapy was administered as salvage treatment to 20 pts before transplantation. Disease status at transplantation is: 103 pts in partial response (PR), 55 pts in complete response (CR) including 10 pts in unconfirmed CR (CRμ) and 17 pts in failure. Peripheral HSC was collected by cytapheresis after mobilization with G-CSF alone. The median rate CD34 + cells is 3 x 106/kg (1,03-16,8). Several HDT conditioning regimens were used: BEAM: 78 pts, BeEAM with Bendamustine: 87 pts, Busulphan-Cyclophosphamide: 07 pts and TEAM with Tiothepa : 03 pts). The median follow-up at 01/12/2025 is 110 months (11-315).

Results: The median time to graft (PNC > 0.5x109/l) was 12 days (08-24). Eight early deaths were observed including 6 infections, 1 pulmonary embolism and 1 heart failure (TRM: 4,5%). Of the 167 pts that can be evaluated in post-transplantation, 128 pts (76%) achieved a CR, 33 pts (20%) achieved a PR and 6 pts achieved stable disease (3,5%). A relapse was observed in 52 pts (31%) after a median duration of 06 months (2-52). At 01 of December 2025, 115 pts (65,7%) are alive (108 in CR, 07 in PR), 60 pts (34,3%) died (43 pts from progression disease and other reason for 17 pts). The overall survival (OS) at 27 years is 58% and the event-free survival (EFS) is 54%. The survival of pts who have received immunotherapy is 90% at 2 years versus 77% without immunotherapy (P=0,38).

Conclusions: Our retrospective analysis shows good outcomes in patients who had R/R disease. Patients can be cured with second-line salvage chemotherapy and with HDT followed by ASCT. The introduction of the novel agents, including antibody-drug conjugates and PD-1 blocking antibodies has transformed the management of cHL in multiple settings.

P283

ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANT AS SALVAGE THERAPY FOR MATURE T CELL LYMPHOMA: CLINICAL EXPERIENCE AND OUTCOMES

Jan Miko Aaron Baybay[1], *Carmella Lou Bingcang*[1], *Francisco Vicente Lopez*[2], *Marjorie Rose Bravo*[1]
[1]*St. Luke's Medical Center, Quezon City, Philippines (the),* [2]*St. Luke's Medical Center, Taguig City, Philippines (the)*

Background: Mature T cell lymphomas (MTCLs) are a heterogeneous group of aggressive neoplasms that present a significant haematological challenge in Asia, where they account for up to 20–25% of all non-Hodgkin lymphomas. Subtypes such as Peripheral T-Cell Lymphoma, Not Otherwise Specified (PTCL-NOS) and Anaplastic Large Cell Lymphoma (ALCL) are frequently associated with chemo-refractoriness and dismal survival outcomes following

standard therapies. Furthermore, rare entities like Gamma-Delta (γδ) T Cell Lymphoma are notoriously resistant to multi-agent chemotherapy, often carrying a median survival of less than 18 months. While allogeneic haematopoietic stem cell transplantation (AlloHCT) remains the sole intervention with curative potential for relapsed or refractory (R/R) disease, there is a paucity of granular data regarding its feasibility in Southeast Asia. This study aims to contribute real-world evidence on the practical feasibility and toxicity profile of AlloHCT in a Philippine tertiary centre.

Methods: We conducted a retrospective observational analysis of three consecutive adult patients with R/R mature T cell lymphoma who underwent AlloHCT at our institution. The study assessed key outcomes including engraftment kinetics, the incidence of graft-versus-host disease (GvHD), and disease-free survival. The cohort included high-risk histology: PTCL-NOS, γδ-TCL, and ALCL.

Results: All three patients had exhausted multiple lines of prior therapy. Case 1 underwent haploidentical HCT with FLU-CY-TBI conditioning salvage chemotherapy. He achieved neutrophil engraftment on day 13, developed cutaneous acute graft-versus-host disease (aGVHD) on day 28, and maintains a sustained remission of 5 years. Case 2 presented with highly refractory disease having failed three prior lines, notably experiencing immediate relapse following a prior autologous stem cell transplantation. Following salvage with pralatrexate, she proceeded to haploidentical HCT with FLU-CY-TBI conditioning, achieving engraftment on day 13 and a durable remission of 4 years. Finally, Case 3, pre-treated with four prior lines (including CHOP, radiotherapy, and brentuximab vedotin), underwent a matched sibling donor transplant utilising FLU-BU conditioning post-chemotherapy salvage. He engrafted on day 12 with cutaneous aGVHD onset at day 38 and remains disease-free at 3 years. All patients achieved successful engraftment with manageable toxicity profiles, demonstrating the efficacy of this approach in chemo-refractory settings.

Conclusions: This case series confirms the feasibility and curative efficacy of AlloHCT as a salvage strategy for Filipino patients with high-risk MTCL. The study demonstrates that the graft-versus-lymphoma effect can induce sustained survival even in patients with chemo-refractory disease or prior autologous transplant failure. Furthermore, the successful implementation of haploidentical platforms highlights that donor availability need not be a barrier to life-saving therapy in this region.

Disclosure: No

P284

A CASE REPORT OF MULTI-DRUG COMBINATION THERAPY FOR RELAPSED/REFRACTORY ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA

Shaomei Feng[1]
[1]*Beijing GoBroad Boren Hospital, Beijing, China*

Background: Peripheral T-cell lymphomas (PTCLs) are a heterogeneous group of non-Hodgkin lymphomas characterized by aggressive clinical behavior and poor prognosis.

Angioimmunoblastic T-cell lymphoma (AITL) accounting for approximately 20%-30% of PTCL case. The standard first-line treatment for AITL typically involves the CHOP regimen(cyclophosphamide,doxorubicin, vincristine,and prednisone) or CHOP-like protocols. However, many patients exhibit primary refractoriness or experience relapse after initial response, resulting in a 5-year overall survival rate of only 30% to 40%. For patients with relapsed/refractory (R/R) AITL, there is currently no established standard therapeutic approach.

Methods: We conducted a single-case retrospective analysis of a 54-year-old male patient with R/R AITL who had progressed following prior treatment with first-line CHOPE (CHOP plus etoposide) and second-line GDP (gemcitabine, doxorubicin liposome and corticosteroid) regimens. After one cycle of chidamide, mitoxantrone, azacitidine and corticosteroid therapy at our linstitution, the original lesions showed significant shrinkage with partial resolution; however, a new lesion emerged, indicating disease progression. The pathological specimens were re-evaluated, and immunohistochemical analysis demonstrated a lack of CD7 expression in the tumor cells, thereby ruling out the feasibility of CAR-T cell therapy. The treatment regimen was subsequently modified to a multi-agent combination: chidamide (20 mg twice weekly), decitabine (10 mg d1-5), mitoxantrone liposome (20 mg d2), bevacizumab (600mg day 1), bortezomib (2mg d1, 4, 8) and dexamethasone (20mg d1-4), repeated every 21days. During treatment, serial assessments of complete blood counts, liver and renal function, and imaging studies were performed to evaluate therapeutic response.

Results: Following completion of two cycles of the revised combination regimen, positron emission tomography–computed tomography (PET-CT) demonstrated complete remission (CR) with resolution of previously enlarged lymph nodes. Due to financial constraints, the patient declined allogeneic hematopoietic stem cell transplantation. The same chemotherapeutic regimen was continued and sustained through five cycles, with follow-up PET-CT confirming persistent CR. The patient has completed seven cycles of therapy with favorable tolerability. The main adverse event was grade III thrombocytopenia which resolved with supportive management; no severe infections or significant organ dysfunction were observed. After eight cycles of combination therapy, maintenance treatment with chidamide monotherapy or chidamide in combination with bortezomib is planned.

Conclusions: Chidamide, a histone deacetylase inhibitor, enhances tumor cell sensitivity to chemotherapeutic agents through epigenetic modulation. Decitabine exerts antitumor effects via inhibition of DNA methylation. Bevacizumab targets vascular endothelial growth factor (VEGF) , ameliorating tumor microenvironment-associated vascular abnormalities and immunosuppression. Bortezomib induces apoptosis in tumor cells by inhibiting the proteasome pathway. The six drug combination regimen leverages multidimensional synergy among epigenetic regulation, cytotoxicity, anti-angiogenesis and immune modulation, potentially overcoming resistance to conventional chemotherapy. The predominant adverse event was hematological toxicity, which was manageable with supportive care. No intolerable non-hematological toxicities were observed, indicating controllable treatment tolerability. For patients with R/R AITL who are ineligible for transplantation or CAR-T therapy—particularly when target antigens such as CD7 are negative and cellular therapies are not feasible—this combination represents a promising therapeutic option with high efficacy and low toxicity. Larger-scale clinical studies are warranted to confirm its efficacy and to determine the optimal maintenance strategy.

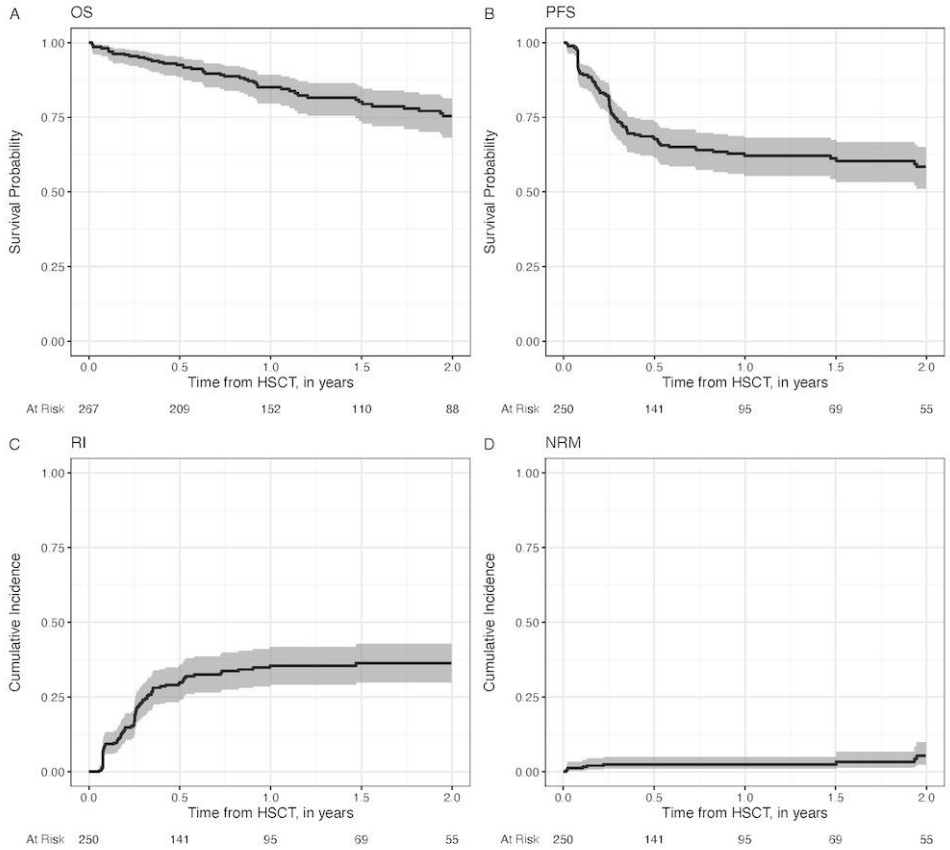
Background: Anti-CD19 CAR T-cell therapy is increasingly used in relapsed/refractory (R/R) primary mediastinal B-cell lymphoma (PMBCL), but dedicated large-scale analyses are scarce. In particular, the clinical factors associated with treatment outcomes in this population remain to be better defined.

Methods: We performed a retrospective registry-based analysis within the EBMT, including adults with PMBCL treated with commercial anti-CD19 CAR T-cell products between 2018–2025. Patients with secondary mediastinal involvement from other large B-cell lymphoma subtypes or with prior allogeneic transplantation were excluded. The primary endpoint was progression-free survival (PFS) from infusion. Secondary endpoints included overall survival (OS), relapse incidence (RI), and non-relapse mortality (NRM). OS and PFS were estimated using the Kaplan–Meier method; RI and NRM were assessed using competing-risk models.

Group comparisons were performed with log-rank tests. Subgroups of interest included CAR-T construct (axicabtagene ciloleucel [axi-cel], lisocabtagene maraleucel [liso-cel], tisagenlecleucel [tisa-cel]) and age (<30, 30–45, >45 years).

Results: A total of 284 patients met the inclusion criteria. Three commercial CAR T-cell products were infused: axi-cel (n=248), liso-cel (n=23), and tisa-cel (n=13). Median age was 35 years (range, 18–77), and 55% were female. The HCT comorbidity index was 0 in most patients (69%), 1–2 in 12%, and ≥3 in 20%. Ten percent had previously received autologous transplantation. At lymphodepletion, 6% were in CR, 27% in PR, and 67% had progressive disease.
With a median follow-up of 1.5 years, 2-year outcomes were OS 75.5%, PFS 58.4%, RI 36.3%, and NRM 5.3% (Figure 1). Two-year PFS was numerically higher with liso-cel (64.6%) than with axi-cel (56.9%) or tisa-cel (58.3%). However, baseline characteristics differed across products: liso-cel recipients were more frequently infused in CR/PR (67% vs. 29% with axi-cel and 38% with tisa-cel), which likely contributed to their lower early RI. No significant difference was observed in OS or NRM between constructs. Age had no significant impact on OS, PFS, RI, or NRM across the three predefined age groups.
The most influential prognostic variable was disease status at lymphodepletion. Patients with progressive disease at lymphodepletion had inferior PFS (HR 2.28, 95% CI 1.60–4.99, p<0.001) and higher RI (HR 2.77, 95% CI 1.53–5.01, p<0.001), while no significant effect was observed on OS or NRM. Other baseline characteristics—including time from diagnosis to CAR-T, sex, prior autologous transplantation, and year of infusion—showed no significant association with outcomes.



Conclusions: This is the largest real-world study to date evaluating CAR T-cell therapy in PMBCL. Survival outcomes were favorable across all age groups and across the three CAR-T constructs. Our findings support the broad use of anti-CD19 CAR T-cell therapy in R/R PMBCL and underscore the importance of disease control prior to infusion.

Background: Chimeric antigen receptor T-cell therapy (CAR-T) therapy has changed the treatment paradigm for patients with relapsed/refractory (R/R) large B cell lymphoma (LBCL) who relapse after ≥2 lines. Recently, it has been positioned in earlier lines and has currently been considered the second-line treatment choice in patients with primary refractory or early relapsed disease. For patients who relapse after CAR-T therapy, whether in ≥3rd or 2nd line, allogeneic hematopoietic stem cell transplantation (allo-HSCT) could be considered a potentially curative treatment in eligible patients. Unfortunately, data regarding efficacy, toxicity and potential role of new treatment strategies to be used to achieve chemosensitivity prior to allo-HSCT in this subpopulation of patients are scarce. Therefore, the aim of this study is to analyse the long term outcomes of patients with LBCL that fail CAR-T cell therapy and receive an allo-HSCT.

Methods: We performed a retrospective multicenter study including patients from centers of GETH-TC/GELTAMO with R/R LBCL after CAR-T therapy who underwent allo-HSCT. The primary endpoints were progression-free survival (PFS), overall survival (OS), NRM and the efficacy of different salvage treatments prior to allo-HSCT. Disease status was defined as complete remission (CR), partial response (PR) and refractory disease (stable disease or progression) assessed by PET/CT.

Results: Fourty-three patients [70% male, median age at allo-HSCT 50 years (20-70)] were included. 75% of the patients received axi-cel; 19/44 (44%) had achieved CR after CAR-T as best response. Median time from CAR-T infusion to relapse was 5 months (range 0-43). The median number of lines between CAR-T and allo-HSCT was 1 (range 1-4) and the median

time 13 months (range 4-53). Most of the patients received targeted therapies as a bridging to allo-HSCT such as bispecific antibodies (23%), polatuzumab (28%) and anti-PD1/PDL1 based regimens (21%). Baseline characteristics are summarized in Table 1. The CR rate with allo-HSCT at day +100 was 74%. After a median follow-up of 17 months (range 6-29), 34/44 (79%) of the patients are alive and 31/34 (91%) of them are free of disease. PFS at 2 years was 68% (95%CI 52-85) and 2y-OS 77% (95%CI 63-92). NRM at day 100 and 1 year was 2% (95%CI 0-7) and 6% (95%CI 0-13), respectively, Figure 1. The main causes of death were disease progression in 67% and infections in 33%. CI of grade III-IV acute GVHD was 16% and moderate/extensive chronic GVHD 14%. None of the variables showed an impact on survival and NRM, most probably due to the small sample size.

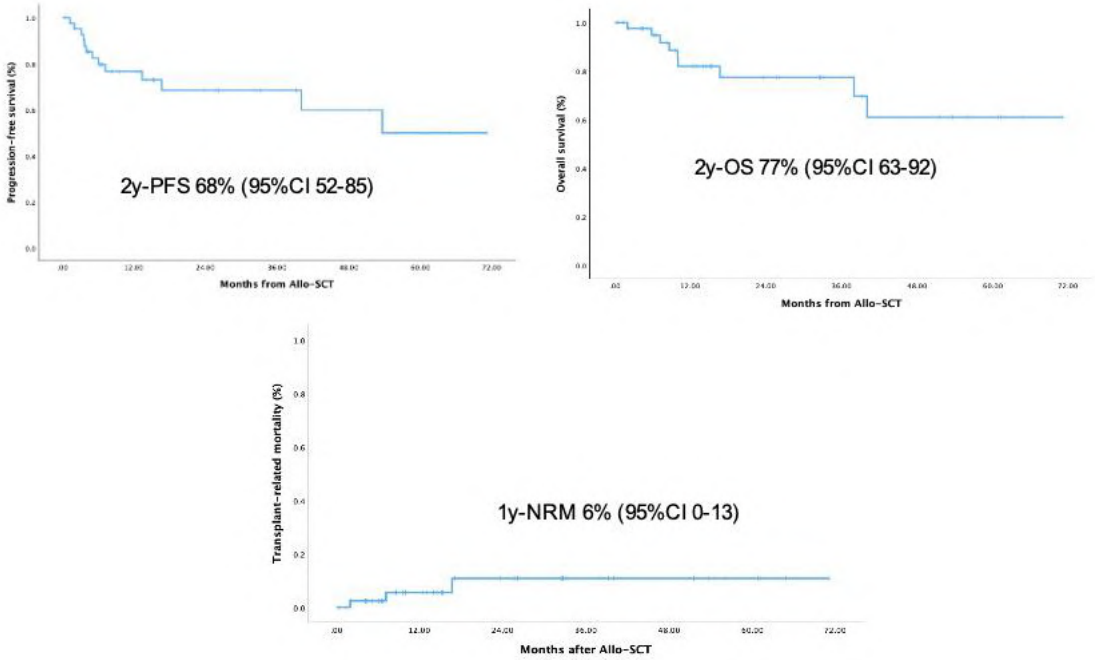
Tacrolimus + Sirolimus	3 (7%)
Other	3 (7%)



Conclusions: Our data confirmed that allo-HSCT is a feasible and a potentially curative option for eligible patients with R/R LBCL failing after CAR-T therapy, with a high PFS and low NRM. Most of the patients received targeted therapies as a bridging to allo-HSCT such as bispecific antibodies, polatuzumab and anti-PD1/PDL1 based regimens. Further prospective studies are needed to confirm these results.

Background: Sufficient treatment of relapsed or refractory (r/r) primary central nervous system lymphoma (PCNSL), particularly after the failure of autologous hematopoietic cell transplantation, remains an unmet medical need. Although emerging evidence suggests that CAR T-cell therapy may offer a promising therapeutic approach with high response rates, published data indicate that responses are often not durable, with most patients ultimately relapsing. Although evidence supporting allogeneic hematopoietic cell transplantation (allo-HCT) for PCNSL is limited, data from the EBMT suggest a potential for durable disease control in selected patients.

Methods: Adult patients with PCNSL reported to the EBMT-registry who received either CD19-directed CAR-T cell therapy or allo-HCT transplantation between 01/2018 and 09/2023 were included.

Results: Of 70 patients, 23 underwent allo-HCT and 47 received CAR T-cell therapy (axi-cel in 66%, tisa-cel in 25.5%, and liso-cel in 8.5% of cases). Overall, 64% of patients were male, and 55% had a performance status < 90%, without significant differences between the two groups. Patients receiving CAR T-cell therapy were older (median 59 vs. 54 years, p = 0.04) and more frequently had refractory disease prior to cellular treatment (56% vs. 23%, p = 0.02). Most patients (57%) had previously undergone autologous HCT. Median time from diagnosis to treatment was 27 and 17 months for the allo-HSC and CAR-T cohorts, respectively (P=0.3). Myeloablative conditioning regimens were used in 55% of allo-HCT patients. Thiotepa was part of the conditioning regimen in 49% of cases, and total body irradiation in 26%.
With a median follow-up of 22.8 months (22.8 after CAR T-cell therapy and 19.2 after allo-HCT), the 18-month overall survival (OS) for the whole cohort was 39.4% (95% CI: 26.2–52.4), and 44.7% (27.2–60.8) for patients treated with CAR-T cell therapy versus 30.0% (12.4–49.8) for patients treated with allo-HCT. The 18-month progression-free survival (PFS) was 27.5% (15.6–40.8) for all patients, 27.1% (12.9–43.5) for CAR T-cell-treated patients and 28.9% (10.7–50.2) for allo-HCT–treated patients. Relapse incidence (RI) after 1.5 years was higher after CAR T-cell therapy, at 66.5% (46.3–80.5), compared with 37.4% (16.0–

58.9) after allo-HCT, while non-relapse mortality (NRM) was 6.5% (1.0–19.7) after CAR T-cell therapy and 33.7% (12.8–56.2) after allo-HCT.
A Cox model using propensity score overlap weighting, including age, disease status before the evaluated treatment, time from diagnosis, and year of procedure, did not demonstrate significant differences between the two groups in survival outcomes.

Conclusions: In this large real-world cohort of r/r PCNSL, both CAR T-cell therapy and allo-HCT achieved a clinically meaningful 18-month PFS of over 25%, with approximately one-third of patients alive at 18 months. Although allo-HCT was associated with lower numerical relapse rates, the high NRM offset this benefit, resulting in similar PFS compared with CAR T-cell therapy. These data underline that both CAR T-cell therapy and allo-HCT are viable treatment options for patients with an otherwise dismal prognosis. However, careful patient selection for allo-HCT is essential, and further studies are needed to develop less toxic conditioning regimens.

Background: Chimeric antigen receptor T-cell therapy (CAR-T) has changed the treatment of relapsed/refractory (R/R) large B cell lymphoma (LBCL). However, its availability is not immediate, as it requires several steps from identifying the candidate to receiving the product. Because of this waiting time, not all candidates for CAR-T therapy ultimately receive treatment, with disease progression being the main reason for non-administration. In recent years, infusion capacity has increased with the incorporation of additional CAR-T centers, reducing the need for interregional referral. Together with the learning curve, this likely has

shortened waiting times and allowed more patients to be treated, although these data are not yet available. Therefore, our objective was to analyze the waiting time from relapse to CAR-T infusion among eligible patients in Spain.

Methods: We performed a retrospective multicenter study based on GETH-TC database of CAR-T. We included patients from GETH-TC/GELTAMO centers with R/R LBCL who were eligible for axi-cel therapy [in 2nd and ≥3rd lines (L)]. Primary endpoints were to assess the time from approval to infusion in the overall cohort, in 3L+ divided in two time periods: before and after June 2022 (point at which more centers were allowed to infuse CAR-T cell products), and in the 2L cohort, as well as the proportion of candidates who ultimately received the product.

Results: 469 patients fulfilled the inclusion criteria. Baseline characteristics are summarized in **Table 1**. Apheresis was performed in 459 patients (98%) and 424 (92%) received the infusion. Among available data, cause of not reaching the apheresis was disease progression in all patients; and causes of not receiving axi-cel were disease progression (n=9), manufacturing failure (n=1), patient decision (n=1) and complete remission after bridging (n=4). Infusion delay was confirmed in 33% of infused patients; causes were infections (n=21), bed capacity (n=20), progression (n=8), second apheresis or reception delay (n=3) and bridge therapy-related issues (n=22). Median time from national approval to apheresis was 11 days (range 4-13), from apheresis to product reception 26 days (range 24-28) and from vein-to-vein 40 days (range 34-44). In the 3L+ cohort there was a significant reduction in the apheresis-reception time (27 vs 25 days, p<0.001) and in the apheresis-infusion time (43 vs 39 days, p=0.009) when comparing the first and second period. Times in the 2L subgroup were similar to those of the most recent period in the 3L+ cohort. No differences in waiting times were observed between patients referred from non-infusion centers and those treated at CAR-T cell infusion centers.

Table 1: Patients with R/R LBCL potential candidates for axi-cel

	N=469

No	147 (35%)
Missing	136 (32%)

Conclusions: In our cohort of patients 90% of initial candidates made it to CAR-T cell infusion. Disease progression remains the main reason for not reaching the apheresis and infusion. Although waiting times have improved slightly, there remains room for improvement, particularly through the identification of factors associated with delays. Further efforts in this direction may help to reduce the loss of potential candidates. Finally, we did not observe delays in patients coming from referral centers compared to those from CAR T centers.

Background: Tisagenlecleucel, an autologous anti-CD19 chimeric antigen receptor (CAR)-T cell therapy has been approved in the US and Europe for adults with r/r FL after ≥2 lines of prior therapy based on the phase 2 ELARA trial (EUCT number: 2023-508127-13-00) in 2022. Final analysis from the ELARA trial after a median follow-up (mFU) of >5 years is reported here.

Methods: Eligible patients with r/r FL (grade 1-3A) previously treated with ≥2 lines of systemic therapy (including an anti-CD20 monoclonal antibody and alkylating agent) received a single tisagenlecleucel infusion (0.6-6 × 10^8 CAR+ viable T cells). Bridging therapy was permitted. Here we report the long-term efficacy and safety analysis, including duration of response, progression-free survival, and overall survival in all patients and patients with high-risk disease characteristics. Cellular kinetics were determined by the measurement of transgene levels by quantitative polymerase chain reaction.

Results: As of May 28, 2025 (mFU: 61.0 months [range: 3.1–67.0 months]), all patients (N=97) were evaluated for safety and 94 patients for efficacy. At baseline, patients with high-risk disease characteristics included 60% with high Follicular Lymphoma International Prognostic Index score (FLIPI ≥3), 62% with progression of disease within 2 years of frontline systemic therapy, 64% with bulky disease (>7 cm or 3 lesions >3 cm), 68% with double refractory to prior CD20 antibody and alkylating agent, and 21% with high tumor burden (total metabolic tumor volume >510 mL). The overall response rate (86.2%) and complete response (68.1%) remained consistent with previous data in overall patients and high-risk disease characteristics subgroups (Dreyling M, *Blood* 2024). Efficacy outcomes at final follow-up are reported in **Table 1**. CAR transgene persistence (T_{last}; time to last quantifiable transgene level) was observed up to 60.9 months; the median T_{last} was 8.6 months (range: 0.6–60.9 months). Tisagenlecleucel demonstrates a favourable safety profile at final analysis with reports of blood and lymphatic system disorders in 11 patients

(13.1%), infection and infestations in 34 patients (40.5%), >1 year after infusion. Adverse events reported >4 years after tisagenlecleucel infusion will be presented at congress. Second primary malignancies (defined as any new cancer occurring post-infusion regardless of tisagenlecleucel relationship) were reported in 7 (7.2%) patients, including 2 events each of basal cell carcinoma, myelodysplastic syndrome, squamous cell carcinoma of skin (n=2), and 1 event each of acute myeloid leukemia, bladder transitional cell carcinoma, Bowen's disease, malignant melanoma, and metastatic squamous cell carcinoma (n=1). In total, 22 patients died during the study; causes of death include disease progression (n=8), AEs (n=13, predominantly infections), and euthanasia.

Table 1: Efficacy outcomes of tisagenlecleucel in patients with r/r FL

Efficacy	**N=94**
Median DOR, month	NR
4-year DOR, % (95% CI)	
In all responders	61% (48.8–71.1)
In patients achieving CR	71.2% (57.7–81.1)
Median PFS, month	53.2
5-year PFS, % (95% CI)	
In all patients	46% (35.0–56.3)
In patients achieving CR	59.8% (46.2–71.1)
5-year PFS in high-risk disease characteristics subgroups, %	
High FLIPI	35.5
POD24	41.1
Bulky disease	45.1
Double refractory	50.5
High tumor burden	NE
Median OS, month	NR
5-year OS, % (95% CI)	
In all patients	74.1% (63.0–82.3)
5-year OS in high-risk disease characteristics subgroups, %	
High FLIPI	64.4
POD24	74.6
Bulky disease	71.1
Double refractory	79.8
High tumor burden	65.5

CI, confidence interval; CR, complete response; DOR, duration of response; FLIPI, Follicular Lymphoma International Prognostic Index, NE, not estimable; NR, not reached; OS, overall

Table 1: Efficacy outcomes of tisagenlecleucel in patients with r/r FL
survival; PFS, progression-free survival; POD24, progression of disease within 2 years of frontline systemic therapy.

Conclusions: After a median follow-up of >5 years, tisagenlecleucel continues to demonstrate durable responses and prolonged survival in patients with r/r FL including patients with high-risk disease characteristics. No new safety signals were reported. More than 75% of patients were alive, and approximately half remained progression-free at this final analysis, indicating the curative potential of tisagenlecleucel in r/r FL after ≥2 lines of prior therapy.

[1]Bristol Myers Squibb, Uxbridge, United Kingdom of Great Britain and Northern Ireland (the), [2]The Ohio State University Comprehensive Cancer Center, Columbus, United States of America (the), [3]Swedish Health Services, Seattle, United States of America (the), [4]NYU Langone Health, New York, United States of America (the), [5]Rutgers Cancer Institute of New Jersey, New Brunswick, United States of America (the), [6]Hackensack University Medical Center, Hackensack, United States of America (the), [7]Flatiron Health, New York, United States of America (the), [8]Bristol Myers Squibb, Boudry, Switzerland, [9]Bristol Myers Squibb, Princeton, United States of America (the), [10]Huntsman Cancer Institute, University of Utah, Salt Lake City, United States of America (the), [11]Roswell Park Comprehensive Cancer Center, Buffalo, United States of America (the)

Background: Lisocabtagene maraleucel (liso-cel) and axicabtagene ciloleucel (axi-cel) are chimeric antigen receptor (CAR) T cell therapies approved for second-line (2L) treatment of relapsed or refractory (R/R) large B-cell lymphoma (LBCL). While pivotal trials of each agent established superior efficacy versus standard of care, the absence of direct comparisons underscores the importance of real-world comparative data to support informed treatment selection, toxicity management, and site-of-care planning. This study investigated the real-world effectiveness, safety, and health care resource utilization (HCRU) of liso-cel and axi-cel in the 2L treatment setting.

Methods: Patients with LBCL who received 2L liso-cel or axi-cel (April 2022–April 2025) were selected from the United States Flatiron Health Research Database, an oncology-specific platform combining electronic health records and other real-world data. Both overall survival (OS) and progression-free survival (PFS) were evaluated using the Kaplan-Meier method. Descriptive statistics were used to describe safety endpoints (cytokine release syndrome [CRS], immune effector cell–associated neurotoxicity syndrome [ICANS], cytopenia) and HCRU (tocilizumab/steroid use, hospitalization).

Results: The study included 473 patients with LBCL who received 2L CAR T cell therapy, of whom 198 received liso-cel versus 275 who received axi-cel (median [interquartile range (IQR)] age, 72 years [63–77] vs 63 years [54–70]; elevated lactate dehydrogenase, 39% vs 33%; high-grade B-cell lymphoma, 41% vs 40%; receipt of bridging therapy, 78% vs 71%; bulky disease, 68% vs 74%; relapsed within 1 year of first-line treatment, 72% vs 86%; and median [IQR] follow-up time, 8 months [4–14] vs 12 months [5–22]).
Early survival outcomes among patients in liso-cel versus axi-cel groups were similar at 6 months with no statistically significant differences observed (OS, 89% [95% confidence interval, 84%–94%] vs 89% [85%–93%]; PFS, 69% [63%–77%] vs 71% [66%–77%]). CRS and ICANS of any grade were less frequent with liso-cel than axi-cel (CRS, 31% vs 64%; ICANS, 15% vs 34%), as were grade ≥ 3 CRS/ICANS (CRS, 1% vs 3%; ICANS, 3% vs 18%; **Figure**). Grade ≥ 3 cytopenia between Day 30 and Day 89 after CAR T cell therapy infusion was less common with liso-cel than axi-cel (19% vs 28%). Patients in the liso-cel group were less likely to receive treatment for CRS/ICANS versus the axi-cel group (**Table**). Infusion in an outpatient setting was more common with liso-cel than axi-cel (21% vs 6%) and was associated with a lower rate of hospitalization after infusion (47% vs 62%; **Table**). For patients infused at an inpatient setting, liso-cel was associated with shorter length of

stay (8 days vs 12 days) and lower rates of rehospitalization (33% vs 40%) compared with axi-cel.

Conclusions: In this retrospective real-world analysis, liso-cel demonstrated similar effectiveness and a more favorable safety and HCRU profile versus axi-cel as a 2L therapy for R/R LBCL. Despite limited follow-up, these real-world findings suggest liso-cel could deliver safety advantages without compromising efficacy in a broad population of patients with 2L LBCL.

ALLOGENEIC TRANSPLANTATION AFTER FAILURE OF CAR-T CELLS AND EXPOSURE TO BISPECIFIC ANTIBODIES: FEASIBILITY, SAFETY AND SURVIVAL OUTCOMES

Angelica Barone[1,2], Chiara De Philippis[3], Gabriele Facchin[4], Federico Stella[2], Anna Dodero[2], Martina Pennisi[2], Armando Santoro[5,3], Carmelo Carlo-Stella[5], Anna Guidetti[1,2], Francesca Patriarca[6,4], Stefania Bramanti[3], Paolo Corradini[1,2], ***Giorgia Gobbi***
[1]University of Milan, Milano, Italy, [2]Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, Italy, [3]IRCCS Humanitas Research Hospital, Rozzano, Milano, Italy, [4]Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy, [5]Humanitas University, Pieve Emanuele, Italy, [6]University of Udine, Udine, Italy

Background: Clinical outcome after Chimeric Antigen Receptor (CAR)T-cell failure in large B-cell lymphoma (LBCL) is dismal. Allogeneic stem cell transplantation (alloSCT) represents a potential curative salvage for relapsed/refractory LBCL, although concerns remain about feasibility and safety in patients exposed to CAR-T and bispecific antibodies (BsAb).

Methods: We retrospectively analysed outcomes of 19 LBCL patients who underwent alloSCT consolidation after failure of CAR-T cells and exposure to BsAb in 3 academic centres, with the aim to describe safety, feasibility and survival outcomes in a heavily pre-treated population.

Results: Median age at alloSCT was 52 years (range 23-68). Prior CAR-T product were axicabtagene ciloleucel (n=8) or tisagenlecleucel (n=11); BsAb was glofitamab (n=18) or epcoritamab (n=1). Patients had received a median of 4 (range 3-9) prior lines of therapy, including autologous SCT in 5 (26%). Median number of BsAb cycles was 8 (range 2-12). Disease status at alloSCT was complete response (n=17) obtained with either BsAb (n=13) or subsequent treatments (n=4), or partial response (n=2) obtained with subsequent treatments. All patients received reduced intensity conditioning, while Graft-versus-Host-Disease (GvHD) prophylaxis was PTCy-based in 10 (52%). Other baseline characteristics are summarized in **Table 1**. Cumulative incidence of 30-days neutrophil engraftment was 100% (median time 17 days, range 10-25), while 30-days cumulative incidence of platelet engraftment was 94% (median time 20 days, range 10-45). The 100-days cumulative incidence of grade II-IV acute GvHD was 26% (95% confidence interval [CI] 9-51); 1-year cumulative incidence of chronic GvHD was 22% (95%CI 6-46). Full donor chimerism was documented at +30 and +90 in all evaluable patients. Median absolute lymphocyte counts at 3, 6 and 12 months after alloSCT were 515, 710 and 1365 cells/μL, respectively. The median number of infectious events per patient was 2 (range 0-5). One fatal fungal infection was observed; all other viral (n=6 patients) and bacterial (n=15 patients) infections resolved with appropriate antimicrobial therapy. Viral reactivations occurred in 9 (47%) patients before and in 5 (26%) patients after day +180, with resolution of all 4 cases of end-organ disease (colitis). Uncommon toxicities included one steroid-responsive hemolytic anemia, one anti-GM2-ganglioside IgM-positive acute demyelinating polyneuropathy diagnosed 10 months after alloSCT, successfully managed with intravenous immunoglobulins with complete recovery, and one case of iatrogenic encephalopathy on a likely microangiopathic basis,

possibly related to cyclosporine. With a median follow-up of 23 months (IQR 12-46), 1-year overall and progression-free survival were 94% (95%CI 68-99) and 89% (95%CI 62-98), respectively. Only one LBCL relapse 5 months after alloSCT and one case of transplant-related mortality occurred. One-year GvHD- and relapse-free survival (GRFS) was 71% (95%CI 43-87).

Table 1.

	Patients n=19
Age at alloSCT, median (range)	52 (23-68)
Median time from last treatment, days (range)	48 (20-98)
Median time from last BsAb, days (range)	71 (22-369)
ECOG 0, n (%)	15 (79%)
HCT-CI score, median (r)	2 (0-4)
0-2, n pts	12 (63%)
≥ 3, n pts	7 (37%)
Donor type, n (%)	
Matched related donor	3 (16%)
Matched unrelated donor	9 (47%)
Haploidentical donor	7 (37%)
Conditioning regimen type, n (%)	
FluCyTBI2Gy	6 (32%)
ThioFluCy	9 (47%)
ThioBuFlu	4 (21%)
GvHD prophylaxis, n (%)	
PTCy-based	10 (52%)
ATG-based	6 (32%)
CSA+MTX +/- MMF	3 (16%)

Conclusions: AlloSCT consolidation after CAR-T cells and BsAb exposure is feasible in selected, fit and responding patients, providing durable disease control with acceptable toxicity. Despite heavy pre-treatment, no unexpected safety signals emerged, with relatively low GvHD rates across donor type, and limited transplant-related mortality. In conclusion,

alloSCT consolidation should be offered to all eligible patients failing both T-cell redirecting strategies, and carefully evaluated also in patients achieving complete remission with BsAb after CAR-T cells failure.

B397

ALLOGENEIC TRANSPLANTATION OUTCOMES IN PATIENTS WITH HIGH-GRADE LYMPHOMA AFTER RELAPSE FOLLOWING CAR-T THERAPY: A MULTICENTER RETROSPECTIVE COMPARATIVE STUDY

*Beatriz Rossi Vargas[1], **Araceli Salamanca Cuenca**[1], Virginia Olivencia plaza[1], Beatriz Chiclana Rodríguez[2], Nazaret Serrano García[3], María Asunción Vallejo Trujillo[4], María Luisa Rubio de la Rubia[5], Sebastián Garzón López[1]*
[1]Hospital Universitario de Jerez de la Frontera, Jerez de la Frontera, Spain, [2]Hospital Universitario Virgen del Rocio, Sevilla, Spain, [3]Hospital Universiversitario Regional de Málaga, Málaga, Spain, [4]Hospital Universitario Reina Sofía de Córdoba, Córdoba, Spain, [5]Hospital Universitario Virgen de las Nieves, Granada, Spain

Background: Relapsed or refractory (R/R) high-grade lymphomas remain a major clinical challenge. Although chimeric antigen receptor T-cell (CAR-T) therapy has improved response rates, relapses still occur and often require allogeneic hematopoietic stem cell transplantation (allo-HCT). The impact of prior CAR-T exposure on allo-HCT outcomes remains unclear.

Methods: **Objectives:** To compare progression-free survival (PFS) and overall survival (OS) between patients with high-grade lymphoma undergoing upfront allo-HCT and those treated with CAR-T therapy followed by allo-HCT.
Methods: We conducted a multicenter retrospective comparative study across five centers in Andalusia, Spain. Patients with diffuse large B-cell lymphoma (DLBCL) or primary mediastinal B-cell lymphoma (PMBCL) undergoing allo-HCT between 2015 and 2025 were included. Sixty-two patients were analyzed: CART-NO (upfront allo-HCT, n=46) and CART-YES (CAR-T followed by allo-HCT, n=16).
Demographic, clinical, disease-related, transplant-related, and post-transplant response variables were collected. OS and PFS were estimated using Kaplan–Meier methods.

Results:

Table 1. Baseline and transplant characteristics and outcomes according to prior CAR-T exposure

Variable	CAR-T No (n=46)	CAR-T Si (n=16)	p value
Baseline characteristics			
Age, years	45.3 (12.6)	48.8 (11.0)	0,26
Male sex	29 (63.0%)	12 (75.0%)	0,542
ECOG 0	28 (62.2%)	5 (41.7%)	0,408
ECOG 1	10 (22.2%)	5 (41.7%)	
ECOG ≥2	7 (15.5%)	2 (16.7%)	
Diagnosis: DLBCL	36 (78.3%)	12 (75.0%)	0,743
Diagnosis: PMBCL	10 (21.7%)	4 (25.0%)	
Stage IV at diagnosis	31 (67.4%)	12 (75.0%)	0,71
≥4 prior lines of therapy	12 (26.1%)	6 (37.5%)	0,523
Prior autologous SCT	32 (69.6%)	5 (31.2%)	**0,014**
Overall response before allo-HCT (CR/PR)	41 (89.1%)	7 (43.8%)	**0,001**
Transplant characteristics			
Age at transplant, years	46.0 (12.6)	50.0 (11.1)	0,25
HLA-identical donor	34 (73.9%)	8 (50.0%)	0,12
Outcomes			
Overall survival, months	51.5 (48.8)	25.0 (23.7)	0,215
Post-allo-HCT response: CR	27 (84.4%)	9 (64.3%)	0,202
Post-allo-HCT response: PR	1 (3.1%)	0 (0%)	
Post-allo-HCT response: PD	4 (12.5%)	5 (35.7%)	
Vital status: alive	24 (52.2%)	8 (50.0%)	1
Vital status: dead	22 (47.8%)	8 (50.0%)	

Footnote: Data are presented as mean (standard deviation) or number (percentage). Comparisons between groups were performed using the Mann–Whitney U test for continuous variables and Fisher's exact test for categorical variables. Statistically significant p values (<0.05) are shown in bold.

Figure 1: Alluvial plots showing disease status before and after allogeneic hematopoietic stem cell transplantation (allo-HCT).

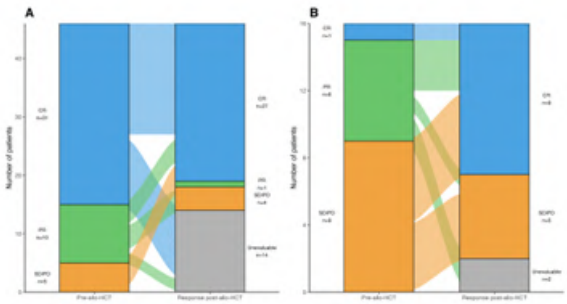

Figure 2: Kaplan-Meier curve, Overrall survival

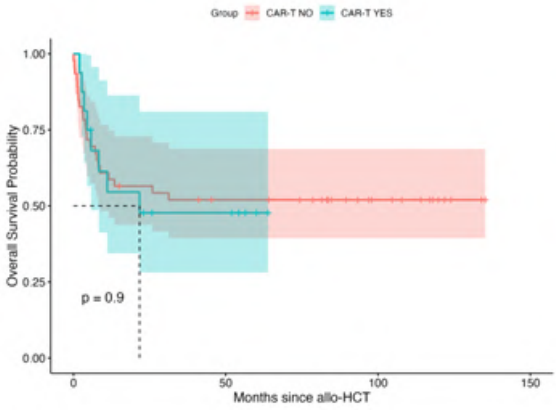

Figure 3: Kaplan-Meier curve, Progression-free survival

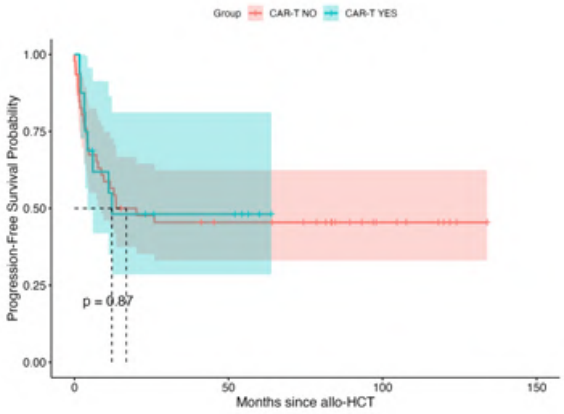

Baseline demographic and clinical characteristics were comparable between groups. Mean age was similar (CART-YES 45.3 vs CART-NO 48.8 years; p=0.26), with no significant differences in sex, ECOG performance status, diagnosis, disease stage, or number of prior treatment lines (Table 1).CART-YES patients less frequently had prior autologous transplantation (31.2% vs 69.6%; p=0.014) and showed a significantly lower overall response rate (CR/PR) before allo-HCT (43.8% vs 89.1%; p=0.001), reflecting a more refractory disease profile. Transplant-related characteristics, including age at transplant and HLA-matched donor availability, were similar between cohorts (Table 1).
Regarding response to allo-HCT, most CART-NO patients were in complete response (CR) before transplant (31/46), with fewer in partial response (PR, 10/46) or stable/progressive

disease (SD/PD, 5/46). Post-transplant, CR was largely maintained (27 patients), although 14 patients were unevaluable due to early death, and only a minority showed PR (n=1) or SD/PD (n=4). In contrast, CART-YES patients presented with more refractory disease before allo-HCT, with fewer patients in CR (1/16) and a higher proportion in PR (6/16) or SD/PD (9/16). After allo-HCT, a marked improvement in disease status was observed, with 9 patients achieving CR, while 5 remained with active disease and 2 were unevaluable (Figure 1).
With a median follow-up of 36.5 months, overall mortality was 47.8% in CART-NO and 50% in CART-YES (median follow-up 16.4 months), without significant differences. Kaplan–Meier analyses showed similar OS and PFS, with early post-transplant events and parallel curves. Median OS was not reached in CART-NO and was approximately 21 months in CART-YES (log-rank p=0.82). PFS was also comparable between groups (log-rank p=0.87) (Figures 2–3).

Conclusions: Our data suggest that prior CAR-T therapy does not negatively impact survival after allogeneic transplantation. Although CART-YES patients showed slightly higher overall mortality and marginally lower OS, and a trend toward improved PFS, these differences were not statistically significant. Notably, despite lower response rates before allo-HCT, CART-YES patients showed a higher degree of response consolidation after transplantation. The main limitation of this study is the small sample size, which may limit statistical power and generalizability. Larger studies are needed to confirm these findings and clarify the impact of prior CAR-T therapy on allo-HCT outcomes.

Background: High-dose chemotherapy followed by autologous stem cell transplantation (ASCT) is a standard consolidation strategy for fit patients with primary central nervous system lymphoma (PCNSL) achieving response after first-line induction with MATRix regimen. Standard conditioning commonly includes thiotepa combined with BCNU; however, therapy-related toxicity remains a concern, particularly in older patients or those with multiple comorbidities. We explored whether a reduced-dose thiotepa conditioning regimen could maintain efficacy while improving tolerability.

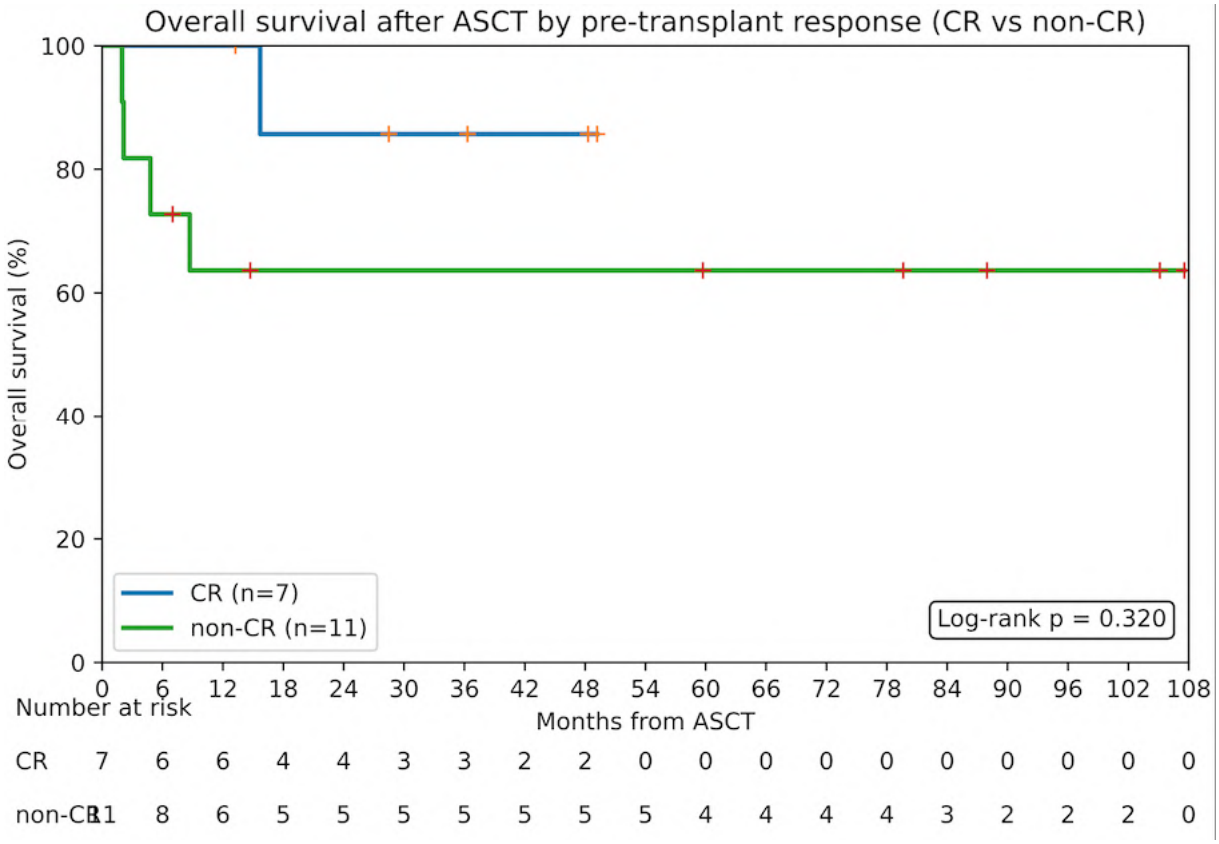
Methods: We retrospectively analyzed all consecutive adult patients with newly diagnosed PCNSL treated at ASST Niguarda in Milan between January 2014 and November 2025 who were eligible for ASCT. All patients received four cycles of MATRix induction chemotherapy.

Patients achieving at least a partial response proceeded to ASCT using a modified conditioning regimen consisting of thiotepa 5 mg/kg/day for two consecutive days (total dose 10 mg/kg) combined with standard-dose BCNU (400 mg/mq). Patients who did not proceed to ASCT were excluded from the analysis. Primary endpoints were overall survival (OS), progression-free survival (PFS), and non-relapse mortality (NRM), calculated from the date of ASCT. Toxicity and transplant-related complications were assessed descriptively.

Results: Eighteen patients underwent ASCT and were included in the analysis. Median follow-up was 59.7 months and median age at transplantation was 58 years (range 36-72). Complete characteristics of the population are listed in Table 1.

Variable	**Patients (n=18)**
Male, n (%)	5 (28%)
Median Age at Transplantation, years (range)	58 (36-72)
ECOG ≥ 2, n (%)	11 (61%)
IELSG ≥ 2, n (%)	8 (44%)
Complete Response Before ASCT, n (%)	7 (39%)
Infused CD34+ cells, mediana (range)	8.8 ×10⁶/kg (2.6-27.22)

Estimated OS at 1 and 2 years was 77.8% and 72.2%, respectively, while PFS at 1 and 2 years was 72.2% and 66.7%. Patients achieving complete remission prior to ASCT showed more favorable outcomes, with a 2-year OS of 85.7% and a 2-year PFS of 71.4%, compared with 63.6% and 63.6%, respectively. Exploratory subgroup analyses suggested that age, IELSG score, and disease status at transplant influenced outcomes.
The most common toxicity was febrile neutropenia which occurred in 62% of patients. Other non-hematologic toxicities were infrequent, with no grade ≥3 organ toxicity or mucositis observed. No cases of non-relapse mortality were observed at day +100 or at 1 year.



Conclusions: In this real-world cohort of PCNSL patients undergoing ASCT in first remission, a conditioning regimen incorporating reduced-dose thiotepa demonstrated a favorable safety profile with preserved disease control. Despite the absence of a comparative control group, survival outcomes appear comparable to those reported in the literature, while severe transplant-related toxicities were limited. This approach may represent a viable strategy to reduce treatment-related toxicity, particularly in patients achieving complete remission or in older and more comorbid populations. Prospective, controlled studies are warranted to confirm these findings and to better define the role of thiotepa dose reduction in ASCT conditioning for PCNSL.

Disclosure: Nothing to declare.

Background: Post-transplant lymphoproliferative disorders (PTLDs) are rare lymphomas that arise as complications of solid organ transplantation (SOT) and hematopoietic stem cell transplantation (HSCT). The Fondazione Italiana Linfomi (FIL) conducted the multicenter, observational, retrospective FIL_PTLD cohort study to assess PTLD management across Italian haematology centers. Primary objectives include the characterization of clinical features and survival outcomes, as well as the identification of prognostic factors affecting disease progression and mortality.

Methods: Adult patients diagnosed with PTLD between January 2011 and December 2021 were retrospectively included. The sample consisted of 241 patients that have been enrolled across 21 Italian centers. Overall Survival (OS) and Progression-Free Survival (PFS) were estimated using Kaplan-Meier method, and compared across groups with Cox model. In particular, the sample was stratified based on type of transplant (SOT vs HSCT) and

correlation with EBV infection; a statistical subanalysis was performed on the subcohort of patients diagnosed with diffuse large B-cell lymphoma (DLBCL).

Results: Most cases followed SOT (92.5%), including thoracic organ (24.1%) and abdominal organ (68.5%) transplants; only 7.5% occurred after HSCT. The median time from transplantation to PTLD diagnosis was 7.8 years (range 2.2-14.8), with shorter latency ($p<0.001$) observed in EBV-positive cases (3.6 years). Early-onset PTLD (within 2 years post-transplant) occurred in 25.4% of patients. EBV-encoded RNA (EBER) status was available for 201 patients: 91 (45,3%) were EBV-positive, with early-onset in 38 (41.8%). The predominant histological subtype was monomorphic PTLD (88.8%), with DLBCL in 66.4% and Burkitt lymphoma in 7.5%. Extranodal localization was observed in 73.9% of cases, central nervous system involvement in 5%. About half of patients had elevated serum LDH (50.2%) and advanced Ann Arbor stage (57.3%). Immunosuppression reduction (RIS) was reported in 162 cases (67.2%). Treatment consisted of RIS alone (7.9%), rituximab monotherapy (41.3%) or associated to chemotherapy (32.5%), or other (18.3%). Overall response rate (ORR) was 71.4%, with 56.3% achieving complete response; 19.3% developed progressive disease. With a median follow-up of 77 months, 5-year and 10-year OS rates were 55% (95% CI, 48–61) and 46% (95% CI, 38–53), respectively; 5-year and 10-year PFS rates were 47% (95% CI, 40–53) and 40% (95% CI, 32–47), respectively. Multivariable analysis with Cox model identified age (HR per 1-y 1.03; $p=.001$), advanced stage (HR 2.4; $p=.001$), and ECOG performance status ≥2 (HR 2.84; $p<.001$) as independent predictors of inferior OS. The same prognostic factors were identified as having a significant impact on PFS. However, EBER positivity (HR 1.26; $p=.335$), elevated LDH (HR 1.29; $p=.247$), extranodal localization (HR 1.49; $p=.163$) and short latency from transplant ≤ 24 months (HR 1.41; $p=.182$) were not significantly associated with survival.

Conclusions: The FIL_PTLD study is the first Italian retrospective observational study evaluating outcome and management of PTLD. The study confirms that PTLD in adults predominantly arises after SOT and frequently presents in the late-onset form. Treatment approaches were heterogeneous across centers. Advanced age, poor performance status, and advanced stage at diagnosis were associated with worse overall and progression-free survival.

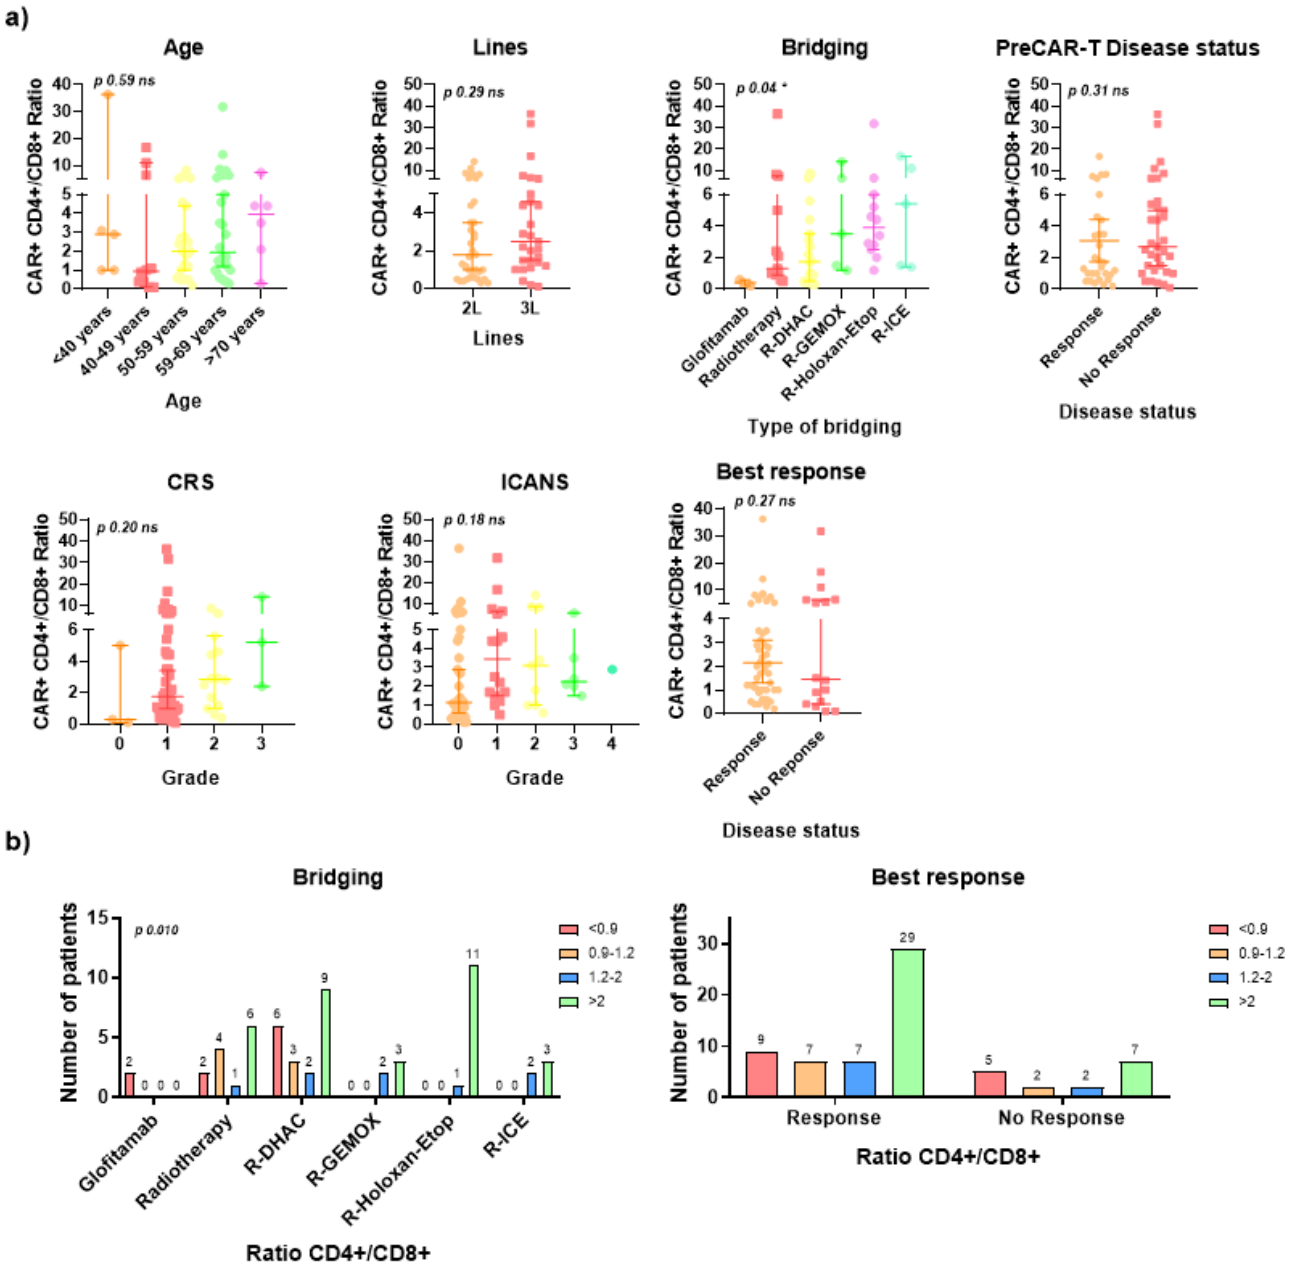
PREDOMINANCE OF CD4+ T-CELLS IS ASSOCIATED WITH IMPROVED OUTCOMES IN PATIENTS WITH DIFFUSE LARGE B-CELL LYMPHOMA TREATED WITH AXICABTAGENE CILOLEUCEL

Jorge Illarramendi[1], *François-Xavier Gros*[1], *Elodie Wojciechowski*[1], *Jonathan Visentin*[1], *Jean Galtier*[1], *Raphaëlle Aubrais*[1], *Clémence Mediavilla*[1], *Chloé Dhunputh*[1], *Krimo Bouabdallah*[1], *Edouard Forcade*[1]
[1]*Bordeaux University Hospital - Haut-Lévêque, Pessac, France*

Background: Emerging evidence suggests that both CAR-T kinetics and subsets may influence treatment response and toxicity. Understanding these parameters could help to optimize patient outcomes in diffuse large B-cell lymphoma (DLBCL) treated with CAR-T therapies. This study evaluates the association between baseline CD4+/CD8+ ratios and both toxicity and response outcomes.

Methods: Retrospective observational study conducted between January 2021 and May 2025 at Bordeaux University hospital. CAR-T cell monitoring and CD4+/CD8+ ratio analysis were performed by multiparametric flow cytometry by indirect staining. Only patients with DLBCL treated with axi-cel were included. Lymphocyte CAR+ ratio CD4+/CD8+ from the infusion bag (day 0) were analyzed according to age, treatment line, bridging therapy, CRS and ICANS development and best response. Only patients with disponible data or detectable CAR-T were included 68/74 (91.8%).

Results: A total of 68 patients were included (female:male 19:49) with a median age of 58 years (range 28–73). CAR-T was administered in 2nd and 3rd line in 36 (52.9%) and 30 (44.1%) patients. Pre-CAR-T disease status (n=63) showed 31 responders (R, 49.2%) and 32 non-responders (NR, 50.8%). Among patients who received bridging therapy (n=64), the most frequently used regimen was R-DHAC (19, 29.7%), followed by radiotherapy (13, 20.3%), R-Holoxan-etoposide (12, 18.8%), R-GEMOX (5, 7.8%), R-ICE (6, 9.4%) and glofitamab (2, 3.1%). For CRS (n=68), grade 0 in 3 (4.4%), grade 1 in 48 (70.6%), grade 2 in 9 (13.2%), grade 3 in 7 (10.3%), and grade 4 in 1 (1.5%). For ICANS (n=68), grade 0 in 36 (52.9%), grade 1 in 16 (23.5%), grade 2 in 9 (13.2%), grade 3 in 6 (8.8%), and grade 4 in 1 (1.5%). Regarding treatment response (n=68), R 51 (75%), while NR 17 (25%).
The median CD4+/CD8+ ratio of 2.1 (IQR 1.0–4.9; range 0.1–36.3). The CD4+/CD8+ CAR+ ratio showed no differences across age groups (*p 0.59*, *ns*). 2nd line patients exhibited ratios closer to 1 compared with 3rd line (1.8 vs 2.5) (*p 0.29, ns*). Across bridging regimens, higher ratios were observed in patients who received immunochemotherapy. Ratios were: glofitamab 0.4, radiotherapy 1.3, R-DHAC 1.75, R-GEMOX 3.5, R-Holoxan-Etoposide 3.9, and R-ICE 5.4 (*p 0.04,* *). Pre-CAR-T disease status showed ratios of 1.6 for R and 2.7 for NR (*p 0.31, ns*). Regarding outcomes, ratios increased with CRS severity (1.0 for grade 0, 2.0 for grade 1, 2.92 for grade 2) (*p 0.20, ns*). Patients with ICANS had higher ratios (2.7 vs 1.15), with medians of 3.45, 3.1, 2.25 and 2.9 for grades 1–4 (*p 0.18, ns*). For best response, ratios were 2.2 for R and 1.5 for NR (*p 0.27, ns*). Overall, 29/51 responders (56.9%) had ratios >2, while 6/17 NR patients (35.3%) had ratios <0.9.



Conclusions: Higher CD4+/CD8+ ratios with predominance of CD4+ T-lymphocytes were associated with better response outcomes and increased severity of CRS and incidence of ICANS. Older age and specific bridging regimens influenced lymphocyte CD4+ and CD8+ distributions. These findings support the potential prognostic relevance of CD4+/CD8+ ratios and lymphocytes subsets in patients undergoing CAR-T therapy.

B402

EFFICACY AND SAFETY OF ENSARTINIB-BASED REGIMENS IN ALK-POSITIVE LYMPHOMA: A REAL-WORLD RETROSPECTIVE STUDY

Xiaorui Fu[1], *Xiao Sun*[2], *Xiuli Yang*[3], *Chuyun Yin*[1], *Bai Li*[1], *Yan Xu*[1], *Mengjie Ding*[1], *Junfeng Jiang*[4], *Xiaobo Wang*[5]
[1]*The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China,* [2]*Nan Yang Central Hospital, Nanyang, China,* [3]*The First Affiliated Hospital of Nanyang Medical College, Nanyang, China,* [4]*Gansu Hospital of Sun Yat-sen University Cancer Center, Gansu, China,* [5]*The Second Hospital of Dalian Medical University, Dalian, China*

Background: Anaplastic lymphoma kinase-positive (ALK+) lymphomas are aggressive malignancies driven by ALK rearrangements. Although conventional chemotherapy is effective for most patients (patients), approximately 30% experience a relapsed or refractory (R/R) disease, with a poor prognosis. Ensartinib has demonstrated efficacy in ALK+ non-small cell lung cancer, but its role in ALK+ lymphoma is unclear. This real-world study aimed to evaluate the efficacy and safety of ensartinib-based regimens in ALK+ lymphoma.

Methods: Between December 1, 2021, and February 20, 2025, patients with R/R ALK+ lymphoma who received ensartinib were included in this multicenter retrospective study. The outcomes included overall response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS), and safety.

Results: A total of 9 patients (6 females; 5 adults; median age 31 years [range: 5-63]) were included, of whom 8 had anaplastic large cell lymphoma and 1 had diffuse large B-cell lymphoma. All patients had an ECOG performance status of 0, with B symptoms and elevated LDH (>ULN). Prior treatments included chemotherapy alone (55.6%), chemotherapy plus transplantation (33.3%), or chemotherapy with radiotherapy (11.1%). Among all patients, 22.2% received ensartinib alone, 22.2% received ensartinib plus R-CHOP regimen, and 55.6% received ensartinib plus other chemotherapy regimens. As of the data cutoff date (March 20, 2025), the median duration of ensartinib-based regimens treatment was 28.1 (range: 0.5-76.5) months. The ORR and DCR were both 100% for all patients (7 [77.8%] complete response; 2 [22.2%] partial response). After a median follow-up of 9.3 (range: 0.9-37.5) months, the PFS and OS were immature. No progression/death occurred as of March 20, 2025. Adverse events (AEs) of any grade occurred in 4 of 9 patients (44.4%), including rash (22.2%), elevated liver enzymes (11.1%), and edema (11.1%). No patients experienced grade ≥3 AEs or severe AEs. No dose adjustments or deaths due to AEs occurred.

Conclusions: Ensartinib-based regimens demonstrated promising preliminary efficacy and manageable toxicity in patients with R/R ALK+ lymphoma, warranting further prospective validation.

Disclosure: Nothing to declare

B403

LONG-TERM FOLLOW-UP OF CD19 CAR-T FOR R/R B-NHL: KI-67 AS A PROGNOSTIC FACTOR FOR SUSTAINED REMISSION

Yinghui Yu[1], *Juan Yue*[1], *Wenxin Wang*[1], *Zhuomao Mo*[1], *Yuanyin Teng*[1], *Dongrui Wang*[1], *Shan Fu*[1], *Jiazhen Cui*[1], *Simao Huang*[1], *He Huang*[1], *Yongxian Hu*[1], *Mingming Zhang*[1], *Guoqing Wei*[1]
[1]*Bone Marrow Transplantation Center of The First Affiliated Hospital & Liangzhu Laboratory, Zhejiang University School of Medicine, Hangzhou, China*

Background: Patients with relapsed/refractory B-cell non-Hodgkin lymphoma (R/R B-NHL) typically experience dismal outcomes. Although CD19 chimeric antigen receptor-T (CAR-T) cell therapy has shown considerable efficacy, the factors influencing its long-term efficacy remain unclear.

Methods: We retrospectively analyzed 79 R/R B-NHL patients treated with CD19 CAR-T cell therapy at our center to evaluate efficacy, long-term survival, and prognostic factors.

Results: Among all evaluable patients, the overall response rate was 89.7%, with a 3-year duration of response (DOR) of 44.9% (95% CI, 34.2%-59.0%), a 3-year progression-free survival (PFS) of 40.2% (95% CI, 30.3%-53.4%), and a 3-year overall survival (OS) of 48.3% (95% CI, 38.0%-61.3%). Long-term adverse events (AEs) included hypogammaglobulinemia, which occurred in 73 of 74 evaluable patients (92.4%), viral reactivation (5.1%), and secondary malignancy (5.1%). Notably, high tumor Ki-67 (> 60%) was associated with lower peak CAR-T cell expansion ($P < 0.01$), reduced area under the curve of expansion from day 0 to 28 ($P < 0.0001$), and inferior complete response rate, DOR, and PFS (all $P < 0.05$). However, CAR-T cell persistence was not significantly associated with long-term remission or survival (all $P > 0.05$).

Conclusions: CD19 CAR-T cell therapy yielded sustained remissions in patients with R/R B-NHL, with manageable long-term AEs. High tumor Ki-67 expression serves as a poor prognostic factor and is linked to limited CAR-T cell expansion, whereas CAR-T cell persistence does not influence long-term prognosis.

Disclosure: Nothing to declare

P285

CLINICAL OUTCOMES AND PREDICTORS OF INTENSIVE CARE ADMISSION IN LYMPHOMA PATIENTS TREATED WITH BISPECIFICS

Lucia Medina de Alba[1], ***Guillermo Ramos Moreno***[1], *Ana Cuervo Fonseca*[1], *Carmen Galiano*[1], *Tycho Baumann*[1], *Zaira Molina Collado*[1], *Silvia Chacón*[1], *Antonia Rodriguez Izquierdo*[1], *Joaquín Martínez López*[1], *Ana Jimenez Ubieto*[1]
[1]*Hospital 12 de Octubre, Madrid, Spain*

Background: CD3/CD20 bispecific antibodies, classified as bispecific T-cell engagers (BiTEs), have seen a rapid expansion in their use for lymphoma treatment. As their toxicity profiles and management strategies become better understood, identifying patients at higher risk of severe adverse events is increasingly important. Identifying risk factors for toxicity is essential to optimize patient management. This aim of this study is to analyze risk factors and clinical evolution of patients treated with bispecific antibodies requiring admission to the ICU.

Methods: Retrospective unicentric analysis on clinical predictors and adverse events in patients receiving bispecific therapy who require ICU admission form June 2019 to June 2025.

Results:

	No. of UCI Patients (n=5, 8.1%)	No. of Non-UCI Patients (n=57, 91.9%)
ECOG pre-treatment, median (range) Frailty Score pre-treatment, median (range)	1 (1-2) 3 (1-3)	0 (1-3) 2 (1-4)
Pre bispecific status • First line • Progressive disease • Partial response	5 (100)	18 (31.6) 36 (63.2) 3 (5.2)
Patients with life-threatening event	5 (100)	2 (3.5)
Inpatients monitoring for treatment administration	5 (100)	41 (71.9)

Interventions • Dexamethasone dose mg, median (range) • Tocilizumab, median (range) • Antibiotic therapy • Vasoactive drugs • Mechanical ventilation • Renal replacement therapy	70 (10-230) 2 (1-3) 5 (100) 5 (100) 0 (0) 0 (0)	20 (10-800) 1 (1-3) 30 (51.7)
Deaths • Progression • Toxicity	3 (60) 3 (100) 0 (0)	10 (17.5) 9 (90) 1 (10)

The study included 62 patients, 32 women (51.6%) and 30 men (48.4%), who received odronextamab (n=14, 22.6%), glofitamab (n=13, 20.9%), epcoritamab (n=16, 25.8%), or mosunetuzumab (n=19, 30.7%). Diagnoses comprised follicular lymphoma (n=34, 54.9%), DLBCL (n=25, 38.7%), mantle cell lymphoma (n=2, 3.2%), and marginal zone lymphoma (n=2, 3.2%). The median age at treatment initiation was 62 years (range 26–85).
CRS occurred in 33 patients (53.2%), predominantly grade 1–2 (85.7%), with 5 cases (14.3%) of grade 3. ICANS was observed in 4 patients (6.3%): two with grade 1 and two with grade 3, the latter deemed non-ICU candidates due to pre-existing comorbidities. Patients admitted to the ICU had significantly worse baseline ECOG performance status (χ^2=6.5, p=0.03), with no differences in Frailty Score. Forty-six patients (74.2%) were hospitalized preventively, no difference in ICU admission was observed between patients managed as outpatients (χ^2=1.8, p=0.1). 46 patients (74.2%) had preventive hospitalization, we foun7 patients (11.2%) developed severe complications requiring ICU-level supportive care: 2 patients (3.2%) with grade 3 CRS receiving full-dose treatment, 1 (1.6%) with a severe flare, 1 (1.6%) with sepsis, and 2 (3.2%) with neurotoxicity who were not considered ICU candidates. Median ICU stay was 3 days. ICU-admitted patients received

significantly more doses of tocilizumab (χ^2=6.7, p=0.03), but not steroids (χ^2=8.1, p=0.4). No deaths occurred during ICU admission; however, 3 patients died after being discharge due to disease progression. No significant difference in progression was observed among patients admitted to the ICU (χ^2=2.6, p=0.1). Table 1.

Conclusions: No significant differences in treatment-related toxicity were seen between ICU and ward patients. Mortality was mostly due to disease progression, with one therapy-related death in a non-ICU candidate. Outpatient administration appears feasible, as complications were infrequent and mild. Early recognition of severe complications is crucial to optimize outcomes.

Disclosure: Nothing to declare.

P286

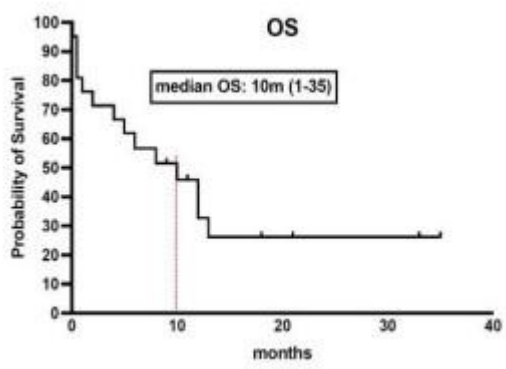
MANAGEMENT OF RELAPSED/REFRACTORY (R/R) B-NON HODGKIN LYMPHOMA (B-NHL) WITH ANTI-CD20/ANTI-CD3 BISPECIFIC ANTIBODIES (BSABS). A SINGLE CENTER EXPERIENCE

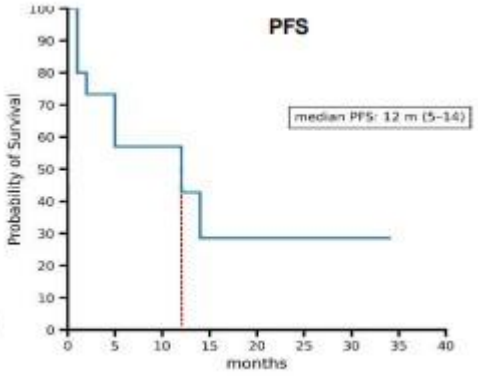
Antonios Patrinos[1], *Chara Giatra*[1], *Athanasios Gakopoulos*[1], *Michael Panousieris*[1], *Kyriaki Kontitsi*[1], *Eleni Porfyriou*[1], *Alexandra Kontoula*[1], *Alexandros Tolias*[1], *Kassiani Papanastasi*[1], *Pavlos Triantafyllou*[1], *Panagiotis Baroutas*[1], *Asimina Kiropoulou*[1], *Christos Masaoutis*[1], *Phoebi Rondogianni*[1], *Ioannis Baltadakis*[1], *Maria Bouzani*[1]
[1]*Evaggelismos General Hospital of Athens, Athens, Greece*

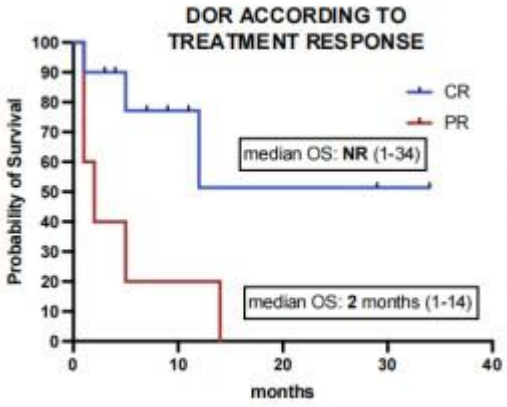
Background: Patients with R/R B-NHL are associated with unfavorable outcomes. Consequently, BsAbs appear to be a game changer in the treatment of B-NHL. Glofitamab, epcoritamab, and mosunetuzumab are all anti-CD20/anti-CD3 BsAbs, showing comparable efficacy and class distinct safety profiles. In view of their favorable profiles, we sought to describe our experience in treating patients with R/R DLBCL, FL or MCL in our department.

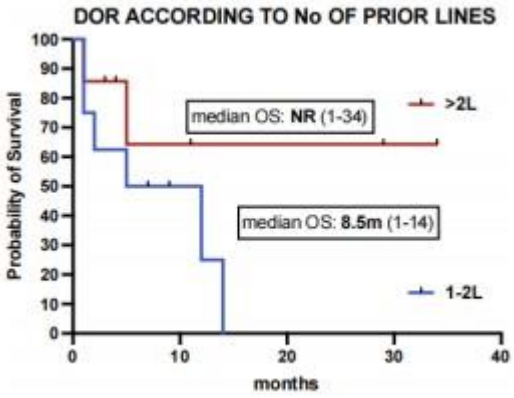
Methods: This is a real world, retrospective, observational, single Center study, based on data from 21 consecutive patients with DLBCL, FL and MCL, treated with BsAbs between 2021 - 2025. Efficacy was estimated based on ORR, OS, PFS and DOR after treatment. Safety was evaluated by retrieving data on adverse events, especially those considered to be treatment class specific, particularly CRS, ICANS, hematological toxicity, necessity for IVIG replenishment and incidence of opportunistic infections.

Results:









From a total of 21 patients (13 females, 8 males), 9 had DLBCL, 2 Grey Zone lymphoma, 2 PMBCL, 5 FL, 1 MCL and 2 Richter transformation. The median age upon 1st administration of a BsAbs was 59 years. Thirteen patients received Glofitamab, five epcoritamab and three mosunetuzumab. All had received at least 1 prior line of treatment. BsAbs preceded CAR-Ts in eight and allogeneic transplantation in one (bridging therapy). CRS (grade I n=5, grade II n=4, grade III n=4) occurred in 13 patients: 12 (1st cycle), 1 (3rd cycle). Any grade of CRS was associated with markedly elevated ferritin levels (>1000μg/mL). One patient developed ICANS grade II. Hematological toxicity was reported in all subjects and was well managed with G-CSF. Only 3 received IVIG replenishment. Best response assessment after BsAbs was feasible in 18/21 patients. ORR was 83.3% (15/18). Ten patients achieved CR, 5 PR and 3 had PD. Median time to best response was 1.76 months (0.8-4.2). With a median FU of 21 months (0.1-35) the median OS was 10 months (0.1-35). Median PFS for responders was 12 months (95% CI, 5–14). For complete responders, the median OS was not reached, whereas in partial responders it was only 2 months. Notably, patients with fewer prior lines of treatment had lower median OS, than more heavily pretreated ones. The former all had primary refractory disease and thus a more aggressive course. This imposed the earlier integration of BsAbs in the treatment sequence and it might explain the poorer survival of these patients. Most of the patients died due to disease progression or sepsis, three patients manifested CMV disease (encephalitis n=1, colitis n=2) and 1 HLH.

Conclusions: Anti-CD20/anti-CD3 BsAbs have already entered routine clinical practice for the treatment of R/R B-NHL. The majority of our patients benefited from BsAbs. Infections, nonetheless, remain a substantial challenge and a major cause of mortality. In accordance with the literature, CRS was manageable. Further real world evidence is required to estimate the suitable timing of articulation with CAR T-cell therapy and the optimal treatment sequencing.

Disclosure: Nothing to declare.

P287

MARIBAVIR TREATMENT IN AGGRESSIVE EBV-ASSOCIATED POSTTRANSPLANT LYMPHOPROLIFERATIVE DISORDER (EBV+ PTLD)

Wei-Han Huang[1], *Chi-Cheng Li*[1]
[1]*Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan (Province of China)*

Background: Epstein-Barr Virus-associated post-transplant lymphoproliferative disorders (EBV+ PTLD) have variable prognoses based on histology, stage, and ability to reduce immunosuppression. Standard treatment includes reducing immunosuppression (RIS) and R-CHOP chemoimmunotherapy. Novel therapies like EBV-specific cytotoxic T lymphocytes or chimeric antigen receptor T cell therapy are often not feasible. Maribavir (MBV) has demonstrated the ability to inhibit EBV BGLF4 viral protein kinase activity, thereby reducing viral genome copies and infectivity.

Methods: A 53-year-old woman with morbid obesity was diagnosed with HTLV-1-associated adult T cell leukemia/lymphoma (ATLL), stage IV, with lymphadenopathy, skin, and bone marrow involvement in August 2023. She received the VCAP-AMP-VECP regimen plus intrathecal chemotherapy for 4 cycles with Ropeginterferon alfa-2b for skin involvement. Following complications, including sepsis and right frontal lobe stroke, she underwent reduced-intensity conditioning (FB2 regimen) with 8/8 matched unrelated donor allogeneic peripheral blood stem cell transplantation on 2024/4/18. GVHD prophylaxis with cyclosporine and mycophenolate was tapered within three months due to *Pneumocystis jirovecii* pneumonitis. Disease relapsed in June 2025 with multiple extramedullary nodal lesions. Treatment included carmustine, brentuximab vedotin, venetoclax, azacitidine, and two donor lymphocyte infusions (5M/kg CD3+ T cells each). She developed severe liver and GI GVHD (bilirubin 15.4 mg/dL), requiring steroids, tacrolimus, mycophenolate, abatacept, ATG (1mg/kg), and ruxolitinib (40mg daily). Post-discharge, she was readmitted with *E. coli* urosepsis, carbapenem-resistant *Acinetobacter baumannii* pneumonia, and *Candida dubliniensis* infection, requiring ICU care with mechanical ventilation and hemodialysis.

Results: In September 2025, progressive neck lymphadenopathy developed with intermittent fever and rising EBV viral load. PET scan showed distinct lymphadenopathy patterns. Excisional biopsy confirmed EBV+ PTLD (EBER positive). Treatment consisted of immunosuppression reduction, maribavir 800mg daily for three weeks, single-dose

Ropeginterferon 250mcg, and one donor lymphocyte infusion (2M/kg CD3+ T cells). EBV viral load decreased from 23,300 IU/mL to 2,000 IU/mL with concurrent lymphoma regression. The patient continues low-dose tacrolimus and ruxolitinib for ongoing GI GVHD and maintains disease-free status.

Conclusions: Approximately half of EBV+ PTLD cases show relapse or resistance to initial RIS or Rituximab-based treatments. While no clinical trials have proven maribavir efficacy in EBV+ PTLD, this case demonstrates promising results in a complex post-transplant setting with multiple complications, highlighting the need for further research in this unmet medical need.

AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PRIMARY CNS LYMPHOMA: A SINGLE-CENTER EXPERIENCE OVER 10 YEARS

Filiz Vural[1], *Denis Bozer*[1], *Ajda Güneş*[1], *Nur Akad Soyer*[1]
[1]*Ege University Hospital, Hematology Department, İzmir, Turkey*

Background: Primary central nervous system lymphoma (PCNSL) is a rare and aggressive subtype of non-Hodgkin lymphoma (NHL). Despite advances in high-dose methotrexate–based induction therapies, the optimal consolidation strategy remains controversial. Autologous hematopoietic stem cell transplantation (auto-HSCT) has been used as a consolidation option in selected patients.

Methods: We retrospectively analyzed patients with PCNSL who underwent auto-HSCT in our center over the last 10 years. During this period, a total of 148 NHL patients received auto-HSCT, of whom 6 patients were diagnosed with PCNSL. Clinical data including demographic characteristics, pathological features, induction regimens, use of radiotherapy, conditioning protocols, and transplant-related outcomes were collected.

Results: A total of six patients with primary CNS lymphoma underwent autologous HSCT during the study period. All patients had diffuse large B-cell lymphoma histology. The mean age at diagnosis was 60 years (range 45–78), and four patients were female. Tumors demonstrated aggressive biological features, with Ki-67 proliferation indices ranging from 70% to 99%, and included both ABC and GCB cell-of-origin subtypes.
All patients received high-dose methotrexate–based induction therapy, followed by consolidative radiotherapy prior to transplantation. Conditioning consisted of BEAM in all cases, and autologous HSCT was successfully performed in every patient. No early (≤100-day) transplant-related mortality was observed.
With a median follow-up of 9.4 months (range 3,2–79.5), two patients remained alive at last follow-up, while four patients died, primarily due to disease progression. Three deaths occurred within the first year following transplantation, reflecting the aggressive clinical

course of the disease. One patient developed secondary acute myeloid leukemia after relapse.
Overall, despite intensive multimodal therapy including radiotherapy and autologous HSCT, long-term survival remained limited in this real-world cohort.

Conclusions: In this single-center experience, autologous HSCT was feasible in selected patients with PCNSL treated with a multimodal approach including radiotherapy. However, long-term survival remained limited, highlighting the aggressive nature of PCNSL and the need for improved consolidation strategies.

Clinical Trial Registry: Not applicable.

B405

OUTCOME OF SINGLE- AND DOUBLE-REFRACTORY HIGH-RISK CHRONIC LYMPHOCYTIC LEUKEMIA (CLL): THE IMPACT OF CELLULAR THERAPY

Joseph Kauer[1,2], Isabelle Krämer[1,2], Patrick Derigs[1,2], Maximilian F. Blank[1,2], Sascha Dietrich[1,2], Julia Meissner[1,2], Niklas Kehl[1,2], Mirco F. Friedrich[1,2], Maria Luisa Schubert[1,2], Elena Busch[1,2], Laura Classen[1,2], Anthony D. Ho[1,2], Anita Schmitt[1,2], Carsten Müller-Tidow[1,2], Michael Schmitt[1,2], ***Peter Dreger***[1,2]
[1]University of Heidelberg, Heidelberg, Germany, [2]Heidelberg University Hospital, Internal Medicine V, Hematology, Oncology and Rheumatology, Heidelberg, Germany*

Background: Guidelines suggest that patients with CLL refractory to both BTKi and BCL2i (double-refractory; DR) and those who have failed BTKi in the presence of *TP53* abnormalities and/or complex karyotype (high-risk single-refractory; SRHR) should be considered for alloHCT. The aim of this retrospective single-center study was to assess the prognosis of patients with SRHR and DR CLL, respectively, and the outcome of cellular therapy (CT; alloHCT and/or CART) in these high-risk categories.

Methods: SRHR was defined as CLL refractory to either BTKi or venetoclax (including relapse within 24 months after venetoclax cessation) in the presence of TP53 abnormalities and/or complex karyotype. DR was defined as refractory to both BTKi and venetoclax. Patients fulfilling these criteria were identified from electronic institutional databases. AlloHCT was performed according to institutional standards (PMI 30630979) from matched related or unrelated donors, and CART with the 3G-CD19 CART Heidagenlecleucel within a clinical trial (PMI 39192036). Primary endpoint for SRHR was event-free survival (EFS;

defining events progression to DR, transformation, and death) and for DR transformation-free survival (TFS; defining events transformation and death).

Results: Between 2016 and 2025, 37 patients were identified fulfilling SRHR criteria and 29 patients DR criteria. Since 18 patients evolved from SRHR to DR during their disease course, they appeared in both cohorts. Median age was 61 (41-83) years. In the SRHR cohort, 70% were BTKi-refractory and 30% venetoclax-refractory, and the HR-defining abnormality was TP53 in 89%. In the DR cohort, all patients were both BTKI- and venetoclax-refractory by definition, and 71% harbored TP53 abnormalities. Median EFS of the SRHR cohort was 23 months and median TFS of the DR cohort was 13 months; median OS of the SRHR and DR cohorts was 51 and 21 months, respectively (p=0.039). In the SRHR group 12 patients underwent CT after study entry (alloHCT 10; CART 2), while 16 additional patients received CT only after having reached DR status (alloHCT 9; CART 7). CT significantly improved EFS for SRHR (HR 0.15; 95%CI 0.06-0.34) and TFS for DR (HR 0.19; 95%CI 0.06-0.62), respectively, compared to patients not undergoing CT. Although PFS after alloHCT tended to be better than after CART (HR 0.46; 95%CI 0.16-1.29; p 0.076), OS was similar with both strategies. In individual patients, alloHCT failure could be salvaged with CART and vice versa. NRM was 16% after alloHCT and 0% after CART. Postponing CT until reaching DR status resulted in a numerically inferior OS from CT (4y-OS DR vs SRHR 29% vs 61%; HR 2.87; 95%CI 0.93-8.9; p 0.095).

Conclusions: These results demonstrate for the first time that the outlook of patients with SRHR CLL is dismal but still better than in patients with DR disease. In both settings, alloHCT and CART are feasible and may overcome clinical and biological disease refractoriness, with better results when used in SRHR status rather than DR status. However, the optimum timing and sequencing of CART and alloHCT, respectively, and the impact of CT on the natural course of SRHR/DR CLL remain to be determined.

P289

THE ROLE OF GENETIC SUSCEPTIBILITY GENES IN THE NECESSITY OF ALLOGENEIC TRANSPLANTATION FOR RICHTER SYNDROME

Shaomei Feng[1]
[1]*Beijing GoBroad Boren Hospital, Beijing, China*

Background: Richter syndrome (RS) has historically been considered curable only through allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, recent advances in chimeric antigen receptor (CAR) T-cell therapy are challenging this paradigm. This study investigates the potential utility of genetic susceptibility testing in guiding clinical decisions regarding the need for allo-HSCT in RS patients who achieve complete remission (CR) following CAR-T therapy.

Methods: A retrospective analysis was performed on the clinical data of a 63-year-old male patient with RS. The patient was initially diagnosed with chronic lymphocytic leukemia (CLL), which later transformed into plasmablastic lymphoma (PBL); clonal relatedness to the original CLL was confirmed by immunoglobulin gene rearrangement and genetic profiling. Following BCMA-targeted CAR-T cell therapy, the patient achieved CR. High-throughput DNA sequencing was conducted on peripheral blood samples to screen for pathogenic variants across more than 900 genes associated with hematologic and immune disorders. Clinical outcomes and therapeutic strategies were evaluated in conjunction with the patient's genetic and disease course.

Results: Genetic analysis identified four pathogenic or likely pathogenic variants: TNFRSF13C c.62C>G (p.P21R) (variant allele frequency 54.29%), associated with impaired BAFF receptor function and increased susceptibility to non-Hodgkin lymphoma (NHL) and immunodeficiency; ALPK2 c.5557C>G (p.Q1853E) (46.7%), linked to loss of tumor suppressor activity and elevated risk of angioimmunoblastic T-cell lymphoma and colorectal cancer; STK11 c.1062C>G (p.F354L) (48.67%), associated with reduced AMPK signaling, Peutz-Jeghers syndrome, and predisposition to multiple malignancies; and BTLA c.590A>C (p.N197T) (100%), resulting in aberrant T-cell inhibitory signaling and increased risk of B-cell lymphomas. Additionally, 12 variants predicted to be potentially deleterious by in silico analysis were detected. The overall genetic profile indicated a high inherited risk for hematologic neoplasms, leading to a recommendation for allo-HSCT. However, the patient declined transplantation and instead received consolidation therapy with a Bruton tyrosine kinase (BTK) inhibitor. Fourteen months after CAR-T therapy, the patient experienced relapse, with pathological confirmation of classical Hodgkin lymphoma (cHL). Immunoglobulin gene rearrangement analysis revealed no clonal relationship to the prior CLL/PBL, suggesting a de novo second primary malignancy. The patient achieved CR again following treatment with ABVD and D-AVD chemotherapy regimens and was subsequently scheduled for allo-HSCT.

Conclusions: This case demonstrates that multiple germline pathogenic variants affecting critical pathways—such as B-cell survival (TNFRSF13C), apoptosis and metabolic regulation (STK11), and immune checkpoint signaling (BTLA)—contribute to an underlying high tumor susceptibility. Although CAR-T therapy induced durable remission initially, the persistent genetic predisposition may have facilitated the development of a secondary malignancy.

Evidence suggests that STK11 mutations impair DNA damage repair mechanisms, accelerating malignant transformation, while TNFRSF13C deficiency may compromise CAR-T cell persistence due to altered microenvironmental support. These findings underscore the importance of considering allo-HSCT as a consolidative strategy in genetically high-risk RS patients, even after achieving CR with CAR-T therapy, to mitigate long-term risks of relapse and secondary cancers.

Background: The CARTITUDE-4 study (NCT04181827), which enrolled patients with lenalidomide-refractory multiple myeloma (MM) after 1–3 prior lines of therapy (pLOT), demonstrated a significant benefit of ciltacabtagene autoleucel (cilta-cel) over established triplet regimens. However, the benefit of cilta-cel for patients with standard-risk cytogenetics remains less defined. Here, we report outcomes in patients with standard-risk cytogenetics from the intent-to-treat and as-treated populations in CARTITUDE-4.

Methods: In CARTITUDE-4, patients randomised to the cilta-cel arm underwent apheresis and bridging treatment with either pomalidomide, bortezomib and dexamethasone (PVd) or daratumumab, pomalidomide and dexamethasone (DPd), followed by lymphodepletion therapy with cyclophosphamide and fludarabine, and then a single cilta-cel infusion. Progression-free survival (PFS) was assessed using a validated computerised algorithm. The intent-to-treat population included 208 patients; 32 patients progressed or died on bridging therapy, resulting in an as-treated population of 176 patients. Patients with high-risk cytogenetics, defined as del(17p), t(14;16), t(4;14), gain/amp(1q) (n=105), or with unknown cytogenetics (n=12), were excluded from the as-treated analysis. The 12-month minimal residual disease (MRD)-negative complete response (CR) was defined per the International Myeloma Working Group criteria as the proportion of participants with CR or better prior to and at 12 months (+/- 3 months), achieving MRD-negative status at 12 months (+3 months) after cilta-cel infusion, as determined by next-generation sequencing (10^{-5}), prior to progressive disease or subsequent anti-myeloma therapy. For the as-treated population, PFS rates were measured from the time of cilta-cel infusion.

Results: In CARTITUDE-4, in the intent-to-treat population, at a median follow-up of 33.6 months, patients with standard-risk cytogenetics had a 30-month PFS rate (95% CI) of 71.0% (58.8–80.2) in the cilta-cel arm (N=69) vs 43.2% (31.3–54.5) in the standard-of-care (SOC) arm (N=70). Patients with standard-risk cytogenetics in the as-treated population (n=59) had a 30-month PFS rate of 80.5% (95% CI, 67.2–88.8). In CARTITUDE-1 (NCT03548207), which evaluated cilta-cel in patients with heavily pretreated relapsed/refractory MM (RRMM; ≥3 pLOT), the 30-month PFS rate among patients with standard-risk cytogenetics (negative for del(17p), t(14;16), or t(4;14); n=68) was 59.9% (95% CI, 47.2–70.5). In the CARTITUDE-4 as-treated population with standard-risk cytogenetics, 8 PFS events occurred within 1 year and 4 PFS events beyond 1 year of cilta-cel infusion. Twenty-six patients achieved MRD-negative CR at 12 months after cilta-cel; 100.0% of these patients were progression free at 30 months. Fourteen patients were not evaluable for MRD due to: calibration failure (n=12), no sample availability for testing (n=1) or indeterminate results post baseline (n=1).

Conclusions: PFS rate at 2.5 years for patients with standard-risk RRMM was higher in CARTITUDE-4 compared with CARTITUDE-1, supporting the use of cilta-cel as early as second line in the treatment course. In CARTITUDE-4 (as-treated population), 80.0% of patients with standard-risk cytogenetics were progression free and off treatment at 2.5 years. In patients with standard-risk cytogenetics who achieved MRD-negative CR at 1 year, this rate increased to 100.0%. The low rate of progression events in cilta-cel-treated patients with standard-risk cytogenetics shows the profound benefit of a single cilta-cel infusion in this population. © *American Society of Hematology (2025). Background: Effective tumour burden reduction using bridging therapy has been associated with better progression-free survival (PFS) and safety outcomes in patients treated with ciltacabtagene autoleucel (cilta-cel). A single infusion of cilta-cel in CARTITUDE-4 (median follow-up, 33.6 months) significantly improved PFS (hazard ratio [HR] weighted, 0.29 [95% CI, 0.22–0.39]) and overall survival (OS; HR, 0.55 [0.39–0.79]; *P*=0.0009) versus standard of care in patients with relapsed and lenalidomide-refractory multiple myeloma after 1–3 prior lines of therapy. Here, we investigate the correlation between bridging therapy response pre-cilta-cel infusion with the efficacy and safety outcomes post-infusion.

Methods: The CARTITUDE-4 study design has previously been described. Patients in the cilta-cel arm underwent apheresis, received ≥1 cycle of bridging therapy (investigator's choice) with either pomalidomide, bortezomib and dexamethasone (PVd) or daratumumab, pomalidomide and dexamethasone (DPd), lymphodepletion (cyclophosphamide and fludarabine), and then a single cilta-cel infusion 5–7 days post-initiation of lymphodepletion.

Results: Among 196 patients who received cilta-cel in CARTITUDE-4 (176 as study treatment, 20 as subsequent therapy), 172 (87.8%) received DPd and 24 (12.2%) received PVd during bridging period (median number of bridging cycles, 2 [range, 1–6]). Following bridging therapy and pre-lymphodepletion, 42 patients had very good partial response or better (≥VGPR), 70 had partial response (PR), 61 had minimal response (MR)/stable disease (SD), 20 had progressive disease (PD) and 3 were not evaluable. Thirty-month PFS rates (95% CI) from cilta-cel infusion were 75.9% (59.8–86.2), 72.9% (60.4–82.1), 56.5% (42.8–68.1) and 30.0% (12.3–50.1), respectively. Thirty-month OS rates (95% CI) were 85.1% (69.9–93.0), 91.4% (81.9–96.1), 74.8% (61.6–84.0) and 40.0% (19.3–60.0), respectively.

No movement or neurocognitive treatment-emergent adverse events (MNTs) were reported in patients with ≥VGPR or PR. There was 1 MNT case in patients with PD and 1 in a patient with a best response of SD (unconfirmed PD at cilta-cel infusion). Cranial nerve palsy was reported in 11.9%, 7.1%, 8.2% and 5.0% of patients with ≥VGPR, PR, MR/SD and PD, respectively. Fatal infections occurred in 2.4%, 4.3%, 13.1% and 15.0%, respectively. Rates of prolonged (grade 3/4 cytopenia that did not recover to grade 2 by day 60 post-cilta-cel) thrombocytopenia were lowest among patients who achieved ≥VGPR (9.5%), followed by patients with PR (11.4%) or MR/SD (11.5%) after bridging, and markedly higher in those with PD (50%). Prolonged neutropenia was lowest in patients achieving ≥VGPR before cilta-cel (2.4%) vs 9.8–15.7% in patients with PR or lower. Non-relapse mortality was 7.1%, 8.6%, 18.0% and 30.0% in patients with ≥VGPR, PR, MR/SD, and PD, respectively.

Conclusions: In patients from CARTITUDE-4, better response to bridging therapy correlated with longer PFS and OS. No MNTs were observed in patients who achieved ≥PR following bridging therapy. Patients with poorer responses to bridging therapy were more likely to develop fatal infections, prolonged thrombocytopenia and neutropenia, and had higher rates of non-relapse mortality following cilta-cel infusion. These data emphasize the importance of optimizing bridging therapy for disease control prior to receiving cilta-cel. © *American Society of Hematology (2025). Reused with permission*.

Background: Minimal residual disease (MRD) negativity and sustained MRD negativity are associated with longer survival and are strong prognostic clinical endpoints. PERSEUS (NCT03710603) evaluated subcutaneous Dara + VRd induction/consolidation + DR maintenance vs VRd induction/consolidation + R maintenance in TE NDMM. DVRd significantly improved progression-free survival (PFS), complete response or better rate (≥CR), and MRD negativity rate. Nearly two-thirds of patients on DR maintenance could stop treatment after achieving sustained remission, leading to DVRd being recommended by NCCN as a preferred TE NDMM regimen. Here, we report the impact of sustained MRD negativity status on PFS in PERSEUS.

Methods: TE patients with NDMM age 18–70 years were randomized 1:1 to DVRd (DVRd induction/consolidation + DR maintenance) or VRd (VRd induction/consolidation + R maintenance). The primary endpoint was PFS; MRD negativity rate (MRD negativity 10^{-5} and ≥CR) was a key secondary endpoint. Sustained MRD negativity, assessed in the intent-to-treat population, was defined as confirmed MRD negativity ≥12 months apart and without MRD positivity in between. Functionally high risk (FHR) was defined as disease progression ≤18 months from treatment initiation, excluding pre-progression deaths.

Results: A total of 709 patients were assigned to DVRd (n=355) or VRd (n=354). At 47.5-month median follow-up, ≥12-month sustained MRD negativity rates were higher overall with DVRd (64.8%; n=230) vs VRd (29.7%; n=105); this pattern persisted across clinically relevant subgroups, including age ≥65 years and high-risk cytogenetics. Similarly, ≥24-month sustained MRD negativity rates were higher with DVRd (55.8%; n=198) vs VRd (22.6%; n=80). Patients with ≥12-month sustained MRD negativity vs those without had improved 48-month PFS rates regardless of treatment arm (**Table**). Compared with VRd, DVRd reduced FHR rates (3.1% vs 6.8%), and rates of FHR or pre-progression deaths were lower with DVRd vs VRd (5.4% vs 11.0%) in the first 18 months.

Conclusions: In TE NDMM, nearly two-thirds of patients treated with DVRd induction/consolidation and DR maintenance achieved ≥12-month sustained MRD negativity, associated with >95% 48-month PFS rate. Moreover, ≥24-month sustained MRD negativity rates with DVRd were 2.5 times as high as VRd, and FHR incidence was halved with DVRd vs VRd. Collectively, these data further support the PERSEUS regimen as standard of care for TE NDMM. *© 2025 American Society of Clinical Oncology, Inc. Reused with permission. Background: Idecabtagene vicleucel (ide-cel) and ciltacabtagene autoleucel (cilta-cel), two B-cell maturation antigen (BCMA)–directed chimeric antigen receptor (CAR) T-cell therapies, have demonstrated remarkable efficacy in relapsed/refractory multiple myeloma (RRMM). We hereby compare safety, efficacy, and survival among patients with RRMM treated with standard-of-care ide-cel or cilta-cel.

Methods: The CTIWP and the CMWP performed a retrospective study based on the European Society of Blood and Marrow Transplantation registry, including all patients receiving ide-cel or cilta-cel between 2020 and 2024 for RRMM with available one year follow-up outcome data.

Results: Overall, 785 patients met the inclusion criteria, with 599 (76.3%) patients receiving ide-cel and 186 (23.7%) patients receiving cilta-cel. The median age was 65 years in both groups (range: 18.4-89.2), 60.9% of the patients were male, and 93.5% had an Eastern Cooperative Oncology Group performance status of 0-1. Most patients received CAR T-cell therapy after at least three lines of treatment. There was no difference regarding exposure to prior BCMA-directed therapy between both groups (6.1% in the ide-cel group versus 5.3% in the cilta-cel group). More patients were penta-refractory in the ide-cel group, 21%, versus 9.8% in the cilta-cel group.
Median follow-up was 12.1 (range, 6.5 to 23.7) months. The 30-day incidence of all grade cytokine release syndrome (CRS) was higher in the ide-cel group, being 77% versus 63% in the cilta-cel group ($p<0.001$), the corresponding grade >=3 CRS was 6% versus 2% ($p=0.048$). There was no difference in the day 30 incidence of all grade ICANS, 10% in the ide-cel group, versus 12% in the cilta-cel group ($p=0.4$), while the day 30 incidence grade >=3 ICANS was 2% in both groups. More patients achieved a response (complete response [CR]+very good partial response [VGPR] +partial response) in the cilta-cel group, 95.4%, versus 88.2% in the ide-cel group. At one-year, overall survival (OS) and progression-free survival (PFS) were significantly higher in the cilta-cel group, being 84% and 78%, respectively versus 78% and 53% respectively, in the ide-cel group ($p=0.024$ and $p<0.001$ respectively). At 12 months, the cumulative incidence of CAR T-cell related mortality (4% in the ide-cel group versus 7% in the cilta-cel group; $p=0.4$) was similar in both groups. In multivariable analysis (Cox model), MM status at time of CAR T-cell therapy (not being in CR/VGPR) and prior exposure to BCMA-directed therapies were associated with a lower OS. Use of ide-cel was also associated with a lower PFS (HR, 0.38 (0.25-0.56), $p<0.001$).

Conclusions: This large real-world comparison of anti-BCMA CAR T-cell therapy for RRMM demonstrates that use of cilta-cel translates to superior efficacy and PFS. Regarding safety, there was no difference in non-relapse mortality between treatment groups. The higher rate of CRS, (including grade>=3), in the ide-cel group, could be related to the fact that patients in the cilta-cel cohort were treated more recently with improvements in CRS prevention and treatment over time.

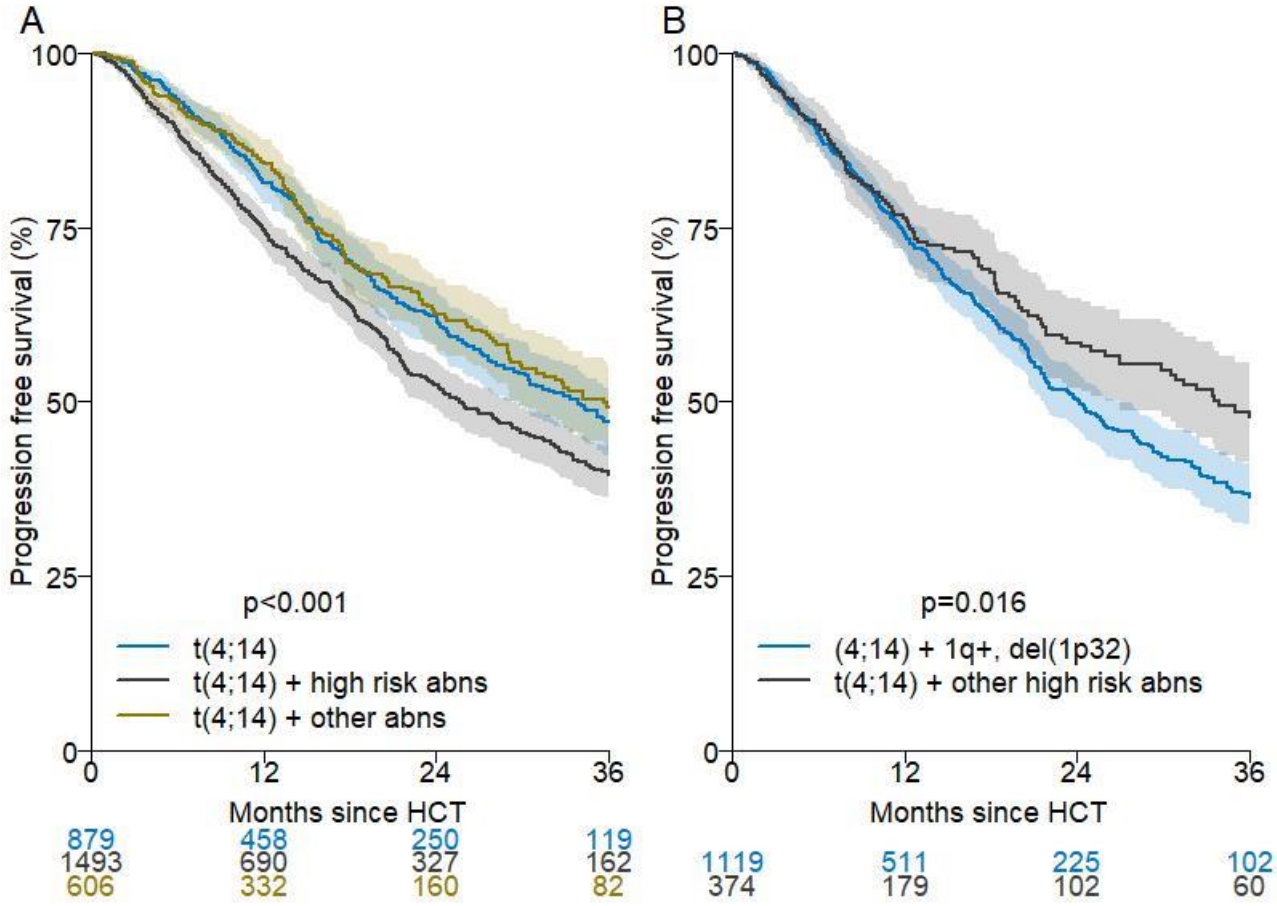
Background: Upfront autologous hematopoietic cell transplantation (auto-HCT) remains the standard of care for younger fitter patients with newly diagnosed multiple myeloma (MM). Both single and tandem auto-HCT strategies are used, depending on the disease risk profile. Fluorescence in Situ Hybridisation (FISH) cytogenetic abnormalities are important prognostic markers of progression-free (PFS) and overall survival (OS) in MM. We here report on the outcomes of patients with t(4;14) multiple myeloma following auto-HCT.

Methods: MM patients aged ≥18 years old with t(4;14) who underwent their first auto-HCT between 2016 and 2022 were selected from the EBMT registry. OS and PFS were analyzed using Kaplan-Meier methods. The cumulative incidence of relapse (RI) and non-relapse

mortality (NRM) were analyzed together in a competing risks framework. Patients were stratified into three groups by the presence of co-existing cytogenetic abnormalities as follows: (1) t(4; 14) as the only detected abnormality, (2) International Myeloma Society (IMS)-defined high risk myeloma based on either t(4;14) with co-existing chromosome 1 abnormalities (1q+ or del(1p32)),or, alternatively, del(17p), t(14;16), or t(14;20), and (3) t(4;14) with any other abnormalities. Additional analysis was performed for the cohort with t(4;14) with 1q+ or del(1p32).

Results:



Overall, 3,103 patients were included. The median age at the first auto-HCT was 60 years (IQR, 54, 65). 1,706 (55%) were male. 573 (23%), 999 (40%), and 898 (36%) patients had ISS stage I, II or III myeloma, respectively. 914 (30%) patients had t(4;14) only, 1,564 (50%) had additional high-risk abnormalities of whom 1,169 (75%) had 1q+ or del(1p32), and 625 (20%) had other abnormalities. The median time from diagnosis to auto-HCT was seven months (IQR, 5, 9). 2,301 (74%) patients achieved a VGPR or better at auto-HCT and 2,312 (75%) patients received Melphalan 200mg/m2 conditioning.
The 3-year PFS and OS for the whole group were 44% (95%CI, 41-46%) and 72% (95%CI, 70-75%), respectively. The 3-year PFS estimates stratified by the three cytogenetic

subgroups were (1) 47% (42-52%), (2) 40% (36-43%) and (3) 49% (43-55%) (p<0.001) (Figure 1A). The respective OS outcomes were 79% (75-83%), 66% (62-69%), and 77% (73-82%) (p<0.001), respectively. RI at 3 years was 53% (50-56%) for the whole group and 50% (46-55%), 56% (53-60%), and 48% (42-54%) for the three subgroups (p<0.001). NRM did not differ between groups (p=0.5) and reached 3% (2-4%) at three years for the entire cohort.
Patients with t(4;14) and either 1q+ or del(1p32) had inferior PFS compared with patients with other high-risk abnormalities [3-year PFS 36% (32-41%) vs. 48% (41-55%), p=0.016] (Figure 1B) due to a higher RI [3-year RI, 59% (55-64%) vs. 48% (41-56%), p=0.018]. There was no difference in OS between the two groups [3-year OS 65% (61-69%) vs. 69% (63-75%), p=0.4] or in NRM.

Conclusions: Patients with t(4;14) and additional co-existing high-risk cytogenetic abnormalities, especially either 1q+ or del(1p32), continue to have significantly poorer outcomes after auto-HCT [vs OS of 81% at 4 years in the IFM-2009 trial Transplant Arm cohort (RVd+ASCT)].

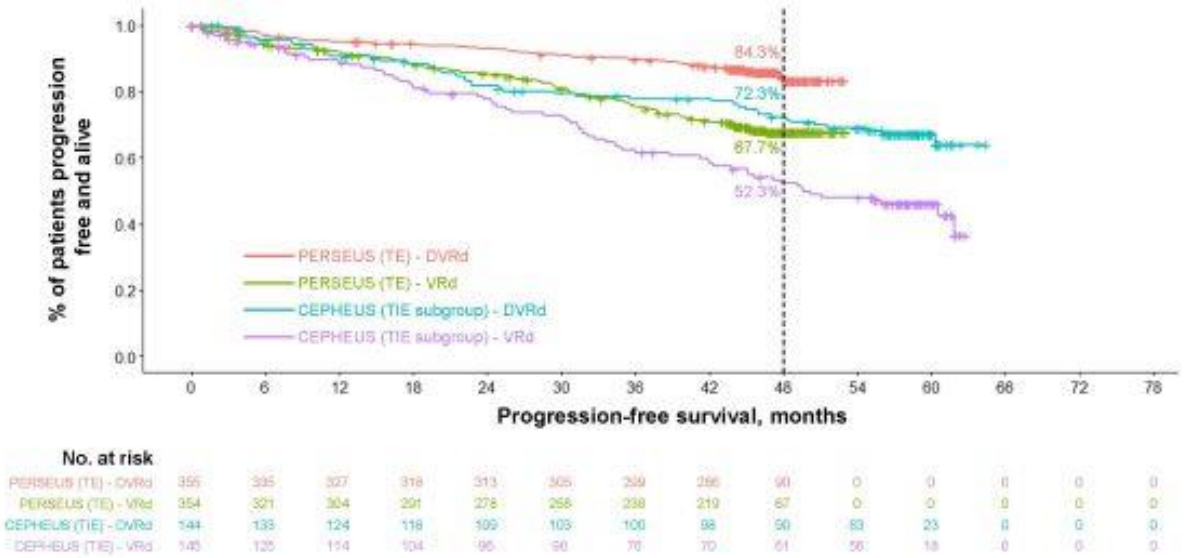
Background: Quadruplet therapy consisting of daratumumab, bortezomib, lenalidomide, and dexamethasone (DVRd) plus DR maintenance therapy showed superior efficacy to VRd with R maintenance in patients with transplant-eligible (TE) newly diagnosed multiple myeloma (NDMM) in the PERSEUS trial, and the CEPHEUS trial showed superiority of DVRd over VRd in transplant-ineligible (TIE) or transplant-deferred patients with NDMM; this analysis aims to extrapolate progression free-survival (PFS) data from the PERSEUS trial intent-to-treat (ITT) population and the TIE subgroup of CEPHEUS to estimate long-term outcomes of DVRd in the frontline setting.

Methods: Following UK National Institute for Health and Clinical Excellence (NICE) guidance on survival data extrapolation, 7 parametric distributions were fitted to model PFS data: exponential, Weibull, gamma, Gompertz, log-logistic, log-normal, and generalized gamma. Individual parametric curves were fit for the DVRd and VRd groups. Long-term extrapolations were capped by UK general population data for 2020–2022 on disease-specific and all-cause mortality, utilizing the median age of the population and the proportion of male patients in the cohort at the initiation of treatment (per NICE guidance). PFS projections begin at the median age of the population.

Results: In PERSEUS, 709 TE patients were randomized (DVRd, n=355; VRd, n=354), with median age 60 years and 59% male. In CEPHEUS, 289 TIE patients were randomized (DVRd, n=144; VRd, n=145), with median age 72 years and 51% male. Observed Kaplan-Meier estimates of PFS at 48 months in TE patients in PERSEUS were 84.3% vs 67.7% in the DVRd and VRd groups, respectively; for TIE patients in CEPHEUS, they were 72.3% vs 52.3% (**Figure**). Based on PFS modeling in the PERSEUS TE population, the range of estimated median PFS across all distributions was 158–255 months (13.2–21.2 years) for the DVRd group and 76–119 months (6.3–9.9 years) for the VRd group. The exponential distribution (best fit) gave PFS estimates of 205 vs 87 months (17.1 vs 7.3 years) for DVRd and VRd, respectively. For the CEPHEUS TIE population, the range of estimated median PFS across distributions was 96–118 months (8.0–9.8 years) for the DVRd group and 52–54 months (4.3–4.5 years) for the VRd group, with the exponential distribution (best fit) giving estimates of 100 vs 53 months (8.3 vs 4.4 years) for DVRd and VRd, respectively.

Conclusions: Across all 7 distributions, PFS projections were significantly longer with DVRd than VRd in both TE and TIE patients with NDMM. As expected, projected PFS with DVRd was longer for TE patients (205 months from baseline age of 60 years) than TIE patients (100 months from age 72 years). These extrapolations provide supportive projections beyond the observed PFS data, helping to inform treatment decisions and reinforcing the benefit of DVRd with a daratumumab-containing maintenance regimen in all patients with NDMM.

Figure: Observed PFS in TE and TIE patients treated with DVRd or VRd in the PERSEUS and CEPHEUS studies



Clinical Trial Registry: Clinicaltrials.gov: NCT03710603 (PERSEUS), NCT03652064 (CEPHEUS); EudraCT number: 2018-002992-16 (PERSEUS)

Background: Early relapse (ER) within 12 months of Autologous Hematopoietic Cell Transplantation (AHCT) is deemed functionally high risk disease. We developed the EBMT early relapse (ER) score based on the International Staging System (ISS), Performance Status and Disease Status (pre-AHCT) (Beksac et al, BMT 2023). This score was based on data from patients aged 40-70 years transplanted with Melphalan 200mg/m2 between 2014 and 2017 and was later validated by the WAUSTIM collaborative group (ASH 2024).
To validate the score in a more recent patient cohort following treatment with more effective induction regimens taking into account the cytogenetic risk classification.

Methods: We selected MM patients from the EBMT Registry who received their first AHCT between 2020 and 2022. We assessed the predictive performance of the EBMT ER score both in terms of discrimination and calibration. Furthermore, we explored possible refinements of the original model and the interplay with cytogenetic risk.

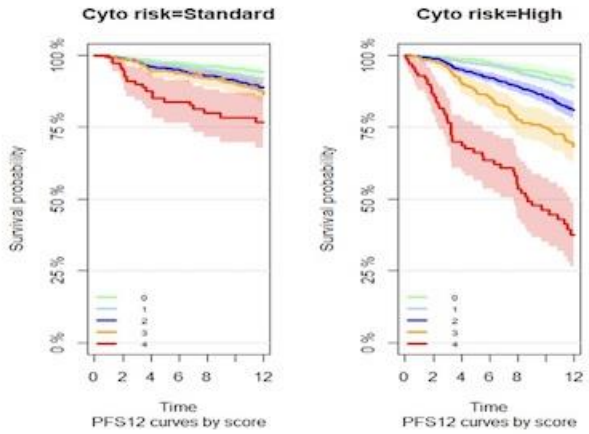
Results: In total 8,833 patients were eligible for the analysis. Median age at AHCT was 61 (range 23-83) years. IgG /IgA/light chain: 53.0%/18.8%/25.4%. Disease status at AHCT was CR/VGPR/PR: 20.8%/51.2%/25.1%. ISS at diagnosis was I/II/III: 34.5%/ 37.5%/ 28.1%; Karnofsky score prior to AHCT-1: ≤70/80/90/100: 6.9%/ 25.9%/ 35.6%/ 31.6%. Cytogenetic risk was standard/high (t(4;14),t(14;16),17pdel): 63.1%/36.9%. Patients received Mel 200/ Mel140: 69.0%/ 10.2%. Regardless of Melphalan dose, 12-month PFS (PFS-12) was 87.9% (95% CI 87.0-88.7) with an ER incidence of 10.4%. which is similar to that observed in the original EBMT study (Mel200 training: 14.7%, Mel200 validation: 11.6%, Mel140: 16.9%).
The EBMT ER score distribution was: 0/1/2/3/4: 22.9% /35.3%/ 31.0%/ 8.4%/ 2.4%. PFS-12 (95% CI) according to scores were as follows: score 0: 94% (92-95); score 1: 91% (90-92); score 2: 86% (84-87); score 3: 78% (75-82); score 4: 58% (50-66) resulting in Hazard Ratios (HRs) compared with the score 0 group: score 1: 1.45; score 2: 2.38; score 3: 3.69; score 4: 9.52 (all p values<0.005). The EBMT ER score behaved similarly in both the original and current populations with a clear separation of curves between groups. Neither age nor Melphalan dose had an impact on PFS-12. There were more ISS III and fewer ISS I cases in the high cytogenetic risk group. In addition, more high cytogenetic risk patients had undergone tandem AHCT (27.6 vs.10.6%). EBMT ER scores 3 or 4 were more frequent among high cytogenetic risk patients (13.0% vs. 9.5%). Cytogenetic high risk vs standard risk PFS-12: 82.7% (95% CI: 81.1-84.4) vs. 90.9% (95%CI: 89.9-91.8); p-value<0.0001). HR for cytogenetics high risk was 1.72 (95% CI: 1.48-1.99 (p<0.0001). In a Cox model, high risk cytogenetics was introduced for each ER score; high cytogenetics risk interacted significantly with scores 3 or 4; there was no significant interaction with score groups 1 or 2.

Conclusions:

Table-1: Distribution and impact of EBMT ER Score on PFS-12 across all patients, standard-risk or high risk patients

		All pts		cyto risk=Standard		cyto risk=High	
EBMT ER score	N (%)	PFS12	95%CI	PFS12	95%CI	PFS12	95%CI
0	2,023 (22.9%)	94%	(92-95)	94%	(93-96)	92%	(89-95)
1	3,118 (35.3%)	91%	(90-92)	92%	(90-93)	89%	(86-91)
2	2,734 (31.0%)	86%	(84-87)	89%	(87-91)	81%	(78-84)
3	744 (8.4%)	78%	(75-82)	86%	(82-91)	68%	(62-75)
4	214 (2.4%)	58%	(50-66)	77%	(68-86)	38%	(26-49)

Figure-1: PFS-12 curves according to EBMT ER score among standard and high cytogenetic risk patients



We have here validated the score regardless of conditioning dose or age. We observed an association between ISS and cytogenetic risk. Cytogenetic risk added to the ER score provided additional predictive value. In conclusion, the EBMT ER score is a widely applicable predictive tool capable of indentifying functionally high risk patients.

INTENSIFIED CONSOLIDATION WITH TANDEM AUTOLOGOUS VERSUS AUTOLOGOUS/REDUCED-INTENSITY CONDITIONING ALLOGENEIC STEM CELL TRANSPLANTATION FROM RELATED OR UNRELATED DONORS IN FIRST-LINE THERAPY IN 149 HIGH-RISK MYELOMA PATIENTS

Melanie Rauch[1], Wolfram Pönisch[1], Madlen Jentzsch[1], Tanja Holzhey[1], Simone Heyn[1], Susann Fricke[1], Thoralf Lange[2], Georg-Nikolaus Franke[1], Vladan Vučinić[1], Markus Scholz[3], Dietger

Niederwieser[1], Maximilian Merz[1], Uwe Platzbecker[1], Klaus Metzeler[1], ***Song-Yau Wang***[1]
[1]University Leipzig Medical Center, Department for Hematology, Cellular Therapy, Hemostaseology and Infectious Diseases, Leipzig, Germany, Leipzig, Germany, [2]Hospital Weißenfels, Hematology and Oncology, Weißenfels, Germany, [3]University of Leipzig, Institute for Medical Informatics, Statistics and Epidemiology (IMISE), Leipzig, Germany, Leipzig, Germany

Background: Autologous/reduced-intensity conditioning allogeneic stem cell transplantation (SCT) has curative potential in multiple myeloma (MM), by combining the dual effect of the direct cytotoxicity of autologous SCT (ASCT) and the graft-versus-myeloma effect of reduced-intensity conditioning allogeneic SCT (RICallo-SCT).

Methods: This analysis included all consecutive patients with newly diagnosed high-risk (HR) MM who received a 2nd ASCT or a RICallo-SCT as intensified consolidation. The indication for performing a 2nd autologous or RICallo-SCT was the presence of <VGPR after 1st ASCT or a HR genetic profile with del(17p), t(4;14) and t(14;16). Additional del13q14 and R-ISS III were temporarily defined as HR. If an HLA identical donor was available, RICallo-SCT was preferred. The 2nd ASCT or RICallo-SCT was performed 3-6 months after the 1st ASCT. The RICallo regimen included fludarabine 30mg/m2 for 3 days plus total-body irradiation 2 Gy (analogous to Seattle Protocol). Prophylaxis of graft-versus-host disease (GvHD) consisted of cyclosporine and mycophenolate mofetil.

Results: 149 HR MM patients underwent a 2nd ASCT (n=84) or RICallo-SCT (n=65) between January 1, 2000 and December 31, 2022. 33 patients received graft from matched related donors (MRD) and 32 patients from matched unrelated donors (MUD).
Tandem-ASCT: with a median follow-up of 93 months of surviving MM patients, median progression-free survival (PFS) and overall survival (OS) were 36 and 78 months, respectively. The ≥VGPR rate rose from 61 (n=51) to 83% (n=70). The relapse mortality rate after one year was 4% and after ten years 46%. Non-relapse-mortality (NRM) was 0% at day 100, 1% (n=1) at one year and 11% (n=9) at ten years.
RICallo-SCT: median PFS and OS were 33 and 80 months, respectively. The ≥VGPR rate increased from 62 (n=40) after 1st ASCT to 86% (n=56) after RICallo-SCT. The relapse mortality rate after one year was 8% (n=5) and after ten years 39% (n=25). NRM was 12% (n=8) at day 100, 15% (n=10) at one year and 25% (n=16) at ten years. Acute GvHD and treatment-related complications were the only reason of the 10 NRM in the first year.
MRD- vs. MUD-RICallo: There was no difference in median PFS between MUD and MRD groups (26 vs 33 months; p=0.4). However, patients in the MUD cohort had an inferior median OS compared to the MRD cohort (46 vs 107 months; p<0.05). The reason for the different OS was the significantly higher occurrence of acute GvHD-triggered deaths in the MUD (n=9; 28%) than in the MRD group (n=1; 3%) (p<0.01).
MRD-RICallo vs Tandem-ASCT: Compared to the Tandem-ASCT group, a trend for better OS was observed in the MRD RICallo group in the long-term follow-up from 36 months onwards. One reason for this is the slightly higher relapse mortality in the Tandem-SCT patients (n=38; 46%) compared to the MRD transplanted patients (n=11; 33%) in the first 10 years.

Conclusions: For selected patients with HRMM, MRD-RICallo-SCT according to the Seattle protocol is a treatment option. However, our results indicate that MUD carries a higher risk

due to a significantly increased treatment-related mortality rate and therefore cannot be recommended.

Background: The erythrocyte Duffy null phenotype, which is associated with lower absolute neutrophil count, plays a key role in cytokine homeostasis, and has known effects on the inflammasome, is present in ~66% of African American (AA) and <1% of White patients and may impact MM pathobiology. We previously reported analyses of progression-free survival (PFS) by Duffy genotype in an initial cohort in the DETERMINATION phase 3 trial (Merz, EBMT 2025) exploring Duffy null status as a pathobiological explanation for differential relative PFS with RVd-alone vs RVd+ASCT in White (n=540/722, 74.8%; median 44.3 vs 67.2 months; hazard ratio [HR] 1.67, 95%CI 1.29–2.15) and AA patients (n=132/722, 18.3%; median not reached [NR] vs 61.4 months; HR 1.07, 95%CI 0.61–1.89), in the context of enhanced access to care in DETERMINATION and race being a social construct. We report updated findings in an expanded cohort of ~500 patients.

Methods: Patients were classified as C/C (Duffy null) or non-C/C (Duffy non-null) based on genomics analysis of baseline peripheral blood samples for SNP rs2814778. PFS was evaluated, overall and by treatment, with Cox proportional hazards regression in univariate and multivariable models, with heterogeneity of treatment effect assessed by a test for interaction.

Results: Of 592 enrolled patients with data on Duffy status, 12% (n=71) had the Duffy null genotype (AA: 63.3%, n=62/98; White/other race: 1.1%, n=5/465). Of these, 493 were randomized (68.3% of intent-to-treat population) to RVd-alone (n=238) and RVd+ASCT (n=255); the cohort was broadly representative of the intent-to-treat population. Of the 493 patients, 53/81 (65.4%) AA and 5/408 (0.4%) White/other race patients were Duffy null (Table 1). In Duffy null vs non-null patients, pooled PFS (arms combined) was similar (median 56.7 vs 62.5 months; HR 0.94, 95%CI 0.62–1.42). In Duffy non-null patients, PFS with RVd-alone vs RVd+ASCT (120/209 vs 85/225 events/patients; median 46.7 vs 67.5 months; HR 1.76, 95%CI 1.33–2.34) favored RVd+ASCT. Findings were consistent in an analysis of the limited number of AA Duffy non-null patients (6/13 vs 3/15 events/patients; median PFS 64.4 months vs NR; HR 5.29, 95%CI 1.20–23.4). In Duffy null patients, PFS with RVd-alone vs RVd+ASCT (9/29 vs 16/30 events/patients; median NR vs 44.0 months; HR 0.64, 95%CI 0.27–1.50; Duffy status interaction p-value 0.005) was not significantly different, but the HR favored RVd-alone. A similar trend was observed in AA Duffy null patients (8/25 vs 15/28 events/patients; median PFS NR vs 45.3 months; HR 0.66, 95%CI 0.27–1.60). On multivariable analysis (Figure), Duffy null vs non-null was a significant prognostic factor for longer PFS with RVd-alone with a lower HR (0.44) than for AA vs White/other race (HR 0.54).

Baseline patient and disease characteristics by Duffy status were assessed for imbalances

	RVd-alone, n=238		RVd+ASCT, n=255		All, N=493

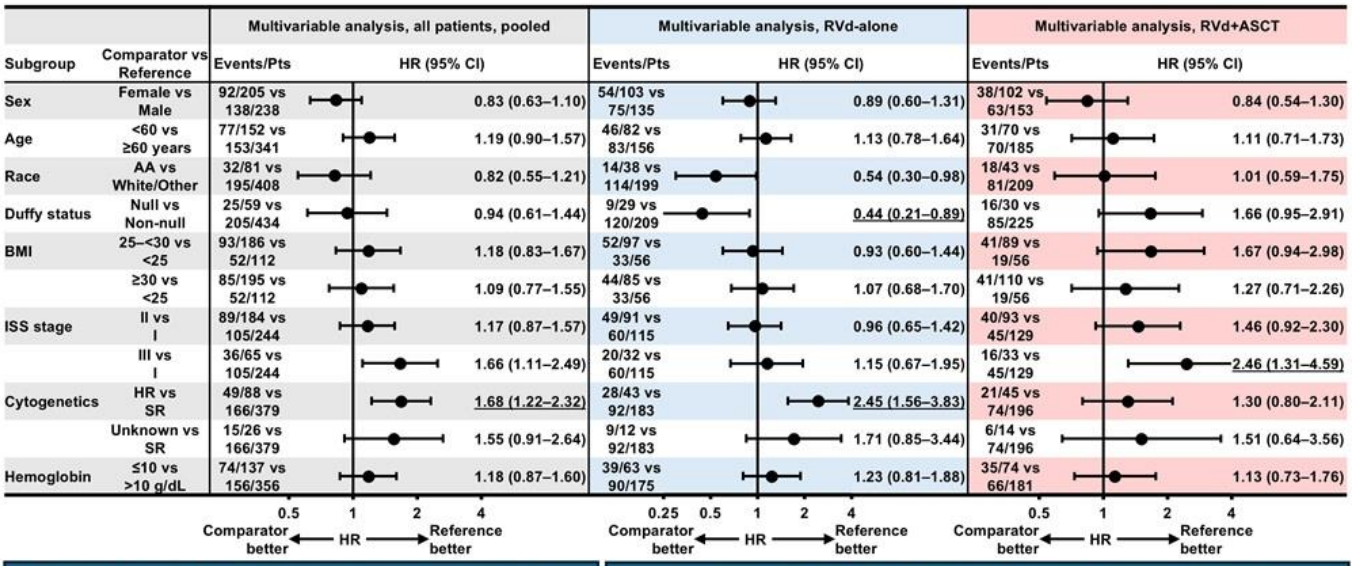
Median ANC x10^9L (IQR)	3.1 (2.1–4.4)	3.4 (2.8–4.7)	2.6 (2.2–4.2)	3.3 (2.4–4.4)	2.8 (2.1–4.3)	3.4 (2.6–4.6)



*Race and Duffy status were included along with the same additional variables in separate multivariable analyses. Data shown for other variables (sex, age, BMI, ISS stage, cytogenetics, hemoglobin) are from the multivariable analysis incorporating Duffy status; findings were consistent in the multivariable analysis incorporating race.

Conclusions: Duffy status was associated with a differential treatment effect more pronounced than previously observed by race in these exploratory analyses of DETERMINATION. In Duffy non-null patients, PFS favored RVd+ASCT, but in Duffy null patients, PFS HRs favored RVd-alone, with similar trends in analyses restricted to AA patients. In multivariable analyses, Duffy status was prognostic for PFS with RVd-alone and a stronger prognostic factor than race.

SOLUBLE BCMA AS AN EMERGING BIOMARKER IN BCMA T-CELL-REDIRECTING THERAPIES

Adolfo Fernández Sánchez[1], *Bárbara Castellanos García*[2], *Alejandro Medina Herrera*[1], *Cristina Agulló Roca*[1], *Diego Clavo Martín*[1], *Cristina Teresa Fuentes Morales*[1], *Carmen Santos Marcos*[1], *Rafael José Malaver Campos*[1], *Miriam López Parra*[1], *Alejandro Avendaño Pita*[1], *Mónica Baile González*[1], *Almudena Cabero Martínez*[1], *Mónica Cabrero Calvo*[1], *Ana África Martín López*[1], *Estefanía Pérez López*[1], *Lucía López Corral*[1], *Elena Alejo Alonso*[1], *Borja Puertas Martínez*[1], *Beatriz Rey Búa*[1], *Noemí Puig Morón*[1], *Verónica González de la Calle*[1], *María Mercedes Garayoa Berrueta*[2], *María Victoria Mateos Manteca*[1]
[1]*Complejo Asistencial Universitario de Salamanca / Instituto de Investigación Biomédica de Salamanca / Centro de Investigación del Cáncer, Salamanca, Spain,* [2]*Centro de Investigación del Cáncer, Salamanca, Spain*

Background: Soluble BCMA (sBCMA) is a promising biomarker for monitoring tumour burden and treatment response in multiple myeloma (MM) patients treated with BCMA T-cell-redirecting therapies; however, its clinical utility remains insufficiently established in routine practice, while potentially enabling early and dynamic assessment of clinical benefit.

Methods: We conducted a prospective observational study including 36 MM patients treated with BCMA-directed CAR-T cells (n=20) or bispecific antibodies (n=16) between March 2022 and October 2024. Clinical and laboratory variables, treatment characteristics, tumour burden markers, sBCMA levels measured by ELISA, and response according to the International Myeloma Working Group 2016 criteria were collected at baseline, pre-infusion/initiation, day +28, day +56, day +100, month 6, month 12, and progression. The statistical analysis was performed to address the study objectives: to explore its correlation with classical tumour burden markers, to assess the clinical value of sBCMA as a dynamic biomarker and to characterize early kinetic differences between responders and those who subsequently progressed.

Results: Baseline characteristics are shown in **Table 1**. Regarding correlation with tumour markers, baseline sBCMA demonstrated a moderate association with bone marrow plasma cell infiltration ($\rho = 0.41$; $p = 0.011$) and with serum monoclonal protein ($\rho = 0.34$; $p = 0.040$), while no significant correlations were found with other tumour burden or inflammatory markers. sBCMA levels decreased markedly by month 1 across the cohort, followed by stabilisation in patients who maintained clinical response. In contrast, persistently elevated or rising values over sequential timepoints were consistently observed in those who later experienced progression. When analysed by treatment modality, both CAR-T and bispecific-treated patients showed comparable overall dynamic patterns, with an early and deeper decline more frequently observed following CAR-T therapy. These trajectories support the role of sBCMA as a dynamic marker in the monitoring of patients receiving BCMA-directed therapies. Finally, when assessed according to clinical response, patients achieving at least partial response showed a mean decrease in sBCMA at month 1 from baseline of 42.5 ng/mL, whereas non-responders exhibited a mean increase of 29.7 ng/mL, indicating a clear separation between responder and non-responder profiles at early treatment timepoints (**Figure 1**).

Table 1. Baseline clinical characteristics, disease burden parameters and soluble BCMA levels in patients treated with BCMA-directed CAR-T cells and bispecific antibodies.

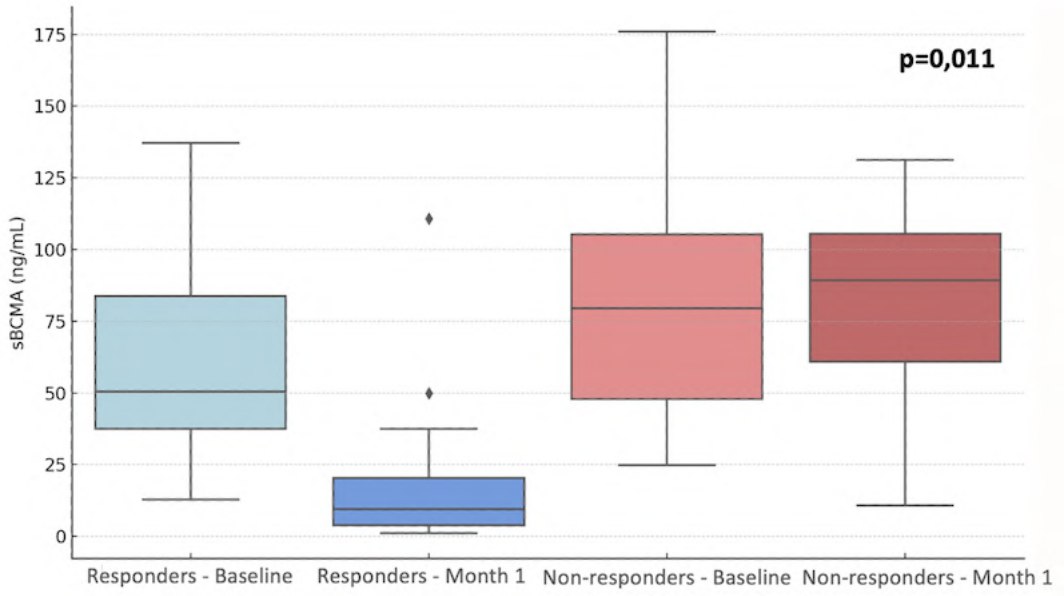

Figure 1. Distribution of sBCMA levels at baseline and month 1 in responders and non-responders treated with BCMA-directed therapies.

Conclusions: sBCMA is a serum biomarker that correlates with established tumour burden indicators. The results of this study demonstrate its value as a dynamic biomarker with early and distinct response patterns, suggesting that it may serve as an early response-predictive biomarker. Although further studies are required to validate these findings, they support its potential incorporation into monitoring strategies for MM patients treated with BCMA-redirecting approaches.

THE EXPERIENCE OF AUTOSCT IN PATIENTS WITH MULTIPLE MYELOMA ON DIALYSIS

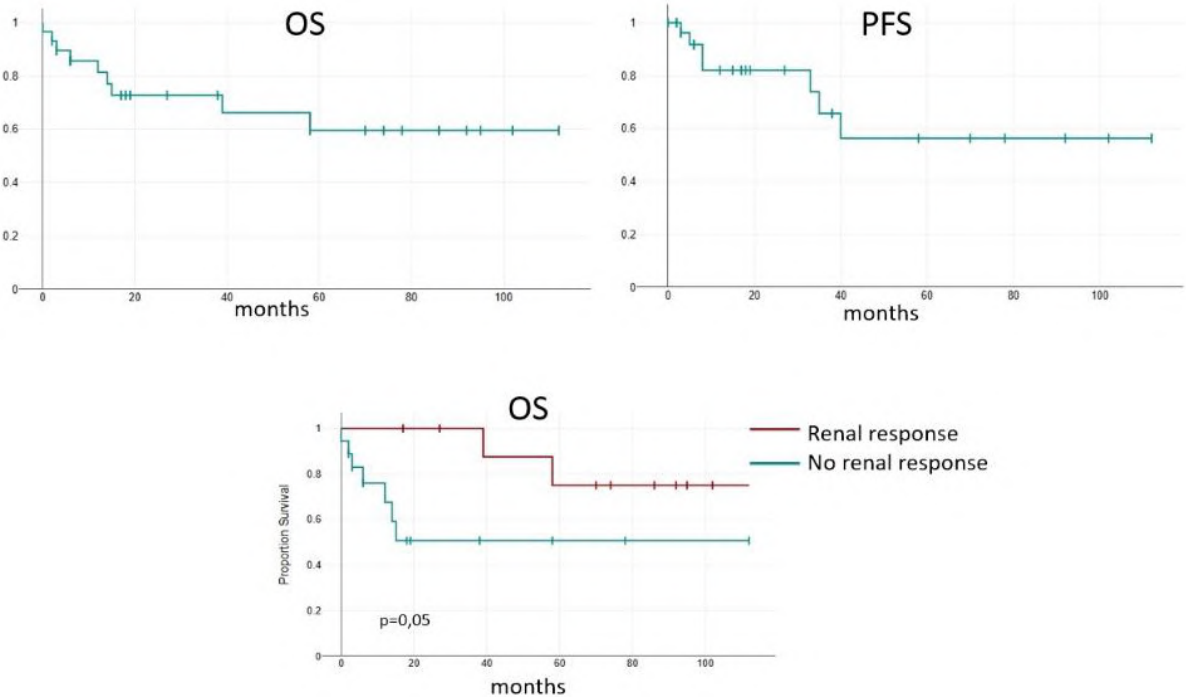
Ekaterina Karimova[1], *Eugenia Zhelnova*[1]
[1]*Moscow Clinical Science and Research Center 52, Moscow, Russian Federation (the)*

Background: Renal failure is a common complication of multiple myeloma. Only 20% of patients achieve independence from dialysis during induction therapy. Auto-HSCT remains a key step in the treatment of multiple myeloma, but patients on dialysis are often excluded from high-dose therapy protocols due to treatment-related toxicity.

Methods:

From 2015 to 2025, 29 patients in age 39-66 years (median 58) on hemodialysis underwent autoSCT at the Moscow Clinical Science and Research Center 52. 6 pts underwent tandem transplantation. 8 patients (27%) had high cytogenetic risk mutations.All patients were on program hemodialysis at the time of autoSCT, with a median GFR of 11.2 ml/min/1.73m2. Anuria was observed in 4 patients (14%), oliguria in 5 (17%), and normal diuresis in 20 patients (69%). In induction patients received bortezomib (100%), lenalidomide-containing courses - 17 patients (59%), anti-CD38-monoclonal antibodies - 8 pts (27%). Before auto-HSCT 11 patients (38%) achieved CR, 11 patients (38%) - VGPR, 7 (29%) - PR. High doses of cyclophosphamide or etoposide with G-CSF were used to mobilize PBSC. Pretransplant conditioning was carried out with melphalan at a dose of 140 mg/m2 (10 patients (34%), 19 patients (66%) added bendamustine 150 - 200 mg/m2 to melphalan. Median number of transfused PBSC: 4.5*10^6 CD34+ cells/kg.

Results: The median of leukocyte engraftment was 12 days (7 - 35 days). Infectious complications are represented by mucositis grade 3-4 (13 patients (45%), pneumonia (4 patients (14%)), sepsis (12 patients (41%)), clostridial colitis (3 patients (10%). Reactivation of HSV-1,2, HHV-6 and CMV infection was noted in 8 patients (27%). Non-infectious complications included gastrointestinal bleeding (1 patient), toxic cardiomyopathy (1 patient), atrial fibrillation (1 patient) and delirium (2 patients). Invasive aspergillosis was diagnosed in 1 patient. Transplant-associated mortality was 7% (2 patients). On day +100 after autologous T-cell therapy, all patients showed a deepening of the response: 19 (66%) patients achieved CR, 3 (10%) achieved VGPR, and 2 (7%) maintained PR. 11 patients (38%) achieved renal response and independence from dialysis, and 2 patients managed to reduce the frequency of dialysis to 2 times per week.
Renal response was achieved in patients with normal diuresis, but not in patients with oligo- and anuria (p=0.019). 2 patients subsequently underwent allogeneic kidney transplantation. In patients who achieved a renal response, there was no progression of renal failure even after the development of MM relapse.
The median follow-up was 18 months (1-112 months). The median OS and PFS were not reached.



3-year OS in patients who achieved renal response is significantly higher than in patients who remained on dialysis (100% vs.50%, p=0.05).

Adding bendamustine to the conditioning did not improve the OS and PFS in dialysis patients.

Conclusions: Dialysis-dependent renal failure in MM patients is not a contraindication to autologous SCT. AutoSCT promotes a deeper hematological response, and achieving a renal response and independence from hemodialysis in patients. Adding bendamustine to conditioning does not have an advantage over melphalan monotherapy in patients with dialysis-dependent renal failure.

Disclosure: No disclosure.

B410

BORTEZOMIB MAINTENANCE AFTER ALLOGENEIC TRANSPLANT IN NEWLY DIAGNOSED MYELOMA PATIENTS: LESS CHRONIC GVHD BUT NO IMPACT ON SURVIVAL

Richard LeBlanc[1,2], Jean-Sébastien Claveau[2,1], Stéphanie Thiant[1], Imran Ahmad[2,1], Léa Bernard[2,1], Sandra Cohen[2,1], Jean-Sébastien Delisle[2,1], Thomas Kiss[2,1], Silvy Lachance[2,1], Denis-Claude Roy[2,1], Guy Sauvageau[2,1], ***Jean Roy***[2,1]
[1]*Institut Universitaire d'Hémato-Oncologie et de Thérapie Cellulaire, Hôpital Maisonneuve-Rosemont, Montréal, Canada,* [2]*Faculty of Medicine, Université de Montréal, Montréal, Canada*

Background: Despite modern therapies, allogeneic (allo) hematopoietic cell transplantation (HCT) remains the only potentially curative approach for MM, unfortunately associated with a high rate (>50%) of relapse. Maintenance therapy could potentially prolong survival and decrease relapse, but its role following allo HCT remains unclear.

Methods: We retrospectively compared the outcomes of newly diagnosed MM patients who underwent upfront tandem autologous (auto) transplant followed 3-4 months later by a nonmyeloablative allo HCT with or without maintenance with bortezomib (BTZ) 1.3 mg/m^2 SC every 2 weeks x 26 doses initiated on D+120 (R. LeBlanc et al. BMT 2022). Patients without partial response to induction therapy, to auto HCT or with progressive disease before allo HCT were excluded. Primary endpoints included comparison of overall survival (OS) and progression-free survival (PFS). Secondary endpoints included relapse, non-relapse mortality (NRM), incidences of acute and chronic GVHD, probability to receive systemic immunosuppressants (IS) post HCT and risk factors for relapse.

Results: Among 176 newly diagnosed MM patients who received upfront auto/allo HCT between May 2001 and December 2024 from an 8/8 sibling or unrelated donor, 116 received no maintenance while 60 patients had at least one dose of BTZ. Both cohorts were comparable for age, sex distribution and staging. More patients in the BTZ group had high-risk cytogenetics (defined as t(4;14) with ISS II or III, del(17p13), t(14;16), t(14;20) and chromosome 1 abnormalities regardless of ISS in ≥10% plasma cells at diagnosis). Most common induction regimen was VAD (59.5%) in the no BTZ and CyBorD (77%) in the maintenance group. Sibling donors were more common in the no-BTZ group (91% vs 35%). More patients in the BTZ group achieved ≥VGPR prior (92% vs 69%; $p< 0.0001$) and after allo HCT (98% vs 90%; $p< 0.0001$). Median follow-up was 16.0 years (95%CI: 15.0-17.1) in the no-BTZ group and 7.4 years (95%CI: 6.1-7.9) in the BTZ group. OS and PFS at 5 years were comparable at 79.9% in no-BTZ group vs 82.2% with BTZ and 54.2% vs 48.6%, respectively (Fig.1 A, B), with no impact of ISS or cytogenetics. Patients achieving complete response status post allo HCT had significant higher PFS compared to those with VGPR in both groups. NRM at 5 years was similar in both groups (8% vs 5.8%, $p=0.72$). We observed no difference in incidence of grade II-IV acute GVHD (17.2% vs 16.7%, $p=0.97$), but moderate/severe chronic GVHD was significantly lower following BTZ (46.7% vs 80.2%; $p< 0.0001$), with delayed onset (6.5 months vs 4.9 months; $p< 0.0001$), leading to reduced IS intake at 3 years (25% vs 54.5%; $p< 0.01$, Fig. 1C). Chronic GVHD had no significant impact on either OS or PFS in patients receiving BTZ maintenance.

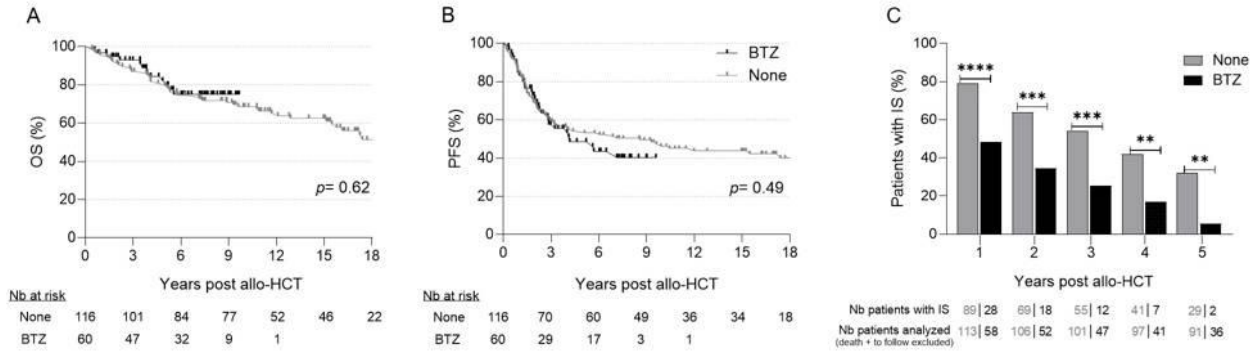


Figure 1. (A) Kaplan-Meier estimates of overall survival (OS) and (B) progression-free survival (PFS) in patients receiving BTZ maintenance or not. (C) Probability of taking oral systemic immunosuppressants after allogeneic transplant in patients with and without BTZ maintenance (Chi square or Fisher test: **p<0.01; ***p<0.001; ****p<0.0001).

Conclusions: BTZ maintenance in newly diagnosed MM patients receiving upfront tandem auto/allo HCT was associated with lower chronic GVHD incidence, reduced IS intake, but no impact on survival despite more patients with high-risk cytogenetics in this group. More effective novel maintenance strategies in the post-allo transplant setting are required to decrease relapse.

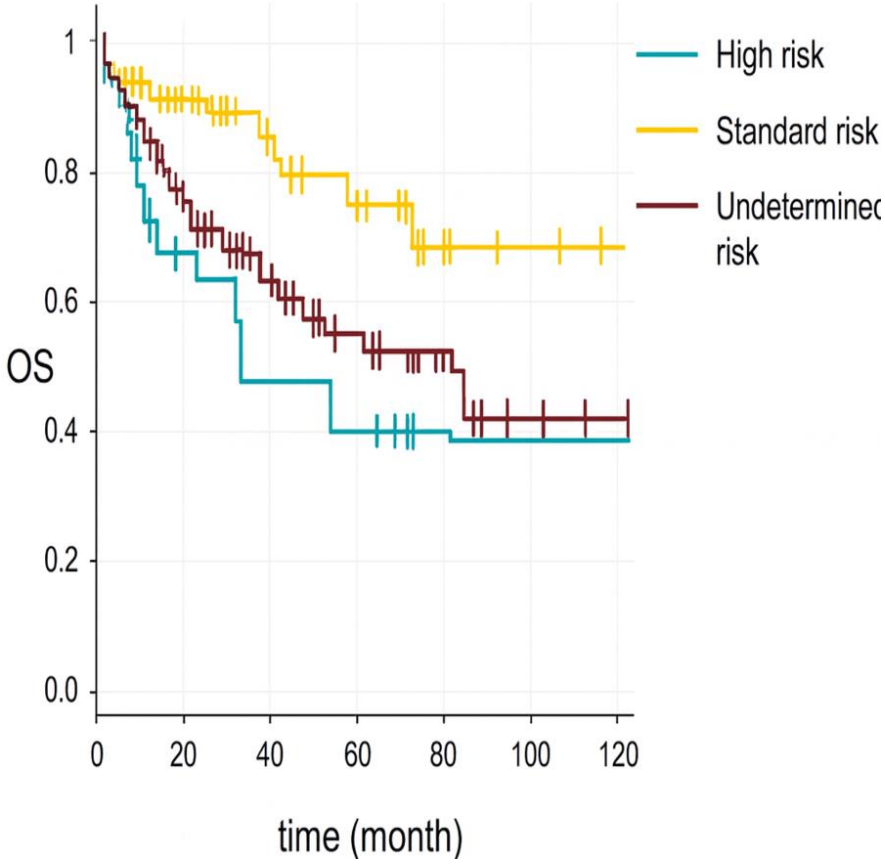
AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA: A 10-YEAR SINGLE-CENTER EXPERIENCE

Evgeniia Zhelnova[1], *Ekaterina Karimova*[1], *Leonid Khordzhasov*[1], *Sabina Kardovskaya*[1]
[1]*Moscow Clinical Research Center Hospital N52, Moscow, Russian Federation (the)*

Background: Multiple myeloma (MM) is one of the most common hematologic malignancies. Autologous hematopoietic stem cell transplantation (ASCT) is the gold-standard consolidation therapy for eligible MM patients. This retrospective single-center study evaluates short- and long-term outcomes in MM patients undergoing ASCT between 2015 and 2025.

Methods: Retrospective analysis of N=314 MM patients (442 ASCTs; 138 tandem) treated from 2015 to 2025 at our center. Patient characteristics: median age 59 years (range 22–72); 49% male; 19% with high-risk cytogenetics; 35% with soft-tissue (extramedullary) disease; median 2 prior therapy lines (range 1–5). Conditioning regimen was Melfalan (N=212), Melfalan+Bendamustin (N=230). Transplant details: median CD34+ cell dose 4.3×10^6/kg; median neutrophil engraftment 13 days; platelet engraftment 13 days. Median follow-up was 16 months (range 1–118).

Results: Overall outcomes: median OS not reached; median PFS 57 months. Three-year OS ~73%; PFS ~62%. Risk stratification: Standard-risk patients had better survival than high-risk patients. Three-year OS was 92.3% (standard) vs 54% (high); three-year PFS was 80% vs 48%. Soft-tissue involvement: Patients without extramedullary disease had better outcomes. Three-year OS 82% (no soft tissue) vs 70%; PFS 65% vs 45%. Pre-transplant response: Patients with ≥VGPR before ASCT had better PFS (3-year PFS 64%) than those with <VGPR (37.7%). Tandem ASCT: Improved outcomes were observed in patients with soft-tissue disease and in those not in complete remission before ASCT. In patients with soft tissue desease OS tandem vs mono ASCT was 70% vs 45% ($p<0.05$), PFS 60% vs 25% ($p<0.05$). Conditioning regimens: In high-risk or soft-tissue subgroups, melphalan + bendamustine showed a trend toward better survival than melphalan. For high cytogenetic group OS Melfalan vs Melfalan+Bendamustine was 40% vs 70% ($p>0.05$), PFS 18% vs 50% ($p>0.05$). For soft tissue subgroup group OS Melfalan vs Melfalan+Bendamustine was 45% vs 50% ($p>0.05$), PFS 19% vs 61% ($p>0.05$). Transplant mortality: early ASCT-related t mortality was 3.2%, in this group infection as a reason 84%. Progression desease 16%.



Conclusions: ASCT remains a critical therapeutic modality for multiple myeloma, yielding high short- and long-term survival rates in a contemporary cohort. Long-term follow-up data highlight the importance of risk stratification and can inform optimized transplant strategies. The addition of bendamustine to melphalan conditioning may improve outcomes in high-risk or extramedullary MM, though differences were not statistically significant. Further larger studies are needed and are planned to validate these findings and refine treatment protocols at our center.

Disclosure: Nothing to declare.

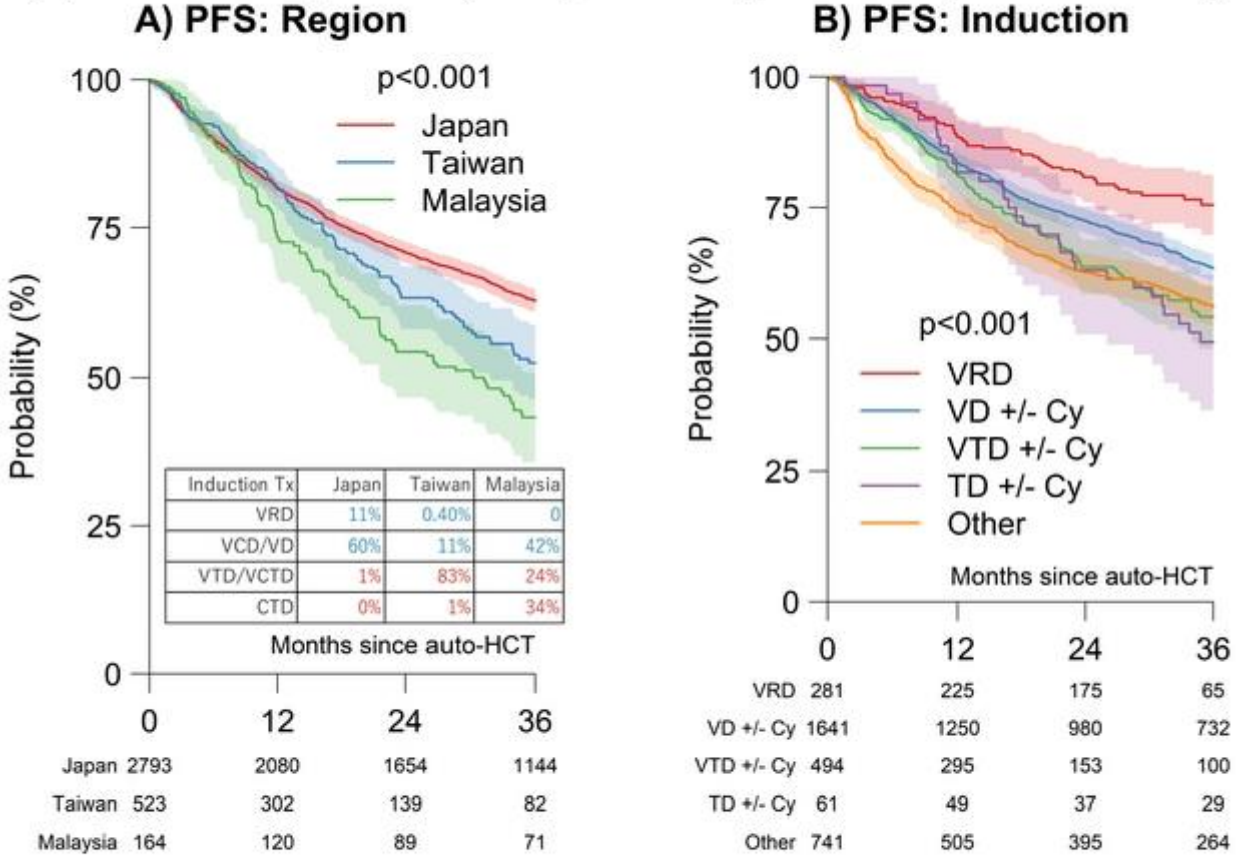
Background: Autologous hematopoietic cell transplantation (AHCT) is considered standard of care in eligible, newly diagnosed multiple myeloma (NDMM) patients after induction therapy. In our previous publication on more than 60000 patients worldwide (Garderet et al., AJH 2024) marked outcome differences were noted between regions and countries for progression-free survival (PFS) (Figure 1A) and overall survival (OS). Because of missing information on pre-transplant therapy, we collected and analyzed the impact of pre-transplant induction therapy from three Asia-Pacific countries with marked outcome differences.

Methods: NDMM patients undergoing upfront AHCT from 2013–2017 were collected through the Worldwide Network for Blood and Marrow Transplantation and the Asia-Pacific Blood and Marrow Transplantation Group. Endpoints included OS (primary) as well as PFS, relapse incidence, and non-relapse mortality (secondary). Kaplan–Meier and log-rank tests were used for survival comparisons. Cox multivariate analyses (MVA) and 6-month landmark models were applied, adjusting for baseline differences.

Results:

Figure 1. PFS according to (A) Japan, Taiwan and Malaysia and (B) induction regimens (VRD, VD+/-Cy, VTD+/-Cy and TD+/-Cy)



A total of 3,820 patients were evaluated (Japan n=3,127; Taiwan n=524; Malaysia n=169) with a median follow-up of 46 months. Induction therapies differed substantially between the Asian countries. In Japan VCD was used in 35%, VD in 24.8% and VRD in 11% of the patients. In Taiwan VTD was administered to 72.1% and in Malaysia VCD in 42.0%, CTD in 29.6% and VTD in 23.7%. The proportion of patients who received maintenance varied across countries and resulted in 100% in Taiwan (1.2% lenalidomide and 30.5% thalidomide), in 32.7% in Malaysia (4.2% and 21.4%, respectively) to 7.1% in Japan (5.2% and 0%, respectively). Induction regimens were significantly associated with PFS and OS (p<0.001) after AHCT (Figure 1B). VRD showed the highest 36-month PFS (76%, 95% CI 70-81%) versus VCD/VD (63%, 95% CI 61-66%), VTD/VCTD (54%, 95% CI 48-60%) and

CTD/TD (49%, 95% CI 37-62%). OS at 36 months was likewise superior with VRD (89%, 95% CI 85-93%) compared with VCD/VD (85%, 95% CI 83-87%), VTD/VCTD (75%, 95% CI 70-80%) and CTD/TD (72%, 95% CI 60-83%). In 6-month landmark analysis, lenalidomide maintenance showed better PFS (70% vs 64%) and OS (90% vs 84%) compared with no maintenance. In MVA, VRD was associated with significantly improved PFS compared with VTD/VCTD (HR 0.68, 95% CI 0.49, 0.93, P = 0.02) and improved OS compared with VTD/VTCD (HR 0.56, 95%CI 0.34, 0.91, P = 0.02). Differences in PFS and OS between VRD and VCD/VD were not statistically significant. Probably due to the small number of patients who received lenalidomide maintenance (n = 87), it showed only a trend toward improved OS (HR 0.49; 95% CI, 0.20–1.20; P = 0.12) in the adjusted MVA.

Conclusions: VRD induction was associated with superior PFS and OS compared with VTD/VTCD, contributing to observed international outcome differences. Maintenance using lenalidomide or thalidomide was not significant. Access to lenalidomide—both for induction and maintenance—varied markedly across countries and likely influenced prognosis. National approval and reimbursement policies enabling consistent access to PI/IMiD-based therapies are essential for optimizing outcomes in MM patients undergoing ASCT.

COMPARISON OF DARA-VTD AND TRIPLE THERAPY AS INDUCTION REGIMENS PRIOR TO AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION IN NEWLY DIAGNOSED MULTIPLE MYELOMA

Maciej Sławomir Tomasiewicz[1], *Magdalena Olszewska-Szopa*[1], *Elżbieta Kalicińska*[1], *Magdalena Karasek*[1], *Donata Szymczak*[1], *Maciej Majcherek*[1], *Bartłomiej Kuszczak*[1], *Iwona Prajs*[1], *Tomasz Wróbel*[1], *Anna Czyż*[1]
[1]*Wrocław Medical University, Wrocław, Poland*

Background: Daratumumab combined with bortezomib, thalidomide, and dexamethasone (Dara-VTD) has emerged as an effective first-line induction regimen for patients with newly diagnosed plasma cell myeloma (PCM). However, real-world data comparing its efficacy and safety with standard bortezomib-based triplet therapies prior to autologous hematopoietic cell transplantation (AHCT) remain limited. This single-center retrospective study compares outcomes of patients undergoing AHCT after induction with either four cycles of Dara-VTD or four to six cycles of bortezomib-based triplet therapy without daratumumab.

Methods:

We analyzed 224 consecutive patients with newly diagnosed PCM who underwent AHCT. Of these, 112 patients received Dara-VTD between 2023 and 2025, and 112 received bortezomib-based triplet therapy (TT) between 2019 and 2024, predominantly VTD (n=80). The median age was 62 years (IQR: 56–66). The groups were comparable with respect to age, sex, cytogenetic risk, and type of monoclonal protein. Patients in the Dara-VTD group had a significantly higher baseline disease burden, reflected by higher International Prognostic Scoring System (IPSS) scores (median 3 vs. 2; p=0.0372) and Revised International Staging System (R-ISS) stages (median 3 vs. 2; p=0.0011).

Results:

A significantly higher proportion of patients treated with four cycles of Dara-VTD achieved at least a very good partial response (VGPR) prior to AHCT compared with the TT group (89% vs. 73%; p=0.0002). Minimal residual disease (MRD) negativity assessed by multicolor flow cytometry with a sensitivity of 10^{-6} was also more frequent in the Dara-VTD group (46% vs. 18%; p=0.0001). Grade 3–4 infections during induction therapy occurred more often in patients receiving Dara-VTD (16.96% vs. 2.7%; p=0.0095).

During AHCT, patients in the Dara-VTD group achieved higher $CD34^+$ cell yields and received a higher median number of infused $CD34^+$ cells (4.42 vs. 3.66 $\times 10^6$/kg; p=0.0063). Despite this, hematopoietic recovery was delayed. Median neutrophil engraftment occurred on day +12 in the Dara-VTD group compared with day +11 in the TT group (p<0.0001), and platelet recovery was delayed to day +14 versus day +12, respectively (p<0.0001). Grade 3–4 infections during the transplantation period were significantly more frequent in the Dara-VTD group (23.2% vs. 9%; p=0.0071). No early transplant-related mortality was observed in either group. Most infectious complications were of bacterial etiology.

Conclusions:

Induction with four cycles of Dara-VTD results in significantly deeper responses, including higher MRD-negative rates, prior to AHCT in newly diagnosed PCM. However, these benefits are accompanied by an increased incidence of severe infectious complications during both induction and transpla
ntation, as well as delayed hematopoietic recovery. The relationship between delayed neutrophil recovery, daratumumab exposure, and infection risk warrants further investigation. In addition, the impact of daratumumab on overall hematopoietic reconstitution during AHCT requires further evaluation. While Dara-VTD improves depth of response, its adverse hematologic and infectious effects during transplantation highlight the need for refined risk stratification and optimized supportive care strategies. Future studies should focus on identifying predictors of toxicity to improve the safety of this highly effective

regimen.

IS THERE STILL A CURATIVE ROLE FOR ALLOGENEIC TRANSPLANTATION IN MULTIPLE MYELOMA? LONG-TERM OUTCOMES IN YOUNG PATIENTS UNDERGOING HLA-IDENTICAL ALLOGENEIC HAEMATOPIETIC STEM CELL TRANSPLANT

Daniele Avenoso[1], *Riccardo Marnoni*[1], *Mirko Farina*[1], *Gabriele Magliano*[1], *Enrico Morello*[1], *Vera Radici*[1], *Rachele De Domenico*[1], *Marco Galli*[1], *Paolo Clementi*[1], *Francesca Bonati*[1], *Laura Donatoni*[1], *Simona Bernardi*[1], *Federica Re*[1], *Alessandro Leoni*[1], *Angelo Belotti*[2], *Claudia*

Crippa[2], Rossella Ribolla[2], Alessandra Tucci[2], Domenico Russo[1], Michele Malagola[1]
[1]Unit of Blood Diseases and Bone Marrow Transplantation, Department of Clinical and Experimental Science, University of Brescia, ASST Spedali Civili di Brescia, Brescia, Italy, [2]SC Ematologia e Dipartimento di Oncologia Clinica, A.O. Spedali Civili, Brescia, Italy

Background: The role of allogeneic haematopoietic stem cell transplantation (allo-HSCT) in multiple myeloma (MM) remains controversial in the era of novel agents, mainly due to concerns regarding non-relapse mortality (NRM) and relapse. However, durable remissions and long-term survival suggest a potential curative role in selected patients, particularly when transplanted young and in early treatment phase. Herein we report the long-term overall survival (OS), relapse-free survival (RFS), graft-versus-host disease–free relapse-free survival (GRFS), and cumulative incidence of relapse and NRM in a cohort of young MM patients exposed to bortezomib- and/or thalidomide-based therapies.

Methods: We retrospectively analysed 46 MM patients aged <65 years (median age 53.7, range 33–63) undergoing allo-HSCT with curative intent at our institution. All patients had received prior treatment with proteasome inhibitors and/or immunomodulatory drugs. Conditioning was myeloablative in 36.9% and reduced-intensity in 63.1%. Donors were HLA-identical siblings (matched related donor - MRD) in 43.5% and unrelated donors (MUD) in 56.5%. Nearly half of the patients (47.8%) underwent allo-HSCT within the first two lines of therapy. OS, RFS and GRFS were estimated by Kaplan–Meier analysis, while cumulative incidence of relapse and NRM were assessed using competing-risk models. Long-term follow-up was available for surviving patients.

Results: With extended follow-up exceeding 10 years, median OS was 33.8 months for the entire cohort, with evidence of a long-term survival plateau. Median RFS was 36.5 months, while median GRFS was 12.5 months. Five- and ten-year overall survival were approximately 40% and 25%, respectively, while non-relapse mortality stabilised at around 25% within the first 24 months after transplantation. Acute GVHD occurred in approximately 60% of patients, most commonly grade II–III, and chronic GVHD developed in 25% of cases, frequently with multi-organ involvement (moderate 90%, severe 10%). Despite the absence of post-transplant cyclophosphamide, GVHD was clinically manageable and did not preclude long-term survival, supporting a clinically relevant graft-versus-myeloma effect in selected young patients. Cumulative incidence analysis showed progressive disease-related mortality over time, while NRM remained relatively stable after the first 24 moths. Importantly, patients receiving allo-HSCT from sibling donors had a significantly superior OS compared with those transplanted from unrelated donors (median OS 77.7 vs 16.5 months, p=0.04 – figure 1A). Younger patients (<55 years) and those transplanted early (figure 1B) demonstrated the most favourable long-term outcomes, with a subset achieving durable remission suggestive of cure.

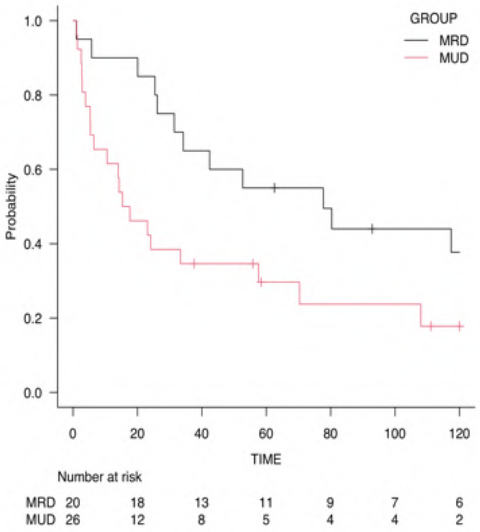

Fig. 1B

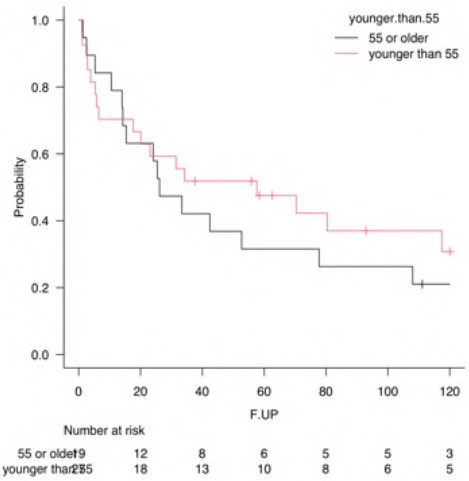

Conclusions: Despite advances in non-transplant therapies, allo-HSCT retains a potential curative role in carefully selected young MM patients. Early transplantation and the availability of an HLA-identical sibling donor appear to be critical determinants of long-term survival and disease control. These findings support reconsidering allo-HSCT as a curative strategy rather than a purely palliative option in the modern treatment landscape of MM.

P291

ZERO PERCENT TREATMENT-RELATED MORTALITY, HIGH EFFICACY AND LONG-TERM SAFETY OF AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION FOR MULTIPLE MYELOMA IN THE ERA OF QUADRUPLETS

*Michail Iskas[1], **Chrysavgi-Elisavet Lalayanni**[1], Zoi Boussiou[1], Vassiliki Douka[1], Christos Demosthenous[1], Maria Papathanasiou[1], Ioannis Batsis[1], Panagiotis Dolgyras[1], Nikos Spyridis[1], Giorgos Karavalakis[1], Marianna Masmanidou[1], Chrysanthi Vadikoliou[1], Panagiotis Kalmoukos[2], Eleni Gavriilaki[2], Anna Vardi[1], Damianos Sotiropoulos[1], Ioanna Sakellari[1]*
[1]Department of Hematology & BMT Unit, General Hospital "George Papanikolaou", Thessaloniki, Greece, [2]2nd Propedeutic Department of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Quadruplets have been introduced as the mainstay of induction treatment in multiple myeloma (MM) patients eligible for autologous hematopoietic cell transplantation (AHCT). We studied the long-term safety and efficacy of AHCT in a large real-world cohort of MM patients receiving quadruplets compared to historic controls induced with triplets.

Methods: We enrolled consecutive patients, of our JACIE-accredited center, that received AHCT over the last decade (2013-2023) for MM. Patients were divided into 2 groups: 79 patients were induced with daratumumab-based quadruplets (Group A) versus 187 patients with bortezomib-based triplets (Group B). All patients received high-dose melphalan (200 mg/m^2) as conditioning regimen, with dose reduction (140 mg/m^2) in 6 patients with chronic kidney disease. Median patient age at transplant date was 59 (41-71) years for group A and 57 (35-70) for group B. Disease status at transplantation was complete response (CR), very good partial response (VGPR), partial response (PR) and progressive disease (PD) in 34/28/11/5 in group A vs 55/64/63/5 in group B. Variables included in the analysis were also CD34+ stem cell yield, time to neutrophil and platelet engraftment and post-transplant outcome regarding overall survival.

Results: We studied 266 consecutive patients with multiple myeloma. No second AHCT or allogeneic transplantation was performed in the study period. There were no transplant-related deaths. Within this period, 5-year OS was 83% in Group A patients vs 60% in Group B patients (p=0.003). There was no statistically significant difference in the disease status at transplantation between the two groups. CD34+ stem cell yield was not different in the two groups, 3.91 (1.70-9.48) in group A vs 3.89 (1.38-9.63) x 10^6/kg in group B (p=ns). There was no impact in median time to neutrophil engraftment, 10.6 (in group A (9-13) vs 11.5 (7-26) days in group B (7, (p=ns). However, patients in group A had significantly shorter median time to platelet engraftment, 12.8 (8-26) vs 14.2 (7-68) days (p=0.045).

Conclusions: Our data confirm that AHCT is safe and effective for MM in the era of quadruplets. Daratumumab-based quadruplets offer an optimal graft yield and seem to exert an enhanced impact on platelet engraftment, probably due to their alkylator-sparing advantage. The significant benefit in overall survival highlights the importance of incorporating novel agents into the first-line setting, even in transplant-eligible patients, so as to improve total outcomes in this still incurable disease.

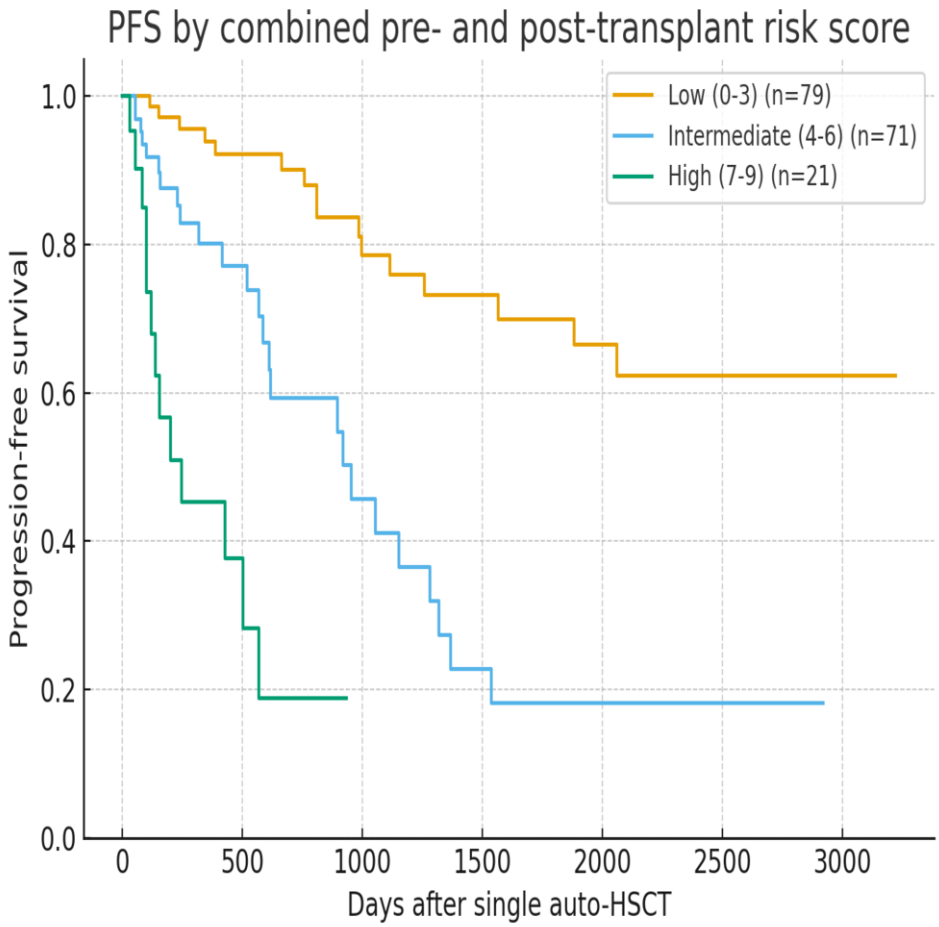
INTEGRATED PRE- AND POST-TRANSPLANT RISK SCORE FOR PROGRESSION AFTER A SINGLE AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA

Leonid Khordzhasov[1], *Ekaterina Karimova*[1], *Evgeniia Zhelnova*[1], *Sabina Kardovskaya*[1]
[1]*Moscow Clinical Research Center Hospital N52, Moscow, Russian Federation (the)*

Background: Autologous stem cell transplantation (ASCT) remains a key component of therapy in multiple myeloma (MM), but long-term outcomes are heterogeneous, even in the era of novel agents and maintenance. There is a need for tools that integrate pre- and post-transplant factors to estimate progression risk, guide the use of a second ASCT and tailor maintenance or treatment intensification. We aimed to identify predictors of progression after single ASCT and to develop a clinical risk score combining pre- and post-transplant variables.

Methods: We retrospectively analysed 171 MM patients who underwent single ASCT at our center. Median age at ASCT was 59 years, and 45.2% were male. According to mSMART cytogenetics, 18.8% had high-risk, 31.5% standard-risk and 44.7% unknown status. A soft tissue/extra-medullary component was present in 27.9% of patients. Conditioning regimens included melphalan monotherapy in 45.7% and bendamustine-containing regimens in 54.3%. Pre-ASCT responses were PR 17.8%, VGPR 44.7%, CR 29.4%, sCR 2.5% and stable disease 1.0%. Median follow-up was 443.5 days (≈1.2 years). PFS was defined as time from ASCT to progression/relapse or death; OS as time to death from any cause. Kaplan–Meier estimates were used for survival, and Cox proportional hazards models for uni- and multivariable analyses, including clinical, cytogenetic, treatment and response variables. A combined pre/post-transplant risk score was then built.

Results: Median OS was not reached; 3-year OS was 74.5%. Median PFS was 1115 days (≈3.1 years), and 3-year PFS was 51.0%. In multivariable analyses, independent adverse factors for PFS were the presence of a soft-tissue component (HR≈2.2, p=0.026) and worse response at day +100 (per-category deterioration on the AX scale, HR≈1.38, p≈0.0001). Standard-risk mSMART cytogenetics were protective (HR≈0.45 vs non-standard/unknown, p=0.027), and achieving CR/sCR before ASCT markedly reduced the risk of progression (HR≈0.18 vs ≤PR/SD, p≈0.00006). Lenalidomide maintenance showed a trend toward lower risk (HR≈0.62, p≈0.11). Age, sex, Durie–Salmon stage, ISS, number of prior lines, haemodialysis, type of induction and conditioning (including bendamustine-containing vs non-bendamustine regimens; HR≈0.81, 95% CI 0.46–1.43, p=0.47) were not significantly associated with PFS (all p>0.05).
Based on Cox coefficients, we constructed a 0–9 point risk score integrating pre-transplant soft-tissue involvement, mSMART risk, depth of response before ASCT, day +100 response and lenalidomide maintenance. Three risk groups were defined: low (0–3), intermediate (4–6) and high (7–9 points). Low-, intermediate- and high-risk groups comprised 79, 71 and 21 patients, respectively. Median PFS was not reached in the low-risk group (3-year PFS 76.5%), 618 days (≈1.7 years) in the intermediate-risk group (3-year PFS 34.4%) and 201 days (≈0.6 years) in the high-risk group (3-year PFS 8.9%). The score showed good prognostic performance for PFS with a concordance index of 0.76.



Conclusions: We developed and implemented a combined pre- and post-transplant risk score for MM patients undergoing single ASCT. This score is being integrated into routine practice in our center to guide treatment strategies, including maintenance, consideration of a second ASCT and intensity of follow-up.

Disclosure: Nothing to declare.

CLINICAL OBSERVATION ON THE NKG2D AND CS1 TARGETED CAR-T TREATMENT OF RELAPSED/REFRACTORY MULTIPLE MYELOMA PATIENT WITH BCMA AND GPRC5D DELETION

Shaomei Feng[1]
[1]*Beijing GoBroad Boren Hospital, Beijing, China*

Background: Although combination regimens based on bortezomib, lenalidomide, and daratumumab have significantly improved survival in patients with relapsed or refractory multiple myeloma (MM), clinical management remains challenging. In recent years, targeted therapies against BCMA and GPRC5D—including CAR-T cell therapies, CD3×BCMA or CD3×GPRC5D bispecific antibodies, and CD3×BCMA×GPRC5D trispecific antibodies—have markedly enhanced clinical outcomes. However, loss of BCMA and GPRC5D antigen expression in patients experiencing disease recurrence or progression after CAR-T therapy or trispecific antibody treatment substantially limits subsequent therapeutic options, underscoring the need for novel therapeutic strategies.

Methods: A 61-year-old female patient with an 11-year history of MM experienced repeated disease progression despite multiple prior treatments, most recently including a CD3×BCMA×GPRC5D trispecific antibody. Baseline evaluation revealed 25% bone marrow (BM) plasma cells and multiple lytic bone lesions. Serum immunofixation electrophoresis confirmed IgAλ type myeloma, with IgA at 27.42 g/L and λ free light chain at 9.72 g/L. Urine immunofixation demonstrated λ light chain restriction, with urinary λ free light chain at 98 mg/dL. Flow cytometry analysis showed absence of BCMA and GPRC5D surface expression on plasma cells, while CS1 and NKG2D were highly expressed, making these targets suitable for autologous CAR-T cell therapy. Peripheral blood mononuclear cells were collected from the patient to generate two separate autologous CAR-T cell products targeting CS1 and NKG2D. The lymphodepletion regimen consisted of fludarabine 30 mg/m² and cyclophosphamide 300 mg/m² administered from day −5 to −3. On November 18, 2024, CS1 CAR-T cells (0.86 × 10^6 cells/kg) were infused, followed by NKG2D CAR-T cells (1.0 × 10^6 cells/kg) on November 26, 2024.

Results: Following CAR-T cell infusion, the patient developed grade 1 cytokine release syndrome (CRS), manifesting as fever and fatigue, with no evidence of immune effector cell-associated neurotoxicity syndrome (ICANS); symptoms resolved with symptomatic management. By day 28 post-infusion, the patient achieved complete remission, as evidenced by the absence of abnormal plasma cells in bone marrow, undetectable serum M protein on electrophoresis, and normalization of serum free light chain ratios. Eleven months after remission, a palpable mass was identified adjacent to the right orbit. Laboratory evaluation revealed recurrent monoclonal λ light chain elevation in both serum and urine. Bone marrow examination showed 1% plasma cells. Biopsy of the orbital mass confirmed extramedullary plasmacytoma. Flow cytometric analysis at relapse demonstrated re-expression of BCMA (81.51% positive) and GPRC5D (40.97% positive) on neoplastic plasma cells.

Conclusions: This case illustrates that sequential CS1- and NKG2D-targeted CAR-T cell therapy induced a durable remission lasting 11 months in a patient with relapsed/refractory MM and prior loss of BCMA and GPRC5D antigen expression, demonstrating therapeutic potential in this high-risk population. The re-emergence of BCMA and GPRC5D expression at relapse restored eligibility for BCMA- and GPRC5D-directed therapies. These findings highlight the importance of dynamic monitoring of antigen expression profiles to guide personalized treatment decisions. Future studies may explore combination strategies—such as immune checkpoint inhibitors or immunomodulatory agents—following CS1- or NKG2D-directed CAR-T therapy to further improve response durability and efficacy.

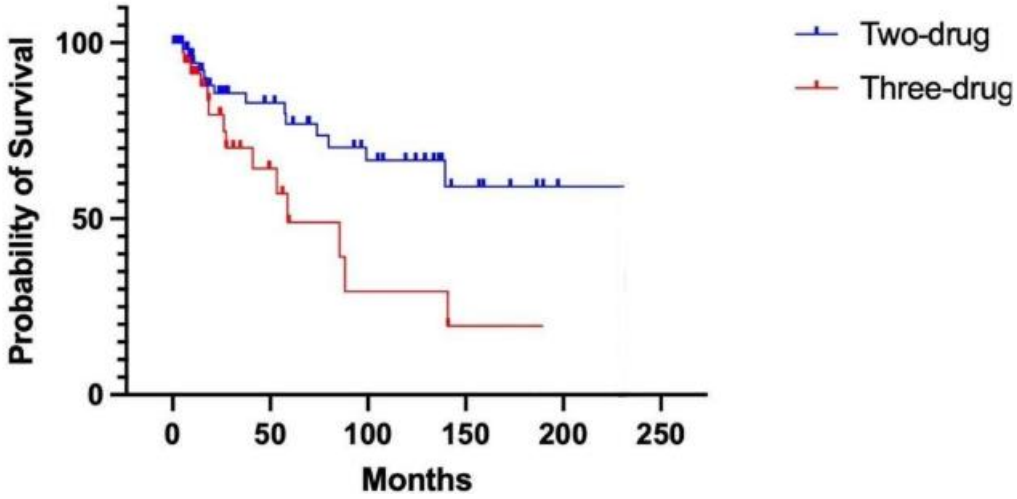
AUTOLOGOUS STEM CELL TRANSPLANTS NEGATE OUTCOME DIFFERENCES BETWEEN DUAL AND TRIPLE THERAPIES IN MULTIPLE MYELOMA: REAL-WORLD DATA FROM A MIDDLE-INCOME COUNTRY

Guillermo J. Ruiz-Argüelles[1], *Sofia Chavez-Martinez*[1], *Lidia Joanna Alberto-Lopez*[1], *Olivia Lira-Lara*[1], *Miguel Angel Viveros-Lugo*[1], *Michelle Lavoignet-Cisneros*[1], *Monica Daniela Salgado-Cabrera*[1], *Miguel Angel Gómez-Cabrera*[1], *Max Robles-Nasta*[1], *Juan Carlos Olivares-Gazca*[1], *Guillermo J. Ruiz-Delgado*[1]
[1]*Centro de Hematología y Medicina Interna, Clínica Ruiz, Puebla, Mexico*

Background: To evaluate the impact of autologous stem cell transplantation (ASCT) and induction regimen (doublet vs. triplet) on overall survival (OS) and progression-free survival (PFS) in multiple myeloma (MM) patients treated in a resource-constrained setting.

Methods: This retrospective cohort included 105 MM patients diagnosed between 1991 and 2025. After excluding 17 due to incomplete data, 88 remained: 56 received doublet therapy (corticosteroid + immunomodulator) and 32 received triplet therapy (addition of a proteasome inhibitor). Survival was assessed using Kaplan–Meier and Cox regression analyses adjusted for ISS stage, age, and ASCT status. A predefined subgroup analysis evaluated outcomes within ISS stage III patients.

Results: Median OS appeared longer in the doublet group (230 vs. 59 months; p = 0.0061), largely reflecting a higher prevalence of ISS stage III disease in the triplet cohort (50% vs. 25%). After adjustment, induction regimen was not independently associated with OS (HR 0.9
1, 95% CI 0.36–2.12). ASCT was the strongest predictor of survival (HR 0.34, 95% CI 0.13–0.86), with ASCT recipients demonstrating significantly longer OS (189 vs. 73.7 months; p = 0.0015). PFS did not differ between regimens (56.6 vs. 56.2 months; p = 0.5941). Among ISS stage III patients (n = 30), OS did not differ by induction therapy (p = 0.6765).



Conclusions: In resource-limited settings, ASCT is the primary driver of long-term survival in MM. When ASCT is feasible, doublet induction yields adjusted survival outcomes comparable to triplet therapy, supporting its use as a pragmatic and cost-effective option.

Disclosure: Nothing to declare

P296

SAFETY, ENGRAFTMENT KINETICS, AND TRANSPLANT-RELATED COMPLICATIONS OF AUTOLOGOUS STEM CELL TRANSPLANTATION IN MULTIPLE MYELOMA: INSIGHTS FROM A RESOURCE-CONSTRAINED REAL-WORLD COHORT

Stalin Chowdary Bala[1], *Chandrasekhar Bendi*[1], *Rajini Priya Yedla*[1], *Praveena Voonna*[1], *Murali Krishna Voonna*[1]
[1]*Mahatma Gandhi Cancer Hospital and Research Institute, Visakhapatnam, India*

Background: Autologous stem cell transplantation (ASCT) remains a critical component of therapy for transplant-eligible patients with multiple myeloma (MM), offering deeper responses and improved disease control. While randomized trials have established its efficacy, real-world data—particularly from resource-constrained settings and patients with baseline renal dysfunction—remain limited. We report comprehensive transplant outcomes, toxicities, and early disease control from a single-center real-world cohort.

Methods: We retrospectively analyzed 64 consecutive MM patients who underwent ASCT over a 5 year period in a newly established transplant centre. Majority of transplants were under state sponsored health insurance scheme reflecting a predominantly publicly funded, real world transplant population. Demographic characteristics, transplant parameters,

engraftment kinetics, transplant-related complications, hospitalization duration, transplant-related mortality (TRM), and post-transplant outcomes were assessed.

Results: Sixty-four patients underwent ASCT, including 62.5% males (40) and 37.5% females (24), with a median age of 55 years. Renal failure at presentation was observed in 43.8% (28). Patients received a median of 4 induction cycles prior to transplant and the most common induction regimen was VRd in 52%(33/64) cases. Conditioning consisted of melphalan 200 mg/m² in 62.5% (40) and melphalan 140 mg/m² in 37.5% (24), primarily due to renal dysfunction or advanced age. The median infused $CD34^+$ stem cell dose was 6 × 10^6/kg.
Hematopoietic recovery was rapid, with a median neutrophil engraftment at Day 10(range, 9-25) and median platelet engraftment at Day 14(range 12-26). Delayed engraftment beyond Day 20 occurred in 7.8% (5/64).
Transplant-related toxicities were frequent but largely manageable. Mucositis occurred in 100% (64), with grade 1–2 in 53.1% (34), grade 3 in 31.3% (20), and grade 4 in 15.6% (10). Febrile neutropenia developed in 90.6% (58). Microbiologically documented infections were identified in 31.3% (20), including gram-negative bacterial infections in 12.5% (8/64)—most commonly Escherichia coli—gram-positive infections in 6.3% (4/64), and fungal infection in 1.6% (1/64). 60% 0f patients needed total parenteral nutrition support for a median of 5 days(range 3-6). Septic shock requiring inotropic support occurred in 4.7% (3). One patient (1.6%) died due to transplant-related complications, resulting in a TRM of 1.6%. The median duration of hospitalization was 20 days (range: 18–40). Despite a high burden of early transplant-related toxicities, complications were predominantly reversible with intensive supportive care. Importantly, no graft failure was observed, and hematopoietic recovery was durable in all evaluable patients.
At a median follow-up of 24 months, disease relapse was documented in 14% (9/64), all of whom received second-line therapy with a progression free survival of 86%.

Conclusions: This real-world experience demonstrates that ASCT in multiple myeloma is feasible and effective, with prompt engraftment, acceptable toxicity, and low TRM, even in a substantial proportion of patients with renal dysfunction and also in resource limited setting. Despite high rates of mucositis and febrile neutropenia, infectious complications were manageable, and early disease control was encouraging. These findings reinforce the continued role of ASCT as safe, effective and generalizable therapeutic strategy for myeloma across diverse real world and resource limited settings.

Clinical Trial Registry: Not Applicable.

PROGNOSTIC FACTORS FOR SURVIVAL IN PATIENTS WITH MULTIPLE MYELOMA UNDERGOING AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN COLOMBIA

Daniel E. Osorio-Rodriguez[1], Luis A. Salazar[1,2], Carlos Orozco-Oviedo[3,2], Maria Luna-Gonzalez[1,2], Angela M. Peña[2,3], Manuel Rosales[3,2], Mario Arenas-Mantilla[2,3], Katherinee Morales-Chacon[3,2], Miguel Ochoa-Vera[1], Maria G. Velasquez-Oliver[1], ***Claudia Sossa-Melo***[1,3]
[1]*Universidad Autonoma de Bucaramanga, Bucaramanga, Colombia,* [2]*Programa para el Tratamiento de Enfermedades Hemato-Oncológicas de Santander PROTHEOS, Floridablanca, Colombia,* [3]*Fundación Oftalmológica de Santander, Floridablanca, Colombia*

Background: Autologous hematopoietic stem cell transplantation (ASCT) remains a cornerstone of treatment for eligible patients with multiple myeloma (MM). However, survival outcomes after ASCT are heterogeneous and depend on patient and treatment-related factors, particularly in real-world settings from low and middle-income countries.

Methods: We conducted a retrospective observational study including adult patients with MM who underwent ASCT at a referral center in Northeastern Colombia between 2009 and 2024. The objective was to identify factors associated with progression-free survival (PFS) and overall survival (OS) at 100-days, 1-year and 5-years post-transplant. Baseline demographic, clinical, biochemical, and transplant-related variables were collected. Survival was estimated using the Kaplan–Meier method, and multivariable Cox proportional hazards regression models were used to identify factors independently associated with PFS and OS.

Results: A total of 150 patients were included. The median age at transplantation was 58 years (range, 53–63), and 48% were male. Most patients underwent ASCT after first-line therapy (63%). All patients received melphalan-based conditioning. Post-transplant strategies included consolidation (61% received) and maintenance therapy which was implemented routinely after 2015 (62% and 89% received from 2009-2014 and 2015-2024 respectively). The 5-year OS was 64.5%, and median OS was not reached during follow-up. Two patients died within the first 100 days after ASCT. No significant differences in OS or PFS were observed according to sex, age (>65 years) or ISS stage. In multivariable analysis, maintenance therapy was independently associated with improved OS at 1-year and 5-years (HR 0.14; 95%CI 0.02 - 0.77; p= 0.024 and HR 0.39; 95%CI 0.20 - 0.76; p= 0.002 respectively). A higher body mass index was associated with an increased risk of disease progression or relapse (HR 1.06; 95%CI 1.01 - 1.11; p= 0.012). Elevated dehydrogenase lactate at diagnosis was consistently associated with inferior outcomes, including a significantly shorter 1-year PFS (HR 4.39; 95%CI 1.04–18.42; p= 0.043) and reduced 5-year OS (HR 3.64; 95%CI 1.66–8.01; p= 0.043). First-line chemotherapy VRD prior ASCT improved 5-year OS (HR 0.13; 95%CI 0.02 - 0.62; p= 0.01) and administering melphalan for two days as a conditioning regimen and a higher pre-transplant hematopoietic stem cell transplant comorbidity index (HR 4.74; 95%CI 1.05-21.21; p = 0.042) were associated with decreased overall 5-year survival (HR 1.89; 95%CI 1.03-3.49; p = 0.039). Post-transplant consolidation-therapy was associated with a significant reduction in mortality (HR 0.38;

95%CI 0.20 - 0.72; p= 0.003), as was maintenance-therapy (HR 0.39; 95%CI 0.20 - 0.76; p= 0.006).

Characteristic	Desease-Free Survival		Overall Survival	
	1 year HR (95%CI) p-value	5 year HR (95%CI) p-value	1 year HR (95%CI) p-value	5 year HR (95%CI) p-value

Maintenance therapy	0.53 (0.15 - 1.82) 0.31	0.54 (0.29 - 1.01) 0.57	0.14 (0.22 - 0.77) 0.02	0.39 (0.20 - 0.76) 0.006

Conclusions: In this real-world cohort of patients with MM undergoing ASCT, survival outcomes were influenced by specific clinical and therapeutic factors. Split-dose melphalan conditioning and a higher comorbidity burden were associated with inferior OS, whereas post-transplant consolidation and maintenance therapies conferred significant survival benefits. These findings support individualized transplant strategies and highlight the importance of local real-world evidence to optimize post-transplant outcomes.

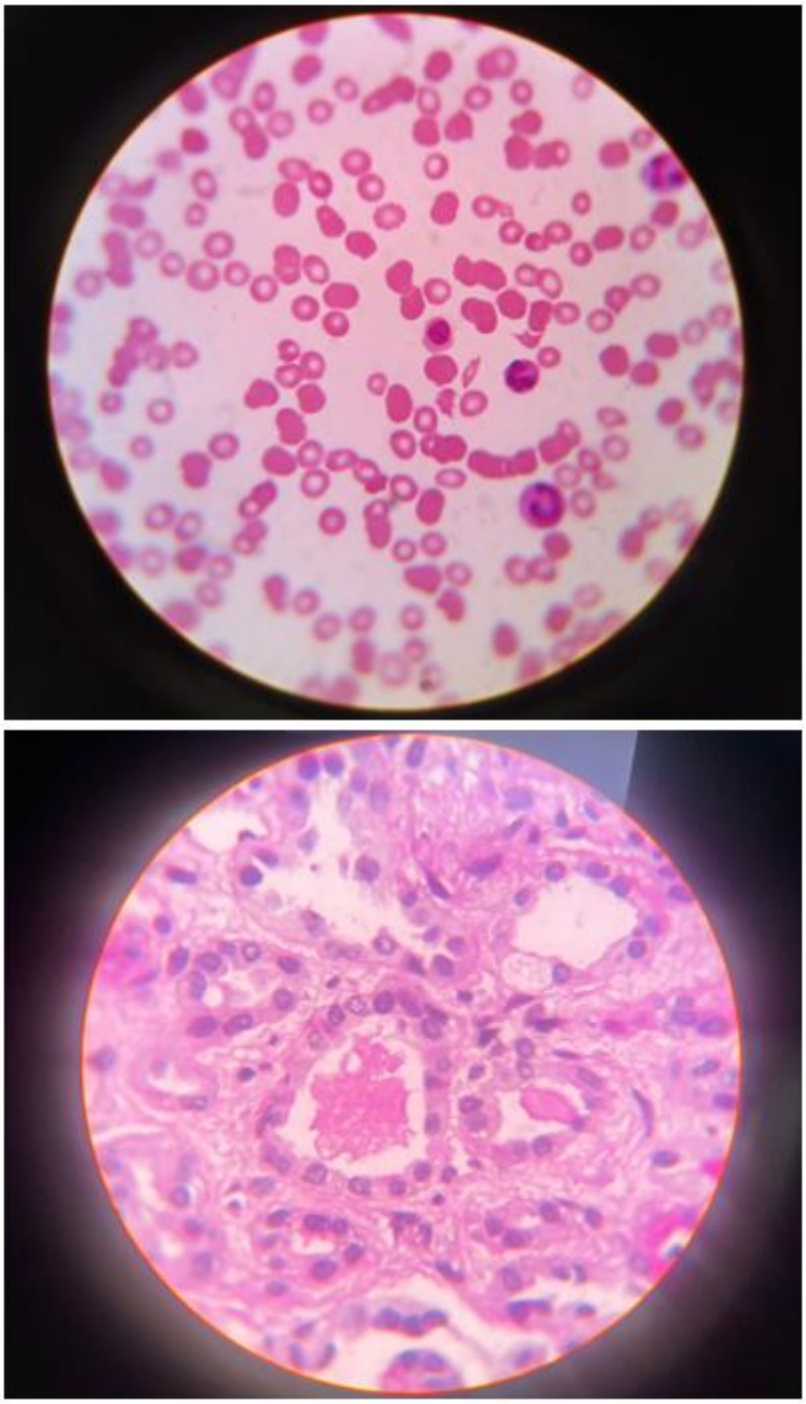
DRUG INDUCED THROMBOTIC MICROANGIOPATHY (TMA) IN A CASE OF MULTIPLE MYELOMA

Ganesan Subramanian[1,2]
[1]Kannappa Memorial Hospital and Cancer Center, Chennai, India, [2]Kannappa Memorial Hospital, Chennai, India

Background: Carfilzomib is a second-generation proteasome inhibitor commonly used in the treatment of relapsed / refractory multiple myeloma. Carfilzomib is used for second-line treatment , following disease progression or resistance to initial treatment regimens. Carfilzomib has been implicated in drug-induced thrombotic microangiopathy (TMA), a rare but severe adverse event, characterized by microangiopathic hemolytic anemia, thrombocytopenia, and acute kidney injury resulting from endothelial injury and microvascular thrombosis leading to end-organ damage.

Methods: A 51-year-old female was diagnosed with IgG kappa multiple myeloma, ISS stage I, in October 2024. At the time of diagnosis, no high-risk cytogenetic abnormalities were identified. Bone marrow aspirate showed 59% plasma cells. Serum protein electrophoresis revealed an M-band of 0.90 g/dL, and the kappa free light chain was 101.64 mg/L First-line chemotherapy with 4 cycles of VRd regimen (bortezomib, lenalidomide, dexamethasone) and 2 cycles of VCD (bortezomib, cyclophosphamide, dexamethasone) was initiated. Bone marrow done as part of pre BMT work up in which aspirate had 19 % plasma cells and biopsy showed sheets of plasma cells. In view of persistent disease she was started on therapy with carfilzomib, cyclophosphamide, and dexamethasone (KCD regimen). First cycle of KCD was tolerated well.
She received the Day 1 dose of carfilzomib of the second cycle as scheduled. Four days later, she presented to the emergency department with complaints of fatigue, vomiting, and reduced urine output. Laboratory investigations revealed acute kidney injury, with serum creatinine elevated to 6.2 mg/dL. Hemoglobin dropped to 8.2 g/dL, and platelet count was 27,000/µL. There was elevated serum lactate dehydrogenase to 2101 IU/L, decreased serum haptoglobin, and the presence of schistocytes (6%) on peripheral blood smear (Fig 1), suggestive of microangiopathic hemolytic anemia (MAHA). Complement studies showed an initially normal C3 level, which subsequently decreased, while C4 remained within normal limits. Other causes of TMA like TTP, aHUS, DIC and malignancy were ruled out.



Results: • The patient was initiated on therapeutic plasma exchange, hemodialysis, and intravenous methylprednisolone, followed by a tapering regimen of oral corticosteroids. Despite undergoing three sessions of plasma exchange and four sessions of hemodialysis ,

the patient remained anuric, with urine output persistently below 10 mL/day. In view of sustained anuria and biopsy-proven TMA, the patient was counselled regarding complement blockade therapy with eculizumab. She was administered her first dose of eculizumab 900 mg intravenously. Maintenance hemodialysis was continued during this period. The patient received a second dose of eculizumab after one week. By Day 15 following the initial dose, her urine output improved to 1500 mL/day, and hemodialysis was discontinued.
• After complete recovery she was started on 2 cycles of VCD chemotherapy following which she was taken for autologous HSCT.
• Conditioning-- melphalan 140 mg/m2.
• Complications during transplant- Grade 2 Mucositis and febrile neutropenia but there was no further episodes of TMA.
• Neutrophil engraftment on D+ 10
• Platelet engraftment on D +10.
She was successfully discharged after D+13 post autologous BMT.

Conclusions: TMA represents a potentially fatal clinical entity that necessitates prompt recognition and immediate therapeutic intervention to mitigate mortality risk.

Disclosure: There is no conflict of interest.

OUTCOMES OF SECOND AUTOLOGOUS STEM CELL TRANSPLANTATION AS RESCUE THERAPY IN RELAPSED MULTIPLE MYELOMA PATIENT, WITHOUT CRYOPRESERVED CD34. CASE REPORT FROM TRANSPLANT CENTER IN VENEZUELA

Marcos Hernandez[1], *Maria Antonietta Aray*[2], *Rosmelvic Becerrit*[2], *Maylu Collazo*[3], *Amyibel Paradas*[2], *Laura Saavedra*[2]
[1]*Bone Marrow Transplante Center Abraham Sumoza/ Universidad de Carabobo/LABMT, Valencia, Venezuela (Bolivarian Republic of),* [2]*Bone Marrow Transplante Center Abraham Sumoza, Valencia, Venezuela (Bolivarian Republic of),* [3]*Bone Marrow Transplante Center Abraham Sumoza/LABMT, Valencia, Venezuela (Bolivarian Republic of)*

Background: Consolidation with Autologous Stem Cell Transplantation (ASCT) after induction therapy has shown a positive impact in Overall Survival (OS) and Event Free Survival (EFS) in patients with Multiple Myeloma (MM), however, the patients in Venezuela with Relapsed MM (RMM) where there is no access to: Anti-CD38-mAb, bi-specifics and cellular therapy (CAR-T), the only option therapeutic options is conventional therapy followed by a Second ASCT (2ASCT).

Methods: We conducted a retrospective study of all the patients with RMM who underwent a 2ASCT in the Bone Marrow Transplant Center "Dr Abraham Sumoza" in Venezuela from 2013 to 2025.

Results: Only one MMR patient underwent a 2ASCT, and it was the case of a 49year-old female diagnosed with MM ISS III in 2013, who was treated with Bortezomib, Thalidomide and Dexamethasone for 8 cycles achieving a Very Good Partial Response (VGPR), then proceeded to ASCT; a total of 4.5x106cell/kg granulocyte colony-stimulating factor (GCSF)-mobilized Peripheral Blood (PB) stem cells were collected and infused at that time, no remaining CD34+ cellular product was cryopreserved for future purposes, the conditioning regimen was Melphalan 180mg/m2, showing signs of engraftment by day 10. Complete Response was achieved by day 120 post-ASCT, and she received maintenance therapy with thalidomide for 2 years.
8 years after the first ASCT, the patient suffered a relapsed and received treatment with Cyclophosphamide, bortezomib, and dexamethasone for 8 cycles, obtaining a VGPR, she underwent a 2ASCT; using fresh collectedGCSF-mobilized PB stem cells as source, a total of 2x106cells/kg CD34 cells was obtained, the conditioning regimen of choice was Melphalan 200mg/m2 (Mel200). Evidence of neutrophile and platelet recovery was on days 13 and 15, respectively. The patient did not present any infection or need for platelet or red blood cell transfusion during the aplastic period. Currently, she has been on Lenalidomide as maintenance therapy for the last 2 years. After 3years of follow-up, she still has VGPR, with no signs of second malignancies or hematologic disorders.
The results presented in the study can be compared with other retrospective studies, where the authors concluded that a VGPR before a 2ASCT, a time between the first ASCT and the start of therapy for RMM of at least 2 years, and the use of Lenalidomide as maintenance therapy after 2ASCT, have a positive impact on OS and EFS.

Conclusions: A 2ASCT in an RMM patient had low toxicity and was associated with a good OS and EFS in our patient. The use of Melphalan as a conditioning regimen in previous ASTC had no impact on a second mobilization and collection of GCSF-mobilized PB stem cells. A VGPR before proceeding to a 2ASCT is key for a better outcome; however, we need more data to statistically prove our results. Therefore, we concluded that a 2ASCT is a feasible treatment for patients with RMM in our institution.

Background: The hypocellular Myelodysplastic Syndromes (h-MDS), a rare subtype accounting for 10–15% of Myelodysplastic Syndromes (MDS) patients, that is defined by reduction of ≤25% bone marrow cellularity, age adjusted according to WHO-2022. These patients are typically younger and characterized by more severe cytopenias, higher transfusion dependence and lower blast percentages as compared to normo/hypercellular MDS (n-MDS). The objective of this study is to describe the clinical characteristics and transplantation outcomes of patients with h-MDS compared to those with n-MDS, based on data from the Latin American Registry.

Methods: This is a retrospective study with 458 patients undergoing HCT at diagnosis. Clinical data were obtained from the transplant registry of 38 centers in Latin America (LA) between January 2000 to June 2025. Survival curves were performed the Kaplan-Meier method, and log-rank test. The statistical program used was SPSS v.23.1 $p<0.05$ were considered statistically significant.

Results: Among a total of 458 patients, 69 (15.07%) were diagnosed with h-MDS, while 389 (84.93%) had n-MDS. The median age was 52 years in the h-MDS cohort and 57 years in the n-MDS cohort. In the h-MDS group, 39 patients (56,52%) were male, with a mean age of 57.0±20.3 years, According to the IPSS-R, (53.85%) of patients were classified as intermediate risk, (25.64%) as low/very low risk, (15.38%) as high risk, and (5.13%) as very high risk. Most received grafts from compatible related donors (62,32%) and peripheral blood stem cells (55,07%) using myeloablative conditioning (68,12%). Death occurred in 31.88% of patients with MDS-h, post-transplant complications were observed in (75.36%) of patients and most patients did not relapse (98.25%) (Table 1). Compared with patients with n-MDS, those with h-MDS were younger (<65 years; $p=0.017$) and more frequently classified in the IPSS-R Low and Intermediate risk categories ($p=0.017$). They were also more likely to have received prior chemotherapy ($p=0.030$) and reduced-intensity conditioning regimens ($p=0.030$). In addition, h-MDS patients had a significantly lower relapse rate compared with n-MDS patients (p=0.023) (Table 1). No statistically significant difference in overall Survival (OS) was observed between patients with h-MDS and n-MDS undergoing allo-HCT, both at 5 years ($p=0.07$; Figure 1A). At 5-years, progression-free survival (PFS) patients with h-MDS had a significantly lower risk of relapse or death compared to n-MDS after allo-HCT (HR=0,63; CI 95%=0,40-0,99; p=0,046; Figure 1B). The Non-relapse mortality (NRM) at 5 years after allo-HCT did not differ significantly between patients with h-MDS and n-MDS ($p=0.392$; Figure 1C). In the univariate analysis, IPSS-R very high-risk was associated with an increased risk of mortality (HR=2.18; 95%CI:1.33–3.59; $p=0.002$). In the multivariate analysis, male sex (HR=1.36; 95% CI:1.00–1.85; $p=0.047$) and IPSS-R very high-risk (HR=2.85; 95% CI: 1.69–4.81; $p<0.001$) remained significant independent predictors of worse survival.

Figure 1: Overall survival (OS), Progression Free-Survival (PFS) and Non-relapse mortality (NRM) at 5 Years After Allo-HCT in Patients with (h-MDS) and (n-MDS) (n=458).

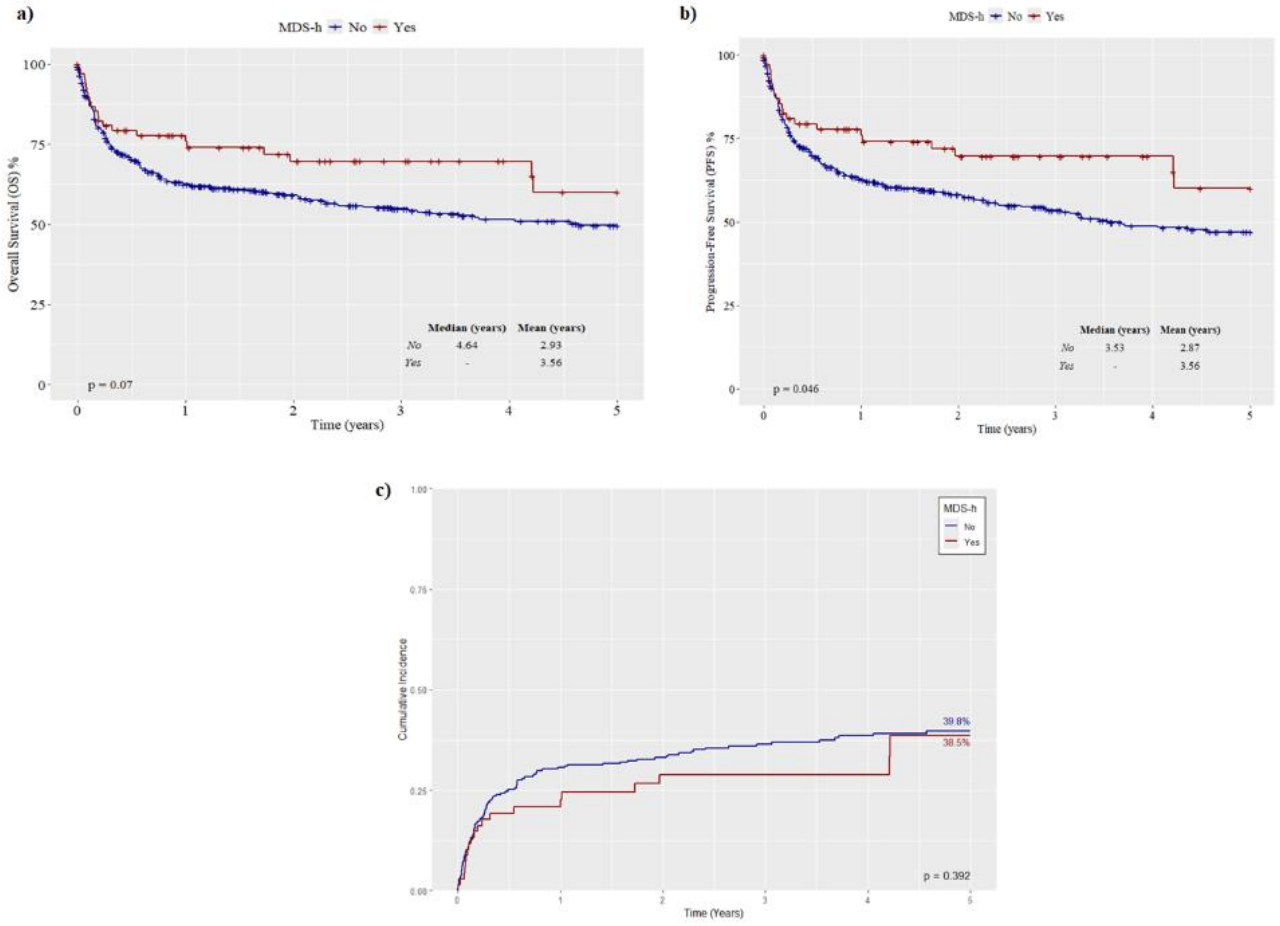

Table 1: Patient characteristics (N=458).

Variable	Group		
	MDS-h (n = 69)	MDS-n (n = 389)	*p*
Age Group			

Table 1: Patient characteristics (N=458).

< 65 anos	63 (92,65%)	316 (81,87%)	**0,042** [a]
65 years or older	5 (7,35%)	70 (18,13%)	
IPSS-R b			
Very Low Risk	0 (0%)	2 (0,87%)	**0,017**[b]
Low	10 (25,64%)	31 (13,54%)	
Intermediate	21 (53,85%)	81 (35,37%)	
High Risk	6 (15,38%)	84 (36,68%)	
Very High Risk	2 (5,13%)	31 (13,54%)

Myeloablative	47 (68,12%)	263 (67,61%)	
Non-Myeloablative	0 (0%)	27 (6,94%)	
Relapse			
Yes	1 (1,75%)	44 (13,21%	**0,023**[a]
No	56 (98,25%)	289 (86,79%)	

Note: p-value a. Fisher Exact Test b: Chi-Square Test.*Bacterial infections, including multidrug-resistant bacterial infections, and fungal infections. Abbreviations: GVHD: graft-versus-host disease; HLA: Human Leucocyte Antigen; HCT: Hematopoietic Cell Transplantation; R-IPSS: Revised International Prognostic Scoring System.

Conclusions: We found that h-MDS was associated with distinct clinicobiological characteristics, as evidenced by significant differences in survival and IPSS-R risk category distribution. These findings reinforce the biological heterogeneity between subgroups and its impact on prognosis, which may influence decisions regarding HCT.

IMPACT OF CONCURRENT GENETIC ALTERATIONS ON OUTCOMES AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH TP53-MUTATED AML/MDS: A MULTI-CENTER COHORT STUDY

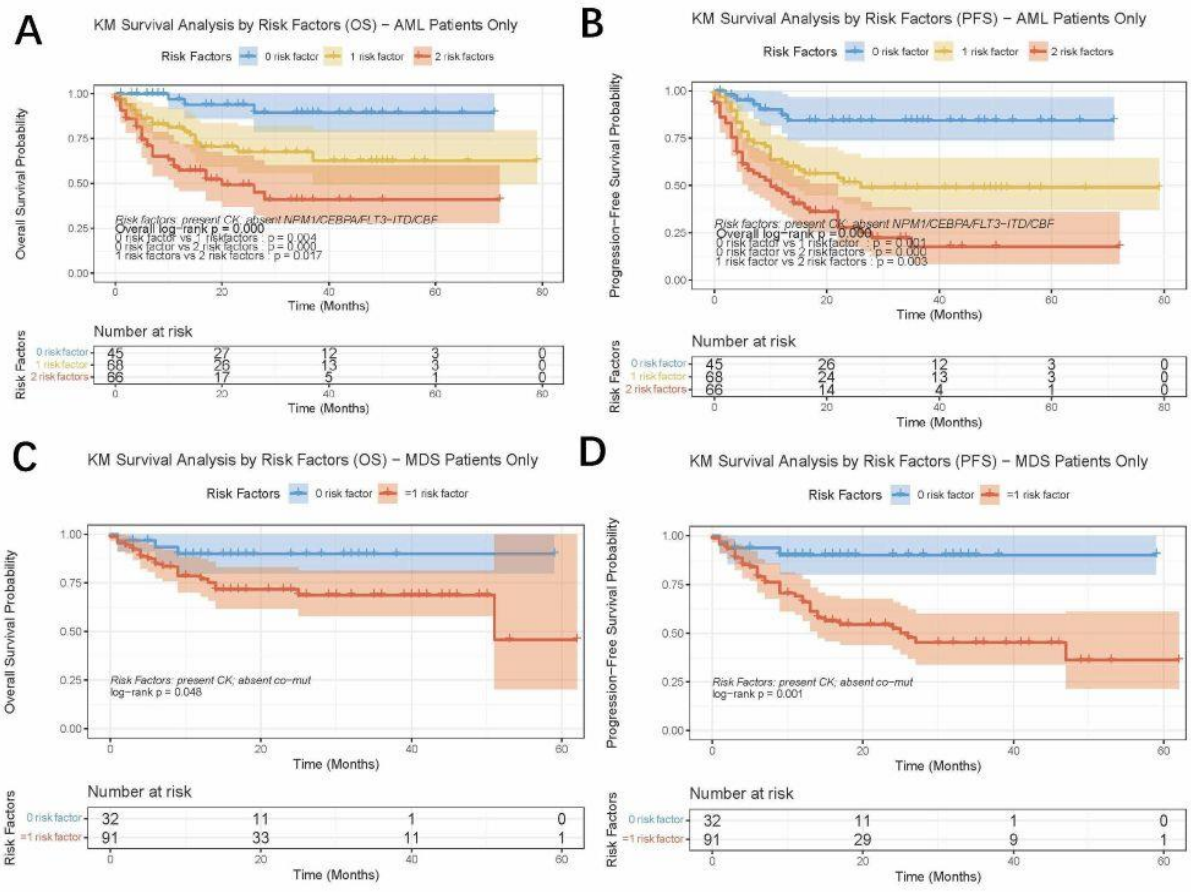
*Yao Sun[1], Jing Liu[2], Jia Chen[3], Li Xuan[4], Jia Liu[5], Shengye Lu[2], **Zhengli Xu**[2], Lanping Xu[2], Menglin Fan[4], Xi Zhang[5], Qifa Liu[4], Depei Wu[3], Xiaojun Huang[2], Daihong Liu[1]*
[1]Chinese PLA General Hospital, Beijing, China, [2]Peking University People's Hospital, Beijing, China, [3]The First Affiliated Hospital of Soochow University, Suzhou, China, [4]Southern Medical University, Guangzhou, China, [5]Army Medical University, Chongqing, China

Background: TP53 mutations are associated with poor prognosis in acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS), even after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Discrepancies in the criteria used to define TP53 mutation status across professional societies and landmark studies, coupled with limited access to comprehensive TP53 allelic state assessment, have led to inconsistent clinical interpretations of outcomes in this population. While complex karyotype (CK) is a well-established adverse prognostic factor in TP53-mutated myeloid neoplasms, the impact of other coexisting genetic alterations on prognosis remains incompletely understood.

Methods: This multi-center, retrospective study analyzed 303 consecutive patients with TP53-mutated AML or MDS who underwent first allo-HSCT between January 2018 and December 2023. All patients had TP53 mutation confirmed by next-generation sequencing. Endpoints included overall survival (OS), progression-free survival (PFS), cumulative incidence of relapse (CIR), and non-relapse mortality (NRM). Univariate and multivariate Cox models were used to identify prognostic factors. Subgroup and combined risk factor analyses evaluated the integrated impact of cytogenetic and molecular profiles.

Results: The cohort included 179 AML and 124 MDS patients. A complex karyotype was present in 133 (43.9%) patients, and 47 (15.5%) had chromosome 17p deletion. The median number of co-occurring myeloid mutations was 1; 180 (59.4%) patients had ≥1 co-occurring mutation, and 122 (40.2%) had ≥2. The overall burden of co-occurring somatic mutations was significantly higher in AML patients than in MDS patients (median 2 vs. 0, $p<0.001$). The most frequently co-mutated genes in the entire cohort included *TET2* (14%), *ASXL1* (9%), *DNMT3A* (7%), *RUNX1* (6%), and *FLT3-ITD* (4%). With a median follow-up of 21 months, the 3-year OS, PFS, CIR, and NRM rates for the entire cohort were 68%, 50.4%, 32.8%, and 17.6%, respectively. Univariate analysis identified CK as a significant predictor

for inferior OS (HR=2.813, 95% CI: 1.613–4.905, p<0.0001) and PFS (HR=2.745, 95% CI: 1.762–4.276, p<0.0001). In AML patients, the presence of specific concurrent genetic alterations (SCGAs)—CBF fusion genes, NPM1, FLT3-ITD, or CEBPA mutations—was associated with significantly improved OS (HR=0.157, 95% CI: 0.056–0.435, p<0.0001) and PFS (HR=0.198, 95% CI: 0.095–0.412, p<0.0001). Integration of CK and SCGA status enabled stratification of AML patients into three distinct prognostic tiers (favorable: 0 risk factors; intermediate: 1 factor; adverse: 2 factors) for both OS and PFS (all p<0.0001) (**Figure 1A-B**). In MDS, the presence of any co-occurring myeloid mutation (≥1) was a favorable factor for PFS (HR=0.457, 95% CI: 0.230–0.911, p=0.023). We therefore established a model that categorized patients based on the presence of at least one adverse risk factor (either CK positivity or the absence of any co-mutation). This model effectively stratified patients into two distinct risk tiers, with significant differences observed in both OS (p = 0.048) and PFS (p < 0.001) (**Figure 1C-D**).



Conclusions: For patients with TP53-mutated AML/MDS undergoing allo-HSCT, integrating complex karyotype, co-mutation burden, and specific fusion gene status provides significant prognostic information. These findings suggest the potential utility of a comprehensive genetic risk stratification model to guide clinical decision-making for this high-risk population.

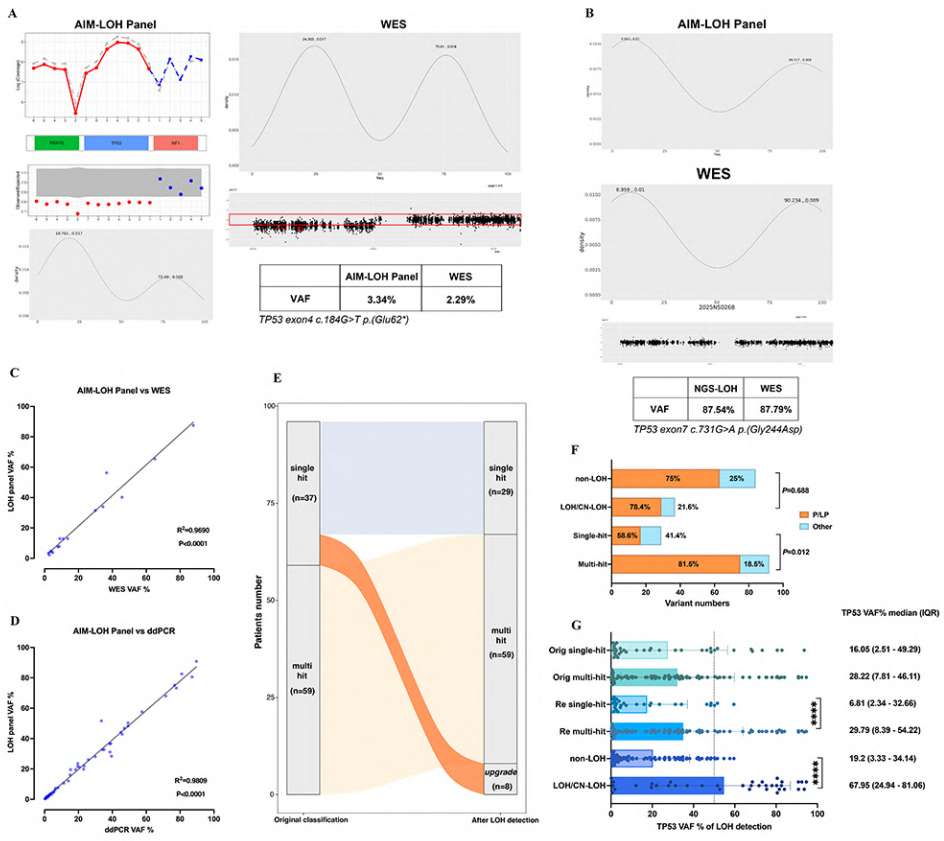
Background: TP53 mutations occur in around 10% of de novo AML or MDS and are frequently accompanied by copy-neutral loss of heterozygosity (CN-LOH), leading to biallelic TP53 inactivation and an intrinsically adverse prognosis. Current LOH detection relies on costly and time-consuming WGS/WES or SNP arrays, hindering routine clinical application and consequently leading to the misclassification of some multi-hit patients as single-hit. To address this gap, we established a novel targeted NGS-based assay for the direct detection of TP53 LOH/CN-LOH, validated its concordance with WES, and assessed its clinical significance.

Methods: A targeted SNP panel spanning the TP53 exonic region and ±500 kb flanks were designed (AIM-LOH Panel). Genomic DNA was sequenced on an Illumina NovaSeq platform, followed by quality control and alignment. A depth-matched reference was generated by dynamically selecting control samples with similar coverage profiles. Copy-number states across the target region were inferred using DECoN and categorized as deletion, neutral, or duplication. Variant allele frequencies (VAFs) at informative heterozygous loci were modeled using kernel density estimation (KDE) and were integrated with CNV calls to distinguish CN-LOH from LOH with deletion. The assay was applied to 96 TP53-mutated patients; 14 samples were cross-validated by WES. The association between biallelic status, upgraded by the LOH assay, and clinical outcomes was investigated.

Results: Bone marrow samples were obtained at diagnosis or pre-transplant during non-remission (61 MDS, 33 AML, 2 CMML/MPN). TP53 multi-hit at diagnosis was defined as: (i) ≥2 TP53 mutations, (ii) a single TP53 mutation with VAF >55%, or (iii) a single TP53 mutation with del(17)/del(17p). At diagnosis, 60.4% (59/96) were classified as multi-hit. AIM-LOH Panel detected LOH events in 34.4% (33/96) of patients (9 LOH, 24 CN-LOH) and

reclassified 8 patients from single-hit to multi-hit ("upgrade multi-hit"). VAFs were higher in reclassified multi-hit cases and in LOH-positive cases (P<0.0001). LOH events were fully concordant with WES (7 LOH/CN-LOH, 7 non-LOH), with strong VAF correlation (R^2=0.9590, P<0.0001). VAFs of ddPCR in 53 samples also showed high concordance with NGS-LOH (R^2=0.9809, P<0.0001). Notably, multiple TP53 mutations were more frequent in the non-LOH group than the LOH/CN-LOH group (33.3% vs 12.1%, P=0.024) and were inversely associated with LOH in multivariable analysis (adjusted OR 0.22, P=0.015). Patients were stratified as single-hit (n=29), multi-hit (n=59), or upgrade multi-hit (n=8). The single-hit group had higher 1-year OS than the multi-hit group (77.8% vs 57.4%, P=0.0215). Among 78 transplanted patients, post-transplant outcomes did not differ significantly across groups. In the entire cohort, HSCT independently predicted improved OS (HR=0.34, P=0.0043) and PFS (HR=0.49, P=0.034).



Factors associated with TP53 LOH	Univariate HR (CI95)	p.value	Multivariate OR (CI95)	p.value
CK/MK	1.5 (0.63-3.7)	0.366	1.99 (0.79-5.29)	0.154

TP53 >1 mutations	0.27 (0.075-0.82)	0.0308	0.22 (0.057-0.68)	0.0149
Age (per 10 years)	1.39 (0.99-2.05)	0.0726	1.46 (1.03-2.17)	0.0426
Factors influenced OS in whole cohort	**Univariate HR (CI95)**	**p.value**	**Multivariate HR (CI95)**	**p.value**
CK/MK	1.93 (1.02-3.67)	0.044	1.78 (0.88-3.61)	0.1108
Received HSCT	0.33 (0.16-0.67)	0.002	0.34 (0.16-0.71)	0.0043
LOH	1.33 (0.68-2.58)	0.401	NA	NA
Multi-hit	2.21 (1.1-4.44)	0.026	1.45 (0.62-3.38)	0.3954
>1 mutations	1.45 (0.77-2.72)	0.252	1.14 (0.56-2.29)	0.7205
Factors influenced PFS in whole cohort	**Univariate HR (CI95)**	**p.value**	**Multivariate HR (CI95)**	**p.value**
CK/MK	1.26 (0.75-2.13)	0.377	NA	NA
Received HSCT	0.46 (0.24-0.86)	0.016	0.49 (0.26-0.95)	0.0338
LOH	1.26 (0.72-2.23)	0.418	NA	NA
Multi-hit	1.52 (0.88-2.6)	0.132	1.38 (0.8-2.4)	0.2498
>1 mutations	1.2 (0.68-2.1)	0.527	NA	NA

Conclusions: This AIM-LOH Panel demonstrated complete concordance with WES at lower cost and shorter turnaround time. It reclassified 8 patients from single-hit to multi-hit, suggesting that LOH inference based on karyotype and VAF may misassign multi-hit. LOH was more common in older patients and those with a single TP53 mutation, and HSCT associated with improved outcomes. Limitations include the small sample size and the lack of validation in samples with low VAF. Overall, this method may facilitate risk stratification and support timely clinical decision-making.

Background: Myelodysplastic/Myeloproliferative neoplasms (MDS/MPN) are heterogeneous category of myeloid malignancies characterized by overlapping pathological and molecular features of both Myelodysplastic Syndrome (MDS) and Myeloproliferative neoplasms (MPN). Chronic myelomonocytic leukaemia (CMML), MDS/MPN with neutrophilia, MDS/MPN with SF3B1 mutation and thrombocytosis, and MDS/MPN, not otherwise specified (NOS) forms. These disorders often present with varying degrees of cytopenias and cytoses, and their prognosis remains poor despite advances in treatment. The objective of this study is to describe the clinical characteristics and transplantation outcomes of patients with MDS/MPN

who underwent allo-Hematopoietic Cell Transplantation (HCT) in Brazil and compare their outcomes with those of patients with other MDS.

Methods: This retrospective registry based-study included all consecutive 570 patients who received their first allo-HCT from any donors for MDS/MPN between 2012 and 2024, and reported to the Brazilian Registry of the Hematopoietic Cell Transplantation and Cell Therapy (RBTCH-TC), a partnership between the Brazilian Society of Hematopoietic Cell Transplantation and Cellular Therapy (SBTMO-CT) and the Center for International Blood & Marrow Transplant Research Registry. Categorical variables were compared using the Chi-square test or Fisher's Exact Test were conducted. Survival probabilities were estimated by the Kaplan-Meier method ($p<0.05$). Multivariable analysis was performed using Cox proportional hazards regression with a, stepdown approach, ($p<0.1$), using R Software (V. 4.2.1).

Results: Of 570 included patients, 94 (16.5%) had MDS/MPN and 476 (83.5%) had other MDS classifications (MDS). Among the 94 patients with MDS/MPN, the most frequent types were unclassifiable (60.6%) and CMML (29.8%). In the MDS/MPN group, 48.9% of patients were aged ≥60 years, 60.6% were male, most received grafts from haploidentical donors (47.9%), the majority had HCT-CI scores of 0 (57.4%), the mobilized peripheral blood was the predominant graft source (69.1%), and conditioning regimen was myeloablative in 50% of cases. MDS/MPN patients were significantly older ($p<0.001$) and more frequently had Karnofsky performance status (KPS) ≤80% ($p=0.004$) compared with MDS patients (Table 1). At 25 months, overall survival (OS) was significantly lower in MDS/MPN patients (41.9%) compared to those with MDS (59.7%, $p=0.03$; Figure 1a). Relapse-free survival (RFS) was also inferior in MDS/MPN patients (39.2% vs. 56.6%, $p=0.003$; Figure 1b), while non-relapse mortality (NRM) showed no statistically significant difference between groups ($p=0.331$; Figure 2C). In univariate analysis, MDS/MPN was associated with inferior OS (HR=1.44, 95%CI 1.03–2.00, $p=0.031$) and RFS (HR=1.58, 95%CI 1.16–2.14, $p=0.003$). In multivariable analysis, MDS/MPN remained an independent risk factor for inferior RFS (HR=1.35, 95%CI1.03–1.88; $p=0.0079$). The main limitation of this study was the heterogeneous patient characteristics.

Table 1: Patient and transplant characteristics of the study cohort (N=570).

Characteristics	MDS (n = 94)	MDS/MPN (n = 476)	P value
Age at transplant, median years (range)	50 (23-62)	59 (45.5-65.8)	**< 0.001***
Patient sex, n (%)			0.30
• Female	215 (45.2)	37 (39.4)	

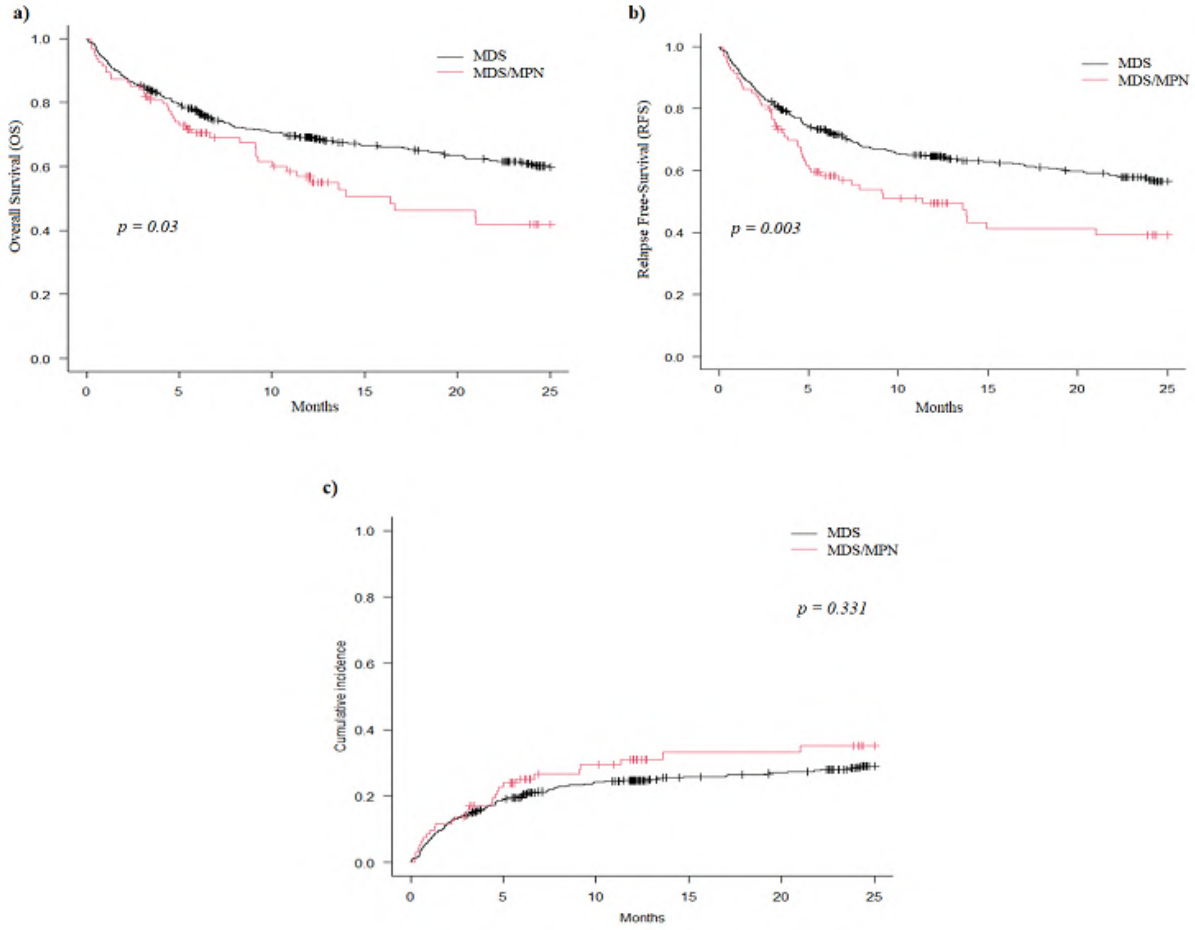
Table 1: Patient and transplant characteristics of the study cohort (N=570).

• Male	261 (54.8)	57 (60.6)	
HLA donor type, n (%)			0.243
• Matched Related	153 (32.1)	22 (23.4)	
• Matched Unrelated	119 (25)	27 (28.7)	
• Mismatched (Haploidentical)	204 (42.9)	45 (47.9)	
Graft cell source, n (%)			0.23
• Mobilized peripheral blood	284 (59.7)	65 (69.1)	
• Bone marrow	188 (39.5)	29 (30.9)	
Karnowfsky Performance Status at transplant, n (%)			**0.004***
• 100-90	383 (80.5)	65 (69.1)	
• ≤80	86 (18.1)	23 (24.5)	
Survival Status, n (%)			0.244
• Alive	284 (59.7)	50 (53.2)	
• Dead	192 (40.3)	44 (46.8)	
Note: p-value Chi-square test, *p<0.05. Abbreviations: HLA, Human Leukocyte Antigen;			

Table 1: Patient and transplant characteristics of the study cohort (N=570).

MDS: myelodysplastic syndromes; MDS/MPN: Myelodysplastic/myeloproliferative neoplasms.

Figure 2: Overall Survival, Relapse-Free Survival (RFS) and Non-relapse mortality (NRM) after First Allogeneic HCT in Patients with MDS (N=476) versus MDS/MPN (n=94). (A) The survival estimates at 25 months were 59.7% (95% CI, 54.7-64.4) for patients with MDS (black line), and 41.9% (95% CI, 29.3%-53.9%) for patients with MDS/MPN (red line). (B) The survival estimates at 25 months were 56.5% (95% CI, 51.5-61.2) for patients with MDS (black line), and 39.2% (95% CI, 27.5%-50.7%) for patients with MDS/MPN (red line). (C) The cumulative incidence of relapse estimates at 25 months were 29% for patients with MDS (black line), 35.2% for patients with MDS/MPN (red line).



Conclusions: In conclusion, patients transplanted for MDS/MPN were older, had poorer performance status, and experienced inferior OS and RFS compared with patients transplanted for other MDS subtypes. These findings confirm the adverse prognosis of MDS/MPN and underscore the need for further studies aimed at optimizing conditioning

strategies, donor selection, and post-transplant management to improve curative outcomes for this challenging patient population.

OUTCOME OF UNRELATED AND HAPLOIDENTICAL HSCT AMONG CHILDREN WITH MYELODYSPLASTIC SYNDROME

*Rimma Khismatullina[1], Larisa Shelikhova[1], Olga Molostova[1], **Mariya Ilyushina**[1], Sergey Blagov[1], Darya Shasheleva[1], Anna Bogoiavlenskaia[1], Svetlana Kozlovskaia[1], Evelina Lyudovskih[1], Medina Gurzhihanova[1], Anna Kazakova[1], Marina Gaskova[1], Yakov Muzalevsky[1], Aleksey Kazachenok[1], Dmitry Pershin[1], Yulia Rodina[1], Anna Scherbina[1], Dmitriy Balashov[1], Aleksey Maschan[1], Michael Maschan[1]*
[1]The Dmitry Rogachev National Medical ResearchCenter of Pediatric Hematology, Oncology and Immunology of Ministry of Healthcare of the Russian Federation, Moscow, Russian Federation (the)

Background: Myelodysplastic Syndrome (MDS) in children is a rare hematologic disorder, characterized by dysregulation of hematopoiesis and a high risk of progression to acute myeloid leukemia. Despite significant advances in the diagnosis and treatment of MDS in adults, there remains a need in pediatric practice to accumulate clinical experience and analyze outcomes.

Methods: 36 patients with MDS received allogeneic hematopoietic stem cell transplantation (HSCT). 16 patients were treated using the αβ T-cell depletion platform, 17 patients were treated using post-transplant cyclophosphamide (PTCy), 3 – with conventional CNI-based GVHD prophylaxis (group characteristics, table 1).
All patients had cytopenia: transfusion dependence, leukopenia with neutropenia moderate to severe, 5 patients had progression to acute myeloid leukemia (AML).
17 cases had germline condition predisposing to MDS: 2 - Shwachman-Diamond syndrome (SDS), 2 - Severe Congenital Neutropenia, 2 unspecified primary immune deficiency, 1 patient due to Diamond-Blackfan anemia, 2 patients had Down syndrome, 1 patient had Noonan syndrome. Eight patients (22.2%) were found to have SAMD9/SAMD9L (all had monosomy 7), 1 patient had GATA1 (Down syndrome), 1 patient had GATA2, and 1 patient had CHECK2. Cytogenetic characteristics of MDS: monosomy 7 was detected in 14 patients (38.9%), trisomy 8 in 2 patients (5.5%), and 20 patients (55.6%) had no cytogenetic rearrangements.
27 patients (75%) did not receive chemotherapy before HSCT. 5 patients with AML received various courses of hypomethylating agents.
Preparative regimen included treosulfan 42 gr/m^2, fludarabine 150 mg/kg, thiotepa 10 mg/kg or melphalan 140 mg/m^2. Thymoglobulin 5mg/kg or ATGAM 100 mg/kg and rituximab 200mg/m^2 were used in a proportion of cases.
Post-transplant GVHD prophylaxis included for αβ T-cell depletion tacrolimus until day 180. In the PTCy group ruxolitinib 10 mg/m² until day +90, vedolizumab 10 mg/kg on days 0, +14,

+28, +60, abatacept 10 mg/kg on days +5, +14, +28, +60, +90 and PTCy on days +3, +4. For PBSC grafts were depleted of TCRαβ and CD19 cells with CliniMACS device. For PTCy unmanipulated bone marrow was used.

Group characteristics, table 1

Sex, male/female	16/20
Age, median at HSCT, years	8.7 (0.96-16.92)
Median time from diagnosis to HSCT, years	0.69 year (0.07-11.12)
Type of donor	
Haploidentical/ unrelated matched (MUD)/ matched related (MRD)	18/17/1
Graft characteristics	
αβT-CD	
CD34, *10^6/kg	7.15 (2.76-13.2)
T cells, *10^6/kg	13.35 (4.3-23.03)
PTCy	
CD34, *10^6/kg	5.03 (2.51-6.49)
T cells, *10^6/kg	29 (0.3-61.48)

Results: Cumulative incidence (CI) of engraftment were 0.917 (95% CI 0.83–1) for all patients. αβ T-cell depletion: the median 13 (9-26) days for white blood cells (WBC); 13 (9-29) days for platelets, PTCy: the medians 24.5 (15-33) days for white blood cells (WBC); 23.5 (13-256) days for platelets.
CI rejection was 0.26 (95% CI 0.14-0.48), 1 patient (competing events – 3 patients with no engraftment, 8 patients died). Eight patients died: 4 from TRM (1 patient with no engraftment, 1 patient with rejection, 2 patients from severe infection), 4 from progression (3 patients with AML, 1 patients with SDS). A median follow-up is 3.6 (0.29-13.43) years for all patients. Event–free survival was 66% (95% 49.5-82.8), respectively. Overall survival is 72.5% (55.8-89.2)

Conclusions: Significant proportion of pediatric MDS are associated with PID and inherited predisposition syndromes. Haploidentical and MUD HSCT provide a good chance of survival in pediatric MDS. Both key modern platforms of GVHD prevention, αβ T-cell depletion and PTCy, ensure acceptable outcome, although non-relapse mortality remains a problem.

P303

IMPACT OF ALCOHOL CONSUMPTION AND SMOKING HISTORY ON OUTCOMES AFTER ALLO-HCT IN PATIENTS WITH MDS-RELATED DISEASES

Tomohiro Kohmoto[1], *Hiroko Otsuji*[1], *Tomohiro Yamada*[1], *Atsushi Kubo*[1], *Norie Nakatani*[1], *Harunobu Tahara*[1], *Yuki Takeuchi*[1], *Yusuke Kagaya*[1], *Tatsunori Goto*[1], *Tetsuya Nishida*[1]
[1]*Japanese Red Cross Aichi Medical Center Nagoya Daiichi Hospital, Nagoya, Japan*

Background: Several studies have suggested associations between alcohol consumption, smoking, and the development of myelodysplastic syndromes (MDS), as well as disease prognosis. However, the impact of these lifestyle factors on outcomes after hematopoietic stem cell transplantation (HCT) in patients with MDS-related diseases remains unclear. We conducted a single-center retrospective study to evaluate the effects of alcohol consumption and smoking history before diagnosis on post-transplant outcomes.

Methods: We retrospectively analyzed 112 adult patients with MDS, acute myeloid leukemia with myelodysplasia-related changes (AML-MRC), or MDS/myeloproliferative neoplasm who underwent HCT between 2010 and 2024. Stem cell sources included bone marrow (n=57), peripheral blood stem cells (n=33), and cord blood (n=22).
Alcohol history was classified as drinkers (n=55) and non-drinkers (n=57) and further stratified into heavy (n=16) and light drinkers (n=32) according to the Japanese Ministry of Health recommendations, excluding missing data. Smoking history was categorized as ever-smokers (n=60) and never-smokers (n=52); ever-smokers were subdivided into current (n=15) and former smokers (n=45). Pack-years were used as a quantitative smoking index. Overall survival (OS), relapse rate (RR), and non-relapse mortality (NRM) after HCT were analyzed. Multivariable Cox proportional hazards models were constructed after confirming acceptable multicollinearity using variance inflation factors, adjusting for age, diagnosis, HCT-CI score, and IPSS-R.

Results: Drinkers showed inferior OS compared with non-drinkers (1-year OS, 55.2% vs 80.3%, P=0.005). Among drinkers, heavy drinkers demonstrated markedly worse OS than non-drinkers (1-year OS, 21.9%, P<0.001) and were identified as a strong adverse prognostic factor (HR 4.85, 95% CI 2.40–9.80, P<0.001). Drinkers tended to have higher early relapse rates than non-drinkers (1-year RR, 34.5% vs 15.8%, P=0.06), while heavy drinkers had a significantly higher relapse rate (1-year RR, 50.0%, P=0.005). NRM was numerically higher among heavy drinkers, although no statistically significant difference was observed.
Smoking history was not significantly associated with OS, although ever-smokers showed a trend toward inferior survival. No dose-dependent association with pack-years was identified. In contrast, ever-smokers had a significantly higher early relapse rate than never-smokers (1-year RR, 35.0% vs 13.5%, P=0.013), while NRM did not differ by smoking history.
In multivariable analyses, heavy alcohol consumption remained independently associated with inferior OS together with age and AML-MRC (HR 3.20, 95% CI 1.29–7.97, P=0.01). Neither alcohol consumption nor smoking history was independently associated with relapse

after adjustment, whereas IPSS-R high risk was the only significant predictor of early relapse.

Conclusions: In patients with MDS-related diseases undergoing HCT, heavy alcohol consumption was strongly associated with inferior overall survival and increased relapse in unadjusted analyses and remained an independent adverse prognostic factor for OS after multivariable adjustment. Smoking history was associated with higher relapse rates, although this effect was attenuated after adjustment. These findings suggest that alcohol consumption represents an important modifiable factor influencing post-transplant outcomes.

P304

CASE REPORT: CLEARANCE OF TP53 MUTATION POST ALLOGENEIC STEM CELL TRANSPLANT IN THE SETTING OF CHRONIC GVHD, WITH SUBSEQUENT TP53 MYELOID SARCOMA

Alma Corker[1,2,3], *Gai Fairnham*[1], *Alana Paterson*[1], *Vinita Agarwal*[1,2], *Adam Bryant*[1,2,3], *Lindsay Dunlop*[1,2,3], *Ashley McEwan*[1,2,3], *Anne-Marie Watson*[1,2,3], *Bartlomiej Getta*[1,2,3]
[1]*South Western Sydney Local Health District, Sydney, Australia,* [2]*NSW Health Pathology, Liverpool, Australia,* [3]*University of New South Wales, Sydney, Australia*

Background: *TP53* mutations in myeloid malignancies are well documented as adverse-risk genetic aberrations with extremely poor prognosis. Allogeneic haematopoietic stem cell transplant (allo-HSCT) is a potential curative therapy for *TP53-mutated* myeloid malignancies but outcomes remain poor in this population.

Methods: A 21-year-old male underwent a reduced intensity conditioning sibling HLA matched allo-HSCT (fludarabine and melphalan) in October 2021 for *TP53* (VAF 26%)-mutated myelodysplastic syndrome with marrow fibrosis and excess blasts in the context of Swachman-Diamond Syndrome (SDS). A female sibling was HLA matched and was identified as a heterozygous carrier of the pathogenic SDBS variant. The *TP53* (pTyr220) mutation was confirmed somatic.

Results: This TP53 variant was tracked using next generation sequencing (NGS) on post allograft samples and remained detected at VAF of 3% on day +30 despite full donor chimerism. During ciclosporin wean, the patient developed chronic GVHD of the mouth, eyes and liver. cGVHD was managed with topical steroids and intermediate dose oral prednisolone. As cGVHD developed, there was evident clearance of the TP53 mutation.
TP53 was sequenced at the following time points:

- Day+30 TP53 pTyr220 VAF 3%
- Day +100 TP53 pTyr220 <1% VAF
- Day +180 TP53 pTyr220 not detected
- Day +360 TP53 pTyr220 not detected
- 13 months post allo-HCT confirmed relapse with myeloid sarcoma

12 months post stem cell transplant (December 2022) the patient was diagnosed with relapsed *TP53*-mutated myeloid malignancy (CD13/CD33/CD34/CD117/HLA-DR+ and MPO weak) as myeloid sarcoma in the right shoulder and left paravertebral space. This was despite active cGVHD and no *TP53* mutation detectable on bone marrow biopsy one month prior. At the time of relapse, the bone marrow demonstrated 100% donor chimerism by XY FISH. Biopsy sample of the sarcoma was sent for next generation sequencing and identified *TP53* (pTyr220), *RUNX1* (pPro 325) and *NRAS* (pGln61) mutations The *TP53* and *RUNX1* mutations were detected on the initial diagnostic marrow in 2021 but the *NRAS* mutation was new. Despite salvage therapy the patient died due to progressive myeloid sarcoma.

Conclusions: Somatic mutations in acute myeloid leukaemia can be monitored as minimal residual disease (MRD) markers pre and post allograft. TP53 is not currently recognised as a valid MRD marker. Typically, persistence of MRD early post-transplant is highly associated with imminent relapse and few cases have described clearance of somatic mutations in the setting of developing cGVHD. The myeloid sarcoma was found to have a new *NRAS* mutation as well as the ancestral TP53 and RUNX1 variants. RAS pathway mutations are enriched in myeloid sarcoma and monocytic malignancies, which are known to have a predilection for sarcoma development.

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN LOW-RISK MYELODYSPLASTIC SYNDROME: A CASE SERIES OF SINGLE-CENTER EXPERIENCE

Nur Soyer [1], *Ajda Güneş*[1], *Fatma Keklik Karadag*[1], *Filiz Vural*[1]
[1]*Ege University, Izmir, Turkey*

Background: The indication for allogeneic hematopoietic stem cell transplantation (HSCT) in patients with lower-risk myelodysplastic syndrome (MDS) is controversial. Here we report the outcome of allogeneic HSCT in patients with low-risk MDS.

Methods: A total of 275 allogeneic stem cell transplantations (HSCT) were performed at Ege University Adult Bone Marrow Transplantation Unit in Turkey from January 2016 to November 2025. Six of them had undergone allogeneic HSCT with a low-risk MDS diagnosis. Medical records were evaluated retrospectively.

Results: Three of 6 patients were female and median age of diagnosis was 56.5 (28-69). Five of the six patients were diagnosed with MDS with low blasts, and one was diagnosed with MDS with low blasts and ring sideroblasts. Three patients had an ECOG score of 1 and three had a score of 0. The median ferritin level before transplantation was 1318 µg/L (140-6199). The median time to transplantation was 527.5 days (281- 2096) and the infused median stem cell count was 5.15 × 10^6/kg (range: 4.2– 8.25). The median donor age was 31 (range 20-52), and 4 donors were male and 2 were female. All patients and donors were

CMV positive. There was one major and one minor blood group incompatibility between recipients and donors. All transplants were performed using reduced-intensity conditioning. The median neutrophil and thrombocyte engraftment time were 24.5 (12-30) and 18 (12-27) days, respectively. Severe HSOS developed in 2 patients. CMV reactivation occurred in 1 patient and treated successfully. Acute GVHD (grade 1-2) developed in the gastrointestinal system in 1 patient. Median overall survival was 56 months (11-85.5). Median disease free survival was 12.75 months (1-68). At the last follow-up, 3 patients had died while 3 patients were healthy. Two patients died within the first 100 days because of severe HSOS.

Table 1: Characteristics of case series

Patients	Sex	Age at HSCT	R-IPSS	Risk Factors	Time to HSCT (days)	HCT-CI	Donor type	Conditioning regimen	HSOS	TRM	Alive
1	M	61	Low	Failure to erythropoietin, Severe neutropenia, > 2 U erythrocytes transfusion per month	2096	0	Haploidentical	Bu-Flu-TBI	Yes	Yes	No
2	F	44	Low	Failure to erythropoietin, > 2 U erythrocytes transfusion per month	527	0	MRD	Bu- Flu-AraC	No	No	Yes
3	F	29	Low	Severe thrombocytopenia	478	1	MMUD	Bu- Flu-AraC	No	No	Yes
4	M	70	Int	Poor cytogenetics, Severe thrombocytopenia	281	4	MMUD	Bu-Flu-ATG	No	No	No
5	F	59	Int	Severe thrombocytopenia	528	1	MUD	Flu-Cy-ATG	No	No	Yes
6	M	64	Int	Failure to erythropoietin	616	4	MUD	Bu-Flu-ATG	Yes	Yes	No

*R-IPSS: revised international prognostic score, Severe thrombocytopenia (<20 x 10^9/L), Severe neutropenia (<10 x 10^9/L), HCT-CI: Hematopoietic cell transplantation - specific comorbidity index, MUD: Matched unrelated donor, MMUD: Mismatched unrelated donor, MRD: Matched related donor, Bu: Busulfan, Flu: Fludarabine, TBI: Total body irradiation, ATG: Anti-thymocyte globulin, AraC: Cytarabine, HSOS: Hepatic sinusoidal obstruction syndrome, TRM: transplant related mortality.

Conclusions: In this small retrospective case series, we demonstrated the success of early allogeneic transplantation in patients with young, fully matched, related or unrelated donors. Thus, selecting an appropriate donor and promptly performing allogeneic transplantation appears to increase the success rate for low-risk MDS patients with risk factors.

Background: HSCT is the only potential curative therapy in CMML. The aim of our study is to analyze risk factors in transplanted CMML patients.

Methods: All adult patients transplanted in the SFGM-TC registry between 2010 and 2023 for CMML were included. In univariate analyses, estimates were given at 24 months and used the log-rank test for overall survival (OS), and Progression-free Survival (PFS); and Gray's test for cumulative incidence outcomes (relapse incidence (RI), non-relapse mortality (NRM), graft-versus-host (GVH)). Multivariable analyses used Cox proportional hazards models for OS, PFS and cause-specific Cox models for competing risk endpoints.

Results: 516 patients were included. Among patients with available data, 249 (62.7%) and 148 (37.3%) were classified as CMML-1 and 2, respectively, and 223 (55.6%) were considered as proliferative CMML at diagnosis. Cytogenetic risk according to CPSS was high, intermediate or low in 81 (17.5%), 51 (11%) and 332 (71.6%), respectively. 165 (62.5%), 58 (36.5%), 70 (44%), and 26 (18.4%) were mutated for *ASXL1*, *NRAS*, *RUNX1*, and *SETBP1*, respectively. The conditioning regimen was reduced intensity in 410 (79.6%). Donor type was matched sibling donor in 117 (22.7%), unrelated in 305 (59.1%) and mismatched related in 94 (18.2%).
Median age at HSCT was 62.52 years [IQR: 57.4-66.3]. In the entire cohort, 24-months OS and PFS were 55% (95% CI: 51-60) and 45% (95%CI:41-50) respectively. NRM and RI were 21% (95% CI: 18-25) and 33% (95% CI: 29-37). Grade II-IV and III-IV acute GVHD incidences were 32% (95%CI:28-36) and 12% (95% CI: 10-15), respectively. Extensive chronic GVHD incidence was 31% (95% CI: 27-35).
In univariate analysis, an HLA mismatched donor (OS 48% vs. 59% for matched donor, p=0.004), and red blood cell transfusion before SCT (OS 48% vs 66%, p<0.001) increased the risk of death. Thrombocytopenia <100x10^9/l at SCT increased the risk of relapse (38% vs. 26%, p=0.0084) or death (OS 51% vs. 62%, p=0.028). An HLA mismatch donor (31% vs. 17%, p<0.001) and sex mismatch (female donor to male recipient, 27% vs. 20% for other gender match, p=0.0114) increased the risk of NRM. Regarding genetic alterations, cytogenetic risk was not significantly associated (p=0.06) with OS (45%, 52%, 59%, in high, intermediate and low risk, respectively) PFS or NRM but was associated with RI (44%,

40%,29%, respectively, p=0.0397). After adjustment (Table 1), cytogenetic risk was confirmed as a risk factor for RI and OS. Univariate analysis highlighted *ASXL1* mutation as a risk factor for worse OS, PFS and NRM but not RI. *N-RAS* and *SETBP1* mutations were risk factors for PFS, while *RUNX1* mutation increased the risk of mortality. After adjustment (Table 1), *ASXL1* and *NRAS* mutations were significant predictors for OS or PFS while no mutation predicted RI. *ASXL1* mutation was strongly associated with NRM.

			95.0% CI		
		HR	Inferior	Superior	p

	***NRAS* mutation**	**1.81**	**1.09**	**3.01**	**0.0227**
	RUNX1 mutation	0.89	0.52	1.52	0.661
	SETBP1 mutation	1.59	0.8	3.16	0.186
	Karyotype CPSS intermediate vs. high	0.66	0.38	1.12	0.124
	Karyotype CPSS low vs. high	0.79	0.57	1.1	0.167
RI	*ASXL1* mutation	1.04	0.61	1.77	0.885
	NRAS mutation	1.23	0.66	2.27	0.512
	RUNX1 mutation	1	0.52	1.92	0.996
	SETBP1	1.49	0.62	3.62	0.376
	Karyotype CPSS intermediate vs. high	0,8	0,43	1,48	0,469
	Karyotype **CPSS low vs. high**	**0.64**	**0.42**	**0.97**	**0.0375**
NRM	***ASXL1***	**3.45**	**1.48**	**8.03**	**0.00413**
	NRAS	2.03	0.79	5.24	0.142
	RUNX1	0.7	0.26	1.88	0.473
	SETBP1	1.94	0.65	5.83	0.236
	Karyotype CPSS intermediate vs. high	0.4	0.13	1.2	0.101
	Karyotype CPSS low vs. high	1.08	0.62	1.87	0.796

Conclusions: This registry study showed that more than half of patients were alive and free of their disease 2 years after HSCT. Cytogenetic risk is useful in predicting relapse in these patients. While *ASXL1* mutation is the strongest predictor for OS and NRM, none of the mutations predict risk of relapse.

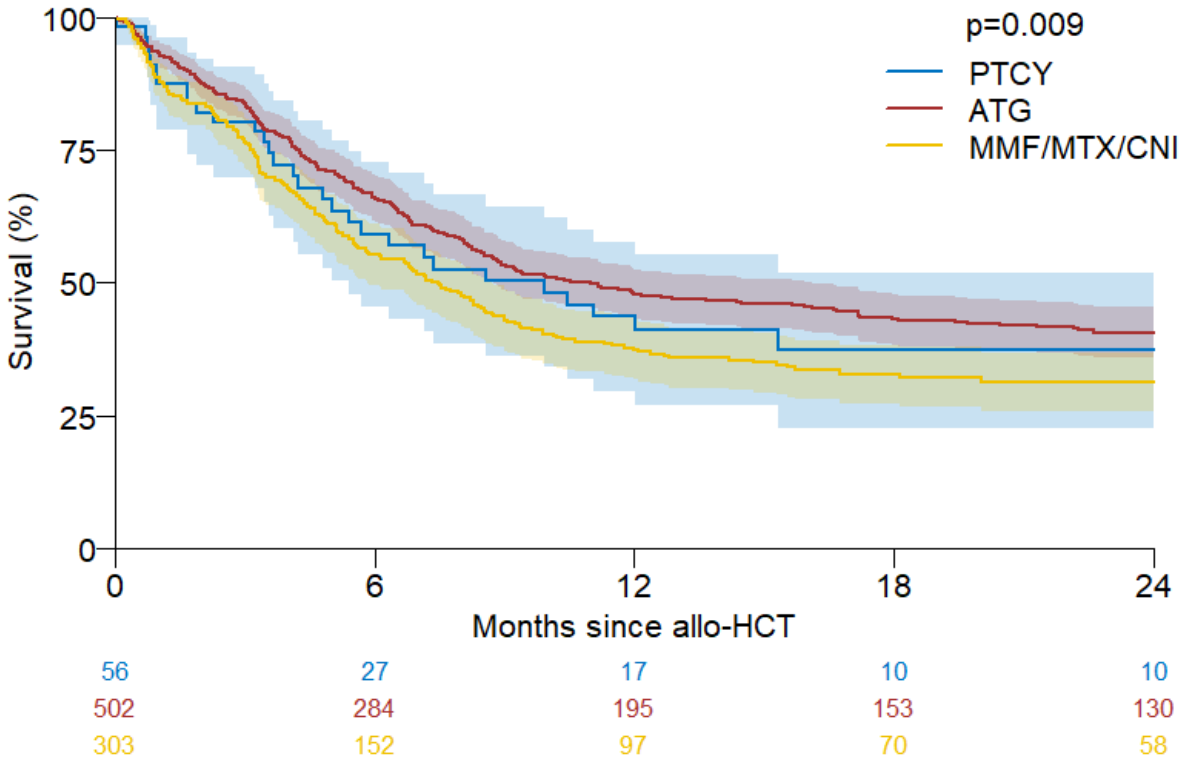
Background: Post-transplant cyclophosphamide (PTCy)-based prophylaxis has been successfully extended to matched related donor (MRD) allogeneic hematopoietic cell

transplantation (allo-HCT), although limited data are available on its efficacy and safety compared to conventional approaches in myelofibrosis (MF) patients undergoing MRD allo-HCT. We hereby present the outcomes of PTCy vs other GvHD prophylaxis regimens in MF patients transplanted with MRD, using data from the EBMT registry.

Methods: A total of 902 MF patients undergoing their first allo-HCT with a MRD between 2014 and 2022 across 227 participating centers, received either PTCy-based, ATG-based, or conventional prophylaxis (CP) with MMF/MTX/CNI without PT-CY or ATG. Patients with history of leukemic transformation were excluded. Primary endpoint of the study was GRFS.

Results: Overall, with a backbone of CNI prophylaxis, 58 patients received PTCy (35 with MMF), 526 received ATG-based prophylaxis (246 with MMF and 185 with MTX) and 318 received CP (126 with MMF and 165 with MTX). Baseline characteristics of the three groups were comparable, except for a higher proportion of patients with HCT-CI>3 in the PT-CY group (41% vs 21% and 23%). Busulfan-based conditioning regimen was used in the majority of pts across all three cohorts.
GRFS at 2 years was 37% (PTCy), 41% (ATG), and 31% (CP) (p=0.009), being significantly higher for ATG compared to CP, while no statistically significant difference was found comparing PTCy and ATG (p=0.4) (Fig.1). Neutrophil engraftment by day +28 was significantly better with ATG and CP as compared to PTCy (88% vs 89% vs 77%, p=0.012), platelet engraftment at day +100 was similar into the three groups (72%, 76%, 75%, p=0.17). With a median follow-up of 36.9 months, 2-ys OS rates were 67% (PTCy), 71% (ATG), 63% (CP), p=0.3.
The 2-yr PFS was 56% (PTCy), 56% (ATG), 58% (CP), p=0.7. The 2-yr cumulative incidence of relapse (CIR) was 29% with PTCy, 22% with ATG and 15% with CP, with no significant difference between PTCy and ATG (p=0.4), while a significantly higher rates of relapse was associated to PTCy and ATG as compared to CP (p=0.038 and p=0.006, respectively). There was no significant difference in 2-yr non relapse mortality (NRM) rates across the 3 groups: 15% in PTCy, 22% in ATG and 27% in CP. CI of Grade II-IV aGvHD was 14% for PT-CY, 18% for ATG, 29% for CP with significantly differences observed between PTCy and CP (p=0.011) and between ATG and CP (p<0.001). CI of extensive cGvHD at 2-yr was 23% for PT-Cy, 22% for ATG, 33% for CP with statistically significant differences between ATG and CP (p<0.001).



Conclusions: These results suggest that in the setting of MRD-HCT for MF, PTCy and ATG-based prophylaxis result in similar outcomes, although the hematologic recovery appears slower with PTCy. Both strategies are associated with lower rates of grade II-IV aGVHD and extensive cGVHD compared with CP, but they are associated with an increased relapse risk. While no differences in overall survival were observed across the three groups, the 2-yr GRFS with PTCY or ATG was slightly higher than with CP.

Disclosure: Nothing to declare

OS01-03

PHASE II SINGLE-CENTER PROSPECTIVE STUDY OF RUXOLITINIB ADMINISTERED BEFORE, DURING AND AFTER STEM CELL TRANSPLANTATION IN PATIENTS WITH MYELOFIBROSIS

Rachel Salit[1], *Kevin Ng*[1], *Nellie Ratasamee*[1], *Anna Halpern*[1], *Raya Mawad*[1], *Cristina Ghiuzeli*[1], *H. Joachim Deeg*[1], *Bart Scott*[1]
[1]*Fred Hutchinson Cancer Center, Seattle, United States of America (the)*

Background: Risk factors specific to myelofibrosis (MF) patients considering hematopoietic cell transplantation (HCT) include splenomegaly associated poor graft function and relapse, decreased performance status due to constitutional symptoms, bone-marrow fibrosis creating a poor environment for stem cell engraftment, and portal and pulmonary hypertension-associated non-relapse mortality (NRM). Use of pre-HCT ruxolitinib (Rux) has ameliorated many of these factors resulting in improved HCT outcomes. However, high rates of acute (71% Grade II-IV) and chronic graft-vs-host disease (GVHD) (55% at 3 years (44% moderate/severe)) in MF patients at our Center with standard tacrolimus and methotrexate GVHD prophylaxis remain an issue, and post-HCT Cytoxan is difficult to tolerate in older patients and those with organ dysfunction.

Methods: We conducted a Phase II single-center prospective study of peri-HCT Rux in patients with primary and secondary MF with a primary endpoint of grade II-IV acute GVHD powered to detect a 20% decrease (90% at a one-sided significance level of .05) compared to historical controls. Patients had to have at least Dynamic International Prognostic Staging System (DIPSS) Intermediate I stage disease, not have received prior HCT, and not transformed to AML. Patients were treated with at least 8 weeks of planned Rux prior to conditioning chemotherapy (cyclophosphamide 120 mg/kg and targeted 4-day busulfan, or fludarabine 150 mg/m2, and melphalan 140 mg/m2). Rux was then tapered to 5mg BID by Day -4 pre-HCT and could be increased up to 10mg BID after post-HCT Day +28 if tolerated. In addition to Rux, GVHD prophylaxis included tacrolimus (Tac) (target level 5-10) and MTX 10mg/m2 on Days 1, 3, 6 and 11; Tac was tapered starting at Day +100 over 4 months and Rux was scheduled to taper between 9-12 months post-HCT.

Results: Forty-five patients median age 63 (range 42-71) received HCT between 2021-2025. The majority had primary MF (56%), were JAK2 mutated (60%), had intermediate-2 or high-risk DIPSS (78%) disease and had at least 1 high-risk molecular mutation (51%). Most had unrelated donors (87% (25% HLA 9/10) and received fludarabine/melphalan conditioning (67%). Patients received Rux for a median of 5.2 (2.6 - 35.8) months prior to conditioning and were continued until a median of 14.5 months post-HCT. All patients engrafted at median Day 18 (range 13 – 43). Acute GVHD grade II-IV was diagnosed in 31% (n = 14), and grades III-IV in 4% (n = 2) patients respectively. The estimated probability of all grades chronic GVHD at one year was 22% (95% CI: [11%, 35%]); 1-year CI for moderate-to-severe chronic GVHD was 7.1% (95% CI: [1.8%, 17%]. Kaplan-Meier estimates of survival at 1 year and 2 years were 95% (95% CI: [89%, 100%]) and 86% (95% CI: [76%, 98%]), respectively. The estimated probability of relapse and NRM at one year were 6.9% (95% CI: [1.8%, 17%]) and 2.5% (95% CI: [0.19%, 12%]), respectively.

Conclusions: Compared to MF patients given standard tacrolimus and methotrexate GVHD prophylaxis at our Center, the incidence of acute GVHD was 40% lower and moderate/severe chronic was < 10% at 1-year evaluation. A multivariate matched comparison analysis is ongoing.

OS01-04

THE RECENT DEVELOPED AND MULTI-CENTER VALIDATED CONCISE OBJECTIFIABLE RISK EVALUATION (CORE) SCORE PREDICTS NRM RISK PRIOR TO ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN MYELOFIBROSIS PATIENTS

Gunnar Weise[1], *Rolf Krause*[1], *Radwan Massoud*[1], *Maraike Harfmann*[1], *Matthias Schäfersküpper*[1], *Evgeny Klyuchnikov*[1], *Catherina Lück*[1], *Ina Rudolph*[1], *Silke Heidenreich*[1], *Jochim Reinert*[1], *Francis Ayuk*[1]
[1]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: The CORE score was recently established in a large, single-center cohort and validated in a multi-center cohort (Weise et al, Cancers 2024, BMT 2025) for prediction of non-relapse mortality (NRM) after allogeneic hematopoietic stem cell transplantation (allo-HCT). This study sought to confirm its ability to predict NRM risk in myelofibrosis patients.

Methods: Three hundred sixteen (316) consecutive adult patients who had undergone allo-HCT for myelofibrosis between 2013 and 2025 at our center, were analysed in regards to NRM (with relapse as competing risk). Of these 208 were diagnosed with primary myelofibrosis, whereas the remaining 108 patients had either post-essential thrombocythemia (ET, n=58) or post-polycythemia vera (PV) myelofibrosis (n=50). Patients with secondary acute leukemia were excluded. 71 patients who had been included in the initial cohort used for the development of the CORE score were excluded from the analysis. HLA-matched unrelated donors were used in 66%, followed by HLA-matched related donors (12%). Haplo-identical related and other HLA-mismatched related donors were used in 5% and 16% of cases, respectively. Myeloablative conditioning was performed in 30%, while reduced intensity conditioning was used for the remaining 70% of patients.
A comparison between CORE score and HCT-CI was conducted using the area under the receiver operating characteristics (ROC) curve and the findings are presented as c-statistics with the corresponding confidence interval (CI). All reported p-values are two-sided and p-

values <0.05 were considered statistically significant. Statistical analysis was performed using RStudio (version 2024.04.1) and SPSS (version 27).

Results: Among 182 patients, for whom full data were available and did not contribute to the development of the CORE score, with a median follow-up for NRM of 711 days, low-risk and intermediate- risk groups accounted for 46% and 49% of the patients with 10 and 28 observed events, respectively. Only a very small population of 9 patients (5%) were high-risk with 4 observed events. The corresponding 2-year NRM rates after allo-HCT were 11% for the low-risk group, 27% for the intermediate-risk group and 44% for the high-risk group (p=0.002). OS rates at 2 years posttransplant were 85%, 65% and 56%, respectively (p<0.001). The CORE score did not significantly impact relapse incidence (p=0.128) (figure 1 and table 1).
In direct comparison, the CORE score performs superior to the HCT-CI score with c-statistics of 0.617 (CI 0.51-0.73) compared to 0.461 (CI 0.35-0.58) for the HCT-CI and 0.484 (CI 0.37-0.6) for the age adjusted HCT-CI. Furthermore, the HCT-CI as well as the age adjusted model fails to predict NRM risks in our cohort with 2-year NRM rates of 24%, 27% and 16% for the low-, intermediate-, and high-risk group, respectively (p=0.614), and 2-year NRM rates of the age adjusted model of 24%, 24% and 21% for the intermediate-, high-, and very-high-risk group, respectively (p=0.939), while the low-risk group contained only one patient without an event.

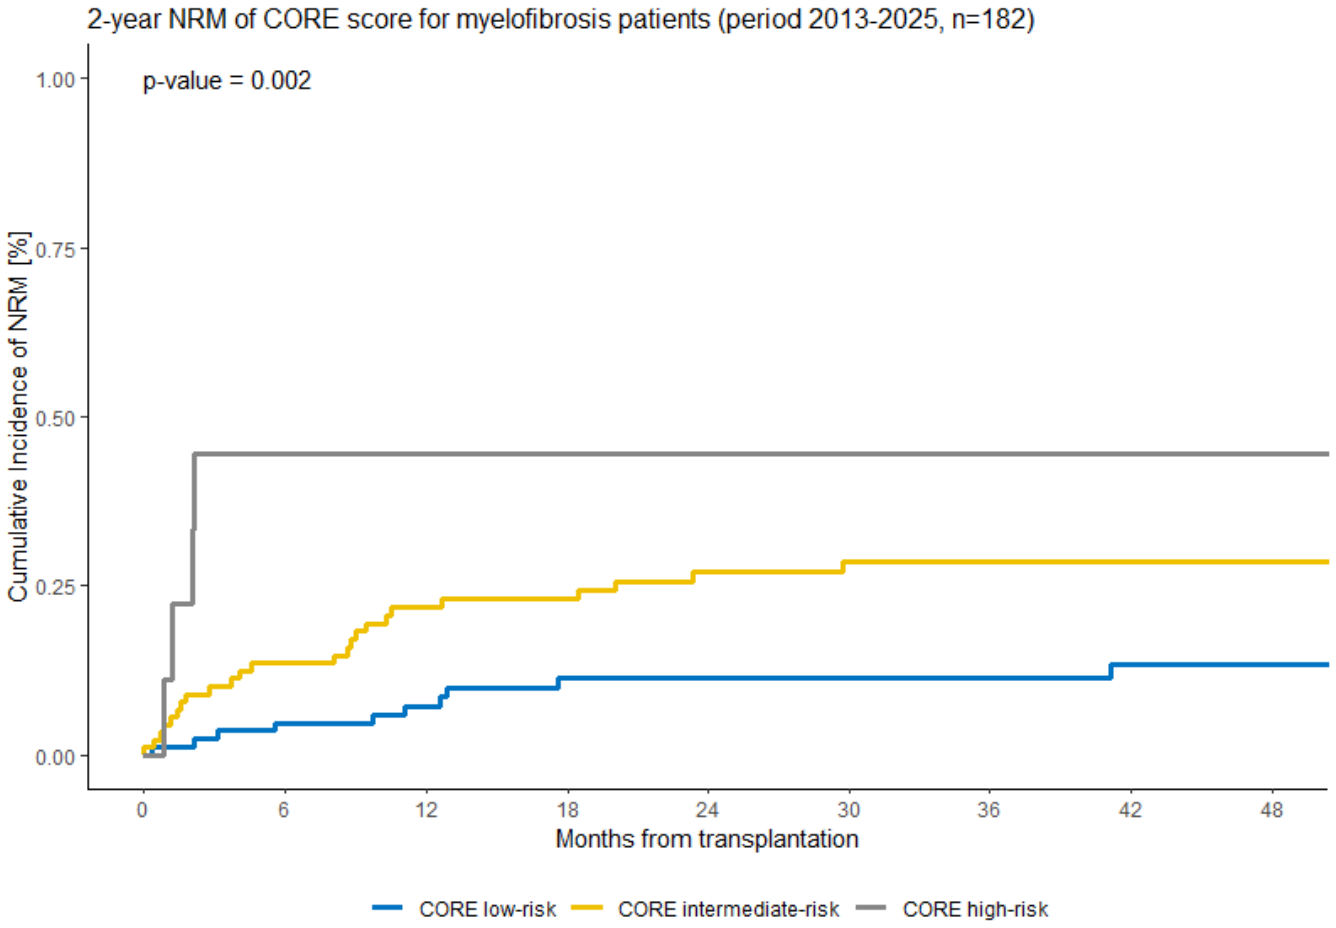

Table 1: CORE risk score prediction for non-relapse mortality, overall survival and relapse in myelo

	NRM			OS			R
Score	HR (95% CI)	P (%)	2-y (%)	HR (95% CI)	P (%)	2-y (%)	HR (95% CI)
Total		0.002			<0.001		
0-1	reference		11	reference		85	reference
2-4	2.94 (1.4-6)	0.003	27	2.79 (1.7-4.6)	<0.001	65	2.13 (1-4.6)
≥5	5.36 (1.5-19.5)	0.011	44	5.39 (2.3-12.6)	<0.001	56	1.83 (0.5-7)
N=182							

Conclusions: The CORE score is a multi-center validated, concise and objectifiable risk evaluation tool which offers improved predictive capability compared to the HCT-CI with regards to the risk of NRM and OS prior to allo-HCT in myelofibrosis patients.

OS01-05

OLVEREMBATINIB-MEDIATED DEEP REMISSION IMPROVES ALLOGENEIC STEM CELL TRANSPLANTATION OUTCOME IN PATIENTS WITH BLAST CRISIS CHRONIC MYELOID LEUKEMIA: THE FIRST REAL-WORLD PRACTICE

Xiaoyu Zhang[1], *Bingcheng Liu*[1], *Weihua Zhai*[1], *Qiaoling Ma*[1], *Donglin Yang*[1], *Aiming Pang*[1], *Sizhou Feng*[1], *Mingzhe Han*[1], *Yi He*[1], *Hui Wei*[1], *Erlie Jiang*[1]
[1]*Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China*

Background: Despite therapeutic advances, blast crisis chronic myeloid leukemia (BC-CML) remains poor outcomes. Long-term survival depends on achieving a second chronic phase (CP) followed by allogeneic hematopoietic stem-cell transplantation (allo-HSCT). We aimed to investigate whether the novel tyrosine-kinase inhibitor (TKI) olverembatinib improves responses and optimizes allo-HSCT outcomes compared to the first-/second-generation TKIs (1/2G-TKIs) in BC-CML.

Methods: This real-world practice analysis captured data from consecutively enrolled BC-CML patients aged ≥14 years undergoing allo-HSCT at the Institute of Hematology and Blood Diseases Hospital Chinese Academy of Medical Sciences between November 2021 and July 2025, including both *de novo* and chronic phase-transformed cases. Collected data included demographic and clinical characteristics, treatment responses and transplant-related outcomes. Cumulative incidences of complete cytogenetic response (CCyR), major molecular response (MMR), and complete molecular response (CMR) were calculated using the Fine-Gray test. Categorical variables were analyzed by Fisher's exact test, continuous variables by Mann-Whitney U test. Overall survival (OS) and progression-free survival (PFS) were calculated according to Kaplan Meier. Institutional Review Board (IRB) approval was obtained in accordance with the Declaration of Helsinki.

Results: A total of 69 patients with BC-CML receiving pre-transplant TKIs treatment were included in the study (median age 33 years, range 14–61). At BC diagnosis, 40.6% (n=28) exhibited additional cytogenetic abnormality, including 20 complex karyotype. Twenty-one patients (30.4%) harbored ABL1 mutations, predominantly E255K and Y253K. T315I was seen in 6 cases. Thirty-five (50.7%) patients carried additional genetic mutations, including myeloid neoplasm-associated mutations (e.g., ASXL1, RUNX1) and IKZF1 deletions. All patients received TKIs+chemotherapy before transplantation and were stratified by pre-transplant TKIs exposure: 1/2G-TKI cohort (n=43, imatinib, nilotinib, flumatinib or dasatinib) versus olverembatinib (n=26). The olverembatinib cohort demonstrated advanced pre-

transplantation treatment responses: higher hematologic remission rates (100% vs 81%, p<0.05) and CCyR rate (80.8% vs 55.8%, p=0.041). Notably, olverembatinib achieved significantly improved molecular remission at transplantation: MMR 53.8% vs 16.3% (p<0.001) and CMR 23.1% vs 4.7% (p<0.05).
Haploidentical transplants were the predominant HSCT type (olverembatinib 80.8% vs control 58.1%) with no graft failure documented. Both cohorts showed a high incidence of grade II-IV aGVHD (57.7% vs 79.1%) and infections (23.1% vs 65.1%). Olverembatinib cohort showed improved survival: the one-year OS (89% vs 70.8%), and PFS (78% vs 68%), lower NRM (10.6% vs 23%), and reduced relapse incidence (12.5% vs 14.6%).

Conclusions: This real-world analysis provides the first clinical evidence supporting the efficacy and safety of olverembatinib in transplant-eligible BC-CML. Olverembatinib significantly enhances pre-transplant molecular responses, compared to 1/2G-TKIs, associating with improved survival after transplantation. With a manageable safety profile, olverembatinib represents a promising bridging strategy prior to allo-HSCT, potentially redefining frontline management of BC-CML.

OS01-06

COMPARING THE MTSS AND MYELOFIBROSIS ALLORISK STRATIFIER SCORES FOR PREDICTING EARLY MORTALITY AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION: A SINGLE-CENTER EXPERIENCE

Daniele Sannipoli[1], *Ludovica Lo Turco*[2], *Maria Helena Parrinello*[1,2], *Simona Piemontese*[1], *Andrea Assanelli*[1], *Lorenzo Lazzari*[1], *Alessandro Bruno*[1], *Elisa Diral*[1], *Francesca Lunghi*[1], *Maria Teresa Lupo Stanghellini*[1], *Annalisa Ruggeri*[1], *Fabio Ciceri*[1,2]
[1]*IRCCS San Raffaele Hospital, Milano, Italy,* [2]*Università Vita-Salute San Raffaele, Milano, Italy*

Background: Early transplant-related mortality (TRM) remains a major barrier to the use of allogeneic hematopoietic stem-cell transplantation (allo-HCT) in patients with myelofibrosis (MF). Although several prognostic scoring systems guide candidate selection based on biological disease risk, few tools are specifically designed to estimate TRM, such as the Myelofibrosis Transplant Scoring System (MTSS), which nonetheless presents several limitations. More recently, EBMT has proposed the machine-learning–based AlloRisk Stratifier as a dynamic AI-driven tool to improve the prediction of early TRM.

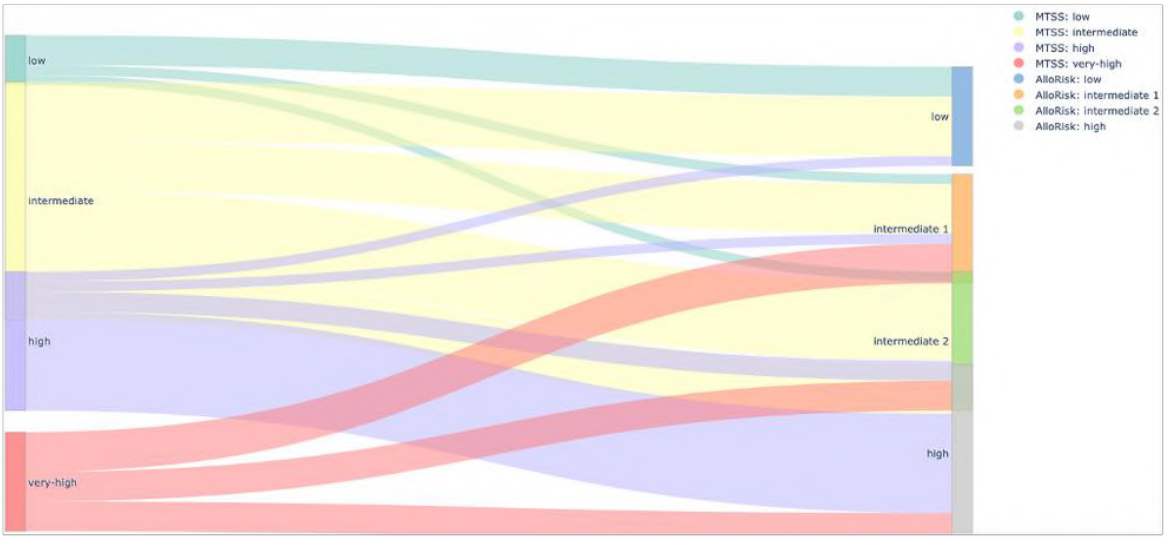
Methods: We retrospectively analyzed 54 consecutive patients with MF who underwent allo-HCT at San Raffaele Hospital (Milan, Italy) between January 2013 and November 2024, with a minimum follow-up of 12 months (with 80% of HCT performed in the past five years). Patients transplanted in blastic phase, undergoing a second transplant, or diagnosed with MPN/MDS overlap were excluded. Donor selection and the management of transplant-related complications followed international standards. MTSS scores were assigned according to Gagelmann et al., while AlloRisk categories were derived using the EBMT open-access calculator. Statistical analyses included Fisher's exact test for group comparisons and Harrell's concordance index (C-index) to evaluate discriminative performance.

Results: Among the 54 patients, 63% were older than 57 years and 80% had a Karnofsky performance status >80%. JAK2V617F mutations were present in 65%, ASXL1 in 44%, and ≥2 additional high-risk mutations in 41% of evaluable cases. According to MTSS, 9%, 45%, 26%, and 20% of patients were classified as low, intermediate, high, and very-high risk, respectively. Most patients (96%) received reduced-toxicity conditioning, including dose-adjusted treosulfan–thiotepa–fludarabine (52%) and treosulfan–melphalan–fludarabine

(24%). PTCy-based GvHD prophylaxis was used in 96% of cases. Donor types included matched unrelated (30%), mismatched unrelated (36%), and haploidentical donors (11%).After a median follow-up of 20.5 months, overall survival was 63%, with 20 deaths (37%), predominantly transplant-related. The 1-year cumulative incidence of non-relapse mortality was 25.9%, with relapse treated as a competing event. MTSS-defined 1-year mortality rates were 20%, 16%, 35%, and 27% across increasing risk categories (p = 0.35). In contrast, the AlloRisk Stratifier assigned 19%, 20%, 26%, and 35% of patients to low, intermediate-1, intermediate-2, and high-risk groups, with corresponding 1-year mortality rates of 0%, 9%, 29%, and 47% (p = 0.085) (Figure 1). Patients classified as high-risk by AlloRisk showed significantly higher 1-year mortality compared with all other categories combined (9/19 vs 5/35; p = 0.02) (Table 1). Discrimination for 1-year mortality was superior for the AlloRisk Stratifier (C-index 0.726) compared with MTSS (0.587).

MTSS Risk-category	Total	1-year deaths	1-year mortality rate	AlloRisk Stratifier category	Total	1-year deaths	1-year mortality rate
Low	5	1	20%	Low	10	0	0%
Intermediate	24	4	16%	Intermediate-1	11	1	9%
High	14	6	35%	Intermediate-2	14	4	29%
Very-high	11	3	27%	High	19	9	47%
Global p-value			0.35 (NS)				0.085 (trend)
Higher vs others p-value			0.13 (NS)				0.02 (sig)

Conclusions: In this homogeneous single-center cohort uniformly treated with contemporary conditioning and PTCy-based prophylaxis, the EBMT AlloRisk Stratifier outperformed the MTSS in predicting early NRM. The model showed a clear risk gradient, with no deaths in the low-risk group and progressively increasing mortality across categories, whereas MTSS displayed limited discriminatory ability. The AlloRisk Stratifiermay serve as a pragmatic aid for pre-transplant decision-making, particularly in centers using modern allo-HCT platforms.



Clinical Trial Registry: Not applicable.

Background: Since the introduction of tyrosine kinase inhibitors (TKIs), allogeneic hematopoietic stem cell transplantation (HSCT) is no longer first-line therapy for chronic myeloid leukemia (CML) in chronic phase (CP). However, HSCT remains indicated for pediatric CML (pCML) patients with failure of multiple treatment lines. We analyzed HSCT outcomes in pCML over the last two decades.

Methods: This retrospective registry-based analysis used data from the EBMT Pediatric Diseases Working Party. Patients younger than 18 years at the time of HSCT, with pCML at any disease stage, transplanted between 2006 and 2022, and with sufficient data available were included.

Results: A total of 209 patients were analyzed (55.5% male). Median age at diagnosis was 11.3 years (range, 0.2–17.3) and at HSCT 12.6 years (range, 1.6–17.9). First-line TKI therapy was administered in 82% of patients. Molecular remission following first-line TKI (n=179) was reported in 24.0% of patients (26.9% in CP1, 10.7% in ≥CP2, and 23.8% in ≥accelerated phase [AP]). A second treatment line was given to 35.1% of patients, predominantly TKIs (62/72), achieving molecular remission in 29.5% (25.0% in CP1, 33.3% in ≥CP2, and 40.0% in ≥AP). After third-line TKI therapy (n=23 of 27 receiving third-line treatment), molecular remission was achieved in 28.6%.
At HSCT, disease status was CP1 in 72.2%, CP2 in 14.4%, >CP2 in 1.0%, and advanced phases in 12.4% of patients. Over time, disease stage at HSCT shifted significantly toward more advanced phases (p=0.002).
Conditioning regimens were total body irradiation (TBI)-based in 16.8% of patients. The remaining patients received BuCy (50.5%), BuFlu (4.8%), BuFluThio (4.8%), TreoFluThio (4.3%), FluMelThio (13.0%), or other combinations (5.8%). Stem cell sources were bone marrow (55.0%), peripheral blood (39.7%), or cord blood (5.3%). Donors were HLA-identical siblings (47.0%), other matched relatives (2.9%), mismatched relatives (2.9%), or unrelated donors (47.3%). Ex vivo T-cell depletion was performed in 7.7% of grafts. Cumulative incidence of acute GVHD grade II–IV was 33.5% by day 100. With a median follow-up of 8.9 years, chronic GVHD at 8 years occurred in 30.2%, with extensive disease in 18.1%. Overall survival (OS) at 8 years was 82.5% and declined with more advanced disease stage (CP1: 85.5%; ≥CP2: 77.2%; AP/BP: 71.3%). Compared with CP1, hazard

ratios for OS were 2.55 (p=0.04) for >CP2 and 2.15 (p=0.09) for AP/BP. Progression-free survival and relapse incidence at 8 years were 68.6% and 19.6%, respectively, and both worsened with advanced disease. Non-relapse mortality was 11.9% at 8 years and was not associated with disease stage. Compared with busulfan-based conditioning, FluMelThio and FluMelTreo-based regimens were associated with superior OS (HR 0.18; p=0.02), with FluMelThio showing 100% OS at 2 years and no NRM at 8 years. Compared with busulfan-based regimens, TBI-based conditioning was associated with improved PFS (HR 0.37; p=0.03).

Table 1. Outcomes according to conditioning regimen

Variable	Regimen	2-year OS (%)	8-year PFS (%)	8-year RI (%)	8-year NRM (%)
Regimen	Bu-based (n=133)	78.0 [69.7–84.3]	62.0 [52.8–69.9]	22.5 [15.5–30.3]	15.5 [9.8–22.3]
	TBI-based (n=29)	88.4 [72.0–95.5]	82.7 [65.4–91.8]	14.5 [5.2–28.4]	2.9 [0.2–12.9]
	FluMel-based (n=30; 27/30 with thiotepa)	100	89.7 [71.3–96.5]	10.3 [2.5–24.6]	0
	Other (n=11)	77.9 [35.4–94.2]	51.9 [16.3–79.0]	26.0 [2.8–60.1]	22.1 [2.5–53.8]
	P value	0.04	0.02	0.56	0.03

Conclusions: HSCT remains an important therapeutic option for pCML patients with inadequate response to TKI therapy. While the optimal conditioning regimen according to disease status requires further clarification, FluMelThio appears to be a particularly promising approach.

Northern Ireland (the), [2]Memorial Sloan Kettering Cancer Center, New York, United States of America (the), [3]Azienda Ospedaliera-Universitaria Careggi, University of Florence, Florence, Italy, [4]Princess Margaret Cancer Centre, Toronto, Canada, [5]Moffitt Cancer Center, Tampa, United States of America (the), [6]University of Michigan, Ann Arbor, United States of America (the), [7]Hôpital Saint-Louis, Université Paris Cité, Paris, France, [8]Wake Forest University, Winston-Salem, United States of America (the), [9]The University of Texas, Houston, United States of America (the), [10]Tisch Cancer Institute, New York, United States of America (the), [11]Nice University Hospital, Nice, France, [12]Novartis Ireland Limited, Dublin, Ireland, [13]Novartis Pharma AG, Basel, Switzerland, [14]Novartis Pharmaceuticals Corporation, Hyderabad, India, [15]Novartis Pharmaceuticals UK Limited, London, United Kingdom of Great Britain and Northern Ireland (the)

Background: Myelofibrosis (MF) is a progressive myeloproliferative neoplasm with limited curative options, where haematopoietic stem cell transplantation (HSCT) remains the only potentially curative therapy. However, eligibility for HSCT is often restricted by disease severity, symptom burden, and other comorbidities. Pelabresib (PELA), a bromodomain and extra-terminal inhibitor, in combination with ruxolitinib (RUX), has demonstrated deep and durable spleen volume reductions and symptom improvement in the MANIFEST and MANIFEST-2 studies. This analysis aims to evaluate the impact of PELA+RUX on clinical parameters relevant to HSCT eligibility in Janus kinase inhibitor (JAKi)-naïve patients with MF enrolled in MANIFEST and MANIFEST-2.

Methods: Data from the open-label Phase 2 MANIFEST study arm 3 (NCT02158858) and Phase 3 global randomised double-blind active control MANIFEST-2 study (NCT04603495) were analysed in a post-hoc analysis to identify patients who underwent HSCT after treatment with either PELA+RUX or placebo (PBO)+RUX and assess the timing of HSCT and clinical response to study treatment. Key endpoints included: spleen volume reduction of 35% from baseline (SVR35), total symptom score improvement by 50% (TSS50), and time to HSCT eligibility.

Results: As of the Week 96 data cutoff for MANIFEST-2, 15/214 (7.0%) patients in the PELA+RUX arm and 18/216 (8.3%) patients in the PBO+RUX arm were eligible for, or received, HSCT. In this subgroup, patients' baseline characteristics were similar to the full population (Rampal RK, et al. *Nat Med*. 2025;31:1531–1538). In the PELA+RUX arm, 6/15 patients had haemoglobin levels of ≤10 g/dL versus 10/18 in the PBO+RUX arm. Haemoglobin response was achieved by 3/15 and 3/18 patients in the PELA+RUX and PBO+RUX arms, respectively. PELA+RUX demonstrated notable improvements in spleen volume reduction, with 66.7% SVR35 (10/15) versus 16.7% (3/18), and greater improvement of symptoms, with 53.3% TSS50 (8/15) versus 38.9% (7/18) in the PBO+RUX arm at Week 24. Median time from treatment start to HSCT was similar between arms, with 344.0 and 343.5 days in the PELA+RUX and PBO+RUX arms, respectively. As of 9 January 2025, in arm 3 of the MANIFEST study (PELA+RUX in JAKi-naïve MF), 13/84 patients underwent HSCT with 69.2% SVR35 (9/13) and 66.7% TSS50 (8/12) at Week 24. In arm 3, median time from treatment start to HSCT was 395.0 days.

Conclusions: PELA+RUX enabled a subgroup of JAKi-naïve MF patients to undergo HSCT, demonstrating significant reductions in spleen volume and notable improvements in

symptoms, indicating potential as a bridging therapy to HSCT in MF and supporting broader clinical utility.

Background: Despite the emergence of Janus kinase (JAK) inhibitors, allogeneic hematopoietic stem cell transplantation (allo-HSCT) remains the only curative treatment for

myelofibrosis (MF). Haploidentical HSCT (Haplo-HSCT) expands access to transplantation for patients lacking an HLA-matched sibling donor or matched unrelated donor. However, data on Haplo-HSCT for MF are currently scarce. This study aimed to evaluate the real-world outcomes of Haplo-HSCT in the treatment of MF in China.

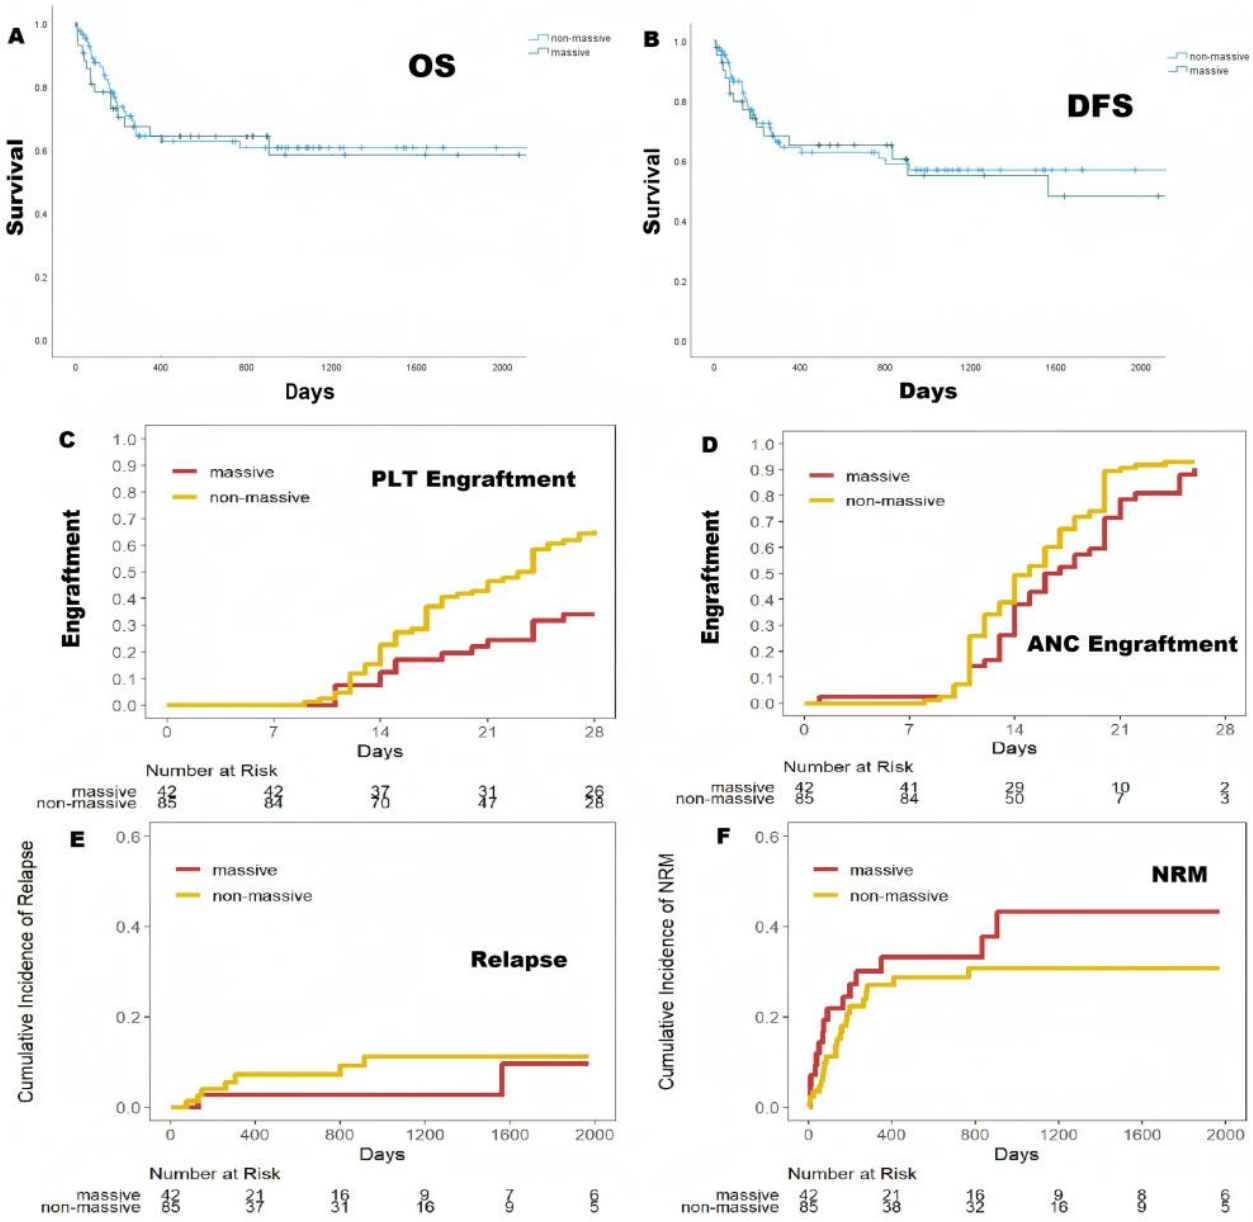
Methods: This study retrospectively analyzed clinical data of 127 MF patients who underwent haplo-HSCT at 32 hematology centers in China between December 2008 and December 2024. Kaplan-Meier survival analysis and competing risk models were used to calculate the 1-year and 3-year overall survival (OS), disease-free survival (DFS), cumulative incidence of relapse (CIR), and non-relapse mortality (NRM) rates post-transplantation. Competing risk models were also applied to estimate the incidence of graft failure (GF) and engraftment. Competing risk regression analysis was performed to identify factors associated with GF. The adjusted probabilities of OS and DFS were estimated using the Cox proportional hazards model, with adjustment for other significant clinical variables included in the final multivariate models.

Results:

Characteristics	Value
Age, Median (Range)	53 (13-69)
Sex	
Male, n (%)	76 (59.8)
Female, n (%)	51 (40.2)
Diagnosis	
PMF, n (%)	83 (65.4)
Post-PV/ET MF, n (%)	16 (12.6)
MF-AML, n (%)	28 (22)
Risk (DIPSS-plus)	
Int-1 risk, n (%)	12 (9.5)
Int-2 risk, n (%)	108 (85)
High risk, n (%)	7 (5.5)
Pretransplant splenomegaly	
No splenomegaly	19 (15)
Mild splenomegaly	66 (52)

Massive splenomegaly	42 (33)
MNC, Median (Range)	11.83 (2.62-157.25)×10^8/Kg
CD34, Median (Range)	6.33(1-23.64)×10^6/Kg

Among the 127 patients, 83 were diagnosed with primary myelofibrosis (PMF), 16 with post-essential thrombocythemia/polycythemia vera MF (post-ET/PV MF), and 28 with MF transformed into acute myeloid leukemia (MF-AML). The last follow-up date was December 31, 2024. The neutrophil engraftment rate at day 28 was 92.9% and the platelet engraftment rate at day 100 was 62.5%. The 60-day good graft function (GGF) rate was 62.5%. Graft failure occurred in 17 patients (14 primary, 3 secondary), corresponding to an incidence of 13.2%. Splenomegaly negatively affected GGF rates (non-massive splenomegaly: 71.4%, massive splenomegaly: 44.1%; P = 0.008) and increased the incidence of GF (non-massive splenomegaly: 8.8%, massive splenomegaly: 21.8%, P = 0.038). The incidences of Epstein-Barr virus (EBV) infection and cytomegalovirus (CMV) infection were 25.2% and 20.5%, respectively. The incidences of acute graft-versus-host disease (GVHD, grades II–IV) and chronic GVHD (moderate to severe) were 44% and 25%, respectively.
With a median follow-up duration of 830 days, the 3-year OS and DFS rates were 60.3% and 56.7%, respectively, with a CIR of 8.45% and an NRM of 34.3%. In univariate analysis, only massive splenomegaly was associated with OS (hazard ratio [HR] = 2.924; 95% confidence interval [CI], 0.993–8.605; P = 0.051) and DFS (hazard ratio [HR] = 2.431; 95% confidence interval [CI], 0.893–6.617; P = 0.082). Pre-transplant white blood cell count, hemoglobin level, platelet count, MF grading, Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI), donor-specific antibodies, graft mononuclear cell count, and CD34+ cell count were not associated with survival, engraftment, GVHD, or infection.



Conclusions: Haploidentical HSCT (Haplo-HSCT) is a feasible curative option for patients with MF. However, the relatively high incidences of NRM and GF compromise the efficacy of Haplo-HSCT, particularly in patients with massive splenomegaly. These findings highlight the importance of pre-transplantation management.

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR MYELOFIBROSIS: PATTERNS AND OUTCOME AFTER RELAPSE AND LONG-TERM FOLLOW UP

Avichai Shimoni[1], *Noga Shem-Tov*[1], *Ronit Yerushalmi*[1], *Ivetta Danylesko*[1], *Alexandra Tsynman*[1], *Yulia Volchek*[1], *Abraham Avigdor*[1], *Arnon Nagler*[1]
[1]*Chaim Sheba Medical Center, Tel Hashomer, Israel*

Background: Allogeneic hematopoietic stem-cell transplantation (HSCT) is the only potentially curative approach in patients with myelofibrosis. However, data on long-term outcome after HSCT are relatively limited.

Methods: This is a retrospective analysis of HSCT outcomes of patients with myelofibrosis following HSCT in a single institution, between 2002 and 2025. Patients who had transformation to AML before HSCT were not included.

Results: The study included 102 patients, median age 60 years (range, 27-74). The donor was an HLA- matched sibling (n=37), matched-unrelated (n=50) or mismatched unrelated/ haploidentical (n=15). The conditioning regimen was fludarabine and reduced dose intravenous busulfan (FluBu, total 6.4-8 mg/kg, n=25); fludarabine, thiotepa, busulfan (TBF, n=61) or other regimens (n=16). GVHD prophylaxis included cyclosporine and methotrexate or mycophenolate and ATG (grafalon).
With a median follow-up of 5.6 years (range, 0.1-22 years), 56 patients are alive and 46 have died, 30 of non-relapse causes and 16 of relapse. The estimated 10-year overall survival (OS) is 48% (95%CI, 35-60). The estimated 10-year non-relapse mortality (NRM) and relapse mortality was 34% (95%CI, 24-48) and 18% (95%CI, 11-29), respectively. 10-year OS tended to improve in more recent years ($\geq$2015), 61% (95%CI, 49-74) compared to earlier years of HSCT, 36% (95%CI, 20-53), respectively (P=0.16). 10-year OS also tended to improve with TBF conditioning, 63% (95%CI, 50-76) compared to FluBu conditioning, 28% (95%CI, 10-45), respectively (P=0.15).
A total of 32 patients were alive and disease-free 5-years after HSCT. Six patients subsequently relapsed 5.3 to 18.9 years after HSCT and 1 of them died. Four patients had late NRM, 2 second malignancies, 1 chronic GVHD and 1 cardiovascular event. For patients who were alive and disease-free 5 years after HSCT, the estimated subsequent 5-year OS and disease-free survival were 77% (95%CI, 56-98) and 56% (95%CI, 33-78), respectively. In all, 26 patients relapsed after HSCT, estimated 5-year and 10-year rate 22% (95%CI, 15-32) and 31% (95%CI, 21-45), respectively. Median time to relapse was 1.2 years (range, 0.2-18.9). Ten patients are alive, a median of 1.3 years (range, 0.3-18.1) and estimated 5-year OS 30% (95%CI, 9-51) after relapse. There were 3 patterns of relapse with different outcomes. Four patients relapsed as Polycythemia-Vera (PV). One achieved CR with DLI and is in CR for more than 18 years. The 3 others progressed again to myelofibrosis 38, 64 and 156 months later and are all alive, a median of 9.6 years (range, 5.3-18.1). Thirteen patients relapsed as myelofibrosis in chronic phase. Five are alive and 8 died, median survival 2.4 years (range, 0.2 to >7.5) after relapse. Nine patients relapsed as MDS/ AML, only one is alive, median survival of 0.8 years (range, 0.1-1.5).

Conclusions: Allogeneic HSCT can allow long-term survival and possible cure in myelofibrosis. However, long-term survivors are at continuous risk for late relapse and late NRM. For those who are not cured, HSCT may reset the pattern of progression of the myeloproliferative process. Patients who relapse as PV or chronic phase myelofibrosis can achieve long-term survival after relapse, while patients relapsing as MDS/ AML have dismal prognosis.

Background: Post-transplant cyclophosphamide (PT-Cy) is increasingly being adopted as a universal platform for GvHD prophylaxis, regardless of donor type. However, specific challenges in myelofibrosis (MF), such as higher risks of graft failure and poor graft function, require a careful evaluation of PT-Cy in this disease. Reducing PT-Cy dose to improve tolerability is under investigation, particularly in HLA-matched transplants, and may be particularly relevant for MF patients.

Methods: In January 2023, a clinical practice protocol was developed under the auspices of the GETH-TC (Grupo Español de Trasplante Hematopoyético y Terapia Celular) to harmonize transplant procedures for MF across centers in Spain. The core elements of the protocol included the use of PT-Cy at either standard (50 mg/kg on days +3 and +4, for HLA-mismatched transplants) or reduced dose (30 mg/kg on days +3 and +4, for HLA-matched transplants) combined with calcineurin inhibitors or rapamycin +/- mycophenolate. JAK inhibitor treatment was discontinued prior to stem cell infusion. The recommended conditioning regimens were based on combinations of thiotepa (T), busulfan (BU), and

fludarabine (Flu). The reduced intensity conditioning regimen was T5Flu120BU2 for HLA-matched transplants and T5Flu150BU2 for HLA-mismatched transplants, whereas the myeloablative regimen consisted of Flu120BU4 for HLA-matched transplants and T10Flu150BU3 for HLA-mismatched transplants. Here, we present preliminary results of the protocol, including overall survival (OS), engraftment, relapse, non-relapse mortality (NRM), and acute and chronic GvHD.

Results: Fifty-seven adult patients with MF in chronic (n=55) or accelerated phase (n=2) who underwent allo-HCT between January 2023 and October 2025 in 11 centers were included. Main deviations from the protocol were: use of treosulfan instead of BU (n=3), standard-dose PT-Cy with an HLA-matched donor (n=7), reduced-dose PT-Cy with an HLA-mismatched donor (n=2), and addition of ATLG to reduced-dose PT-Cy (n=9, all from a single center). Median interval from diagnosis to allo-HCT was 21.1 months. The main characteristics of the series are shown in Table 1.

Table 1. Main characteristics at transplantation in 57 myelofibrosis patie

Age at transplant, year	Median (Interquartile range)
Sex	Male
Myelofibrosis type	Primary myelofibrosis
Genotype	JAK2
	CALR
	MPL
	Triple negative
High molecular risk	Mutation in ASXL1, SRSF2, IDH1, IDH2, U2A
Splenectomy	Yes
Prior JAKi treatment	Yes
Spleen irradiation	Yes
Karnofsky performance status	<90
Hematopoietic Cell Transplant-specific Comorbidity Index	High (>=3)
Conditioning regimen	Myeloablative
Stem cell source	Peripheral blood
Donor type	MRD / MUD / MMUD / Haplo / MMRD, other

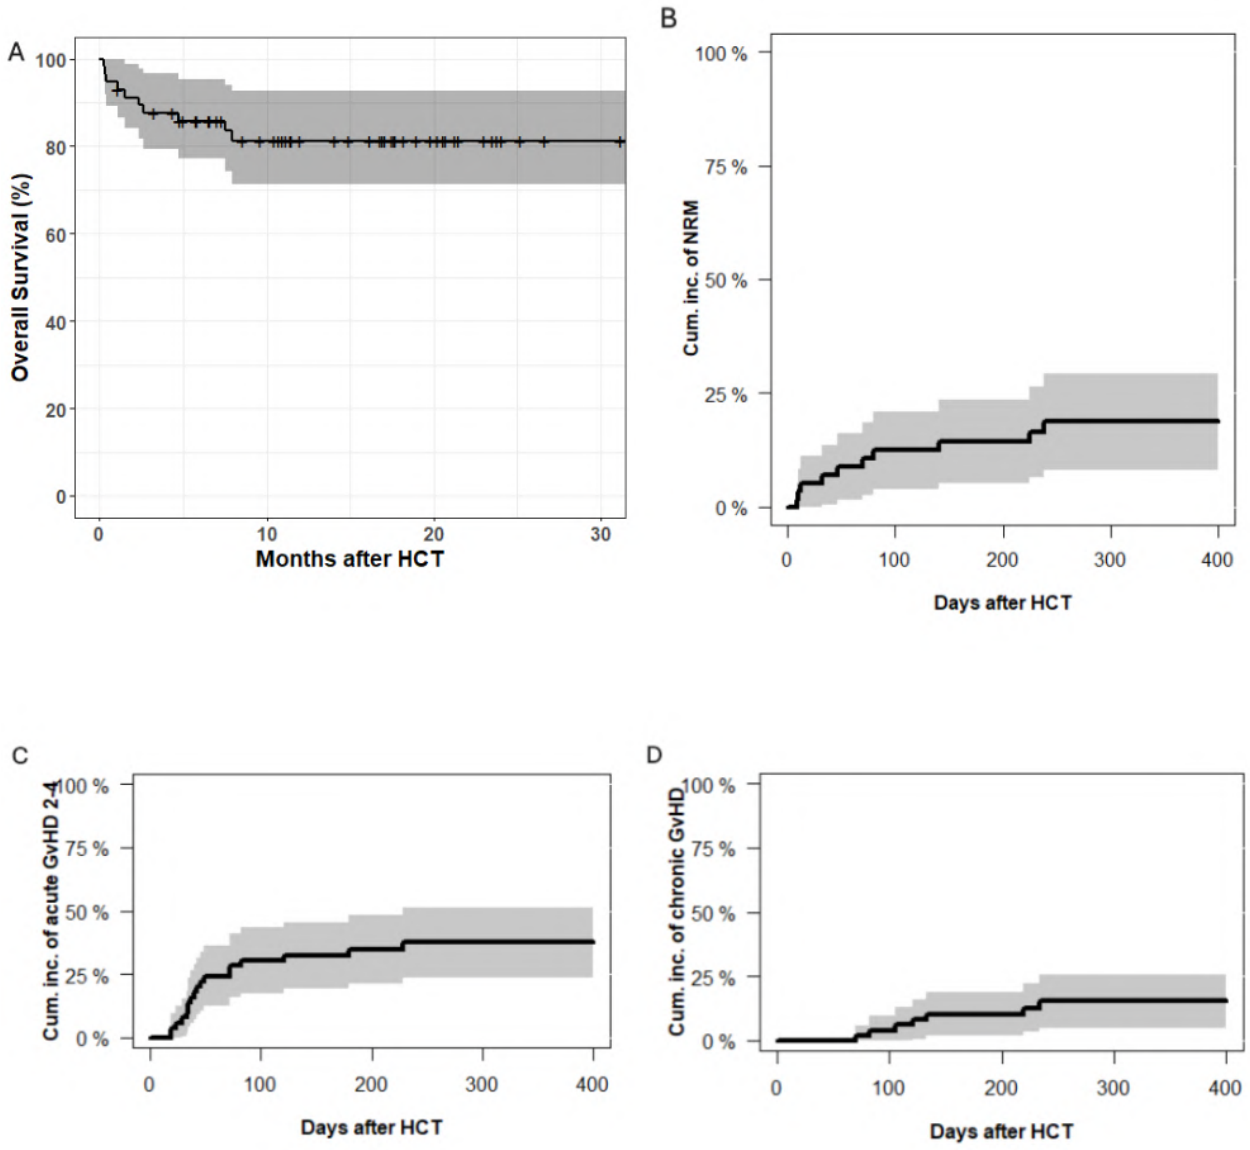
Table 1. Main characteristics at transplantation in 57 myelofibrosis patie

Post-transplant cyclophosphamide	100 mg/kg / 80 mg/kg / 50-60 mg/kg

MRD: matched related donor. MMRD: mismatched related donor (one allelic diference). MUD: matched unrelated

Three patients developed sinusoidal obstructive syndrome. One patient experienced primary graft failure. Median time (95% CI) to neutrophil and platelet engraftment was 19 days (17-20) and 27 days (23-30), respectively. Twenty patients (35%) had poor graft function, two of whom received a CD34+ cell boost. Two patients had disease relapse. Incidence of acute GvHD grades II-IV and III-IV at 120 days and moderate/severe chronic GvHD at 12 months were 37% (95% CI: 23-52), 16% (95% CI: 4-28), and 15% (95% CI: 5-26), respectively (Figure 1, C-D). After a median follow-up of 16.8 months from transplant, the estimated 2-year OS rate and NRM rate were 81% (95% CI: 70-92), and 19% (95% CI: 8-29), respectively (Figure 1, A-B). Causes of death were GvHD (n=5) and infection (n=5). The estimated 2-year OS rates were 84%, 83%, 91%, and 53% for transplants from MRD, MUD,

MMUD, and haploidentical donors, respectively (p=0.40).



Conclusions: This preliminary analysis shows an encouraging 2-year OS with our protocol, with NRM being the main cause of treatment failure. Poor graft function constitutes a common complication. Cohort expansion, longer follow-up, and harmonization of molecular monitoring are underway.

[1]*University Hospital Essen, Essen, Germany,* [2]*University Hospital Hamburg-Eppendorf, Hamburg, Germany,* [3]*Fred Hutch Cancer Center, Seattle, United States of America (the),* [4]*Università Cattolica del Sacro Cuore, Rome, Italy,* [5]*ASST Papa Giovanni XXIII, Bergamo, Italy,* [6]*University of Tor Vergata, Rome, Italy,* [7]*Centre Hospitalier Régional Universitaire, Nancy, France,* [8]*Hôpital Saint-Louis, Paris, France,* [9]*Université de Paris Cité, Paris, France,* [10]*Taussig Cancer Center, Cleveland, United States of America (the),* [11]*MD Anderson Cancer Center, Houston, United States of America (the)*

Background: Allo-SCT is the only potential curative option for pts with primary or secondary myelofibrosis (MF). Outcome after allo-SCT is affected by several factors, including the selection of an appropriate donor. Matched related (MRD) and matched unrelated (MUD) donors are the preferred donor source in MF. The introduction of PTCy has extended the option of allo-SCT to patients with only haploidentical donor options and substantially improved the outcome after haplo-transplant in hematological malignancies. However, data on the use of haploidentical donors in pts with MF are limited, and were not included as an independent risk factor in the Myelofibrosis Transplant Scoring System (MTSS). We aimed to estimate the prognostic impact of the haploidentical donor source in the context of different conditioning regimen and other risk factors we took advantage of a large multicenter cohort.

Methods: We performed a retrospective analysis of patients with MF, who received first haploidentical allo-SCT at nine transplant centers between 2015 and 2024. Uni- and multivariate analyses were performed to determine variables which are associated with overall survival (OS), relapse, non-relapse mortality (NRM), neutrophil engraftment and GvHD.

Results: One hundred pts (54% primary/46% secondary MF) with a median age of 60 years (range, 29-78) received a haplo-SCT after RIC (47%) or MAC (53%) using PB (73%) or BM (27%) stem cells. MIPSS70 was low, int and high in 1%, 55% and 44% respectively, while MTSS was low, int, high and very high in 2%, 24%, 32% and 42%. With a median follow-up of 5.9 years, the OS, relapse and NRM at 6 years for the entire cohort was 46%, 21% and 34%, while aGvHD grade 3/4 and cGvHD were observed in 11% and 29% of pts. Patients with MTSS low/intermediate, high and very high-risk group demonstrated 6-yr OS of 66%, 48%, 33% and NRM of 18%, 31%, 46% respectively. Furthermore, in univariate analysis Flu-Bu-based conditioning was significantly associated with lower relapse probability and higher engraftment rate compared to TBI-based and Flu-Mel-based conditioning. In multivariate analyses the presence of a portal vein thrombosis before allo-SCT was significantly associated with adverse outcomes for OS (p=0.001, HR 4.17), relapse (p=0.02, HR 2.07) and NRM (p=0.03, HR 3.88), while triple-negative MF was an independent adverse risk factor for decreased OS (p=0.005, HR 4.54).

Conclusions: In this multicenter cohort primarily NRM seems to limit outcome after haplo-SCT in MF pts. While haploidentical transplant may be the only donor source for some patients with MF, careful consideration should be paid to risk factors including the MTSS before recommending this donor source.

Disclosure: Nothing to declare.

LONG-TERM MINIMAL RESIDUAL DISEASE MONITORING BY DIGITAL DROPLET PCR AFTER ALLOGENEIC STEM CELL TRANSPLANTATION IN MYELOFIBROSIS IS PREDICTIVE OF RELAPSE: A RETROSPECTIVE AND PROSPECTIVE STUDY

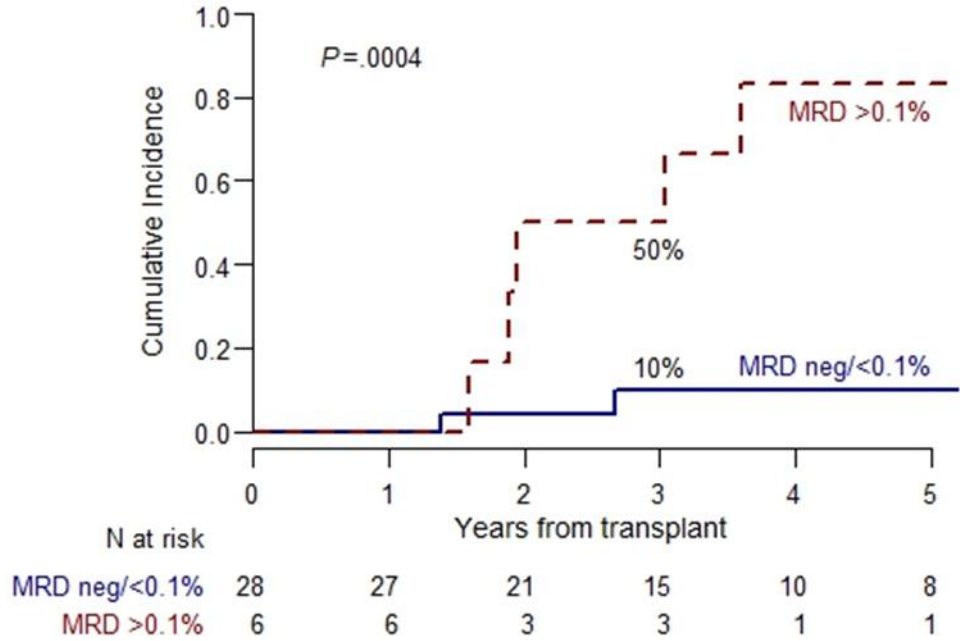
Maria Chiara Finazzi[1], *Silvia Salmoiraghi*[1], *Chiara Pavoni*[1], *Sara Rotini*[1], *Francesca Valsecchi*[1], *Anna Grassi*[1], *Alessandra Algarotti*[1], *Benedetta Rambaldi*[1], *Giuliana Rizzuto*[1], *Gianluca Cavallaro*[1], *Emanuela Carlotti*[1], *Orietta Spinelli*[1], *Federico Lussan*[2,1], *Alessandro Rambaldi*[2,1]
[1]*Hematology and Bone Marrow Transplant Unit, ASST Papa Giovanni XXIII, Bergamo, Italy,* [2]*Department of Oncology and Onco-Hematology, Univeristy of Milan, Milano, Italy*

Background: Relapse is one of the leading causes of transplant failure in myelofibrosis (MF), and post-transplant molecular monitoring of the driver mutation is recommended. Achieving minimal residual disease (MRD) negativity at days 30, 100, and 180 post-HCT appears to be associated with improved transplant outcomes. However, little is known about the clinical significance of long-term (beyond 12 months) MRD positivity.

Methods: This is an ambispective analysis of consecutive patients with primary or secondary MF who were transplanted between 2007 and 2025 at our institution. MRD monitoring was performed using digital droplet PCR (ddPCR) in patients carrying *JAK2V617F* mutations, *MPL* mutations or alternative mutations in triple-negative patients, with a sensitivity of at least 0.05%. Patients with *CALR* mutation were excluded, as they are not currently evaluable by ddPCR. All patients had molecular characterization before transplant by a next-generation sequencing (NGS) panel including 30 myeloid genes.

Results: Of 83 MF patients evaluated, 51 (61%) patients were assessable for MRD monitoring by ddPCR. Median age at transplant was 59 years (range 42-68). Very high-risk cytogenetic abnormalities were found in 9 (19%) patients. Seven patients (14%) experienced blastic evolution before transplant. The donor type was matched unrelated (57%), haploidentical (17%), mismatched unrelated (16%) and HLA-identical sibling (10%). The driver mutation was *JAK2V617F* in 40 (78%) patients and *MPL* in 10 (20%) patients. One patient was triple negative but had a *ZRSR2* mutation, which could be monitored by ddPCR. NGS analysis revealed at least one HMR (high molecular risk) mutation in 21 (48%) patients. The most frequent additional mutations were *ASXL1* (41%), *DNMT3A* (16%), *TET2* (11%), *SF3B1* (11%) and *EZH2* (9%).
After a median follow-up of 2.3 years (range 0.1-15.5), the 3-year overall survival (OS),

progression-free survival (PFS), cumulative incidence of relapse (CIR), and non-relapse mortality (NRM) were 70%, 57%, 29%, and 14%, respectively. MRD positivity was detected in 62%, 45%, and 28% of patients at day +30, +90, and +180 after transplant, respectively. An MRD-positive status at day +90 was significantly associated with an increased risk of relapse (HR 1.79, 95% CI, *p=0.04*).
Thirty-four patients were alive at 1 year after transplant and were evaluable for MRD status. Ten patients were identified as MRD-positive during long-term follow-up (≥ 1 year after transplant), with 4 showing very low levels of positivity (< 0.1%).
Long-term detection of MRD positivity > 0.1% was significantly associated with a lower PFS (HR 7.77, 95% CI, *p=0.005*) and a higher CIR (HR 12.24, 95% CI *p=0.002*) compared to patients MRD-negative or with a very low level (<0.1%) of MRD positivity. The 3-year CIR for patients with long-term MRD positivity > 0.1% was 50%, compared to 10% for those MRD-negative or with MRD levels below 0.1% (95% CI, *p=0.004*; Figure 1).
Univariate analysis suggested *JAK2V617F* mutation (HR 3, 95% CI, *p=0.3*) and HMR mutations (HR 3.25, 95% CI, *p=0.1*) as risk factors for persistent long-term MRD positivity, though not statistically significant.



Conclusions: This study reinforces the value of MRD monitoring after transplant and underscores the importance of ongoing surveillance during long-term follow-up.

Clinical Trial Registry: Not applicable.

Disclosure: Nothing to declare.

B429

HAPLOIDENTICAL STEM CELL TRANSPLANTATION USING NOVEL PROTOCOL DEMONSTRATED EXCELLENT OUTCOMES FOR PATIENTS WITH MYELOFIBROSIS

Borui Tang[1], Rui Ma[1], Yi Liao[1], Xueyi Luo[1], Jie Sun[1], Rong Wei[1], Zhengli Xu[1], Tingting Han[1], Jun Kong[1], Yu Wang[1], Lanping Xu[1], Yuanyuan Zhang[1], Xiaodong Mo[1], Xiaohui Zhang[1], Xiaojun Huang[1], ***Yuqian Sun***[1]
[1]*Peking University People's Hospital, Peking University Institute of Hematology, National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Cell and Gene Therapy for Hematologic Malignancies, Beijing, China*

Background: Allogeneic stem cell transplantation (allo-HSCT) is the only curative option for myelofibrosis (MF). For patients without a matched sibling (MSD) or unrelated donor (MUD), haploidentical donors are a valid alternative. However, there are relatively few reports of haplo-HSCT for MF, partly due to high graft failure and non-relapse mortality (NRM). Our previous study suggested pre-transplant massive splenomegaly as the main risk factor of graft failure after haplo-HSCT (*Bone Marrow Transplant. 2025 Nov 25. doi: 10.1038/s41409-025-02746-4.*). Therefore, we recently developed a novel protocol based on the pre-transplant spleen size (Fig. 1A). And this prospective study aims to evaluate the efficacy of this novel transplant protocol in MF.

Methods: This was a prospective single-center study performed at Peking University People's Hospital. MF patients (primary or secondary to polycythemia vera/essential thrombocythemia) was eligible if they had no MSD/MUD but an available haploidentical donor. Patients with active infection or ECOG score > 2 or estimated survival＜30 days were excluded. The pre-transplant spleen size-based stratification strategy and the novel DTBFA conditioning regimen was described in Fig 1. The primary endpoint was good graft function (GGF) at day 60 which was defined engraftment of both neutrophil and platelet. Secondary endpoints include overall survival (OS), disease free survival (DFS), cumulative relapse incidence (CIR), non-relapse mortality (NRM), graft versus host disease (GVHD), immune reconstitution. This study was registered on Clinical trial (NCT06674382).

Results:

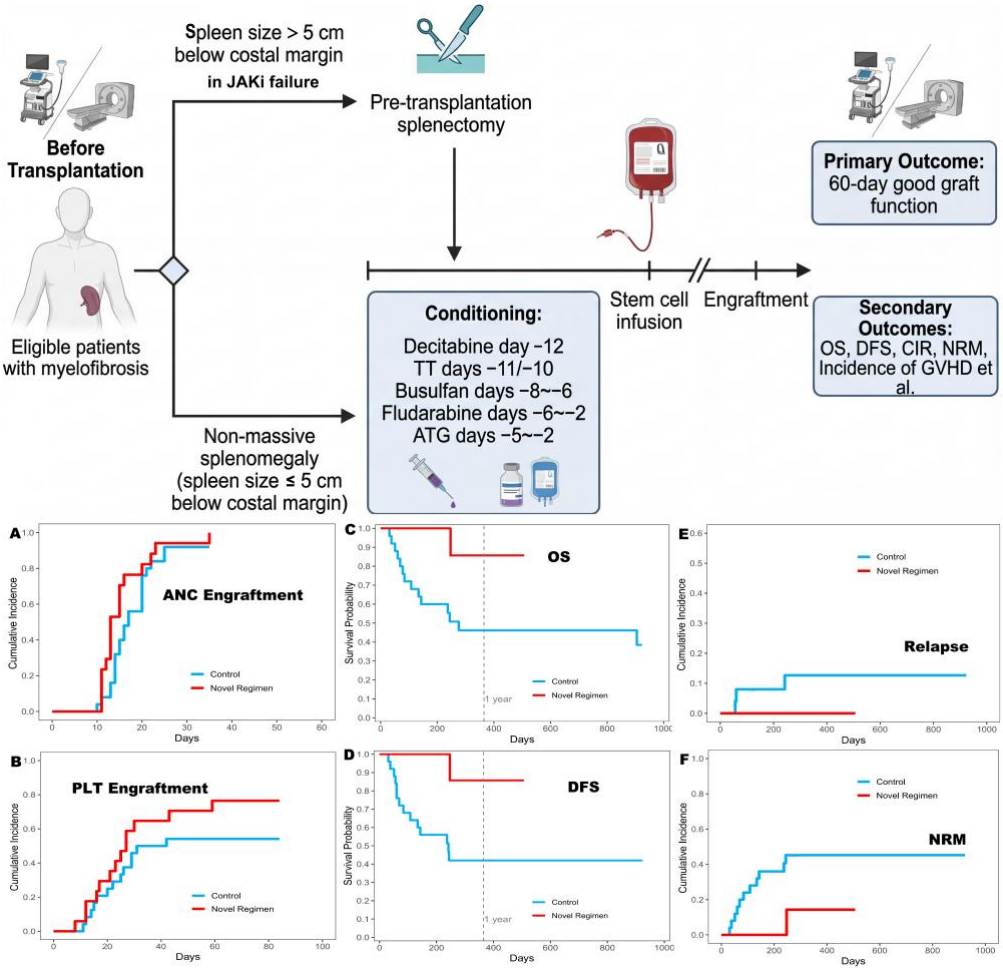
This was an Interim Result of the Prospective Study. During January 2024-September 2025, seventeen MF patients were prospectively enrolled. The last follow-up was November 30, 2025 with a median 351 days (Table 1). The 60-day GGF was 82.4%. The engraftment of neutrophil and platelet was 100% and 82.4%, respectively. The grade II-IV acute GVHD and moderate/severe chronic GVHD was 33.3% and 11.9%, respectively. The 1-year OS, DFS, CIR and NRM was 85.7%, 82.4%, 0% and 14.3%, respectively (Fig.1). All patients had significant myelofibrosis regression(≥1 WHO MF grade reduction) within 3 months post-transplant. The median time of significant myelofibrosis regression was 1 month post-transplant.
Furthermore, 25 MF patients who received haplo-HSCT at our center during December 2008–2023 were treated as historical controls. Patients in novel regimen group demonstrated a trend of improved 60-day GGF (82.4% vs 56%, P=0.13), ANC engraftment (100% vs 92%, P=0.088), PLT engraftment (82.4% vs 56%, P=0.13), better survival (1-year OS: 85.7% vs 46.2%, P=0.015; DFS: 85.7% vs 42.0%, P=0.007;) and lower NRM (14.3% vs 45.2%, P=0.027).



Conclusions: Haplo-HSCT using a novel protocol based on pre-transplant spleen size demonstrated promising outcomes in patients with MF. However, this should be further validated in multicenter study.

THE EFFICACY AND SAFETY OF PD-1 MONOCLONAL ANTIBODY IN THE TREATMENT OF HEMOPHAGOCYTIC SYNDROME：SYSTEMATIC REVIEW

*Fangyuan Lai[1], **Shaoyan Hu**[2], Xuejuan Li[1], Mi Zhou[2]*
[1]Shenzhen Children's Hospital, Shenzhen, China, [2]Children's Hospital of Soochow University, Suzhou, China

Background: Hemophagocytic lymphohistiocytosis (HLH), also known as hemophagocytic syndrome (HPS), is a life-threatening hyperinflammatory syndrome characterized by immune dysregulation. While standard protocols (HLH-1994/2004) utilizing glucocorticoids and etoposide are effective for many, patients with refractory or relapsed (r/r) HLH face poor prognoses. Recently, Programmed cell death protein-1 (PD-1) monoclonal antibodies have emerged as a potential targeted therapy, particularly for Epstein-Barr virus (EBV)-associated HLH, by reversing T-cell exhaustion. This study retrospectively analyzed the clinical efficacy, and safety profile of PD-1 inhibitors in the treatment of HLH.

Methods: A comprehensive search of the case reports, retrospective studies, and clinical trial data was conducted on PubMed, Web of Science, and Embase, up to July 2025. Data regarding the efficacy and safety of PD-1 monoclonal antibodies used (such as sintilimab, nivolumab, camrelizumab, and tislelizumab) in both pediatric and adult patients with HLH were included.

Results: A total of 12 studies were involved，covering with Epstein-Barr virus-associated hemophagocytic lymphohistiocytosis (EBV-HLH) and related malignancies. In pediatric patients (aged 3–7 years) with CAEBV and r/r EBV-HLH, sintilimab (3mg/kg, once every 3-4 weeks, monotherapy or combined with L-DEP regimen (pegaspargase, liposomal doxorubicin, etoposide, and high-dose methylprednisolone)) induced partial or complete clinical remission and significantly reduced plasma EBV-DNA levels (>50%), successfully serving as a bridge to allogeneic hematopoietic stem cell transplantation (HSCT) in some cases. Regarding adult patients, A retrospective study of seven R/R EBV-HLH patients (aged 15–36 years) treated with nivolumab reported positive outcomes, with a 16-month overall response rate (ORR) of 85.7% and a complete response (CR) rate of 71.4%. Some studies have reported that, sintilimab salvage therapy effectively restored complete donor chimerism and eradicated viral loads in patients who received allo-HSCT due to EBV-HLH/CAEBV.
In terms of combination therapies, regimens integrating PD-1 inhibitors with chemotherapy or targeted agents showed superior outcomes. A comparative study involving 98 patients with extranodal NK/T-cell lymphoma-associated HLH revealed that adding PD-1 monoclonal antibody to chemotherapy significantly improved overall response rates (73.3% vs. 45.5%) and survival compared to chemotherapy alone. Furthermore, novel combinations with ruxolitinib, venetoclax, or thalidomide achieved rapid clinical remission in EBV-HLH. Safety assessments indicated that PD-1 blockade following HSCT was associated with a high risk of graft-versus-host disease (GVHD, incidence up to 55%). Rapid immune reactivation triggered by PD-1 inhibitors may paradoxically exacerbate cytokine storms, necessitating vigilant monitoring.

Adverse Events: Persistent observed in 4 responders Transient worsening of cyt increased ferritin/sCD25 w patients (pseudoprogressio pruritus and depigmentatio patient during maintenanc

Conclusions: PD-1 monoclonal antibodies demonstrate significant therapeutic potential as salvage therapy for r/r EBV-HLH, effectively reducing viral loads and inducing remission. However, immune checkpoint inhibition acts as a double-edged sword; while it reactivates immune function, it carries risks of aggravating hyperinflammation and inducing severe GVHD in transplant recipients. Clinical application requires careful risk-benefit assessment, particularly regarding dosage and timing relative to the inflammatory peak. Further large-scale clinical trials are needed to establish standardized protocols.

INCIDENCE, CLINICAL OUTCOME, AND THERAPEUTIC IMPLICATIONS OF RELAPSE AFTER ALLOGENIC STEM CELL TRANSPLANTATION FOR PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS

*Giacomo Coltro[1], Giulia Borgi[2], Antonella Gozzini[1], Ilaria Cutini[1], **Chiara Camerini**[1], Edoardo Simonetti[1], Mirella Giordano[1], Gaia Mirabella[2], Paola Guglielmelli[1,2], Alessandro M. Vannucchi[1,2], Chiara Nozzoli[1]*
[1]Azienda Ospedaliera-Universitaria Careggi, Florence, Italy, [2]University of Florence, Florence, Italy

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) represents the only potentially curative option for myelofibrosis (MF) and blast-phase myeloproliferative neoplasms (BP-MPN), but its effectiveness is limited by a substantial risk of disease recurrence, ranging from 10% to 45% depending on disease phase.

Methods: We conducted a retrospective, single-center study to evaluate the incidence and clinical outcomes of relapse in MPN patients undergoing allo-HSCT. Molecular relapse (MR) was defined as reappearance of a driver mutation (*JAK2*, *CALR*, or MPL) without evidence of hematologic disease; hematologic relapse (HR) was defined as overt clinical recurrence (e.g., leukocytosis, new/worsening cytopenias, peripheral blood [PB] blasts).

Results: The study included 47 patients who underwent allo-HSCT for either MF (n=35; 74%) or BP-MPN (n=12; 26%) between 2013 and 2024. Median age was 59.8 years (range, 41.9-69.6), 18 (38%) were female. All patients received PB stem cells as graft source. Donor was HLA-matched unrelated in 29 (62%), haploidentical in 11 (23%), and identical sibling in 6 (13%). Reduced-intensity conditioning was used in 40 (85%) patients.
After a median follow-up of 3.5 years (95% CI, 1.2-4.5), 10 (21%) patients experienced disease recurrence (6 MF; 4 BP-MPN). Cumulative relapse incidence at 1, 3, and 5 years was 19%, 35% and 35%, respectively. Driver mutation status included mutant *JAK2* (m*JAK2*) in 5 patients, m*CALR* in 3, m*MPL* in 1, and a triple-negative profile in 1.
Molecular relapse occurred in 8 (17%) patients at a median of 6.3 months (range, 1.6-32.9) after allo-HSCT (6 MF; 2 BP-MPN). All MR cases were accompanied by decline in donor chimerism. Driver mutation distribution was m*JAK2* in 4 (50%) patients, m*CALR* in 3 (38%), and m*MPL* in 1 (12%). Most MRs (n=6/8) occurred within the first year after transplantation. Three patients relapsed while receiving calcineurin-inhibitor (CNI) prophylaxis/therapy; in all cases, CNI discontinuation did not induce molecular remission.
Besides CNI discontinuation, therapeutic management of MR included donor lymphocyte infusion (DLI) in 7 of 8 patients (mean administrations number, 2 [range, 1-3]; dose range, 1×10^6/Kg-1×10^7/Kg). Four patients developed graft-versus-host disease (GVHD), prompting DLI discontinuation. Three patients failed to clear their mutation and progressed to HR, whereas 4 achieved molecular remission and remained in sustained MR-free status. Among responders, 1 (25%) carried m*JAK2*, 2 (50%) m*CALR* (type-1/like), and 1 (25%) m*MPL*. Non-responders had m*JAK2* (n=2) or m*CALR* type-2/like (n=1).
Finally, HR occurred in 5 (11%) patients at a median of 21.4 months (range, 2.7-53.9) post-transplant (2 MF; 3 BP-MPN). Three had preceding MR and are currently managed as lower-risk MF. The remaining 2 patients relapsed with aggressive BP-MPN and died shortly thereafter.

Conclusions: Post-transplant relapse remains relatively frequent and clinically challenging. DLI demonstrates meaningful activity in MR, particularly in patients with *CALR*- or *MPL*-mutated disease, which is associated with better post-transplant outcomes and may potentially exert an "antigenic activity". These findings gain relevance with emerging targeted therapies—such as anti-mCALR monoclonal antibodies—that could expand therapeutic options also for managing post-transplant relapse. Limitations include the retrospective design and small cohort, underscoring the need for larger studies.

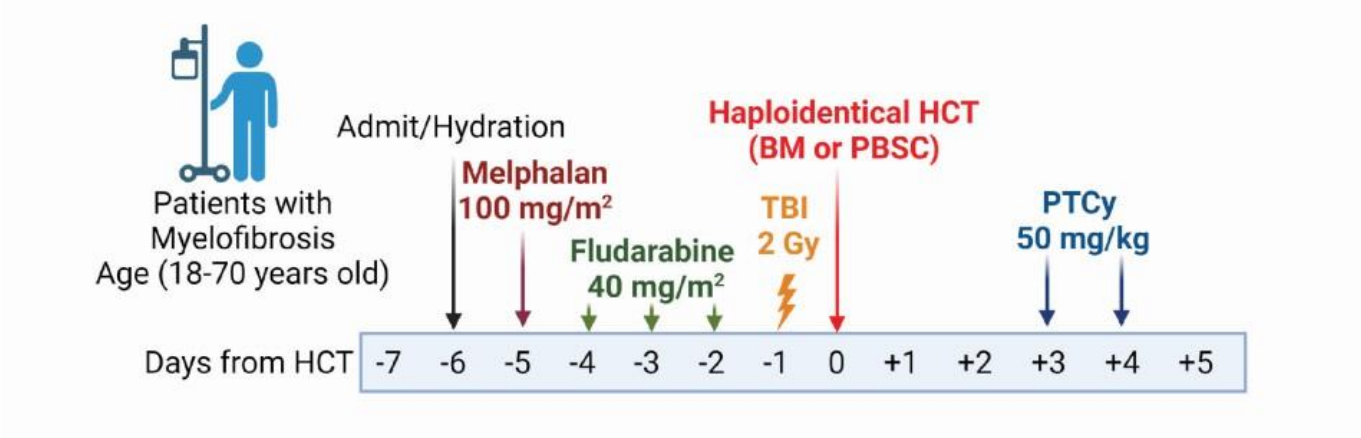
REDUCED-INTENSITY HAPLOIDENTICAL HEMATOPOIETIC CELL TRANSPLANTATION WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE IN PATIENTS WITH ADVANCED MYELOFIBROSIS

Monzr M. Al Malki[1], *Dongyun Yang*[1], *Nicole Tsai*[1], *Sally Mokhtari*[1], *Diana Knobler*[1], *Anna Keryan*[1], *Geoffrey Shouse*[1], *Ahmad Aribi*[1], *Joshua Mansour*[1], *Firoozeh Sahebi*[1], *Idoroenyi Amanam*[1], *Salman Otoukesh*[1], *Guido Marcucci*[1], *Stephen J. Forman*[1], *Ryotaro Nakamura*[1], *Haris Ali*[1]
[1]*City of Hope, Duarte, United States of America (the)*

Background: Allogeneic hematopoietic cell transplantation (HCT) remains the only curative therapy for myelofibrosis (MF); however, many patients—particularly older adults—lack a suitable HLA-matched donor. The development of HLA-haploidentical transplantation (HaploHCT) using post-transplant cyclophosphamide (PTCy) has significantly expanded donor availability. We conducted a pilot study (NCT03118492) to evaluate the safety and feasibility of a reduced-intensity conditioning (RIC) regimen integrating fludarabine with Melphalan (FM100) and low-dose TBI (2 Gy) prior to HaploHCT in patients with advanced MF.



Methods: Twenty-two patients were enrolled across two sequential cohorts. After observing early toxicity in the first four patients (CH-1), eligibility was refined to exclude those with accelerated-phase disease, significant pulmonary hypertension, and to implement strict fluid management in the subsequent 18 patients (CH-2). The primary endpoint was safety, defined as the incidence of unacceptable toxicity (UT), including any Bearman grade 3–4 regimen-related toxicity, prolonged grade 4 neutropenia, or death. Secondary endpoints included rates of cytokine release syndrome (CRS), acute and chronic GVHD, engraftment, progression-free survival (PFS), and overall survival (OS).

Results: Median age was 59 years (Range= 48-70), with 55% male, 59% primary MF, and 32% high risk disease. The median interval from MF diagnosis to HCT was 1052 days (range: 27-7651). Two of four patients in CH-1 experienced UTs (persistent grade 3 anorexia; acute kidney injury and prolonged neutropenia), prompting protocol modification. In CH-2, only 1 of 16 patients experienced a UT (acute kidney injury).
A total of 20 patients (3 in CH-1 and 17 in CH-2) had neutrophil engraftment with median

time to engraftment of 20 days in CH-1 and 21 days in CH-2. All patients achieved complete donor chimera (>95%) by day 100. A total of 18 patients (2 in CH-1 and 16 in CH-2) had platelet engraftment with median time to engraftment of 53 days in CH-1 and 36 days in CH-2. With median follow up of 24 months (range: 12-25), 2-year OS and PFS for the entire cohort were 77% (95% CI, 53–90) and 59% (95% CI, 33–77), respectively. CH-2 demonstrated markedly improved outcomes versus CH-1, with 2-year OS of 83% vs 50% and 2-year PFS of 60% vs 50%, respectively. No patients experienced relapse at 1 year, and cumulative incidence (CI) of relapse was 18% in year 2. NRM was also improved in CH-2, with 100 day- and 2-year NRM of 6% and 18%, respectively, versus 25% and 50% in CH-1. Day 100 CI of Grade 2-4 and 3–4 acute GVHD was 32% and 5%, respectively. At 2 years, moderate/severe chronic GVHD CI was 5% in the entire cohort.

Patient and Transplant Characteristics

	CH-1 (N=4)	CH-2 (N=18)	Total (N=22)
Age at HCT, years Median (Range)	60 (48-68)	59 (50-70)	59 (48-70)
Gender Female Male	 2 (50%) 2 (50%)	 8 (44.4%) 10 (55.6%)	 10 (45.5%) 12 (54.5%)
Race/Ethnicity Non-Hispanic White African American Asian Hispanic	 2 (50%) 0 (0%) 1 (25%) 1 (25%)	 3 (16.7%) 6 (33.3%) 3 (16.7%) 6 (33.3%)	 5 (22.7%) 6 (27.3%) 4 (18.2%) 7 (31.8%)
HCT Comorbidity Index 0 1-2 3+	 1 (25%) 2 (50%) 1 (25%)	 12 (66.7%) 4 (22.2%) 2 (11.1%)	 13 (59.1%) 6 (27.3%) 3 (13.6%)
Karnofsky Performance Status 70 80 90 100	 1 (25%) 2 (50%) 1 (25%) 0 (0%)	 0 (0%) 4 (22.2%) 9 (50%) 5 (27.8%)	 1 (4.5%) 6 (27.3%) 10 (45.5%) 5 (22.7%)
Days from Diagnosis to HCT Median (Range)	1067 (449-2500)	798 (27-7651)	1052 (27-7651)

Patient and Transplant Characteristics

MF Type			
Primary	1 (25%)	12 (66.7%)	13 (59.1%)
Secondary	3 (75%)	6 (33.3%)	9 (40.9%)
MF Risk			
High	2 (50%)	5 (27.8%)	7 (31.8%)
Intermediate II	2 (50%)	13 (72.2%)	15 (68.2%)

Conclusions: This pilot study demonstrates that RIC HaploHCT using FM100 TBI200 and PTCy based GvHD prophylaxis is safe and feasible for patients with advanced MF, with low rates of NRM, relapse, and severe acute or chronic GVHD—particularly when performed early before progression or development of significant pulmonary hypertension. These results support HaploHCT as an effective and accessible curative option for MF patients, including those from racial and ethnic minority backgrounds who lack HLA-matched donors.

INFLUENCE OF HLA-DPB MATCHING ON OUTCOMES AFTER ALLO-HSCT FOR MYELOFIBROSIS

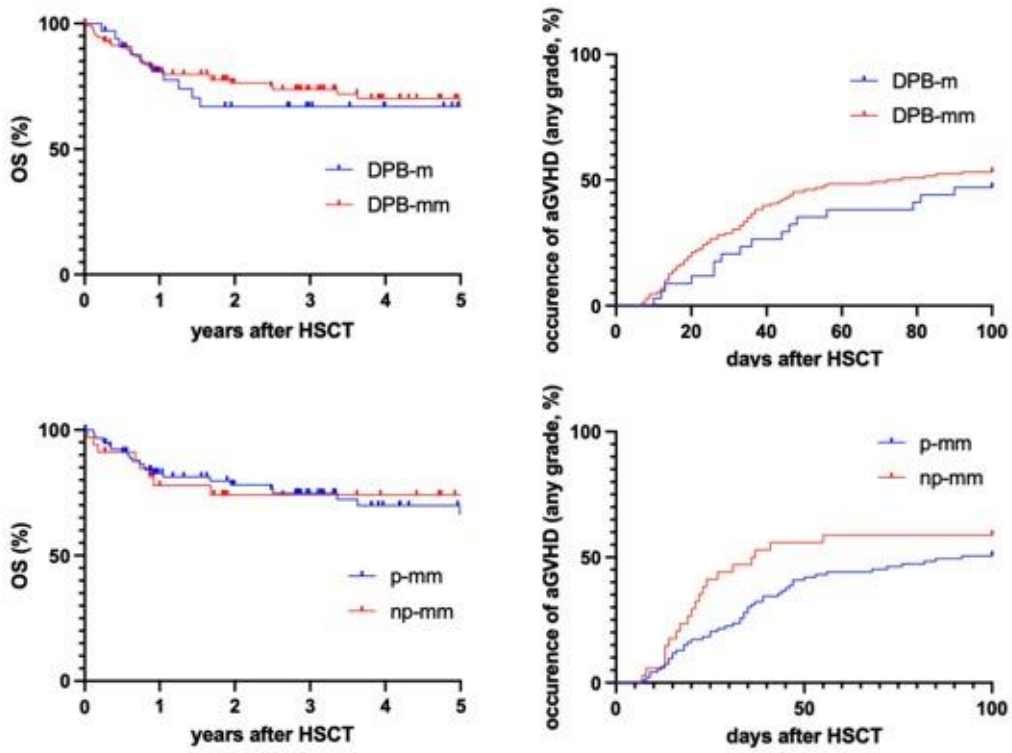
Mathias Schäfersküpper[1], *Anita Badbaran*[1], *Radwan Massoud*[1], *Gunnar Weise*[1], *Nico Gagelmann*[1], *Kristin Rathje*[1], *Johanna Richter*[1], *Catherina Lück*[1], *Jochim Reinert*[1], *Silke Heidenreich*[1], *Evgeny Klyuchnikov*[1], *Ina Rudolph*[1], *Maraike Harfmann*[1], *Tamara Kunze*[1], *Benno Lickefett*[1], *Jette Lüdersen*[1], *Maroly Bohorquez Manjarres*[1], *Franzsika Marquard*[1], *Christian Niederwieser*[1], *Sofia Oechsler*[1], *Fatma Elif Öztürk*[1], *Mirjam Reichard*[1], *Rusudan Sabauri*[1], *Hui Ting Tang*[1], *Max Wichmann*[1], *Frederik von Daak*[1], *Nicolaus Kröger*[1], *Boris Fehse*[1], *Francis Ayuk*[1]
[1]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Donor selection for allogeneic hematopoietic stem cell transplantation (alloHSCT) is an important factor influencing post-transplant outcomes. Especially HLA-matching determines overall survival, treatment-related mortality, disease-free survival, and the occurrence of acute and chronic graft-versus-host-disease (aGvHD and cGvHD). In recent

years, the discovery of the DPB-system as part of the HLA class II antigens has introduced a new factor for donor selection. Retrospective data showed a significant influence of HLA-DPB mismatch on transplant outcome depending on their T-Cell Epitope (TCE) group. Whether the described influence is relevant for alloHSCT in myelofibrosis remains unknown.

Methods: A total of 163 patients undergoing alloHSCT for myelofibrosis in a single center from 2017 to 2025 with available data for HLA-DPB were included in this retrospective analysis. The median follow-up time was 1147 days (3.14 years). There was no statistical difference in diagnosis (PMF; postET-MF, postPV-MF), risk score, or conditioning regimen between the groups. TCE group and subsequently permissivity of mismatch was defined as reported in Lancet Oncology (2012) 13:366-74. Survival functions were calculated using the Kaplan-Meier estimator. Statistical curve comparison was performed using the log-rank test for Overall Survival (OS), Disease-free Survival (DFS), Transplant-related Mortality (TRM) and occurrence of aGvHD. Hazard-ratios (HR) are given as a pike estimator.

Results: Our exploratory analysis showed no difference in OS among all compared groups. Comparing DPB-matched (DPB-m) and DPB-mismatched (DPB-mm) groups, disregarding TCE groups or permissivity, the HR for OS was 1.09 (95%CI:0.52 to 2.24) with no difference between the curves (p=0.80). The HR comparing permissive-DPB-mismatches (p-mm) and non-permissive-DPB-mismatches (np-mm) was 0.90 (95%CI: 0.41 to 1.98).
Comparing the TRM of DPB-m to DPB-mm yielded similar results, with a HR of 1.46 (95%-CI: 0.55 to 3.83) and no significant difference between the curves (p=0.39).
When looking at DFS, no difference was found regarding HLA-DPB-matching. Comparing DPB-m to DPB-mm, the calculated HR was 1.32 (95%CI: 0.6910 to 2.549) with a p-value of 0.36 for curve comparison. Similarly, when looking at permissive vs. non-permissive mismatches within the DPB-mm group, no statistical difference was found. HR for DFS comparing p-mm and np-mm was 1.08 (95%CI: 0.5426 to 2.179), while the curve comparison p-value was 0.82.
Analysis for the occurrence of aGvHD showed a small trend favoring the DPB-matched cohort. HR for aGvHD between DPB-m and DPB-mm was 0.70 (95%CI: 0.4517 to 1.094) with curve comparison missing statistical significance with a p-value of 0.12. Surprisingly, the same could be observed between p-mm and np-mm with a HR of 0.71 (95%CI: 0.4051 to 1.243) and a p-value of 0.17.



Conclusions: In this retrospective dataset, there is a trend towards a higher rate of aGvHD for the DPB-mismatched cohort, while not reaching statistical significance in this small patient sample. No difference is found in OS, DFS, and TRM regarding HLA-DPB-matching for patients undergoing alloHSCT for myelofibrosis.
To further delineate the relevance of HLA-DPB-matching for patients suffering from myelofibrosis, more data is needed beyond this exploratory analysis.

POOR GRAFT FUNCTION FOLLOWING ALLOGENIC STEM CELL TRANSPLANTATION FOR PH-NEGATIVE MYELOPROLIFERATIVE NEOPLASMS: INCIDENCE, RISK FACTORS, AND PROGNOSTIC IMPLICATIONS FROM A SINGLE-CENTER EXPERIENCE

*Giacomo Coltro[1], Giulia Borgi[2], **Edoardo Simonetti**[1], Chiara Camerini[1], Ilaria Cutini[1], Antonella Gozzini[1], Mirella Giordano[1], Gaia Mirabella[2], Paola Guglielmelli[1,2], Alessandro M. Vannucchi[1,2], Chiara Nozzoli[1]*

[1]Azienda Ospedaliera-Universitaria Careggi, Florence, Italy, [2]University of Florence, Florence, Italy

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) remains the only potentially curative treatment for myelofibrosis (MF) and blast phase myeloproliferative neoplasm (BP-MPN). However, it is burdened by substantial risks, including graft failure (GF) and poor graft function (PGF), both major determinants of post-transplant morbidity and mortality.

Methods: This retrospective, single-center study aimed to determine the incidence of PGF, its clinical implications, and potential risk factors; PGF was defined using both the EBMT definition (Bone Marrow Transplant. ;2024;59(6):832–837) and the criteria by Alchalby H. *et al.* (Bone Marrow Transplant.;2016;51(9):1223-7).

Results: Forty-eight patients undergoing allo-HSCT for MF (n=36; 75%) or BP-MPN (n=12; 25%) were included. Median age was 59.9 years (interquartile range [IQR], 9.6); 30 (63%) were male. All patients received peripheral blood stem cells as graft source. Most had HLA-matched unrelated donors (n=30; 63%), followed by haploidentical donors (n=11; 23%). Reduced-intensity conditioning was used in 41 patients (85%), whereas myeloablative conditioning was used in 7 (15%).
The cumulative incidence of leukocyte engraftment was 91%. The median time to leukocyte and platelet engraftment was 19 days (IQR, 6.5) and 25 days (IQR, 23), respectively. A total of 9 (21%) patients fulfilled the EBMT criteria for PGF with a cumulative incidence of 17%.
In univariate logistic regression analysis, pre-transplant factors associated with increased risk of PGF at day +100 (PGF^{100}) included severe splenomegaly (palpable >10 cm) (odds-ratio [OR], 14.7; 95%CI, 2.5-43.8; p=.0057), mutant *EZH2* (m*EZH2*) (OR, 10.5; 95%CI, 1.3-49.7; p=.0262), and *m*ASXL1 (OR, 5.8; 95%CI, 1.1-36.4; p=.0441). Conversely, non-*CALR*/*MPL* driver genotype was associated with reduced risk of PGF^{100} (OR, 0.03; 95%CI, 0-0.26; p=.0005). Upon multivariate Firth's logistic regression analysis, severe splenomegaly (OR, 8.2; 95%CI, 1.3-33.2; p=.0399) and non-*CALR*/*MPL* genotype (OR, 0.04; 95%CI, 0-0.39; p=.0134) remained significantly associated with a higher and lower risk of PGF^{100}, respectively.
Subsequently, by applying the definition provided by Alchalby H. *et al.*, 9 (21%) patients fulfilled the criteria. Univariate Cox proportional hazards analysis identified severe splenomegaly (hazard-ratio [HR], 12.1; 95%CI, 3.1-47.1; p=.0003), pre-transplant JAK-inhibitor therapy (HR, 5.6; 95%CI, 1-45.2; p=.0457), m*EZH2* (HR, 6.1; 95%CI, 1.6-23.1; p=.0069), m*ASXL1* (HR, 5.7; 95%CI, 1.2-27.5; p=.0152), and m*U2AF1* (HR, 5.1; 95%CI, 1.1-24.8; p=.0425) as significant risk factors for PGF. Conversely, non-*CALR*/*MPL* genotype was confirmed to be associated with a lower risk of PGF (HR, 0.04; 95%CI, 0-0.36; p<.0001). Upon multivariate analysis, severe splenomegaly (HR, 4.3; 95%CI, 1.1-17.1; p=.0099) and non-*CALR*/*MPL* genotype (HR, 0.07; 95%CI, 0-0.57; p=.0022) remained independent predictors of PGF. Figure 1 displays the unadjusted cumulative incidence curves of PGF for the two indipendent prognostic factors.
Finally, PGF did not significantly affect overall survival, non-relapse mortality, disease relapse/progression, or graft-versus-host disease incidence, although the limited sample size may constrain interpretability.

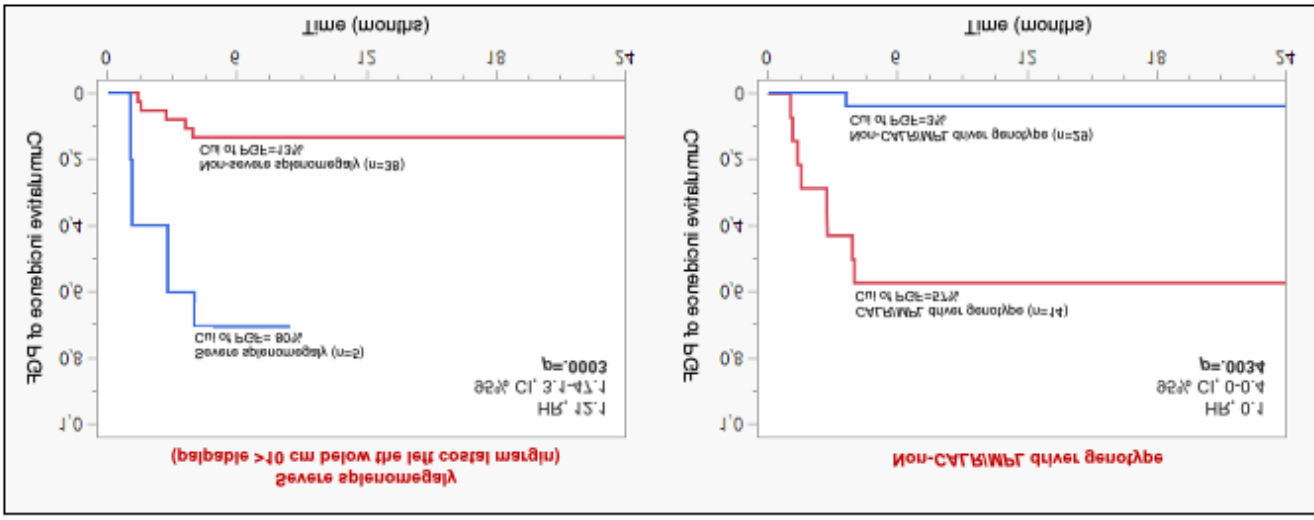

Figure 1. Unadjusted cumulative incidence (CIR) of poor graft function (PGF) according to the independent predictive factors identified in multivariable analysis

Conclusions: In our cohort, PGF emerged as a frequent post-transplant complication. Both severe splenomegaly and non-*CALR*/*MPL* driver genotype were independently associated with higher PGF risk, suggesting a shared pathogenic continuum. Although high molecular risk (HMR) mutations did not retain independent significance, their association with PGF in univariate models supports a potential biological role in compromising hematopoietic recovery and niche reconstitution.

IMPACT OF SPLENIC RADIOTHERAPY BEFORE HAEMATOPOIETIC STEM CELL TRANSPLANT ON ENGRAFTMENT AND TRANSFUSION NEEDS IN PATIENTS WITH MYELOFIBROSIS

Gerard Gurumurthy[1], *Gemma Barnard*[1], *Charles Crawley*[1], *Gail Horan*[1], *Thankamma Ajithkumar*[1]
[1]*Addenbrooke's Hospital, Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Splenomegaly at the time of haematopoietic stem cell transplant for myelofibrosis is associated with a risk of graft failure and poor survival. Splenic radiotherapy before transplant may be beneficial and this has been offered in our centre since 2020. We report on the safety, efficacy and outcomes of splenic radiotherapy before transplant and compare these against those who have not had splenic radiotherapy.

Methods: Splenic radiotherapy (5Gy in 5 fractions) was given a week before transplant conditioning. Survival was analysed using Kaplan-Meier methods. Engraftment, transfusion independence, serial blood count and donor lymphocyte infusion (DLI) were assessed between radiated and not radiated groups.

Results: Thirty-four patients underwent transplant for myelofibrosis. Median follow-up was 35.1 months. Of which, 21 received pre-transplant splenic radiotherapy (median age 63.5) and 12 did not (median age 62.0). Of the radiated group, 12 (57.1%) had primary myelofibrosis, the median DIPSS score was 3 and the median Charlson co-morbidity index was 4. Ruxolitinib therapy before radiotherapy was reported in 16 (76.2%).
The median spleen size prior to radiotherapy was 22.0cm. The median spleen reduction post-radiotherapy was 3.0 cm (15%, 95% CI: 10-28%), with no difference between previous ruxolitinib exposure and non-exposure (median 3.0 vs 3.25 cm, p=0.51). Radiotherapy-related toxicities occurred in 61.9%, mostly nausea and vomiting. One patient developed tumour lysis syndrome.
The median overall survival was not reached in either group (HR=0.95, 95% CI: 0.31-2.89, log-rank *p*=0.90). Engraftment times were similar (neutrophils 19 vs 17 days, platelets 22 vs 19 days, p>0.05). Chimerism remained comparable at day +30 (94.3% vs 94.5%, p=0.97), day +60 (89.0% vs 94.5%, p=0.36) and day +100 (92.8% vs 95.1%, p=0.86).
The radiated group required fewer red cell transfusions per inpatient day (0.62 vs 0.82, p=0.047). Platelet transfusion rates were similar (0.98 vs 1.03 bag/day, p = 0.96). Kaplan-Meier analysis similarly suggested a trend toward earlier transfusion independence among radiated patients (log-rank p=0.07, HR = 2.11, 95% CI: 0.91-4.89). At day +100, haemoglobin was higher among radiated patients (97.5 vs 87 g/L, p=0.027) but other counts were similar. DLI requirement (33.3% vs 23.1%, p = 0.70) and GvHD incidence (52.4% vs 61.5%, p = 0.73) did not differ.
On univariate analysis of the radiated cohort, only higher DIPSS score predicted poorer survival (HR = 7.71, p=0.043).

Conclusions: We report less transfusion needs whilst in patient and a trend toward faster transfusion independence post-transplant in those who received splenic radiotherapy. Splenic radiotherapy was not associated with inferior survival, engraftment kinetics, chimerism, GvHD or DLI incidence.

P308

ALLOGENEIC STEM CELL TRANSPLANTATION IN MYELOFIBROSIS: SINGLE CENTRE EXPERIENCE

Guillermo Morán Cortés[1], *Laura Contreras Rujas*[1], *Bernardo Manuel Soto Román*[1], *Ángela Figuera Álvarez*[1], *Rafael De La Cámara De Llanza*[1], *Valle Gómez García De Soria*[1], *Adrián Alegre Amor*[1], *Beatriz Aguado Bueno*[1]
[1]*Hospital Universitario de La Princesa, Madrid, Spain*

Background: Allogeneic stem cell transplantation (AHSCT) is the only potentially curative treatment for myelofibrosis, achieving overall survival rates between 40-60%, transplant-related mortality of 30% and relapse rate of 25%.

Methods: We conducted a single-center, retrospective study including 15 patients with primary and secondary myelofibrosis who underwent AHSCT between January 2000/June 2025. All transplants used peripheral blood as stem cells source and received antifungal and antiviral prophylaxis (letermovir for CMV-seropositive since available), as well as graft-versus-host disease (GVHD) prophylaxis with different regimens.

Results: Table and image 1: patients and transplants' main characteristics.

Patient	Age (years)	Year	Type of myelofibrosis	Driver mutations	Additional genetic abnormalities	DIPSS/ DIPSS+	Exposure to JAK inhibitors (ruxolitinib) and response	Splenomegaly (cm)	Spleen treatment
1	53	2000	Primary	-	-	Int-2	No	Yes (24)	No
2	58	2003	Primary	-	-	Int-2	No	Yes (21)	Radiotherapy
3	55	2005	Primary	-	-	High	No	Yes (15)	No
4	55	2005	Primary	-	-	Int-1	No	Yes (16)	No
5	46	2007	Primary	-	-	Int-2	No	Yes (-)	No
6	61	2012	Secondary (ET)	-	-	High	No	Yes (20)	No
7	57	2012	Primary	-	-	Int-2	No	Yes (20)	Radiotherapy
8	52	2017	Secondary (ET)	CALR	-	Int-2	No	No	No

9	61	2019	Primary	CALR	-	Int-2	Yes (no response)	Yes (22)	Radiotherapy
10	37	2021	Secondary (ET)	JAK2	-	Int-2	Yes (no response)	Yes (15)	No
11	58	2022	Secondary (PV)	JAK2	-	Int-1	Yes (no response)	Yes (30)	Radiotherapy Splenectomy
12	52	2023	Secondary (ET)	CALR	-	Int-1	Yes (response)	Yes (20)	No
13	50	2023	Primary	MPL	-	Int-2	Yes (no response)	No	No
14	56	2024	Secondary (ET)	JAK2	ASXL1, NRAS, SRSF2, TP53	Int-2	Yes (lost response)	Yes (22)	Splenectomy
15	43	2025	Secondary (ET)	CALR	SF3A1	Int-1	Yes (switch to momelotinib)	Yes (21)	No

Table 1

Proportion of primary and secondary myelofibrosis was 54% vs 46%, the latter secondary to essential thrombocytemia (ET) in 6 patients and to polycythemia vera (PV) in one. JAK2 and CALR were the most frequent driver mutations. No available molecular alterations before 2017. One patient had high-risk mutations ASXL1 and TP53. All but 4 patients had intermediate-2 or high risk DIPSS and DIPSS-plus score.
All patients but 2 (86%) presented splenomegaly at diagnosis. Median spleen size: 20.5 cm. Four received radiotherapy and 2 splenectomy.
Seven patients received pre-transplant ruxolitinib; two responded to treatment: one had initial response that later lost, and the other one switched to momelotinib because of secondary anemia.

Patient	Donor (HLA)	Conditioning regimen	HCT-CI	Infused cell dose (CD34+x10⁶/kg)	GVHD prophylaxis	Leukocyte graft (days)	Platelet graft (days)	Complications	Graft function	Survival (months)
1	MRD (id)	BuCy	2	12.1	CsA + MPD	-	-	- VOD - Died pre-engraftment	Primary graft failure	Dead (1)

12	MUD (11/12)	TBF	2	6.3	CsA + MMF + Cypost	32	41	- CMV reactivation - cGVHD	Normal	Alive (29)
13	MUD (9/10)	TBF	3	5.7	CsA + MMF + Cypost	28	28	- aGVHD - CMV reactivation	Normal	Alive (29)
14	MUD (id)	FluBu	2	4.7	CsA + Cypost	24	53	aGVHD	Normal	Alive (22)
15	MUD (id)	TBF	3	6	CsA + MMF + Cypost	25	55	VOD	Poor graft function	Alive (6)

Image 1: Transplants' main characteristics. MRD: matched related donor. MUD: matched unrelated donor. Id: identical. Haplo: haploidentical donor. FluBu: fludarabine-busulfan. TBF: thiotepa, busulfan and fludarabine. BuCy: busulfan-cyclophosphamide. FluMel: fludarabine-melphalan. aGVHD: acute graft-versus-host-disease. cGVHD: chronic graft-versus-host-disease. CsA: cyclosporine A. MTX: methotrexate. MMF: mycophenolate mofetil. MPD: methylprednisolone. VOD: veno-occlusive disease.

Regarding donor type: 40% (6/15) were from matched related donors, 40% (6/15) mismatch unrelated, 13.3% (2/15) matched unrelated and 6.6% (1/15) haploidentical. Most commonly conditioning regimen was fludarabine-busulfan. Four patients received TBF (thiotepa, busulfan and fludarabine) and the rest other regimens (BuCy, FluMel).
For GVHD prophylaxis, cyclosporine A was mainly used in combination with other immunosuppressants (methotrexate, mycophenolate mofetil). Since 2019, post-transplant cyclophosphamide was widely used in haploidentical or unrelated donor transplants.
Median time to leukocyte engraftment was 23 days and 33 days to platelet engraftment. Eight patients experienced poor graft function, with slow recovery. Additionally, 3 patients suffered graft loss, 2 of them secondary to CMV reactivation. Of these patients, one experienced adequate hematopoietic recovery after CMV treatment, another underwent second allo-transplant, and the third one declined second transplant. Only one patient had primary graft failure and donor cell-boost was infused.
CMV reactivation was frequent (7/15); none of these were under letermovir prophylaxis at the time of reactivation. Chronic GVHD was also common in 6/15. Two patients suffered veno-occlusive disease.
Survival rate was 66% (10/15). Causes of death: primary graft failure in 1 patient, hepatic and pulmonary cGHVD in another, secondary graft failure in 2 patients; one patient died during pre-engrafment period. To date, alive patients remain in complete remission with a

median follow-up of 46 months, except for one patient who relapsed 34 months after transplant.

Conclusions: Our cohort supports that AHSCT in myelofibrosis can be curative, with high survival rate. Changes in management of these patients over the years can be observed, with trend toward improved transplant outcomes, partially explained by introduction of JAK inhibitors, molecular monitoring and post-transplant cyclophosphamide. Poor graft function and graft failure remain relevant complications representing main causes of post-transplant mortality. Further studies are needed to improve management of these complications and patient prognosis.

Disclosure: Nothing to declare.

P309

ASCIMINIB AS BRIDGE TO ALLOGENEIC-HEMOPOIETIC STEM CELL TRANSPLANT (ALLO-HSCT) IN A MULTICENTER CHRONIC MYELOID LEUKEMIA (CML) PATIENTS' COHORT

Stefania Leone[1], *Mariagela Pedata*[1], *Federica Ardizzoia*[2], *Benedetta Cambò*[3], *Luca Castagna*[4], *Michele Malagola*[5], *Annalisa Natale*[6], *Attilio Olivieri*[7], *Annamaria Raiola*[8], *Federica Sorà*[9], *Serena Marotta*[1], *Maria Celentano*[1], *Filiberto Pollio*[1], *Martina Boccola*[1], *Mario Annunziata*[1], *Alessandra Picardi*[1]
[1]*AORN Cardarelli, Naples, Italy,* [2]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [3]*University of Parma, Parma, Italy,* [4]*Ospedale Villa Sofia Cervello, Palermo, Italy,* [5]*University of Brescia, Brescia, Italy,* [6]*Pescara Hospital, Pescara, Italy,* [7]*Università Politecnica delle Marche Ancona, Ancona, Italy,* [8]*Istituto di Ricovero E Cura A Carattere Scientifico, Ospedale Policlinico San Martino, Genova, Italy,* [9]*Università Cattolica del Sacro Cuore, Roma, Italy*

Background: In the last decades, major molecular response (MMR) achieved by tyrosine kinase inhibitors (TKIs) in CML patients has significantly reduced the indication for allo-HSCT. However, a small percentage of patients are resistant or intolerant to multiple TKI lines, resulting in worse outcome and subsequent indication for allo-HSCT. Asciminib, a selective BCR::ABL1 allosteric inhibitor, has recently been approved for chronic-Phase (crP) CML with resistance or intolerance to at least two previous TKIs. Therefore, the safety and efficacy of Asciminib as bridge therapy before allo-HSCT is still an unexplored issue.

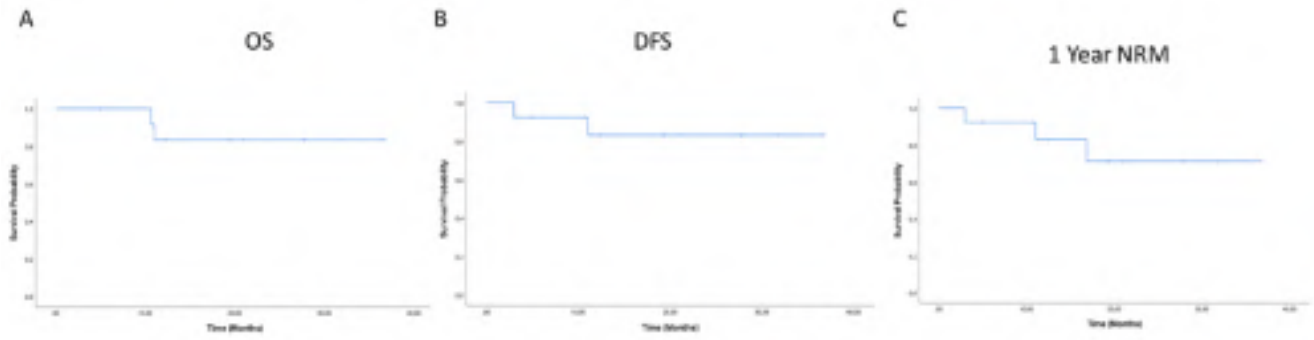
Methods: Therefore, we retrospectively collected data of 13 CML patients treated with Asciminib and allo-HSCT, across 9 Italian allo-HSCT Programs. Baseline clinical characteristics of patients are summarized in Table 1. Median follow-up time, Overall survival (OS), Disease Free Survival (DFS) and 1-Year Non-Relapse Mortality (NRM) have been estimated with Kaplan Meier method.

Total number of patients	13

Age: Years, median (range)	56 (20-70)
Sex: Male, number (%)	7 (54)
Additional genetic alteration: Number of patients, (%)	4 (31)
State of Disease pre allo-HSCT:	
Active chronic disease, number (%)	6 (46)
Active accelerated/blastic disease, number (%)	1 (8)
CHR and CcyR, number (%)	5 (38)
MR3, number (%)	1 (8)

Results: In our heavily pre-treated cohort, median TKIs lines before Asciminib was 4, among which 11/13 were previous Ponatinib exposed. Reason to start Asciminib was resistance, intolerance or both to others TKIs in, respectively, 8, 3 and 2 out of 13 patients. About safety, 7/13 patients discontinued the therapy due to grade 3/4 Adverse Events, followed by a definitive stop in 3/13 of them. At 3 months, Complete Hematological (CHR), cytogenetic (CcyR), Molecular (MMR) and no response were observed in 3, 2, 1 and 6 patients, respectively, out of 12 evaluable patients.
Median time between Asciminib start and allo-HSCT was 6.77 months (range: 3.1-21.3). All patients but one underwent allo-HSCT in crP, state of disease before allo-HSCT is detailed in Table 1. Donors were MRD, MUD, mMUD, haploidentical and from multiples Cord blood in 5, 3, 1, 3 and 1 patients, respectively. Conditioning intensity accordig to EBMT 2018 was intermediate in 3 cases and high in 10 cases. All patients engrafted as PMN and PLTS. At 90 days after allo-HSCT, all crP patients showed a full donor chimerism and a deep molecular response, while the patient in accelerated phase (aP) had a mixed chimerism and did not reach any response. Cumulative incidence of aGVHD was 23% but no patients developed grade 3-4 aGVHD nor cGVHD. Molecular relapse after allo-HSCT occurred in two cases, treated with Asciminib and Ponatinib, obtaining an MMR. Two transplant related side effects, consisting in Pure Red Cell Aplasia and thrombotic microangiopathy, were observed and successfully treated. With a median follow up of 20.64 months from allo-HSCT, OS, DFS and 1 year NRM were respectively 84%, 77% and 7% (Figure 1, A, B and C). Overall, 2 patients died: one for persistence of aP disease and one for encephalitis.

Figure 1



Conclusions: In conclusion, in TKIs resistant CML, allo-HSCT remains the best clinical option, with excellent results in terms of deep molecular response and limited incidence of complications. In our cohort of advanced-lines patients, the use of Asciminib seems to be a potential bridge strategy for allo-HSCT, although the discrete incidence of related adverse events. Further studies in larger cohorts are warranted in order to confirm these results and drive clinical decisions.

Disclosure: Nothing to declare.

P310

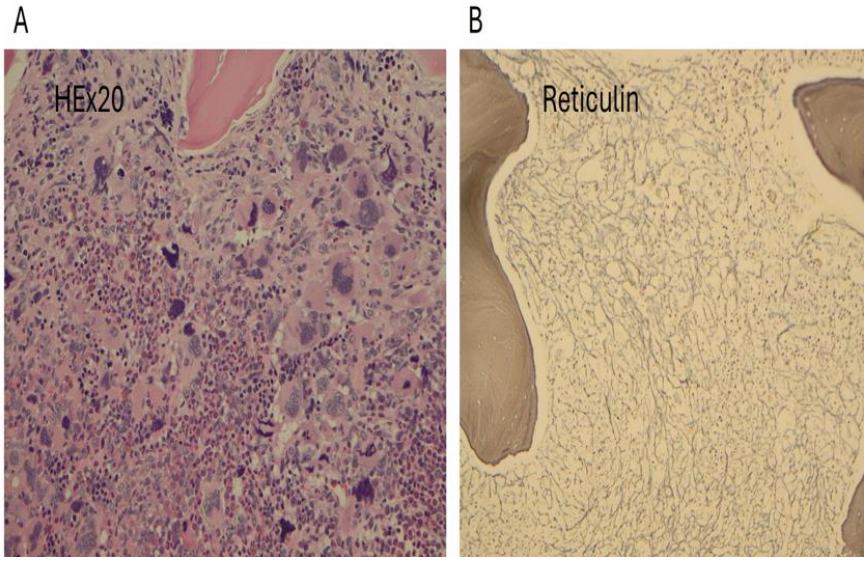
ALLOGENEIC HSCT IN A 7-YEAR-OLD GIRL WITH ADULT-TYPE PRIMARY MYELOFIBROSIS: A RARE CASE REPORT

Maria Ebbesen Soerum[1], *Raheel Raja*[1], *Peter Pontoppidan*[1], *Trine Plesner*[1], *Henrik Hasle*[2], *Hilde Hylland Uhlving*[1], *Marianne Ifversen*[1], *Marianne Hoffmann*[1], *Tania Masmas*[1]
[1]*Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark,* [2]*Aarhus University Hospital, Skejby, Denmark*

Background: Primary myelofibrosis (PMF) is a myeloproliferative neoplasm characterized by clonal proliferation of myeloid cells, leading to reactive bone marrow fibrosis, progressive marrow failure, hepatosplenomegaly, and extramedullary hematopoiesis. Driver mutations such as *JAK2*, *CALR*, or *MPL* are common, while triple-negative disease is associated with a more aggressive clinical course. PMF is extremely rare in children and may present as a reactive, often reversible secondary form, which differs substantially from the adult disease. In contrast, adult-type PMF in children exhibits the same clinicopathological features as adult PMF, including megakaryocytic atypia with reticulin or collagen fibrosis, splenomegaly, and constitutional symptoms. This form is typically more severe, and although JAK inhibitors have shown promising results in reducing symptom burden, allo-HSCT remains the only curative therapy, yet historically associated with a high risk of graft rejection.

Methods: **Case presentation:** A previously healthy 7-year-old girl presented in December 2024 with a one-month history of abdominal pain, headache, fatigue, and weight loss.

Results: Blood tests showed leukocytosis with neutro- and monocytosis, thrombocytosis, elevated LDH, and 3% blasts. Bone marrow biopsy revealed a hypercellular marrow with atypical megakaryocytic proliferation, reticulin fibrosis grade II–III, collagen fibrosis, and osteosclerosis, consistent with PMF (Figure 1). Karyotype was normal, and extended NGS and whole-genome sequencing detected no somatic or germline variants.



Follow-up showed persistent leukocytosis (30 ×10⁹/L), thrombocytosis (891 ×10⁹/L), elevated LDH (1600 U/L), and splenomegaly, but no blast excess. EWOG board review in February 2025 confirmed triple-negative adult-type PMF. A two-month watch-and-wait approach showed no improvement in bone marrow pathology, supporting the indication for HSCT. Bridging therapy with the JAK inhibitor ruxolitinib was given for 30 days to facilitate engraftment with tapering prior to conditioning.

In May 2025, the patient underwent allo-HSCT from a matched sibling donor using EWOG-MDS–based conditioning with busulfan (AUC 75 mg·h/L), cyclophosphamide (120 mg/kg), melphalan (140 mg/m² ×1), and ATG Grafalon (30 mg/kg). GvHD prophylaxis consisted of tacrolimus and methotrexate. Neutrophil engraftment occurred on day +21.

Early post-transplant complications included acute skin GvHD stage 3 (overall grade II) on day +14, responding promptly to steroids, and prolonged dysuria and hematuria. At day +84, the patient developed dyspnea and a restrictive pulmonary function pattern consistent with cryptogenic organizing pneumonia—a non-infectious pulmonary complication—diagnosed radiologically and treated with pulse steroids (15 mg/kg ×3 for three courses), resulting in clinical recovery and near-normal lung function. Full donor chimerism was achieved by day +35, but a four-week period of cytopenia occurred from day +70, which resolved spontaneously. At day +180, the patient maintains full donor chimerism with normal hematologic recovery and a CD4+ T-cell count of 128 cells/µL. Tacrolimus is maintained at 4–6 µg/L due to the risk of graft rejection, with gradual tapering planned.

Conclusions: Adult-type primary myelofibrosis in childhood is extraordinarily rare, with only very few pediatric cases described, leaving no evidence-based guidelines for transplant management. This case adds clinical experience for HSCT decision-making in such patients. Despite significant post-transplant complications, the patient achieved full donor chimerism and remains clinically well six months post-transplant.

Disclosure: Nothing to declare.

P311

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH PRIMARY MYELOFIBROSIS

Dina Ait Ouali[1], Farih Mehdid[1], Nadia Rahmoune[1], Mounira Baazizi[1], Sabrina Akhrouf[1], Hanane Bouarab[1], Sarah Zerkout[1], Fouzia Louar[1], Hanane Moussaoui[1], Mounira Bitam[1], Amira Fahem[1], Belkis Dekhili[1], Fateh Boukhemia[1], Naima Abdennebi[1], Yacine Kinane Daouadji[1], Farida Harieche[1], Rose-Marie Hamladji[1], Redhouane Ahmed Nacer[1], ***Malek Benakli***[1]
[1]*Department of Hematology-Bone Marrow Transplantation, Pierre and Marie Curie Center, Algiers, Algeria*

Background: Primary myelofibrosis (PMF) is a rare Philadelphia chromosome–negative myeloproliferative neoplasm with a heterogenous clinical course, with a poor prognosis. JAK inhibitors improve symptoms without providing a cure. Allogeneic hematopoietic stem cell transplantation (HSCT) remains the only curative option, reserved for young and high-risk patients (pts). We report the outcomes of a series of 15 pts who underwent this procedure over a period of 257 months.

Methods: From May 2002 to December 2024, an HLA-identical allogeneic HSCT was performed in 15 pts with PMF, including 3 pts in leukemic transformation and 3 pts with post-essential thrombocythemia myelofibrosis (post-ET MF). Median age at transplantation was 45 years (37–59) and a sex ratio (M/F) of 1.1. The median interval between diagnosis and transplantation was 35 months (5–108). Molecular analysis identified the JAK2 mutation in 3/13 pts, CALR in 4/5 pts and MPL in 1/1 pt. According to the DIPSS prognostic score: intermediate-1 in 1 transfusion-dependent pt, intermediate-2 in 9 pts, and high-risk in 5 pts. Pre-transplant management was heterogeneous due to the long study period: transfusion program in 5 pts, Hydroxyurea alone or combined with Interferon in 5 pts, splenectomy in 2 pts, and splenic irradiation in 6 pts. Two conditioning regimens were used sequentially: Busulfan–Fludarabine (4 pts), and Busulfan–Fludarabine combined with antithymocyte globulin (11 pts). GVHD prophylaxis consisted of Cyclosporine and Methotrexate. A peripheral blood stem cell graft was used for all pts, with a mean CD34+ cell dose of 8.9 × 10^6/kg (5.9–12.5). As of July 31, 2025, follow-up ranged from 8 to 276 months.

Results: The mean time to neutrophil recovery was 17 days (13–57). One primary graft failure occurred in a pt with 73% donor chimerism, corrected with a CD34+ cells boost. Early complications (all with favorable outcomes) included 1 case of VOD, 1 case of TMA, and 1

case of hemorrhagic cystitis. Acute GVHD occurred in 1 pt (7%), grade III, and extensive chronic GVHD was observed in 6 pts (46%) after a mean delay of 5 months (4–9). CMV reactivation occurred in 3 pts (21%). Three pts (21%) relapsed, two of whom received donor lymphocyte infusion (DLI). Seven pts (46%) are alive after a median follow-up of 26 months (7–71), and 8 pts (53%) died (early infection: 1, pulmonary aspergillosis: 2, GVHD: 4 pts, relapse: 1 pt). Overall survival (OS) and event-free survival (EFS) at 23 years were 47% and 45%, respectively.

Conclusions: Allogeneic HSCT is currently the only curative treatment for primary or secondary MF in eligible pts with intermediate-2/high-risk DIPSS scores or unfavorable mutations. Reduction of splenomegaly (with JAK2 inhibitors or splenic irradiation) is essential to improve engraftment and reduce transplant-related mortality.

Disclosure: Nothing to declare

P312

THIRD-LINE TREATMENT OF CHRONIC MYELOID LEUKEMIA WITH TKI IN THE POST-BMT SETTING IN PATIENT WITH POSITIVE MRD

*Jose Emilio Salinas[1], **Felipe Lopez**[1], Blaz Lesina[1], Lillian Pilleux[1], Susana Calderon[1], Diego Reyes[1]*
[1]Universidad Austral de Chile, Valdivia, Chile

Background: Since incorporation of TKI, progression to accelerated phase of CML rarely occurs. Nevertheless, progression to blast phase contemplates a very poor prognosis with overall survival of 9 to 12 months. In this setting BMT has a key role associated to TKI maintenance in cases of positive MRD. Third and forth generation TKI are of great importance in refractory cases, often associated with drug related toxicity. In our settings, there are financial and access boundaries.

Methods: We present a clinical case that illustrates the benefits in this clinical scenario.

Results: 32 year old man, with no clinical records. Presents with 3 months of weight loss, malaise and feverish feeling. Palpable spleen 20 centimeters under costal margin. At diagnosis: Hb: 8.8 WBC: 90.100 Blast: 5% Eosinophils: 13% Basophils: 25% Platelets: 69.000; RT-PCR BCR-ABL p210: detected. Bone marrow flow citometry: Myeloid blasts: 4% Lymphoid blasts: 1%. Configures diagnosis of Chronic Myeloid Leukemia of high risk (by Sokal, Hasford and ETLS). Starts on Dasatinib 100 mg per day, after one year only achieves complete hematologic response (CHR), remaining qPCR BCR-ABL: 72%^{IS}; T315I mutation by PCR: undetected. Switch of therapy with Nilotinib 800 mg per day with no molecular response in 6 months (qPCR BCR-ABL: 44%^{IS}). There was a petition to starts third generation TKI, delayed for financial reasons.
Evolves with loss of hematologic response and progression to accelerated phase; in this context starts on Ponatinib 45 mg per day with CHR but no molecular response (qPCR BCR-ABL: 16,7%^{IS}) and Ponatinib was discontinued due to hematologic toxicity grade 3.
Intense chemotherapy was conducted with 7+3 protocol, resumes Ponatinib 45 mg every

other day. TKI was stopped due to cardiological toxicity. Allogenic BMT was performed with related identical donor with RIC conditioning (BuFlu2). Hematologic recovery by day 16, resumes TKI with Ponatinib 15 mg every other day by day 46. Does not achieve Major Molecular Response (MMR) by day 90 (qPCR BCR-ABL: 0,138%^{IS}). Ponatinib was again discontinued due to hematologic toxicity.
Starts oh Asciminib by day 124, achieving MR 4.0 by day 195 which is maintained by day 395.

Conclusions: This clinical case shows that there still cases of chronic myeloid leukemia resistant to second generation TKI, even with early initiation at diagnosis. Toxicity is often associated with resistance. In our case, starting Ascminib as maintenance treatment post BMT, instead of Ponatinib due to hematologic and cardiologic toxicity, had a major impact on response achieving MR 4.0 sustained with no toxicity associated.

Disclosure: No potential conflict of interest.

P313

IMPACT OF DOSE-ESCALATION STRATEGIES ON CLINICAL OUTCOMES OF ROPEGINTERFERON ALFA-2B IN POLYCYTHEMIA VERA: A SYSTEMATIC REVIEW AND META-ANALYSIS

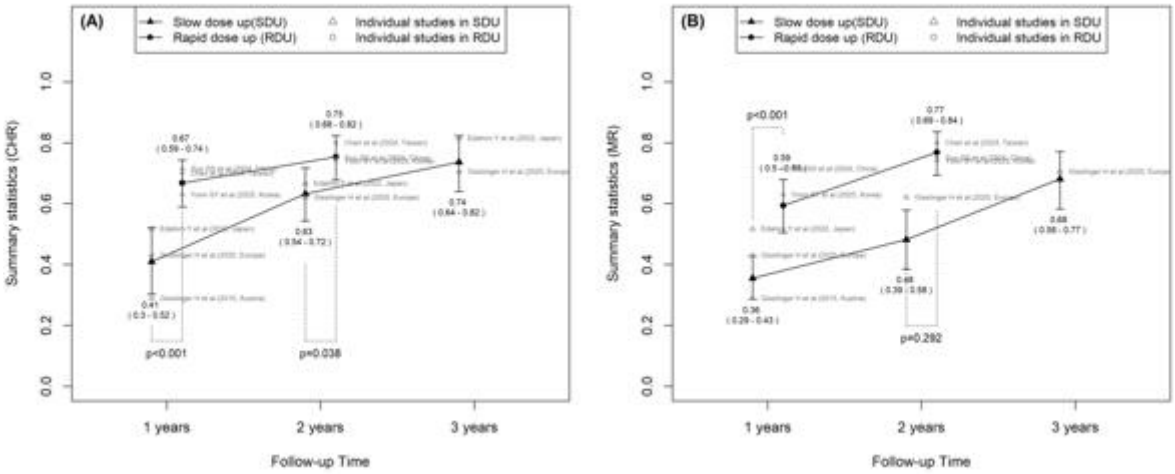
Seug Yun Yoon[1], Kyoung Ha Kim[1], Sung-Eun Lee[2], ***Jong-Ho Won***[1]
[1]Soonchunhyang University Seoul Hospital, Seoul, Korea (the Republic of), [2]Seoul St. Mary's Hospital, Seoul, Korea (the Republic of)

Background: Ropeginterferon alfa-2b is a long-acting interferon increasingly used for cytoreduction and molecular response in polycythemia vera (PV), yet the impact of different dose-escalation strategies on efficacy and safety remains unclear.

Methods: A systematic review and meta-analysis was performed according to PRISMA guidelines. PubMed, Embase, and the Cochrane Library were searched through September 24, 2025 for studies evaluating ropeginterferon alfa-2b in adult patients with PV. Eligible studies reported at least one clinical outcome, including complete hematologic response (CHR), molecular response (MR), *JAK2* V617F allele burden, adverse events (AEs), treatment discontinuation, thrombosis, or disease transformation. Randomized trials and non-randomized interventional or cohort studies were included. Studies were categorized by dose-escalation strategy into slow dose-up (SDU), starting at 50–100 µg with gradual increases, and rapid dose-up (RDU), initiating at 250–350 µg with early escalation to 500 µg. Random-effects meta-analyses were conducted using restricted maximum likelihood estimation. Subgroup analyses compared SDU and RDU strategies at 1-, 2-, and 3-year follow-up intervals. Risk of bias was assessed using RoB 2 and ROBINS-I tools according to study design.

Results: Nine studies met inclusion criteria. At 1 year, the pooled CHR proportion across all studies was 0.59 (95% CI, 0.47–0.71) with substantial heterogeneity. Subgroup analysis

demonstrated significantly higher CHR rates with RDU compared with SDU (0.67 vs. 0.41; p < 0.001). This difference persisted at 2 years, with CHR proportions of 0.75 for RDU and 0.63 for SDU (p = 0.038). At 3 years, CHR data were available only for SDU-treated patients, yielding a pooled proportion of 0.74. Molecular response analysis at 1 year showed a pooled MR proportion of 0.40 (95% CI, 0.28–0.53). MR was significantly higher in the RDU group than in the SDU group at 1 year (0.59 vs. 0.36; p < 0.001). At 2 years, MR proportions increased in both groups (0.77 for RDU and 0.48 for SDU), although the between-group difference was no longer statistically significant (Figure). Five studies reported quantitative changes in *JAK2* V617F allele burden at 1 year, demonstrating a significant pooled mean reduction of −22.2%. Safety analyses including all nine studies showed low pooled incidences of thrombosis (4.0%), serious adverse events (5.0%), treatment discontinuation (7.0%), and disease transformation (1.0%), with no consistent signal of increased toxicity associated with rapid dose escalation.



Conclusions: Ropeginterferon alfa-2b is an effective and well-tolerated treatment for PV. Rapid dose-escalation strategies are associated with earlier and higher hematologic and molecular response rates without compromising safety, suggesting that titration speed is a clinically relevant factor in optimizing early treatment outcomes.

Disclosure: Nothing to declare.

Solid Tumours

B436

SEQUENCE ORDER IN BU MEL CONDITIONING FAILS TO PREDICT SURVIVAL: PK AND OUTCOME DATA FROM A PEDIATRIC NEUROBLASTOMA AND EWING SARCOMA COHORT

Srijib Mukherjee[1], *Christa E. Nath*[1], *Madeleine Powys*[1], *Melissa Gabriel*[1], *Peter J. Shaw*[1], *Steven J. Keogh*[1]
[1]*The Children's Hospital at Westmead, Westmead, Australia*

Background: Busulfan (Bu)–melphalan (Mel) conditioning was historically standard for autologous transplantation in high-risk neuroblastoma, though less common in the era of tandem transplants. The optimal sequence (Bu-Mel vs. Mel-Bu) remains unclear, as sequence-related pharmacokinetic (PK) interactions may influence drug exposure, sinusoidal obstruction syndrome (SOS), and overall survival (OS).

Methods: To retrospectively assess whether conditioning sequence affects Bu or Mel PK, SOS risk, and OS in 36 children (0.7–16.8 years) undergoing autologous HSCT between 2010–2024 for solid tumours (30 neuroblastoma, 6 Ewing's sarcoma) at a single centre. Methods: Conditioning comprised Bu (3.2–5.65 mg/kg daily ×4) and Mel (140 mg/m²). Twenty-one patients received Bu-Mel, fifteen Mel-Bu. First dose Bu area-under-the-concentration-versus-time curve (AUC0-∞, trapezoidal rule) was available for all patients; in 27 full 4-day Bu PK enabled calculation of cumulative AUC (cAUC) by summation. The Bu dose was not PK-adjusted, though one patient had a dose omitted for elevated AUC. Mel PK data was available for 18 patients (5 Bu–Mel, 13 Mel–Bu). First-dose Bu and Mel clearance (CL) were compared using the Mann-Whitney test. Associations of Bu cAUC above/below median (72.4mg/L·h) and Mel AUC above/below median (9.0mg/L·h) on SOS incidence were assessed using the Friedman test, and on OS with Kaplan–Meier and multivariate Cox regression. Additional covariates assessed in multivariate models included disease relapse/progression, moderate/severe SOS, age and glomerular filtration rate.

Results: Pharmacokinetics
First day Bu and Mel clearance did not differ between the Bu-Mel and Mel-Bu groups (median Bu CL 4.9 versus 4.1 L/h , median Mel CL 8.6 versus 10.6 L/h, respectively), indicating no sequence effects on Bu or Mel disposition. In the four-day Bu PK data, Bu clearance declined significantly over successive treatment days in both groups ($p<0.05$, Friedman test), consistent with metabolic saturation. Median Bu cAUC was 72.4 (IQR:59.2– 79.5) mg/L.h, with no difference between sequence groups.
Toxicity
SOS occurred in 44% of patients; 28% were classified as moderate–severe. SOS incidence did not differ between Bu-Mel(43%) and Mel-Bu(47%), $p>0.05$. Neither elevated Bu or Mel exposure, nor total mg/kg Bu dose predicted SOS severity.
Survival

Sixteen patients have died; disease relapse/progression was the leading cause of death. Bu cAUC >72.4mg/L.h was associated with a trend toward longer OS (mean 11.0 versus 6.8 years, p=0.14); similar mean survival times were observed for the Mel-Bu and Bu-Mel groups (9.9 and 9.0 years, respectively, p=0.35). In the multivariate analysis, only disease relapse/progression was significantly associated with mortality: HR 367.5 (95% CI 1.1–117106; p<0.05).

Conclusions: The Bu-Mel and Mel-Bu conditioning sequences produced equivalent PK, SOS risk, and survival outcomes. Bu clearance declined daily regardless of sequence. A trend toward improved survival with higher cumulative Bu exposure was noted. Disease progression was
the sole independent predictor of OS, underscoring the dominance of neuroblastoma biology over conditioning optimisation. These findings support flexibility in sequencing Bu-Mel conditioning and highlight the need to focus on post-transplant disease control strategies. Larger multicenter studies are needed to evaluate whether refined exposure targets can improve disease outcomes without increasing toxicity.

P315

MULTI-MISMATCH SEARCHES IN HAP-E SEARCH

Christine Urban[1], *Daniel Schefzyk*[1], *Denis Flaig*[1], *Julia Pingel*[1], *Jan Hofmann*[1]
[1]*DKMS, Tuebingen, Germany*

Background: In the context of allogenic human stem cell transplantations (HSCT) so called matching algorithms are used to identify the best matching donors for a patient.

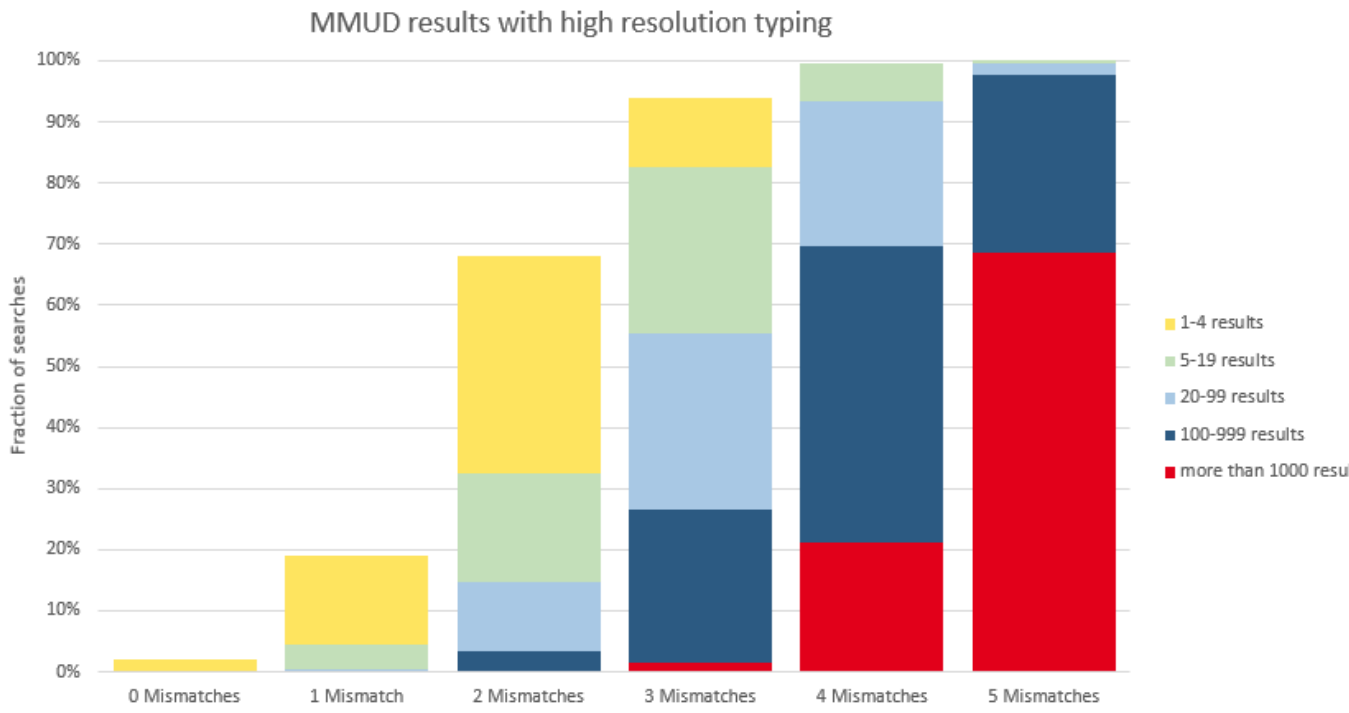
Methods: As clinical practice evolves, the requirements for donor–recipient matching algorithms must likewise adapt. To address the increasing use of mismatched unrelated donors (MMUD) in transplantation, we extend Hap-E Search to support higher-level multi-mismatch searches. In the context of this work, a MMUD search is defined as one that returns donors with match grades down to 4/8 (A, B, C, DR) or 5/10 (A, B, C, DR, DQ). Such MMUD searches are meant to complement the already existing standard mismatch searches. To improve performance and reduce data volume while focusing on clinically meaningful results, we introduced the following constraints for MMUD searches:
• MMUD searches are performed only for patients with high-resolution HLA typing at the

relevant search loci (A, B, C, DR for 4/8; A, B, C, DR, DQ for 5/10).
• Only donors with high-resolution HLA typing at the corresponding search loci are included.

- We call an HLA typing "high resolution" if all contained alleles fall into the same "g" group. "g" grouping combines alleles with identical DNA sequences over exons 2 and 3 (including null alleles) with alleles that show synonymous mutations n this region.

• With these restrictions in place, match-probability calculations are no longer required.

Results: With these MMUD searches, a high number of donors can be found even for challenging searches when the number of allowed mismatches exceeds two (see figure 1), justifying our approach. Including donors with non-high resolution or incomplete typing would only result in extensive lists of search results, the majority of which would possess negligible matching probabilities.
This behavior can already be seen in standard mismatch searches in Hap-E Search which allow for match grades as low as 4/6 (A, B, DR), 6/8 (A, B, C, DR), and 8/10 (A, B, C, DR, DQ), including matching probability calculations without imposing resolution requirements on either donors or patients. For example, up to ~500,000 potential donors in an 8/10 search for a high resolution patient have been seen with very low (<1%) probabilities of achieving an 8/10 match.
We have evaluated our MMUD search approach on a cohort of one million donors, whose HLA typing distribution is representative for the WMDA donor pool. Our new MMUD search, down to a match grade of 5/10, was conducted for 184 challenging patient typings, for which standard mismatch searches (8/10) yielded no or only a very limited number of matching donors. Median search duration for all MMUD searches was one minute.



Conclusions: Rising global demand for MMUD transplantation increases the urgency for robust, scalable matching tools. Hap-E's new MMUD capability provides a practical, technically efficient new feature that, combined with the standard (mismatch) search, provides a comprehensive search result list focusing on clinically relevant results.

Disclosure: Nothing to declare.

P316

EVALUATING 2.5 YEARS OF OMOP IMPLEMENTATION IN THE EBMT REGISTRY: APPROACH, CHALLENGES AND OUTCOMES

Igor Ariz Extreme[1], Fernando Cid Samper[1], Alina Kuliesh[2], Nikolaos Glentis[2], Eden Tsehay Abera[1], Hendrikus Bernhard Bouwman[2], Ignacio García Sánchez-Migallón[2], ***Annelot van Amerongen***[2]
[1]*EBMT, Barcelona, Spain,* [2]*EBMT, Leiden, Netherlands (the)*

Background: In its transition to a new database, the EBMT has replaced the original relational database structure with the Observational Medical Outcomes Partnership (OMOP) Common Data Model (CDM) for its analytical database.

Methods: In August 2023, the new EBMT Registry went live. The system is a successor to ProMISe, and a migration of legacy data was carried out. We evaluate the results of the implementation of OMOP CDM in the EBMT Registry based on the following criteria: 1) suitability of the available dictionaries for EBMT data collection, measured by the percentage of custom concepts, 2) suitability of the model for the EBMT Registry, assessed by experiences preparing data using OMOP, and 3) adoption by end-users, which could only be evaluated by feedback received from EBMT study unit staff and external database users.

Results: OMOP is a well-known and commonly used CDM, but it lacks haematology- and oncology-specific terminology. In the 2.5 years since go-live, the EBMT Registry team has mapped all data to the OMOP CDM and used it as a basis for exports. Out of 5012 mapped concepts, 48.5% are custom concepts, making our OMOP implementation substantially different from a more standard OMOP CDM. This difference, together with a lack of standardised definitions for key concepts, can impair the reproducibility of studies across different OMOP CDMs. Attending to the particularities of the EBMT Registry data, the Registry relies on: i) relationships between different questions to explain an event, ii) the capture of absence of events, and iii) the usage of longitudinal data; none of which are reflected by OMOP. On one hand, EBMT has tried to work around the absence of an event hierarchy in OMOP using the fact-relationship tables and visit occurrence details. On the other hand, capturing negatives is important for outcome analysis, as the absence of a positive response in the EBMT Registry does not necessarily mean an event did not happen. The only method to get longitudinal data from OMOP is by generating separate tables, which has been done by the Registry IT team. Finally, regarding the adoption by users, both internal and external users of the EBMT Registry, covering data managers, clinical data specialists, and statisticians across Europe and outside, are not responding positively to the OMOP implementation. They prefer a wide-format dataset with variables for studies and statistical analysis. Despite all the aforementioned drawbacks, the EBMT Registry IT team has managed to build a library of robust OMOP-based reports end users are satisfied with.

Conclusions: Although it is possible to work with the OMOP data model and adapt it to accommodate EBMT's needs, its usability and user-friendliness remain debatable. The EBMT has managed to build a repository of study-ready data based on OMOP information. Still, the time and expertise required for such transformations set a high entry barrier for adoption. Furthermore, the necessary adjustments to the model to ensure it adapts to different research needs lead to slight differences between organisations' OMOP models, complicating the model's data-sharing objective.

Disclosure: Nothing to declare

P317

HLA: A MICROSCOPIC MARVEL CREATING A MACROSCOPIC CHALLENGE IN HSCT DATA MANAGEMENT - UNDERSTANDING THE STRUGGLE AND THE CASE FOR AUTOMATION

Marie Wilson[1], *Julia Lee*[1], *Rachel Pearce*[1], *Francis Adams*[1], *Ruth Paul*[1], *Clementina Abamba*[1]
[1]*Guy's and St. Thomas' NHS Foundation Trust, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: HLA data is critical for HSCT outcomes, yet its complexity presents persistent and significant challenges for Data Management Staff (DMS) responsible for entering it into the EBMT Registry. Despite the EBMT HLA manual, released September 2024, HLA training remains inconsistent, and mismatch entry is particularly problematic. Discontinuation of the BSBMTCT Data Registry (BSBMTCT-DR) HLA data entry service in February 2025 further increased difficulties for UK and Republic of Ireland (UK&ROI) DMS. Due to HLA entry requirements of the EBMT Registry, the BSBMTCT-DR assessed DMS experience, confidence, consistency and completeness with HLA entry, and further examined barriers hindering accurate and complete entry.

Methods: A two-pronged approach was employed to assess HLA data entry by UK&ROI DMS:
1. Survey of DMS
An online survey was sent to 31 allograft centres in the UK&ROI targeting DMS responsible for HLA data entry. The survey assessed experience, confidence and barriers to consistent and accurate HLA data entry.
2. Registry HLA Data Analysis
EBMT provided an export of HLA typing and mismatch entry counts. Analysis focused on June 2024 to September 2025 (inclusive), covering the introduction of mismatch fields in the Registry and the last full month of data before export. Completeness of typing and mismatch data was assessed across all loci. Data migrated from ProMISe were excluded.

Results: Survey:
Twenty-two DMS from 20 centres participated. The majority of respondents were Data Managers (82%), others included Quality Managers and Data Coordinators. There was variable HLA data entry experience (32% of respondents ≥5 years, 23% <6 months). Before February 2025, 40% relied on BSBMTCT-DR for HLA entry. The HLA manual delivered clear benefit, boosting confidence for nearly a third of users for typing and mismatch entry. While 86% of respondents always entered HLA typing, only 73% consistently recorded mismatches. Barriers to HLA data entry included:

- HLA complexity and insufficient confidence
- Time-constraints
- Registry useability issues
- Perceived low priority
- Inconsistent access to pre-calculated mismatch data
- Difficulty in calculating mismatches

- HLA training deficiencies

Registry HLA Data Analysis:
EBMT export data highlighted that molecular HLA typing entries dominated per locus (2,077–2,428), while serology entries were minimal (20–81), particularly for donors.
Mismatch entries were far lower indicating incomplete data entry; 1,050-1,078 molecular entries per locus, 15-17 serology entries per locus. No single locus was systematically neglected.
Approximately 46% of fully typed molecular pairs had corresponding mismatch records, compared with 83% for serological typing.
Examining missing HLA data, 23% of allografts had no HLA typing and 47% had no mismatch data regardless of whether HLA typing had been entered.

Conclusions: HLA data entry, particularly mismatches, remains a major challenge for DMS due to complexity, workload, and insufficient training. While enhanced training, improved Registry usability, and wider adoption of the HLA manual can support accurate HLA data entry, manual entry is still inherently inefficient and error-prone. Automated solutions, like direct report uploads and autocalculation of mismatches, offer a more sustainable and reliable approach. Without automation, incomplete or inaccurate HLA data will persist compromising research quality and HSCT outcomes, now and in the future.

Disclosure: Nothing to declare.

P318

A STRONGER EUROPEAN VOICE TO SUPPORT GENE AND CELL THERAPIES: EUROGCT AS A COMMON TOOL

Aurélie Mahalatchimy[1], *Hsin-Yu Kuo*[2], *Heather Love*[2], *Luc-Sylvain Gilbert*[1], *Auxane Delage*[1], *Valentin Roby*[1], *Anna Couturier*[2], *Clare Blackburn*[2]
[1]*Aix Marseille Univ, CNRS, DICE, CERIC, Aix-en-Provence, France,* [2]*The University of Edinburgh/Institute for Regeneration and Repair, Edinburgh, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Gene and cell therapies (GCTs) face various communication and comprehension challenges when transitioning from bench to bedside. These challenges include complex science, regulation, and ethics, impacting clinical adoption and the GCTs sector. Moreover, the challenges are often exacerbated by misinformation and voices dominated by AI-mediated search platforms owned by tech giants.

Methods: The EuroGCT consortium was built through connecting 47 European partner organisations including academic institutions, learned societies, national centres of excellence, and patient organisations. Funded by the European Commission, the consortium has created a network of expertise and an online information hub that focusses on the pivotal role of science communication in navigating the complexities of therapy development and public comprehension. It is dedicated to demystifying GCTs as it extends beyond the

laboratory and enters the realms of broader societal impact.
We began from the position that digital spaces – particularly search engines like Google – create the backbone of the informational environments that inform non-expert interactions. Through targeted science communication initiatives, building and updating our information hub at www.eurogct.org, we explore the significance of engaging with diverse stakeholders, including patient advocacy groups, regulators, clinicians, developers, media, bioethicists, social scientists, artists, computer scientists, and the public at large. By fostering two-way dialogue and disseminating accessible information including explainers, factsheets, films, and educational material, we empower these stakeholders as they search for high quality referential information online. Through implementing self-developed, research-led search engine optimisation and metadata enhancements, we improve EuroGCT resources' visibility in search engines and generative AI searches.
By fostering engagement, promoting transparency, and advocating for collaborative resource development, EuroGCT endeavours to realise the full potential of these transformative treatments to improve health outcomes while contributing to a fair and equitable society.

Results: EuroGCT is a common information hub for pre-competitive, international and interdisciplinary collaboration to address pressing concerns faced by our research community as well as the patients and publics.
To empower the public and patient stakeholders to actively and effectively participate in shaping the trajectory of GCT development, we have developed accurate and accessible information explaining the science, the ethical and social impact in the Discover section of the hub.
To help stakeholders interested in developing GCTs navigate the complex pathways bringing therapies from lab to patients, the Research Pathways section facilitates their access to information on practical steps needed at each stage of product development.
Our results extend beyond the boundaries of public facing information to address key considerations in all stages of therapy development, such as regulatory frameworks, accessibility, and equitable access. Website traffic and search engine (including AI search) integration demonstrate EuroGCT's success in achieving its objectives.

Conclusions: The EuroGCT consortium's work underscores the critical importance of collective science communication in driving responsible and inclusive translation of gene and cell therapies beyond the laboratory through accessible information. EuroGCT's information hub is an established common tool for all European stakeholders.

Disclosure: The authors have no conflict of interest to declare.
This work has been funded by the European Union's Horizon 2020 research and innovation programme under Grant Agreement No 965241 (EuroGCT project).

P319

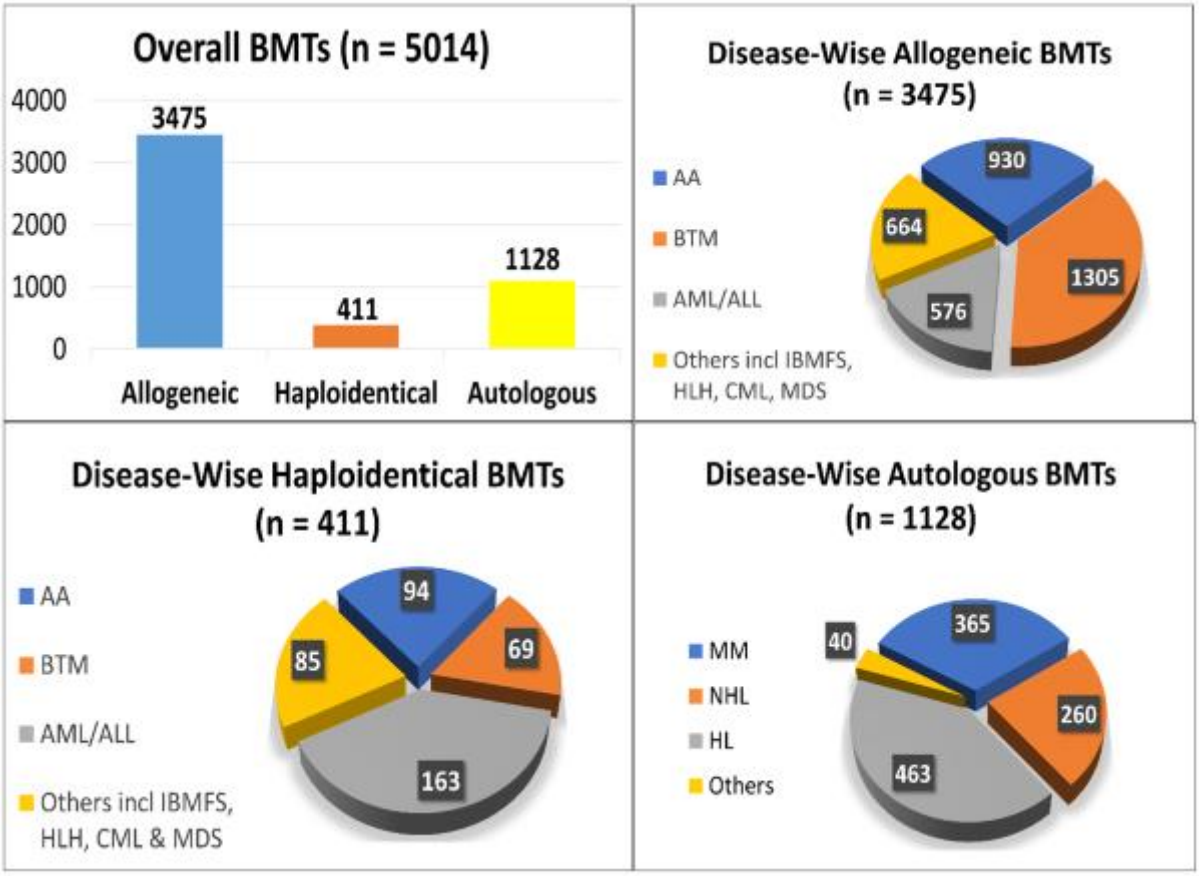
PBMT DATA MANAGEMENT GROUP: BUILDING FOUNDATIONS AND FOSTERING NATIONAL COLLABORATION

Shahid Iqbal[1], *Husnain Ali*[2], *Mohsin Ali*[1], *Syeda Momna Aziz*[1], *Hira Tariq*[1], *Ammad Akram Chaudhary*[1], *Raheel Iftikhar*[1], *Tariq Ghafoor*[1], *Syed Kamran Mahmood*[2]
[1]*Armed Forces Bone Marrow Transplant Centre (AFBMTC), Rawalpindi, Pakistan,* [2]*PATHWEL Center of Hematology and Bone Marrow Transplant (BMT), Rawalpindi, Pakistan*

Background: Hematopoietic stem cell transplantation (HSCT) services in Pakistan have expanded rapidly, with multiple centers established between 1999 and 2024. To support this growth and ensure standardized national reporting, the Pakistan Blood & Marrow Transplant Group (PBMT) Data Management Group (DMG) was established as a central coordinating body for HSCT data governance and oversight. The PBMT is currently undergoing registration with the Islamabad Capital Territory Administration (ICTA), Government of Pakistan, under the applicable Societies Registration Act. Through coordinated efforts, the PBMT DMG has strengthened national collaboration in bone marrow transplantation, hematology-oncology, and emerging areas such as cellular and gene therapies, promoting research and evidence-based clinical practice.
The PBMT DMG has implemented a unified HSCT data collection framework across affiliated centers, aligned with international standards set by the CIBMTR and EBMT. To sustain national HSCT growth, there is a critical need to enhance capacity building, accelerate digital transformation, and further institutional collaboration. This study summarizes national HSCT activity, identifies existing gaps, and outlines outcome-driven DMG initiatives for 2024–2025, with particular emphasis on developing a comprehensive strategy for digitizing the national data center. A key milestone was the structured review of the 2024 national survey to improve alignment of local reporting with international registry requirements.

Methods: Annual survey data were collected from 14 PBMT-affiliated centers, capturing cumulative transplant numbers, transplant modalities (autologous, fully matched allogeneic, and haploidentical), and primary disease indications. National and international collaboration was assessed by documenting center participation in CIBMTR, EBMT, and WBMT activities.

Results: As of June 2025, a total of 5,014 HSCT procedures have been performed nationally. The highest transplant activity was reported by AFBMTC (n=1,849), followed by NIBD & BMT (n=803), SIH (n=594), AKU (n=559), and SKMCH&RC (n=428), with additional contributions from other centers. Allogeneic HSCTs constituted the majority of procedures, with beta thalassemia major, aplastic anemia, and acute leukemias (AML/ALL) being the most common indications. Detailed transplant-specific analyses are presented in Figure 1. National collaboration remains strong, with five centers contributing to CIBMTR, three to EBMT, and all 14 centers participating in WBMT reporting through the PBMT platform.



Conclusions: The PBMT Data Management Group has established a robust foundation for nationwide HSCT data collection and effective integration with the global transplant community. However, reliance on predominantly paper-based systems limits efficiency, data quality, and timely research output. Transitioning to a fully digital infrastructure is essential to maximize the value of national HSCT data. Adoption of REDCap is recommended as a scalable, secure, and internationally recognized platform to formalize the national data center and support the sustainable development of HSCT services in Pakistan.

Disclosure: Nothing to declare.

P321

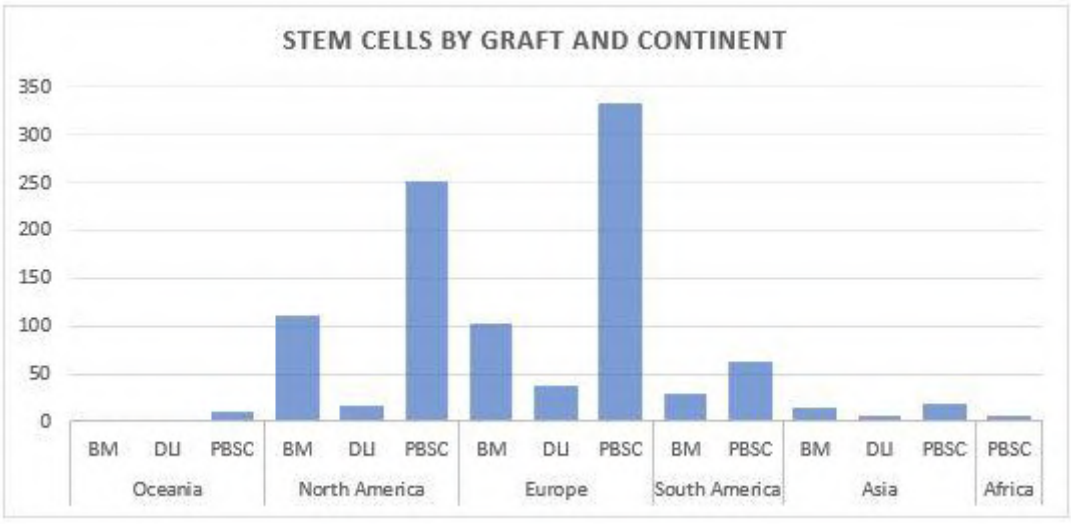
THE STRATEGIC ROLE OF BRAZIL IN THE INTERNATIONAL SUPPLY OF STEM CELLS: THE CONTRIBUTION OF REDOME TO LATIN AMERICA AND THE WORLD

Natiele Tavares[1], *Andrea Copello*[1], *Danielli Oliveira*[1], *Renata Esterque*[1], *Adriana Nunes*[1]
[1]*Brazilian National Cancer Institute, Rio de Janeiro, Brazil*

Background: Access to a diverse and extensive pool of unrelated hematopoietic stem cell donors is critical for successful allogeneic transplantation. While global collaboration is the cornerstone of donor searches, the geographic distribution of registries is marked by strong geographic asymmetry. Brazil hosts the third-largest bone marrow donor registry globally (REDOME), with over 6 million potential donors, establishing itself as the largest repository of genetic diversity in Latin America. This analysis aims to quantify Brazil's role in providing cellular products such as Bone Marrow (BM), Peripheral Blood Stem Cells (PBSC), and Lymphocytes for international transplantation, with a focused assessment of its strategic importance for Latin America, a region with limited national registry infrastructure.

Methods: We conducted a retrospective, observational study of all international requests for cellular products facilitated by Brazil's registry from January 2013 to December 2024. Data on product type (BM, PBSC, Lymphocytes), recipient location (by continent and country), and request outcomes were extracted from the REDOME database. The analysis included descriptive statistics that were used to analyze donation volumes, temporal trends, and geographic distribution of recipients.

Results:



Between 2013 and 2024, Brazil provided 999 cellular products for international transplantation. PBSC was the predominant graft source (68.2%, n=681), followed by BM (25.7%, n=257) and donor lymphocytes (6.1%, n=61; note: some donations may involve multiple products). Europe was the primary recipient continent (47.3%, n=473), followed by

North America (37.8%, n=378), South America (9.2%, n=92), Asia (3.7%, n=37), Oceania (1.2%, n=12), and Africa (0.7%, n=7). Within the Americas, a detailed analysis reveals that Latin American and Caribbean nations received 20% of all international Brazilian donations, underscoring a vital regional partnership. Notably, this support is channeled to a concentrated group of countries with formal donor registries: Argentina (leading recipient in the region), Chile, Uruguay, Paraguay, and Mexico. The remaining donations within the Americas were for the United States and Canada.

Conclusions:
This analysis solidifies Brazil's position as a foundation of the global donor registry network and the undisputed central pillar for hematopoietic stem cell provision in Latin America. The consistent, decade-long support for South American nations underscores a successful model of regional health cooperation showcasing REDOME's strategic impact on the international donation ecosystem. The significant potential for expanding these partnerships is evident. Strategic initiatives should include: 1) Formalizing and streamlining collaborative frameworks with registries in Argentina, Chile, Uruguay, Paraguay, and Mexico; 2) Developing shared logistical and financial mechanisms to further reduce access barriers; and 3) Leveraging Brazil's expertise to support the development of nascent registries in other Latin American and Caribbean countries. Strengthening this regional network is paramount to expanding equity in transplant access and building a more cellular therapy ecosystem more integrated, sustainable and self-sufficient in Latin America.

Disclosure: Nothing to declare

P322

STRENGTHENING NATIONAL TRANSPLANT INFRASTRUCTURE THROUGH INTERNATIONAL COLLABORATION: LESSONS FROM THE DKMS EXPERIENCE IN COLOMBIA

Sandra G. Salamanca Pinzón[1], *Suvi Anniina Lemetyinen*[2], *Paola Andrea Cendales Rodriguez*[3], *Nithya Babu Rajendran*[1], *Gustavo Salguero*[3], *Julia Pingel*[4,1]
[1]*DKMS Registry gGmbH, Tübingen, Germany,* [2]*Fundacion de Beneficencia Pública DKMS CL, Santiago de Chile, Chile,* [3]*Instituto Distrital de Ciencia , Biotecnología e Innovación en Salud (IDCBIS), Bogota D.C., Colombia,* [4]*DKMS Group gGmbH, Tübingen, Germany*

Background: Access to unrelated stem cell transplantation in Latin America remains limited by regulatory, logistical, and infrastructural constraints. DKMS's operational experience in Chile, where it supported multiple transplant centers and helped strengthen donor-related workflows, provided strategic insights for shaping a collaborative model in Colombia. These insights guided the partnership with the Colombian Bone Marrow Donor Registry of IDCBIS "Dar Células" and national transplant centers to improve operational readiness, enhance knowledge transfer, and strengthen national transplant capabilities.
Objectives: To describe the operational context, early outcomes, and transferable practices arising from collaboration between DKMS, IDCBIS, and Colombian transplant centers.

Methods: Key challenges in the Colombian unrelated HSCT landscape were identified and addressed through the development of a complementary model between IDCBIS and DKMS Registry. Under this model IDCBIS led domestic donor recruitment and public outreach initiatives, while DKMS Registry provided centralized search coordination and product procurement. Transplant centers were supported through access to affordable high-resolution patient HLA typing, domestic and globally registered unrelated donors via Hap-E Search, and extensive training on search and request procedures aligned with WMDA standards. A bilingual working environment was adopted to enhance engagement and facilitate communication across teams. Early outcomes and outreach impact were analyzed using operational data (2022-2025) from donor search requests, match identification (global and IDCBIS donors), and product procurement and deliveries timelines.

Results: Prior to the collaboration, only one transplant center actively conducted unrelated donors and searches and performed transplants from this source. Following implementation, active participation increased to 13 transplant centers, indicating substantial national engagement. Standardized communication pathways, unified search workflows, structured criteria for assessing donor suitability, and a bilingual working language enhanced process consistency and faster case handling. Access to affordable high-resolution HLA typing and WMDA-aligned training further improved search quality. Colombia's cohesive hematology and oncology community also supported the rapid adoption of the hybrid search and request support program.
Between 2022 and 2025, IDCBIS registered more than 11,000 local donors successfully. In 2024, donor listing on Hap-E Search began, and 10,330 Colombian donors are currently accessible in the system, enhancing match options for Colombian patients, particularly those from ethnic minorities.. During the overall time period 449 unrelated donor searches were coordinated, resulting in 56 matched unrelated donor transplants, with cellular products collected through DKMS or partner registries.

Conclusions: Leveraging lessons from Chile and adapting them to Colombia's context has strengthened national transplant capacity and long-term sustainability. Expanding equitable access to stem cell transplantation in Latin America requires intentional knowledge transfer, structured cooperation, and strong partnerships with transplant centers. Every patient deserves access to unrelated HSCT, and collaboration is key to breaking down barriers. By supporting transplant centers in countries where unrelated donor transplantation in still emerging, DKMS helps expand access to life-saving therapies and brings hope closer to patients. The collaboration between an international operator and a local organization illustrates how internationally supported yet locally driven capacity building can enhance national transplant infrastructure and improve patient access across Latin America.

Disclosure: Nothing to declare.

P323

DETERMINANTS AND TRENDS IN UNRELATED ALLOGENEIC HSCT CANCELLATIONS: A 10-YEAR SINGLE-CENTER ANALYSIS

Pinelopi Samara[1], *Sofia Karatasaki*[1], *Stylianos Graphakos*[1]
[1]*«ORAMA ELPIDAS» Bone Marrow Donor Center, Children's Oncology Hospital «Marianna V. Vardinoyannis-ELPIDA», Athens, Greece*

Background: Cancellations of allogeneic hematopoietic stem cell transplantation (HSCT) remain a significant clinical and operational challenge, adversely affecting patient outcomes, donor engagement, and healthcare resource utilization. These challenges are particularly pronounced in unrelated voluntary donor settings, where donor availability, medical suitability, and logistical constraints critically determine whether a planned transplant proceeds. Although international donor registries, enhanced supportive care, and improved coordination networks have expanded access to transplantation, a substantial proportion of scheduled procedures remain uncompleted. Understanding the determinants of cancellations—especially donor-related factors—is essential for optimizing donor selection, enhancing patient management, and improving the robustness of transplant programs.

Methods: We conducted a retrospective analysis of 659 planned unrelated allogeneic HSCTs at a single donor center from February 2015 to mid-December 2025. 498 transplants were successfully completed, while 161 (24.4%) were cancelled. Cancellations were classified as patient-related, donor-related, or center/logistics-related. Donor-related cancellations were further subclassified into medical unsuitability, personal reasons, professional conflicts, pregnancy, travel abroad, and "graft-source mismatch" (donor offers peripheral blood cells instead of the requested bone marrow). COVID-19–related operational disruptions were included under center/logistics-related factors. Descriptive statistics quantified the distribution and temporal trends of cancellation determinants.

Results: Of the 161 cancellations, 70 (43.5%) were patient-related, 78 (48.4%) donor-related, and 13 (8.1%) center/logistics-related. Patient-related cancellations were primarily due to clinical deterioration: disease relapse happened in 9 cases (5.6%), rapid deterioration in 20 cases (12.4%), and pre-transplant mortality in 18 cases (11.2%). Three patients (1.9%) declined transplantation, and two patients (1.2%) achieved a response which made HSCT clinically unnecessary. Additionally, 18 procedures (11.2%) were cancelled following center decisions to proceed with alternative donors based on dynamic clinical reassessment. Donor-related cancellations were the most common category, slightly exceeding patient-related cancellations. Medical unsuitability accounted for 29 cases (18.0%), personal reasons for 26 cases (16.1%), and professional commitments for 12 cases (7.5%). Donor travel abroad contributed to four cancellations (2.5%), and four donors (2.5%) were willing to donate only peripheral blood, inconsistent with the transplant indication. Pregnancy occurred in three cases (1.9%). These findings underscore the multidimensional vulnerability of unrelated donor pathways, shaped by donor health, availability, personal commitments, and practical considerations.
Center- and logistics-related cancellations totaled 13 cases (8.1%). Eleven (6.8%) were attributable to collection-center delays, and two (1.2%) were due to COVID-19–related operational disruptions. Notably, six patients from the cancelled cohort received

haploidentical related donor transplants, illustrating the clinical utility of alternative donor strategies. Temporal trends indicated that donor-related cancellations were driven by health and personal factors, whereas patient-related cancellations consistently reflected disease progression and pre-transplant mortality throughout the decade.

Conclusions: Unrelated HSCT cancellations arise from a complex interplay of patient instability, donor limitations, and logistical inefficiencies. Donor-related factors represented the most frequent category, highlighting the importance of early donor evaluation, enhanced donor engagement, and systematic backup donor planning. Patient-related cancellations emphasize the need for optimized disease control and timely activation of transplantation. System-level barriers, including collection-center delays and pandemic-related disruptions, highlight opportunities for organizational improvement. Strengthening these domains will reduce preventable cancellations and enhance the efficiency of HSCT programs.

Disclosure: Nothing to declare

P324

MONITORING OF BKV DNAEMIA AND HEMORRHAGIC CYSTITIS AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

Leonardo Michellin Parra[1,2], Anderson João Simioni[2], Iago Colturato[2], Fernanda Rodrigues Barbieri[2], Juliana Ribeiro do Prado Moreno[2], Lilian P. Zanetti[2], Leila Cibele Serra Oliveira[2], Mair Pedro de Souza[2], Vergilio Antonio Rensi Colturato[2], ***Clarisse Martins Machado****[3,2,1]*
[1]São Paulo State University, Botucatu, Brazil, [2]Dr. Amaral Carvalho Foundation, Jaú, Brazil, [3]São Paulo University, São Paulo, Brazil

Background: Hemorrhagic cystitis (HC) is a frequent complication after allogeneic HCT. Irradiation, drug toxicity and polyomavirus BK (BKV) infection are the main causes of HC. The diagnosis of BKV-HC is based on the triad: detection of BKV reactivation, macroscopic hematuria and urinary symptoms. Currently, the management of BKV-HC is mainly based on the use of uroprotective medications and bladder irrigation, since available antivirals have not proven effective. BKV monitoring has not been recommended for a long time. However, recent data show an increase in HC, likely reflecting the rise in the use of PTCy, beyond haploidentical HCT. In this study, we revisit the characteristics of BKV-HC and BKV DNAemia, as well as their risk factors and impact on non-relapse mortality (NRM) and overall survival (OS).

Methods: Single-center, retrospective cohort study based on review of electronic medical records of allo-HCT recipients from 2020–2024. BKV DNAemia was monitored weekly by quantitative PCR. HC grade III and IV were considered severe. The cumulative incidences (CI) of BKV DNAemia and HC, and the variables associated with their occurrence were determined by Fine-Gray proportional hazard regression using the R software. Overall survival was estimated using the Kaplan-Meier method.

Results: 310 allo-HCT were included: 96 (30,9%) MRD, 145 (46,8%) haploidentical and 69 (22,3%) MUD. The median age was 31.6 (2-73) years, 24.8% of the patients (pts) were

children. During monitoring, 154 pts presented BKV DNAemia (CI=49.7%), at a median of 38 (3-423) days post-HCT. Median viral load at reactivation was 599 (599-27,715) copies/mL DNAemia lasted from less than 7 to 140 (median 35) days. Variables associated with BKV DNAemia were haploidentical or unrelated mismatch donor (mMUD). 113 (74%) patients were asymptomatic at DNAemia detection, 19 (12%) developed urinary symptoms before and 22 (14%) concurrently with DNAemia. BKV-HC was diagnosed in 27 patients for a CI of 8.7% (7% MUD, 8% MRD and haplo, 25% mMUD; p=0.23). No variable was associated with the occurrence of BKV-CH. The 2-year overall survival (OS) was 67.4%. Lower OS was observed in haploidentical (p=0.009), mMUD HCT (p=0.002), performance status ≤80% (p=0.015), and non-myeloablative/reduced intensity conditioning (p=0.03). Non relapse mortality (NRM) at 2 years was 20.4%, significantly higher in pts with NMA/RIC conditioning (p<0.0001) and severe BKV-HC (p=0.005). The positive and negative predictive values of DNAemia for the development of HC was 14.9% and 95.5%, respectively.

Conclusions: In this series, BKV-DNAemia was frequently detected in haploidentical and mMUD HCT. Although frequent, BKV-DNAemia did not precede symptoms of hemorrhagic cystitis. Most patients (74%) were asymptomatic, and some developed urinary symptoms before or concurrently with virus detection in the blood. Therefore, our data confirm that monitoring for BKV post-allo-HCT is irrelevant. The cumulative incidence of BKV hemorrhagic cystitis was 8.7%, and in severe cases, it affected NRM, without impacting OS.

IMPLEMENTATION OF THE BRAZILIAN SOCIETY OF CELLULAR THERAPY AND BONE MARROW TRANSPLANTATION EDUCATIONAL PLATFORM: PRELIMINARY RESULTS AND CHALLENGES

Flavia Ferreira da Costa[1], Cinthya Muniz Corrêa Rocha da Silva[2], Anderson João Simione[3], Antonio Vaz De Macedo[4], Alayne Magalhaes Trindade Domingues Yamada[5], Heliz Regina Alves Das Neves[6], Simone Ojima Ferreira[7], Andreia Ribeiro de Almeida[8], Vanessa Aparecida do Nascimento Varjão[9], Monique Ammi[10], Adriana Mendes de Quadros Cavilha[6], ***Fernando Fernando Barroso Duarte***[1]

[1]*Sociedade Brasileira de Terapia Celular e Transplante de Medula Óssea (SBTMO), Rio de Janeiro, Brazil,* [2]*Hospital Israelita Albert Einstein, Sao Paulo, Brazil,* [3]*Hospital Amaral Carvalho, Jaú, Brazil,* [4]*Hospital da Polícia Militar, Belo Horizonte, Brazil,* [5]*Instituto D'OR de Pesquisa e Ensino, São Paulo, Brazil,* [6]*Universidade Federal do Paraná, Paraná, Brazil,* [7]*Hopital Sírio Libanês, São Paulo, Brazil,* [8]*Hospital Vitoria/Rede Americas, Rio de Janeiro, Brazil,* [9]*Grupo de Apoio ao Adolescente e à Criança com Câncer (GRAAC), São Paulo, Brazil,* [10]*Center for International Blood and Marrow Transplant Research, Minneapolis, United States of America (the)*

Background: Continuous education is essential to sustain high-quality standards in hematopoietic cell transplantation (HCT) and advanced cellular therapy. To address the national need for structured, accessible, and standardized training, the Brazilian Society of Cellular Therapy and Bone Marrow Transplantation (SBTMO) developed a digital educational platform aimed at centralizing resources and supporting multidisciplinary capacity building across Brazil.

Methods: Beginning in November 2023, alignment meetings were conducted to define the target audience, access structure , and priority educational needs. The implementation process included planning, technical assessment, customization, and pilot testing to determine qualification criteria, functional requirements, and security standards for platform selection. Following proposal refinement in November 2024, the contract was approved in January 2025. Platform customization included visual identity development, user self-registration settings, standardized data fields, and certificate templates. In April 2025, pilot testing began with the migration of existing materials, starting with the Portuguese version of a Data Manager Manual, thus focusing on data management content as a foundation for broader educational expansionstandardized workflow for handling training-content requests was also introduced to organize and prioritize demands from the SBTMO community. Platform usage metrics were then descriptively analyzed to guide ongoing improvements.

Results: A total of 150 professionals from Brazilian transplant centers registered during the first year. Platform analytics recorded 369 cumulative accesses/views (57 in 30 days, 114 in 90 days, 146 in 180 days, and 152 in 365 days), demonstrating sustained engagement (Figure1). Key educational materials included three versions of the Data Manager Manual; the 5th edition of the Summary Slides of the Brazilian HCT and Cellular Therapy Registry (RBTCH-TC 2025), accessed by 45 institutions (22 downloads; 49% completion rate for automated certificate generation); and two video lectures on WBMT/LABMT data reporting (104 total enrolments, with completion rates still in progress). Preliminary feedback emphasized the relevance, clarity, and accessibility of the content. Identified challenges included regional disparities in internet connectivity, limited institutional time allocated for training, and the need for continuous content updating to reflect the rapid advances in cellular therapy and evolving data-quality standards. Addressing these challenges will be critical for scalability and long-term success; however, early findings indicate strong feasibility and the platform’s potential to improve national standardization and data management competency across Brazilian HCT programs.

Conclusions: The SBTMO educational platform represents a significant milestone in nationwide capacity building for HCT and cellular therapy in Brazil. Preliminary results demonstrate its feasibility, acceptance, and early impact on professional training and data-quality practices. Future developments will expand content beyond data management, reinforcing multidisciplinary education and promoting national standardization.

P326

BUILDING THE LOCAL EVIDENCE BASE: DEMOGRAPHIC PROFILE OF DLBCL PATIENTS IN WALES

*Ibukunoluwa Oginni-Falajiki[1,2], Hannah Crocker[1,2], Mary Warren[1], Rey Consolacion[1], Damith Dhanasekara Koralage[1], **Ceri Jones**[1], Rachel Gemine[2], IoIo Doull[2], Keith Wilson[1,3]*
[1]Cardiff and Vale University Health Board, Cardiff, United Kingdom of Great Britain and Northern Ireland (the), [2]NHS Wales Joint Commissioning Committee, Pontypridd, United Kingdom of Great Britain and Northern Ireland (the), [3]Cardiff University School of Medicine, Cardiff, United Kingdom of Great Britain and Northern Ireland (the)

Background: Real-world data (RWD) are increasingly important for informing healthcare planning and supporting evidence-based decision-making. Understanding local patient demographics is particularly relevant in Diffuse Large B-Cell Lymphoma (DLBCL), where age is widely recognised as a key determinant of treatment eligibility and tolerance, with older adults remaining underrepresented in clinical trials. International datasets such as SEER (SEER-21, 2018-2022) report that approximately 50% of DLBCL patients are <65 years, 25% are 65–74, and 25% are ≥75 years at diagnosis. However, real-world local demographic data for Wales remain limited. Wales comprises seven Health Boards, with tertiary haemato-oncology and cellular therapy services centralised at Cardiff and Vale University Health Board (CVUHB) for six of these seven, equating to ~80% of the Welsh population.
By characterising the demographic profile of patients diagnosed with DLBCL at CVUHB, this study provides a foundation for reliable local RWD and intelligence to support service planning. The final aim is to expand analyses to an all-Wales dataset.

Methods: This retrospective observational study included all CVUHB residents diagnosed with DLBCL between 1 January 2015 and 31 December 2023. Cases were identified using ICD-10 code C83.3, with patient lists obtained from central databases including Digital Health and Care Wales (DHCW) and Cancer Network Information System Cymru (CaNISC). Coded data were validated, anomalies and discrepancies removed, and diagnoses confirmed using Welsh Clinical Portal (WCP). Demographic data were extracted from WCP, Cardiff and Vale Clinical Portal, and ChemoCare Electronic Chemotherapy Prescribing System. Variables included age, sex, patient residence at diagnosis and year of diagnosis. Descriptive analyses were performed to identify trends in age and sex distribution over time.

Results: Table 1: Annual age-specific case numbers from 2015 to 2023

Years	0-64 (n)	65-74 (n)	75+ (n)	All ages (n)
2015	6	8	20	34
2016	7	13	11	31
2017	8	12	10	30
2018	13	11	13	37
2019	10	9	14	33
2020	5	13	7	25
2021	12	5	7	24
2022	6	11	8	25
2023	13	5	13	31
TOTAL n (%)	80 (30%)	87 (32%)	103 (38%)	270 (100%)

A total of 270 people were identified, with a median age of 71 years (range 21–93). Overall age distribution was 30% <65 years, 32% 65–74 years, and 38% ≥75 years. Fifty-six per cent of patients were male, with sex distribution consistent over the nine-year period. Previous studies suggest that male patients with DLBCL may have slightly worse survival than females, highlighting the clinical relevance of this distribution. Table 1 shows yearly variation in age distribution, with fewer case numbers during 2020–2022, likely reflecting COVID-19–related impacts on diagnosis and healthcare access.

Conclusions: DLBCL patients in Wales were diagnosed at an older age than the US SEER dataset, with a median age of 71 compared to 66 and with 38% aged ≥75 years versus ~25%, respectively, suggesting a larger proportion may be ineligible for intensive therapies. Real-world demographic data are essential for understanding local populations, anticipating treatment needs, guiding treatment planning, and informing resource allocation. Characterising these demographics supports data-driven decision-making, highlights unmet needs, and underpins development of tailored protocols for older or high-risk patients.

P327

LEVERAGING MACHINE LEARNING TO PREDICT POST-TRANSPLANT COMPLICATIONS IN ALLOGENEIC HSCT

Fangchen Xia[1], Florence Mesnil[1], Federico Garnier[1], Catherine Faucher[1], ***Monia Zidane***[1]
[1]*French Biomedicine Agency, Paris, France*

Background: Allogeneic hematopoietic stem cell transplantation (Allo-HSCT) is a potentially curative therapy for hematologic malignancies. Despite its effectiveness, patients remain at risk for serious post-transplant complications, including non-relapse mortality (NRM), relapse, graft rejection, acute graft-versus-host disease (aGvHD), and chronic GvHD (cGvHD). Accurate early prediction of these outcomes can support clinical decision-making and improve long-term outcomes.
Objectives: To develop and evaluate machine learning models for predicting the probability of NRM, relapse, rejection, aGvHD, and cGvHD within one-year post-Allo-HSCT.

Methods: We used pre-transplant clinical data from 16,427 French adult patients who received Allo-HSCT for malignant hematologic diseases between 2013 and 2023, recorded in the European Society for Blood and Marrow Transplantation (EBMT) registry. Following a systematic literature review, six machine learning algorithms were selected: logistic regression, decision tree, random forest, XGBoost, elastic net, and a stacking ensemble model. Predictive variables were chosen based on both clinical relevance and literature evidence. Model performance was evaluated using the Area Under the Receiver Operating Characteristic Curve (AUC) and accuracy. SHapley Additive exPlanations (SHAP) were used to interpret model predictions and identify key variables influencing each outcome.

Results: Of the 16,427 patients included, 59% were male. Patients aged ≥55 years represented 52% of the cohort; 28% were aged 40–55, and 20% were under 40. The most frequent diagnosis was acute leukemia (58.4%), followed by myelodysplastic syndromes (13.2%), lymphoma (11.8%), and myeloproliferative disorders (7.0%). One-year post-transplant outcomes were as follows: NRM occurred in 25.0% of patients, relapse in 19.0%, rejection in 7.8%, aGvHD in 60.0%, and cGvHD in 38.9%. Among tested models, the stacking ensemble showed the best overall performance in terms of AUC and accuracy across most outcomes, except for cGvHD.

- For rejection, the most influential predictors were treatment period, HLA matching, performance status, and conditioning regimen.
- For relapse, treatment period, Disease Risk Index (DRI), conditioning regimen, and Thiotepa based conditioning were key variables.
- For aGvHD, treatment period, donor type, and HLA matching ranked highest.
- For cGvHD, main predictors included treatment period, performance status, Thiotepa based conditioning, CMV match, and HLA matching.
- For NRM, top predictors were patient age, Thiotepa based conditioning, and treatment period.

Conclusions: Machine learning models, particularly ensemble approaches, demonstrated strong predictive performance and could serve as valuable tools to support clinical decision-making in the management of Allo-HSCT patients. The predictive performance of the stacking ensemble model was superior to that of the logistic regression model alone. These findings highlight the potential of data-driven approaches to improve individualized risk stratification and post-transplant care.

Disclosure: Nothing to declare.

Health Economics and Technology Assessment

OS17-08

TEN YEARS OF POST-ALLOGENEIC HSCT HEALTHCARE UTILIZATION IN FRANCE: A NATIONWIDE POPULATION-BASED STUDY (2013–2023)

Monia Zidane[1], *Florence Mesnil*[1], *Federico Garnier*[1], *Catherine Faucher*[1]
[1]*French Biomedicine Agency, Paris, France*

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) remains the treatment of choice for many malignant and non-malignant hematologic disorders. However, the post-transplant period is often marked by intensive and specialized healthcare needs, which remain insufficiently described and poorly quantified.
Objective: To describe the patterns and evolution of healthcare resource utilization in adult patients during the post-allogeneic HSCT period between 2013 and 2023, using French national health insurance claims data (SNDS), with a minimum follow-up of one-year post-transplant.

Methods: We conducted a retrospective, population-based cohort study including all adults who underwent allogeneic HSCT in France from 2013 to 2023. Data were extracted from the French National Health Data System (SNDS), covering sociodemographic and clinical characteristics, inpatient care and outpatient care.

Results: A total of 17,203 patients were included, with males representing 52% of the cohort. Regarding age distribution, 38% were over 59 years, 51% were between 30 and 59 years, and 11% were under 30. The most frequent indication for HSCT was acute myeloid leukemia (38.4%), followed by acute lymphoblastic leukemia (10.5%). At the end of the study period, 60% of patients were alive. The use of outpatient clinic (OC) visits peaked during the first six months post-transplantation, totaling 183,253 visits, and remained stable across the study period. More than half of clinical follow-up and rehabilitation hospitalizations

also occurred within the first six months, a consistent trend over time. A similar distribution was observed for hospitalizations involving intensive care, 57% of which occurred within the first year.
Over time, care utilization patterns evolved, with a marked decline in early mortality: among patients transplanted in 2013, 18% died within six months compared with 13% in 2023. The number of OC visits decreased progressively, reaching 16,357 in year 5. Conversely, the median duration of clinical follow-up and rehabilitation hospitalizations during the first year increased from 13 days in 2013 to 29 days in 2023. Hospitalizations involving intensive care maintained a stable median length of stay throughout the study period.
Beyond hospital care, community-based care played a key role. General practitioner visits represented the majority of consultations and showed steady growth over time. The most frequently consulted specialties were hematology and ophthalmology. Physiotherapy sessions increased by 30% between 2013 and 2023

Conclusions: Our results show a steady increase in post-transplant healthcare needs over the past decade, particularly in rehabilitation services. This study provides a comprehensive overview of post-HSCT healthcare utilization and its evolution over time, which is essential for assessing healthcare provision and adapting to evolving clinical practices. This is a preparatory analysis before matching the current cohort data with data for the same patients from the EBMT registry.

Maximilians-Universität Würzburg/Rudolf-Virchow-Zentrum, Würzburg, Germany, [13]Julius-Maximilians-Universität Würzburg/ Institut für Virologie und Immunbiologie, Würzburg, Germany

Background: Invasive pulmonary aspergillosis poses a life-threatening complication in immunocompromised individuals, including recipients of allogeneic hematopoietic cell transplantation (allo-HCT). By contrast, immunocompetent individuals are usually protected against infection with *Aspergillus fumigatus,* the causative agent of aspergillosis. The mechanisms underlying pulmonary innate immune protection remain poorly understood.

Methods:

We employed super-resolution and dynamic confocal microscopy to investigate the impact of cytokines—primarily M-CSF and IL-34—on the phenotype and migratory behavior of primary alveolar macrophages (AMs) in vitro. In addition, we performed functional in vitro assays to assess AM phagocytic activity.

To evaluate the effects of exogenous cytokine stimulation on the pulmonary immune response in vivo, we used mouse models of allo-HCT (8 Gy total body irradiation, C57BL/6 → BALB/c) and invasive intratracheal *A. fumigatus* infection. Mouse survival and clinical performance were monitored, and local host–pathogen interactions were analyzed using flow cytometry and three-dimensional light-sheet fluorescence microscopy.

Results:

We identified alveolar macrophages (AMs) as key players in pulmonary antifungal defense. In immunocompromised mice, AMs conferred protection against lethal invasive aspergillosis by day 6, but not by day 4, post–allo-HCT. AMs exhibited the highest frequency, proliferation, and phagocytic activity in the lung compared with neutrophils and monocytes, suggesting that tissue-resident AMs are primarily responsible for protecting mice from *A. fumigatus* infection. This observation was confirmed by selective AM depletion, which rendered mice susceptible to uncontrolled infection.

To enhance AM function at the earlier time point, we tested cytokine-based interventions and found that M-CSF—but not IL-34—both of which bind the CSF-1 receptor, promoted greater migratory activity (0.52 vs. 0.30 µm/min, respectively), increased versatility (diffusion coefficient of 0.78 vs. 0.60 µm²/min, respectively), enhanced phagolysosomal function, and improved fungal killing in murine tissue-resident AMs. Notably, similar results were observed in human primary tissue-resident AMs.

In allo-HCT recipient mice, M-CSF locally expanded tissue-resident AMs by 1.5-fold. Furthermore, M-CSF enhanced AM killing capacity and protected 90% of HCT recipients from lethal *A. fumigatus* infection on day 4 post-HCT. This M-CSF–mediated protective effect was abrogated by AM depletion. Moreover, M-CSF treatment preserved lung tissue integrity and reduced serum levels of pro-inflammatory cytokines.

Conclusions: Our findings demonstrate a critical role of tissue-resident AMs in pulmonary antifungal immunity and suggest that therapeutic modulation of AM activity via M-CSF may offer a promising strategy to combat severe fungal infections in immunocompromised patients.

P330

THE USE OF EFFICIENCY ANALYSIS TO EVALUATE UNRELATED BONE MARROW DONOR REGISTRIES

Danielli Oliveira[1], *Carlos Conte Filho*[2,3], *Luiza Braga*[2], *Pamela Lopes*[3], *Marcela Bhering*[3], *Roseli Monteiro*[3]
[1]*Registro Brasileiro de Doadores Voluntários de Medula Óssea (REDOME) / Ministry of Health, Rio De Janeiro, Brazil,* [2]*Universidade de Santa Maria, Santa Maria, Brazil,* [3]*Fundação Instituto Oswaldo Cruz (Fiocruz), Rio de Janeiro, Brazil*

Background: Hematopoietic stem cell (HSC) transplantation is a standard treatment for malignant and non-malignant blood diseases, and selecting a matched donor is essential to achieving good results. To increase the probability of eligible donors, unrelated donor registries were created worldwide. In 2025, around 45 million donors were distributed among registries of 57 countries. The high cost of adding donors and the expenses associated with donor procurement are the main challenges for registries, impacting public and private health systems. The Brazilian Bone Marrow Donors Registry (REDOME) was created in 1993, and it is the only registry of bone marrow donors in the country, maintained exclusively by public resources.
This project has the primary objective of examining and evaluating the efficiency of REDOME compared to other bone marrow donor registries on a global scale, and analyzing its role in this context.

Methods: Using data collected by WMDA in 2022 (Global Trend Reports) and public registries' reports with financial data, production indexes, and an efficiency scale, an efficiency scale was created using Data Envelopment Analysis (DEA). DEA is a non-parametric linear programming technique used to evaluate the relative efficiency and productivity of a set of comparable entities, often called Decision-Making Units (DMUs). This strategy analyzes the efficiency of organizations based on inputs and outputs. To compare registries, the selected inputs were the total of voluntary donors registered on 01/01/2022 and the expenses of the registries. The selected outputs were new donors registered in 2022, HSC collected from national patients, and HSC collected from international patients.

Results: Considering the total number of hematopoietic progenitor cell (HPC) products obtained from REDOME for national and international patients (425 and 77, respectively), REDOME ranks 11th and 18th, respectively. However, the number of cell products collected relative to the number of samples requested for confirmatory typing indicates that REDOME is only in position 66 among 70 analyzed registries, suggesting inefficiency throughout the process. The DEA analysis was performed using data from 18 registries, and the efficiency score indicated that REDOME presented an intermediate score (0,89), confirming the inefficiency of operational processes (Table 1). The most efficient organizations include the two largest registries - NMDP-National Marrow Donor Program (USA) and DKMS Registry gGmbH (Germany) – but also more minor, well-established registries, like Anthony Nolan,

DKMS Chile, Tobias Registry, indicating that the number of donors is not associated with the efficiency itself.

DMU	DEA Score	DMU	DEA Score
NMDP - National Marrow Donor Program (USA)	1	Tobias Registry (Sweden)	1
DKMS Registry gGmbH (Germany)	1	Verein Geben für Leben (Austria)	1
Anthony Nolan (UK)	1	National Bone Marrow Donors Registry named after Vasya Perevoshchikov (Russia)	1
Registro de Donantes de Médula Ósea (REDMO - Spain)	1	Austrian Bone Marrow Donor Registry	0,964787
Fundacja DKMS (Poland)	1	National Registry of Hematopoietic Stem Cells Voluntary Donors	0,907484
Matchis Foundation (Netherlands)	1	REDOME - Registro Brasileiro de Doadores Voluntarios de Medula Ossea	**0,890617**
DKMS United Kingdom	1	Gift of Life Marrow Registry (USA)	0,830797

"Table 1: DEA Analysis for 18 registries. Results equal to 1 indicate the highest level of efficiency."

Conclusions: The complexity and the high costs associated with unrelated donor registry activities make efficiency analysis a priority for these organizations. The use of specific strategies can highlight opportunities for improvement, and the DEA created an "efficient frontier" among 18 registries, stimulating benchmarking among the registries. The REDOME results indicate the need to identify and seek best practices. These data can support decision-making, strengthen registries, and enhance international cooperation, thereby improving outcomes for patients who need a HSC transplantation.

P331

CAR-T COST CONSTRAINTS IN GERMANY: BUDGET IMPACT, PATIENT ACCESS, AND EASYGEN'S POTENTIAL FOR COST-DRIVEN INNOVATION

Rebecca Scheiwe[1], *Dominik Narres*[1], *Carmen Sanges*[2], *David Krones*[2], *Michae Hudecek*[2], *Köhl Ulrike*[2], *Louise McNamara*[3], *Tuula Rintala*[3], *Afschin Ganjour*[4], *Bertram Glass*[5], *Katrin Mestermann*[2], *Sonja Steppan*[6]
[1]*Fresenius SE, Bad Homburg, Germany,* [2]*Fraunhofer Institute for Cell Therapy and Immunology (IZI), Leipzig, Germany,* [3]*EBMT, Barcelona, Spain,* [4]*Frankfurt School of Finance, Frankfurt, Germany,* [5]*Helios Hospital Berlin Buch, Berlin, Germany,* [6]*Fresenius SE, Bad Hom, Germany*

Background: CAR-T cell therapies provide transformative outcomes for patients with hematologic malignancies and are increasingly explored for severe autoimmune diseases. However, high upfront costs raise concerns regarding long-term affordability for healthcare systems. Transparent estimates of current and future budget impact are needed to guide innovation aimed at cost reduction.

Methods: Within the EU-funded EASYGEN project, Germany served as the initial case study. We quantified the share of German healthcare expenditures attributable to CAR-T therapies in 2024 and modelled a 10-year scenario reflecting growth in hematologic indications and potential expansion to autoimmune diseases, illustrating the need for cost-reducing innovation and the role of the EU EASYGEN public–private partnership. Inputs included German 2024 macro-expenditure data and CAR-T activity figures: total healthcare spending €538 billion[1]; ~1,068[2,3] patients treated with CAR-T; and an average hematologic CAR-T product price of €291,674 (products only[4]) plus an estimated ~15% additional treatment-related costs (apheresis, conditioning chemotherapy, CAR-T infusion, hospital stay, and post-treatment monitoring[5]), totaling €338,000 per patient. For autoimmune indications, only product costs (€291,674) were applied. According to a recent IQVIA report[6], only 17% of eligible patients in Germany currently receive CAR-T driven not only by tmanufacturing constraints. But also by limited referral pathways, center capacity, and system-level readiness challenges.
We developed a simplified 10-year projection with the following assumptions: (a) minimum hematologic scenario: 1,068 patients in 2024, increasing by 15% annually to ~4,321 patients in 2034; (b) maximum epidemiology-driven scenario: assuming an annual demographic growth rate of 0.2%[7] ; (c) autoimmune expansion (minimum case): by year 10, autoimmune CAR-T patients equal the minimum hematologic case (4,321), calculated using product-only costs; (d) constant real prices; and (e) healthcare expenditures growing at 3% annually. Economies of scale were not applied, as autologous cell therapies are inherently individualized and do not benefit from conventional bioprocess scaling efficiencies[8].

Results: In 2024, CAR-T expenditures were €361 million (1,068 × €338,000), representing 0.067% of total German healthcare spending. Over 10 years, hematologic CAR-T use increases to 4,321–6,409 patients (1,068 patients in 2024, rising to ~6,409 by 2034), depending on uptake assumptions. Assigning an equal number of autoimmune CAR-T patients in the minimum expansion scenario, total CAR-T use in 2034 reaches 8,642–10,730 patients. Corresponding annual expenditures range from €2.7 to €3.4 billion, with hematologic indications accounting for €1.5–2.2 billion and autoimmune indications for approximately €1.3 billion. With total healthcare spending projected to reach ~€723 billion, CAR-T therapies represent ~0.38–0.47% of total expenditures, corresponding to a 7.5–9.5-fold increase in absolute spending and a ~5.6–7.0-fold increase in budget share compared with 2024.

Conclusions: Although CAR-T therapies currently account for a small fraction of German healthcare expenditures, projected clinical expansion implies a substantial future budget impact. This underscores the need for innovation in manufacturing, logistics, and cost-efficient delivery to enable sustainable access. The EASYGEN consortium is strategically positioned to support such innovation by standardizing CAR-T processes, reducing per-patient costs, and facilitating scalable access across oncology and autoimmune indications.

P334

THE ECONOMIC BENEFIT FOR PATIENTS AND CAREGIVERS OF EXPANDING CAR-T CENTRES IN SPAIN

*Miguel Ángel Rodríguez-Gil[1], Raimundo García Boyero[2], Dunia de Miguel Llorente[3], Maria Teresa Olave Rubio[4], Raquel Domínguez-Hernández[5], **Carlos Pardo**[6], Victoria Martín-Escudero[7], Ana Margarita Redondo Izal[8]*
[1]Hospital Universitario Mancha Centro, Alcázar de San Juan, Ciudad Real, Spain, [2]Hospital General Universitario de Castellón, Castellón, Spain, [3]Hospital Universitario Guadalajara, Guadalajara, Spain, [4]Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain, [5]Pharmacoeconomics & Outcomes Research Iberia (PORIB), Madrid, Spain, [6]Gilead Sciences, Madrid, Spain, [7]Gilead Sciences, Spain, Madrid, Spain, [8]Hospital Universitario de Navarra, Navarra, Spain

Background: Travel to a qualified hospital to receive advanced therapies represents a significant financial burden for patients diagnosed with hematological cancer and their caregivers. This study aims to quantify the direct non-healthcare cost savings experienced by patients and their caregivers as a result of enhanced geographical accessibility to CAR-T cell therapies.

Methods: A geoeconomic model was developed to simulate the territorial distribution of hospitals and patients' home location and caregivers to estimate the travel costs in two scenarios: CAR T management and administration in 29 hospitals (current situation) vs. hypothetical expansion of CAR T access to all 65 hospitals that currently perform autologous stem cell transplants in Spain. Distribution was carried out based on the nearest available treatment center within each region, where possible. A cohort of 3,094 patients with potential indication for CAR T-cell therapy was constructed based on clinical and epidemiological data. Geographic data (latitude and longitude) were used to measure the distance between the hospital and the patient's home location. The distribution of the Spanish population was assumed to represent the patients' addresses. Patients were distributed according to the frequency of use of different means of transport, distinguishing between urban and rural areas. The costs included public and private transportation, accommodation and meals, all derived from public rates. The results were obtained by comparing the distances from the patients' home location to the nearest hospital in each of the scenarios and applying the costs associated with traveling.

Results: The hypothetical expansion of CAR T access from 29 to 65 hospitals was associated with a 76% reduction in the total cost for the entire cohort of patients and caregivers (from €2,218,460 to €535,283). The average cost per patient in the 29-hospital scenario was €717 compared to €173 in 65-hospital scenario, generating a potential saving of €544 per patient. The difference between the 29 and 65 hospitals scenarios in the cost of accommodation was −€1,305,063, followed by the cost of meals (-€300,207) and transportation (−€77,907). The hypothetical expansion of centres reduced the percentage of patients and caregivers requiring accommodation by 14% (18% vs 4%).

Conclusions: Hypothetical expansion of authorised CAR-T centres in Spain reduced the financial burden on patients and caregivers, especially in regions with lower hospital coverage. These potential savings could improve equity of access and represent an opportunity to optimise the efficiency of the healthcare system in the implementation of advanced therapies.

P336

ANALYSIS AND OPTIMIZATION POTENTIALS OF CURRENT CAR-T CELL THERAPY MANAGEMENT: A PROCESS MANAGEMENT PERSPECTIVE

Anika Teichert[1], *Catrina Pietralla*[2], *Jens O. Brunner*[2], *Marija Radic*[1], *Julia Busch-Casler*[1], *Agnes Vosen*[1], *Bertram Glaß*[3], *Dominik Narres*[4], *Sonja Steppan*[4]
[1]*Helmholtz-Zentrum Dresden-Rossendorf, Leipzig, Germany,* [2]*Technical University of Denmark DTU, Copenhagen, Denmark,* [3]*Helios Klinikum Berlin-Buch, Berlin, Germany,* [4]*Fresenius SE & Co. KGaA, Bad Homburg, Germany*

Background: Cell and gene therapies are among the most expensive therapies within the healthcare sector. Systematic reviews of economic evaluations of CAR-T therapies for cancer treatment show that CAR-T therapies tend to be more costly, but also more effective than their comparator treatments. As their use increases and large numbers of new advanced cell therapies are developed, the CAR-T therapy management process needs to be optimized in order to reduce the diagnosis to treatment time (turnaround process). This reduces therapy manufacturing time and associated costs, facilitating better access for patients.

Methods: We conduct eleven semi-structured expert interviews with clinicians, pharmacists, nurses, and coordinators with a CAR-T cell background from Germany, Ireland and Spain. Based on the interview results, we map the CAR-T cell therapy process using Business Process Model and Notation (BPMN) and identify the optimization potentials.

Results: Based on the interviews, we map the entire CAR-T cell therapy process and derive 12 challenges with potential for optimization:

1. Indication - deciding on the right cancer therapy regimen for the individual patient
2. High response rate vs. low long-term remission rate of CAR-T therapies
3. Adverse events - resulting in a revolving door effect between outpatient care and hospitalization in the CAR-T center
4. Poor patient health before or after apheresis
5. Patient access – e.g. due to limited number of CAR-T cell centers patients must travel great distances to receive treatment and be monitored
6. High drug manufacturing cost due to centralized manufacturing and long production time
7. No standardization in terms of contracting between CAR-T manufacturing partners
8. High variety of CAR-T product specifications (different premedication, thawing procedures, treatment of side effects) requires extensive training and process management
9. Highly complex process management including logistics and coordination due to multi-stakeholder involvement
10. High staff workload due to continuous neurological testing
11. Limited number of beds at CAR-T and local centers - increased availability required for the expected scaling of CAR-T therapies
12. Complex regulation on regional, national and European levels

Conclusions: The presented findings lay important groundwork for the definition of an optimized CAR-T cell therapy management process. The project EASYGEN aims to enable an automated, modular manufacturing platform for CAR-T cell production at the point-of-care and thereby reduce treatment cost by 50%, reduce manufacturing time significantly, broaden eligibility for new European patient groups and enable seamless integration of CAR-T cell manufacturing into routine hospital workflows.

Disclosure: The EASYGEN project is funded by the European Union (Grant Agreement 101194710). Views and opinions expressed are however those of the author(s) only and do not necessarily reflect those of the European Union or the Health and Digital Executive Agency. Neither the European Union nor the granting authority can be held responsible for them.
The authors declare no conflicts of interest. The funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results.

P337

FEASIBILITY OF SYSMEX XN-1000 HEMATOPOIETIC PROGENITOR CELL COUNTS FOR REAL-TIME MONITORING OF ALLOGENEIC STEM CELL COLLECTION

Wedad S. Hamdi[1], *Dana Dana*[1], *Aisha Alkaseri*[1], *Abdallah Alkhoujah*[1], *Nasimeh Azadi1*[1], *Jawaher Al-Emadi*[1], *Manal Yaghmour*[1], *Fabio Culurgioni*[1]
[1]*Hamad Medical Corporation, Doha, Qatar*

Background: Background: In allogeneic hematopoietic stem cell (HSPC) collection, the optimal CD34 dose is 6-8 x106/kg, real time monitoring of CD34+ cell yield is critical to avoid excessive collection, which can result in unnecessary splitting and cryopreservation of surplus products. Flow cytometry is the gold standard for CD34+ enumeration, but its turnaround time of at least 45 minutes delays decision-making, during which additional CD34+ cells continue to be collected. The Sysmex XN-1000 provides a rapid, automated hematopoietic progenitor cell (HPC) count that could serve as a surrogate for real-time monitoring. This study aimed to assess the feasibility of using Sysmex XN-1000 HPC counts to estimate the collected CD34+ dose in midway apheresis samples, compared to flow cytometry.

Methods: Forty-two midway apheresis samples from allogeneic HSPC donors were analyzed concurrently using the Sysmex XN-1000 for HPC counts and FACS Canto-II flow cytometry for CD34+ enumeration. Correlation between the two methods was evaluated using Pearson and Spearman coefficients. Agreement was assessed by Bland-Altman analysis.

Results: Sysmex HPC counts showed a moderate positive correlation with flow cytometry CD34+ counts (Pearson $r = 0.612$, $p < 0.001$). Bland-Altman analysis demonstrated a mean bias of +74.2, with wide 95% limits of agreement (-1033 to +1181), indicating that the two methods are not directly interchangeable.

Conclusions: The Sysmex XN-1000 HPC count offers a rapid and practical screening tool for real-time monitoring of HSPC collections, enabling earlier estimation of the collected CD34+ dose compared to flow cytometry. This may help prevent over-collection and reduce the need for splitting and cryopreservation of surplus stem cell doses. However, due to proportional bias and wide limits of agreement, Sysmex XN-1000 could either overestimate or underestimate the $CD34^+$ cell count by a clinically significant margin. Such discrepancies may lead to premature termination or unnecessary prolongation of apheresis, resulting in either insufficient stem cell collection requiring an additional apheresis session—thus exposing the donor to extra procedural risks—or overcollection necessitating further product processing and cryopreservation. Therefore, confirmatory flow cytometry remains necessary for final clinical decision-making.

Clinical Trial Registry: Not applicable

Disclosure: I have no conflict of interest to declare.

P338

MEASUREMENT OF COST IN A VALUE-BASED PERSPECTIVE: COMPARATIVE ANALYSIS OF ONLINE AND OFFLINE EXTRACORPOREAL PHOTOPHERESIS (ECP) MODALITIES IN SPAIN

*Fernando Sanchez[1], Jorge Martinez[1], Jose Abellan[1], **Miguel Blanquer**[2], Oscar Mesa[3]*
[1]Facultad de Economía y Empresa Universidad de Murcia, Murcia, Spain, [2]Facultad de Medicina, Universidad de Murcia, Murcia, Spain, [3]Therakos UK Ltd, Staines Upon Thames, United Kingdom of Great Britain and Northern Ireland (the)

Background: Extracorporeal photopheresis (ECP) is an established immunomodulatory therapy for conditions such as cutaneous T-cell lymphoma, graft-versus-host disease (GVHD), and organ transplant rejection. ECP can be delivered via two modalities: offline (multi-stage) and online (integrated). Understanding the resource utilization and cost implications of each modality is essential for optimizing healthcare delivery.

Methods: An independent assessment was conducted at University Hospital Virgen de la Arrixaca (Murcia, Spain) using Time-Driven Activity-Based Costing (TDABC) methodology. Twenty ECP procedures (10 online, 10 offline) were mapped and analyzed for resource consumption, staff time, and direct costs. Patient experience was also assessed via questionnaire.

Results:

- Procedure Time: Online ECP sessions were significantly shorter, averaging 76 minutes less than offline (218.9 vs. 295.0 minutes; $p < 0.001$). The largest time savings were observed in the treatment phase, with offline procedures requiring 88% more time.
- Cost Analysis: The mean total cost per session was €2,053.5 for online and €2,157.8 for offline ECP, a modest difference that did not reach statistical significance (p =

0.191). Personnel costs were significantly higher for offline procedures (€167.5 vs. €114.5; p = 0.035), driven by increased nursing time. Consumable costs were higher for online ECP, while indirect costs (facilities, equipment) were higher for offline.
- Patient Experience: Patients reported high satisfaction with both modalities, with no significant differences in perceived comfort, staff competence, or self-reported health status. Transportation and hospital waiting times were identified as the main burdens.

Conclusions: Online (integrated) ECP offers substantial operational advantages, with significantly reduced procedure times and lower personnel costs, though total cost differences are modest and context-dependent, they are slightly in favor of Online (integrated) ECP. The findings support the adoption of integrated ECP systems in high-volume centers seeking efficiency gains, but highlight the need for granular local cost structure analysis. Patient satisfaction remains high regardless of modality. Future research should incorporate larger samples, clinical outcomes, and broader societal costs to inform comprehensive value assessments between different ECP modalities.

Disclosure: The study was funded by a sponsorship agreement between the University of Murcia where the authors are employed and Therakos (UK) Ltd.

Quality Management and JACIE

QM1-4

A WORKFLOW-INTEGRATED DIGITAL PLATFORM FOR PROCEDURE PLANNING AND REAL-TIME CAPTURE OF JACIE-REQUIRED KPIS IN APHERESIS UNITS AND CELL THERAPY PROCESSING AND CRYOPRESERVATION LABORATORIES

Lisandra Priscilla Hernández Morales[1], *Gemma María Moreno Jiménez*[2], *Ana Valles Carboneras*[2], *Ana Jiménez Martín*[2], *María Concepción Tenorio Núñez*[2], *Kyra Velázquez Kennedy*[2], *Alejandro Zurdo Castronuño*[2], *Jaime Fernández Eizaguirre*[3], *Víctor Andrés Salto Pineda*[3], *Pilar Herrera Puente*[2], *Francisco Javier López Jiménez*[2]
[1]*Instituto Ramón y Cajal de Investigación Sanitaria, Madrid, Spain,* [2]*Hospital Universitario Ramón y Cajal, Madrid, Spain,* [3]*Universidad Politécnica de Madrid, Madrid, Spain*

Background: Joint Accreditation Committee ISCT-Europe & EBMT (JACIE)-certified centers must report an increasing number of key performance indicators (KPIs) to meet accreditation and quality requirements. In many centers, these metrics are not consistently captured through standardized, workflow-integrated data entry and are instead recorded across multiple data sources, leading to duplicate documentation and manual data compilation for KPI reporting.

Methods: Accordingly, from October 2024 to July 2025, a process improvement project was conducted in the Hematology Service of Ramón y Cajal University Hospital, applying the Lean Six Sigma DMAIC (Define–Measure–Analyze–Improve–Control) framework. Workflows in the Apheresis Unit and the Cell Therapy Processing and Cryopreservation Laboratory were mapped and analyzed to characterize process steps, roles, handovers, information flows, and activity volumes. Based on this assessment, functional requirements were defined for the development of a digital platform within the hospital's institutional digital environment. The solution was designed to (i) align real-time capture of JACIE-required KPIs with operational workflows through standardized electronic forms and (ii) provide a unified workspace for planning and scheduling, structured data entry, and real-time operational monitoring, enabling end-to-end traceability of all procedures.

Results: The platform was deployed in August 2025, providing web and mobile access with real-time procedure status updates. It is embedded in routine practice with 22 direct and 15 indirect users, including physicians, nurses, and laboratory technicians. Since deployment, the platform has supported monthly planning and coordination of more than 100 procedures for more than 80 patients. Core functionalities include (i) a color-coded operational calendar displaying procedures by day, type, and status, enabling monitoring of occupancy rates and workload distribution; (ii) workflow-embedded standardized documentation to ensure end-to-end traceability; (iii) real-time capture of JACIE-required KPIs; (iv) an integrated calculator estimating donor blood volume for hematopoietic progenitor cell collections based on donor/recipient parameters and target cellular dose; and (v) automated, exportable reports providing audit-ready KPI summaries and real-time performance monitoring. The platform manages a broad procedure portfolio, including leukapheresis, lymphocytapheresis, extracorporeal photopheresis, and cellular therapy product infusions. Standardized data capture has generated a structured database supporting analyses of patient cohorts, procedural performance, and resource utilization, informing ongoing protocol optimization and evidence-based capacity planning.

Conclusions: Lean Six Sigma provides a robust framework to redesign complex clinical workflows and embed quality management into routine operations. In this project, DMAIC enabled integration of JACIE requirements into daily practice through a unified digital platform, strengthening traceability and improving process efficiency while reducing administrative burden and supporting greater clinical focus on patient care. Systematic, real-time KPI capture with audit-ready reporting enables continuous performance monitoring and data-driven decision-making. Beyond its local impact, this initiative demonstrates a scalable, cost-efficient approach that can be transferred to other centers seeking to standardize apheresis and cell therapy workflows within existing institutional digital environments, supporting digital transformation while maintaining alignment with international quality standards.

Disclosure: Nothing to declare.

P341

QM EXPERIENCE OF THE ROME TRANSPLANT NETWORK (RTN): OPTIMIZING AND HARMONIZING QUALITY, CONSISTENCY, AND DONOR–PATIENT SAFETY ACROSS A METROPOLITAN PROGRAM

Gabriella Peluso Cassese[1], *Antonio Bruno*[2], *Anna Chierichini*[3], *Cristiano Tesei*[2], *Maria Cristina Tirindelli*[4], *Michele Vacca*[4], *Donatella Pastorelli*[1], *Eleonora Ceresoli*[1], *Vincenzo Iacoianni*[5], *Maria Paola Bianchi*[6], *Maria Giovanna Cefalo*[7], *Tiziana Datturi*[7], *Eleonora Fiorelli*[2], *Vanessa Velotta*[7], *Elena Papa*[8], *Raffaella Cerretti*[2]
[1]*Azienda Ospedaliera San Giovanni Addolorata, Rome, Italy,* [2]*Tor Vergata University, Rome, Italy,* [3]*JACIE Committee, Barcelona, Spain,* [4]*Policlinico Campus Biomedico, Rome, Italy,* [5]*Iccmed, Milano, Italy,* [6]*Sant'Andrea Hospital, Rome, Italy,* [7]*Sant'Eugenio Hospital, Rome, Italy,* [8]*Istituto Regina Elena, Rome, Italy*

Background: Rome Transplant Network (RTN) is a JACIE accredited Metropolitan HSC Transplant Program established in Rome from 2006 as a cooperative alliance among 6 centers (Policlinico Tor Vergata, San Giovanni Addolorata, Isituto Regina Elena, Policlinico Campus Biomedico, S. Eugenio e S. Andrea Hospitals) for a total of 13 Clinical Units, Cell Collection and Cell Processing Facilities with the partnership of 2 further certificated ACF and PF (San Camillo Forlanini and Policlinico Umberto I Hospitals).The introduction of the new EUSoHO Regulation 2024/1938 and the alignment with JACIE standards highlighted the urgency of implementing harmonized procedures, interoperable traceability systems, and shared donor–patient safety strategies. Ensuring consistency of processes and documentation across multiple centers became essential to guarantee compliance, efficiency and equitable quality of care for donors and recipients. Goals are to implement and evaluate a structured, network-wide QP aimed at harmonizing critical pathways, improving regulatory and accreditation readiness, enhancing donor/patient protection, and establishing a sustainable, collaborative quality culture across a multi-center transplant program.

Methods: From January to October 2025, RTN performed seven inspections across transplant programs of the member hospitals. These assessments were performed by certified JACIE inspectors and qualified QMS assessors and were structured as full accreditation-style visits. This approach ensured rigorous evaluations and enabled the early identification of systemic gaps, risks, and areas requiring standardization.In addition, RTN organized tree multidisciplinary meetings—two on stem cell processing and one on clinical transplant pathways—structured as scientific conferences where each hospital presented its practices, challenges, and performance indicators. A third network-wide meeting, focused on apheresis, is scheduled for early 2026. These meetings were designed not only to share expertise but also to ensure uniform training and alignment of staff competencies and procedures across the network. Furthermore, three operational boards—clinical, apheresis, and processing—hold monthly remote meetings to discuss updates on regulatory requirements, process variations, CAPA and quality indicators. This continuous governance model enables real-time communication, problem solving, and progressive harmonization of workflows across the entire network.

Results: Cross-inspections identified recurrent issues such as variability in donor consent documentation, incomplete ISBT-128 implementation, partial harmonization of cryopreservation workflows, and heterogeneous QMS documentation. Following implementation of the RTN Quality Program, significant goals were achieved: alignment of SOPs and traceability procedures across facilities; adoption of a unified donor–patient pathway through the IAAPP platform; strengthened compliance with SoHO Articles on coding, traceability, and vigilance; improvement in the completeness and reliability of apheresis documentation; creation of a shared audit schedule and a quantitative competency matrix; reduction of inter-center variability in cryopreservation QC monitoring; standardization of vigilance and adverse event reporting through a common RTN form; enhanced communication and shared decision-making through remote board meetings.

Conclusions: The RTN QP strengthened harmonization, donor/patient safety, and regulatory compliance across a multi-center transplant network. By integrating accreditation-style inspections, structured multidisciplinary meetings, and continuous shared governance, the program established a sustainable framework for quality improvement. This model provides a scalable, replicable approach for a metropolitan networks aiming to achieve high levels of consistency, operational resilience, and readiness for SoHO implementation and JACIE certification.

Disclosure: Nothing to declare

P342

IMPROVING JACIE INSPECTOR EDUCATION WEBINAR ATTENDANCE THROUGH STRUCTURED PERFORMANCE IMPROVEMENT

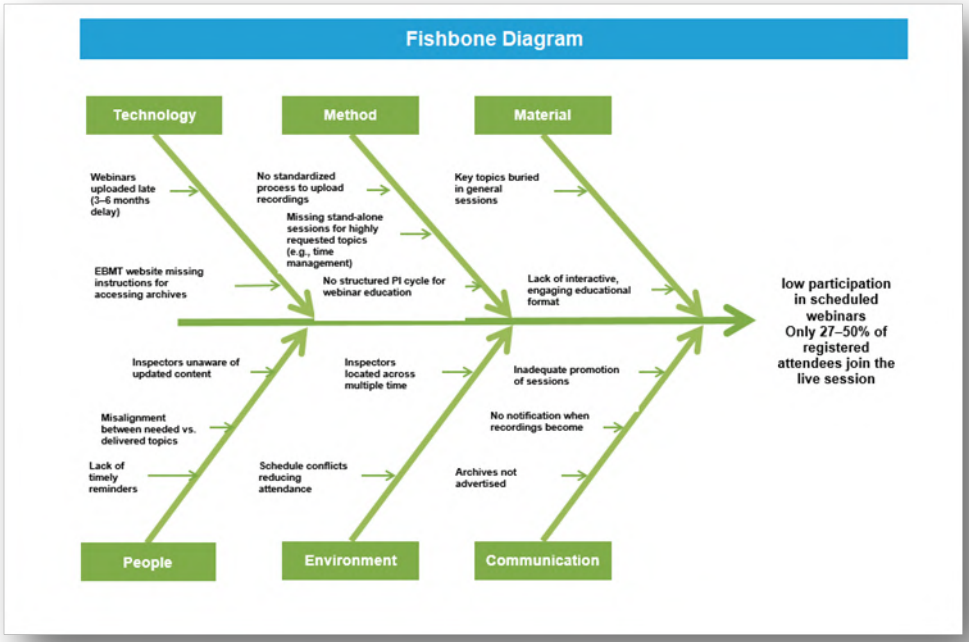
Stuart Kennedy[1]
[1]*John Radcliffe Hospital, Oxford, United Kingdom of Great Britain and Northern Ireland (the)*

Background: The JACIE Inspector Committee delivers 5–6 educational webinars per year to ensure inspectors remain updated, competent, and confident in conducting inspections. Despite having **348 active inspectors**, webinar attendance averaged **only 35 participants** per session (Jan 2024–May 2025).
Our aim - Increase inspector webinar participation by **at least 50%** and improve access/visibility of recorded sessions by implementing targeted PI interventions by Q2 2026.

Methods: The team used **three investigative streams:**

- Feedback – Analysis of post inspection surveys
- Archives – the content and accessibility of the current archives
- Awareness/ advertising – how we make our inspectors aware of the webinars and the archives

We applied **quality tools** to identify root causes and improvement opportunities. Evidence was retrieved from post-inspection surveys, website review, and webinar registration data.



FISHBONE (ISHIKAWA) DIAGRAM Problem: LOW WEBINAR ATTENDANCE - between 27-50% of those registered went on to attend the webinar

Technology

- Webinars uploaded late (3–6 months delay)
- EBMT website missing instructions for accessing archives

Methods:

- No standardized process to upload recordings
- Missing stand-alone sessions for highly requested topics (e.g., time management)
- No structured PI cycle for webinar education

Materials:

- Key topics buried in general sessions
- Lack of interactive, engaging educational format

People:

- Inspectors unaware of updated content
- Lack of timely reminders

- Misalignment between needed vs. delivered topics

Environment:

- Inspectors located across multiple time zones
- Schedule conflicts reducing attendance

Communication:

- Inadequate promotion of sessions
- No notification when recordings become available
- Archives not advertised

5 WHYS ANALYSIS - Problem: *Low attendance at JACIE inspector webinars.*

Why?
Because inspectors do not join live sessions.
➞ *Why?* They may not find the topics relevant or aligned with needs.

Why?
Because key requested topics—time management, labels, validation—were not highlighted or positioned as targeted sessions.
➞ *Why?* Time management had **not been delivered as a stand-alone webinar** despite being the most requested topic

Why?
Because inspectors who miss live sessions do not watch recordings.
➞ *Why?* Archived webinars were delayed by **3–6 months** before being uploaded, making them inaccessible

Why?
Because inspectors were unaware of where or how to access recordings.
➞ *Why?* The EBMT website did not provide clear instructions on accessing the e-learning recordings.

Why?
Because communication and advertising strategies were insufficient.
➞ *Why?* Registered attendees were not notified when recordings became available, and archives not promoted.

Results:

1. **Scheduled a Time Management webinar**—addressing the No.1 inspector request.
2. **Added a clear paragraph to the EBMT website** explaining how to access recordings.
3. **Revamped consent/approval process** to accelerate uploading webinars.

4. **Communicated that all webinars will be uploaded**—reducing pressure to attend live.
5. **Notified registrants when recordings become available.**
6. **Promoted archive improvements** and initiated **EBMT 2026 abstract submission** to increase visibility.

Results (Early Impact) - Although early in the PI cycle, the interventions are expected to deliver:

- Increased attendance through better topic alignment.
- Faster access to recordings (reduced upload delays).
- Improved inspector satisfaction/preparedness.
- Higher engagement through clearer communication and promotion.

Conclusions: **Next Steps:**

- **Monitor attendance trends quarterly**
- **Automate reminders & follow-up emails**
- **Develop KPI dashboard:**

  - Attendance %
  - Recording access rate
  - Timeliness of uploads
  - Post-webinar satisfaction

Disclosure: Nothing to declare

P343

THROUGH THE EYES OF A QUALITY MANAGER: MANAGING THE REGULATORY AND INSPECTION BURDEN OF MULTIPLE INSPECTIONS IN A STEM CELL TRANSPLANT CENTER

Halima Begum[1], *Samah Ali*[1], *Kellsey Richardson*[1], *Amit Trikam*[1]
[1]*Imperial College Healthcare NHS Trust, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: The Clinical Haematology service at Imperial College Healthcare NHS Trust (ICHT) in London, UK boasts a large stem cell transplant (SCT) centre, undertaking 207 autologous and allogeneic transplants in financial year 2023-24 and 191 in 2024-25.
The centre offers treatment with cellular therapies including stem cell and other advanced therapeutic medicinal products (ATMPs) such immune effector cells and gene-modified therapies.
SCTs such as ICHT operate within a highly regulated environment and are routinely subject to multiple inspections, sometimes concurrently, from national and international bodies such as JACIE, HTA, MHRA in addition to mandatory external audits by cell therapy manufacturing

companies as well as internal audits.
Maintenance of certification and monitoring of compliance requires an intensive, rolling quality management programme to ensure organisational adherence against all inspection standards. Some bodies have in excess of 200 standards (JACIE has >900 standards). While these inspections aim to ensure patient safety and compliance, they often create significant operational challenges, including duplication of effort, resource strain, and staff fatigue. Quality managers play a pivotal role in coordinating these processes in applying practical strategies to ensure a comprehensive inspection experience.

Methods: Adopting a qualitative approach, drawing on the experience of a Quality Manager in a large UK stem cell transplant center over a three-year period to assess effective ways of mitigating the burden and coordination of multiple inspections. Data sources during the preparation period included:

- Inspection schedules, and reports from JACIE, HTA, external and internal audits.
- Process mapping and gap analysis identifying areas of risk requiring corrective action as well as highlighting regulatory requirements through utilising matrices and trackers (via Excel).
- Comprehensive communication mechanisms to ensure staff are fully onboarded including inspection preparation material such as staff FAQs and interview practice.

Staff feedback collected through structured interviews and post-inspection debriefs. A thematic framework was applied to categorise strategies that improved efficiency and reduced burden.

Results: Between 2022 and 2025, the center underwent seven major inspections and audits. Inspection preparation time ranged from 8-12weeks based on the nature of the review and inspections notification lead-time. Key findings include:

- Duplication of documentation contributed to preparation workload increase.
- Staff stress and fatigue was affected during consecutive inspections. However, staff felt well supported by inspection readiness material and clear communications particularly when the inspectors provided clear instructions.
- Implementation of a centralised compliance matrix streamlined tasks and reduced workload duplication.
- Inspection compliance and readiness dashboard improved preparedness and reduced last-minute corrective actions.
- Having a reliable document control system which can also act as a key organisation tool through its function as a central evidence depository.

Conclusions: Managing multiple inspections in a SCT requires a proactive, integrated approach. While the burden of inspection can pose a risk to SCTs, implementing strategies such as centralised documentation systems, effective team communication mechanisms, and continuous readiness monitoring helped to reduce regulatory burden and improve staff well-being. Quality managers are uniquely positioned to lead this transformation, ensuring compliance without compromising patient care. Future work should explore digital solutions and collaborative models across centers to further streamline inspection processes.

Disclosure: N/A

P344

ATMP MANUFACTURING INSIDE A JACIE-ACCREDITED FACILITY: MISSION IMPOSSIBLE OR THE NEW STANDARD?

Peter Sahlström[1,2], *Rebecca Axelsson Robertson*[1,2], *Tina Thorberg*[1], *Pablo Giusti*[1], *Lyda M. Osorio*[1], *Teng Wang*[1,2], *Michael Uhlin*[1,2]
[1]*Karolinska University Hospital, Stockholm, Sweden,* [2]*Karolinska Institute, Stockholm, Sweden*

Background: Many academic centres build separate GMP facilities for ATMP manufacturing. At the stem cell laboratory, Karolinska University hospital, we successfully overlaid GMP manufacturing onto the existing JACIE-accredited cell processing laboratory within the same grade C cleanroom suite.

Methods: To highlight differences between GMP manufacturing and JACIE processing, a comparison was made between the procedure for GMP manufacturing of virus-specific T cells (VSTs) and the JACIE-accredited minimal manipulation method for depletion of TCRα/β+ and CD19+ cells.
All cell therapies were prepared in closed systems in a grade C cleanroom with allogenic leukapheresis products as starting material. VSTs were GMP manufactured on the fully automated CliniMACS Prodigy system by virus-specific peptide stimulation followed by antibody-based identification of IFN-γ-secreting cells that were enriched using magnetic bead separation. Depletion of TCRα/β+ and CD19+ cells was conducted by manual antibody labelling and washing of cells followed by magnetic separation on the CliniMACS plus automated system.
GMP manufacturing at the JACIE-accredited facility was achieved by using risk evaluated segregation, extensive GMP batch documentation, validation, enhanced environmental monitoring, and aseptic processing in a single quality management system.

Results: Authorization for GMP manufacturing under the hospital exemption was achieved during autumn 2024. Since then, ATMP batches have been successfully manufactured alongside uninterrupted JACIE cellular processing.

	JACIE	**GMP**
Product	Depletion of TCRα/β+ and CD19+ cells	Virus-specific T cells
Regulatory framework	8th JACIE edition Swedish legislations	EudraLex vol 4 part IV HSLF-FS 2025:1*
Manufactured batches**	11	4

Simultaneous cleanroom activities	Routine in one cleanroom entity	Routine in separate cleanroom entities
Total controlled documents	~7	~36
Documentation system	JACIE SOPs	GMP SOPs and batch records
Production time	12 h	30 h
Number of staff needed	3	7
Staff roles	Combined	Defined for production, QC and QA
Product release by	Clinician	QP
Aseptic process simulation	Not applicable	Process validation and operator validation
Environmental monitoring during production	Air pressure (particle counting and microbial monitoring performed routinely)	Air pressure Continuous particle counting Settle plates Contact plates Glove sampling
Cleanroom	C grade	C grade
Cleanroom classification	Annual external classification Internal environmental monitoring	Annual external classification Internal environmental monitoring
Release assays	TNC Total T cells TCRα/β+ cells B cells Stem cells Viability Viral testing Biosafety testing	TNC Total T cells IFN-γ+ T cells Viability Viral testing Biosafety testing Environmental monitoring
Biosafety testing	Validated clinical sterility	Sterility EP 2.6.1 Endotoxin EP 2.6.14 Mycoplasma EP 2.6.7

*Swedish medicinal product agency authorization for hospital exemption.
**Between October 2024 and November 2025.

Conclusions: JACIE standards set the foundation for manufacturing by establishing robust quality systems, cleanroom operations, and clinical processing expertise in transplant centres. Overlaying EU GMP ATMP manufacturing onto an established JACIE-accredited laboratory is complex but achievable. The approach is safe, enables GMP quality, preserves clinical context, and accelerates patient access to advanced cellular therapies. With the 9th edition JACIE standards and EU GMP guidelines increasingly aligned, this integrated model is enabling a pragmatic standard for hospital transplant centres delivering both hematopoietic grafts and innovative ATMP cell therapies.

Disclosure: Nothing to declare.

P345

JOINT INSPECTIONS FOR INSTITUTIONAL AND JACIE CERTIFICATIONS: THE ITALIAN EXPERIENCE

*Roberta De Blasi[1], **Benedetta Mazzanti**[1], Letizia Lombardini[1], Aurora Vassanelli[1], Elisa Faraci[1], Ursula La Rocca[2], Luciana Teofili[2], Raquel Espada[3], Lynn Manson[4], Charles Crawley[5], Tuula Rintala[3], Giuseppe Feltrin[1]*
[1]Italian National Transplant Centre, Rome, Italy, [2]Italian National Blood Centre, Rome, Italy, [3]JACIE Office, Barcelona, Spain, [4]Royal Infirmary of Edinburgh, Edinburgh, United Kingdom of Great Britain and Northern Ireland (the), [5]Addenbrookes Hospital, Cambridge, United Kingdom, Cambridge, United Kingdom of Great Britain and Northern Ireland (the)

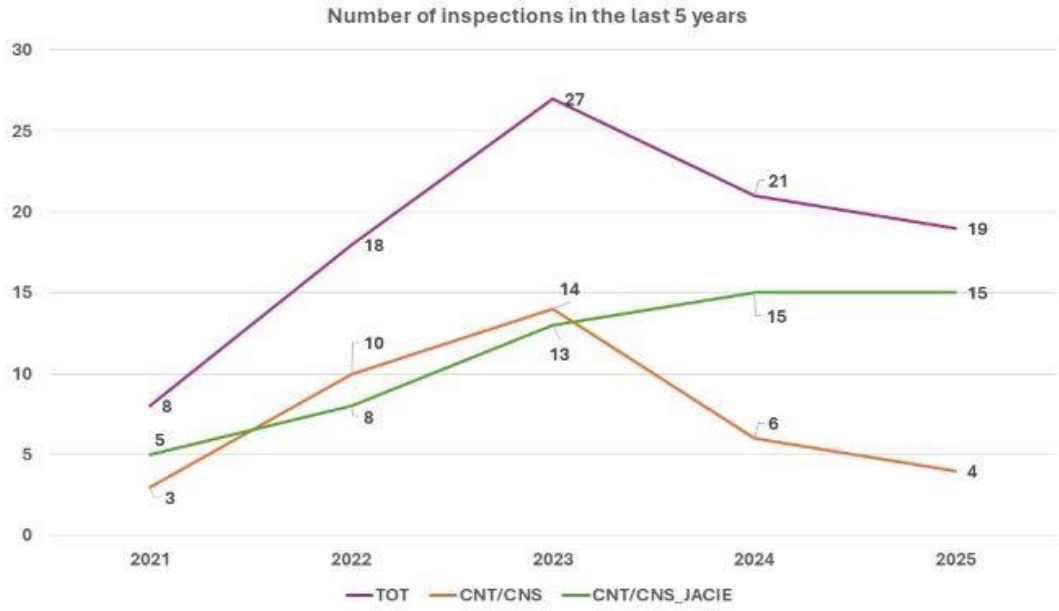
Background: Since 2007, the National Transplant Centre (CNT), in collaboration with the National Blood Centre (CNS), has conducted inspection activities aimed to monitoring italian Transplant Programs (TPs) compliance with national regulations laid down by European directives on tissue and cells (D. Lgs. 191/2007, D. Lgs. 16/2010) and blood (D.M. 2/11/2015).
In parallel, from 2004, the Joint Accreditation Committee–ISCT–EBMT (JACIE) operates as a voluntary professional certification, designed to evaluate the quality of clinical, collection, and processing procedures for hematopoietic stem cell transplantation (HSCT). Over the years, the Italian Competent Authorities (CNT/CNS) and JACIE have collaborated in order to avoid multiple inspections for the TPs.
Following an introduction of a new Italian regulation (ASR No. 49/2021) this collaboration has intensified with the aim of optimising resources and carrying out joint inspections.

Methods: The Italian model integrates two parallel and complementary inspection pathways:

- Institutional inspection by CNT/CNS, based on mandatory requirements derived from European Directives and national Legislative decrees.
- JACIE inspection, focused on professional excellence standards and on the quality management of clinical, collection, and processing units.

Joint inspections involve an inspection team with dual qualification, assessing compliance both with national regulatory requirements and with JACIE standards.

Results: Between 2021 and 2025 the CNT/CNS and JACIE performed joint inspection in 56 full program HSC autologous, allogeneic, adult and paediatric centres in Italy (18% with more than 2 Clinical, Collection or Processing Units, sometimes placed in different Hospitals), involving 211 inspectors.
From 2023, the joined inspections incresead from 50% to 79% in 2025, demonstrating an alignment among institutional inspection and JACIE accreditation programme (fig. 1).



The alignement comes from a strict collaboration between inspection coordinators CNT and JACIE, involved in the organization, that includes:

- Scheduling joint inspections over the year;
- First contact by CNT to propose to the TP a date for inspection;
- First contact by CNT with CNT/Jacie inspectors to define the composition of the inspection team;
- Confirmation by the JACIE office that the TP meets the JACIE requirements for the inspection;
- Organisation of the logistics by CNT and JACIE e.g. number of inspectors, and inspection duration and the inspection schedule;
- Completion of the inspection;
- Completion of reports and outcomes as per institutional procedures.

In addition, in 2025a JACIE Inspector training course was carried out in Italy with the aim to increase the number of inspectors with double qualification. This goal was achieved and to date the 90% (70/78) of the italian CNT/CNS inspectors are also JACIE inspectors.

Conclusions: The Italian experience shows that joint CNT/CNS–JACIE inspections represent an effective model for resource optimisation reducing redundancies. This is useful for a future unified inspection program aimed at mutual recognition between institutional certification and JACIE certification.
This model could be replicable, particularly in view of the application of REGULATION (EU) 2024/1938, which promotes cooperation among Member States, ensuring quality, safety, and consistency in HSCT pathways. The harmonisation of inspection criteria, the independence of assessors, and the potential integration of international standards into institutional requirements are key elements of an increasingly synergistic certification system.

Disclosure: Nothing to declare.

P346

A PATIENT-CENTERED, END-TO-END DIGITAL PLATFORM FOR HSCT AND CAR T-CELL THERAPY: A PROCESS-ENGINEERING APPROACH

Lisandra Priscilla Hernández Morales[1], *Pilar Herrera Puente*[2], *Alejandro Luna de Abia*[2], *Adrián Sánchez-Tornero*[2], *Anabelle Chinea Rodríguez*[2], *Gemma María Moreno Jiménez*[2], *Francisco Javier López Jiménez*[2]
[1]*Instituto Ramón y Cajal de Investigación Sanitaria, Madrid, Spain,* [2]*Hospital Universitario Ramón y Cajal, Madrid, Spain*

Background: Hematopoietic stem cell transplantation (HSCT) and CAR T-cell therapy pathways are complex, multi-step processes requiring coordination across multiple teams, information systems, and decision points. In many centers, transplant and cell therapy committee coordination, procedural planning, longitudinal patient follow-up, and the capture of clinical and quality indicators are still managed through fragmented tools and manual workflows, limiting standardized end-to-end traceability of the patient journey. In addition, currently available commercial solutions are largely product-centered, focusing on cellular product traceability from collection to infusion, and often fail to provide a patient-centered, end-to-end view of HSCT and CAR T-cell therapy pathways.

Methods: At Ramón y Cajal University Hospital, more than 120 HSCT and CAR T-cell therapy procedures are performed annually, while a larger number of patients are evaluated without completing all phases of the pathway. To address this operational complexity, a process and software development project was undertaken using an agile Scrum methodology. A multidisciplinary team, including a process engineer, (i) mapped the as-is HSCT and CAR T-cell therapy patient journey, (ii) conducted gemba walks in clinical and laboratory areas to directly observe workflows, handovers, and information flows, and (iii) performed patient-pathway simulations to test typical and exceptional scenarios and to derive and prioritize functional requirements.

Results: Guided by these analysis, a modular web-based prototype platform was developed within the hospital's institutional digital environment, providing a patient-centered view of the HSCT and CAR T-cell therapy pathway. The platform comprises five main modules: (i)

transplant and cell therapy committee request and assessment, (ii) HSCT management, (iii) CAR T-cell therapy management, (iv) related donor evaluation, and (v) unrelated donor search management. Through a single real-time interface, users access an end-to-end record of each case, including patient and donor status within the circuit, planned and pending activities, and the responsible areas at each step, as well as information on pre-transplant planning, cell collection and cryopreservation, admission to the transplant unit, infusion, post-transplant follow-up, comorbidity scores, and associated clinical documentation. In addition, a shared status dashboard, task lists, and automated alerts support coordination and workflow management for the transplant and cell therapy committee. The data model incorporates fields for key clinical variables and quality indicators aligned with JACIE standards, enabling consistent data capture across HSCT and CAR T-cell cases and facilitating the generation of quality reports.

Conclusions:

This process-engineering–driven platform unifies patient-centered coordination, clinical documentation, and quality-indicator capture within a single end-to-end system. Its implementation at Ramón y Cajal University Hospital has demonstrated feasibility for centralizing patient data, improving traceability, and generating a homogeneous dataset that underpins a high-value clinical repository for quality monitoring, research, outcome analysis, and evaluation of therapeutic strategies. This scalable approach may serve as a model for other centers seeking integrated pathway management solutions in complex cell therapy programs.

Disclosure: Nothing to declare.

P347

SMART, SIMPLE, STREAMLINED: USING MS FORMS TO IMPROVE COMPETENCY MONITORING IN A BUSY BMT UNIT

Samah Ali[1], *Amit Trikam*[1], *Kellsey Richardson*[1]
[1]*Imperial College NHS Trust, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: As a large bone marrow transplant (BMT) unit, up-to-date staff clinical competencies is essential to adhere with regulatory compliance (such as the JACIE standards, section B in particular) and patient safety. Assessments historically relied heavily on a paper-based system where competencies were handed out and completed by hand. These were then marked manually by the assessors who also had the task of tracking the competencies across several departments and staffing levels. Email reminders were often sent, paper forms would go missing and the assessor would have to start the cycle again. This was time consuming and inefficient.
To address this, the quality team decided on Microsoft (MS) Forms as they provided a streamlined simple process and would reduce the administrative burden. It's a platform accessible by all. Following Covid the Trust encouraged a 'paper-light' approach to documentation, therefore this approach met the goal.

Methods: The process to switch to MS forms for competency distribution and assessment was done over 2 phases. Phase 1 was the planning phase. The quality team had focus meetings to discuss processes and workload. This followed by converting all competency assessments into MS forms and automating the marking scheme.
Phase 2 was the implementation phase. Initially this was trialled out by the quality team to ensure that all the fields and options were functioning well and that the marking scheme was consistent. Once happy, this was rolled out to all clinical staff when they were due to complete a competency assessment. Support was always made available from the quality team.

Results: The switch from paper competency assessment forms to MS forms has proved to be very successful. Staff reported that they have found it much easier completing the assessments online and therefore not worrying about misplacing the form or finding time to bring it to the quality team.
Assessors reported a more streamline process, less administrative work, faster results as they were now marked electronically as well as a better storage capability as the results were automatically stored with the option to have them available via an excel sheet for overall reviewing and data collecting.

Conclusions: The decision to adopt MS forms for competency assessments in our BMT unit proved to be very beneficial for both staff and assessors. It has enhanced the efficiency, speed and reliability of the process. The changeover addressed many of the previous challenges such as the manual collection, marking and document loss. It provided a centralised location for the forms to be sent out as well as be stored and monitored easily. The project demonstrated that the change to an online platform for clinical competency assessments and monitoring improved the process for the assessor and staff completing them. As the team grows and as the speciality expands an online solution is the best way forward as long as its user friendly, adaptive and staff support is always available.

Disclosure: Nothing to declare

P348

IMPLEMENTING JACIE QUALITY STANDARDS IN PEDIATRIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE MANDATORY AUDIT OF EARLY OUTCOMES

Donya Qattan[1], *Mohammed Viqaruddin*[2], *Alay Shuaib*[2], *Saadiya Khan*[2], *Waleed Rasheed*[2]
[1]*King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia,* [2]*King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia*

Background: The Joint Accreditation Committee ISCT-Europe & EBMT (JACIE) accreditation framework represents the international benchmark for quality, safety, and outcome-driven practice in hematopoietic stem cell transplantation (HSCT) and cellular therapy programs. Paediatric HSCT Centres face distinct challenges due to the complexity of indications, high-risk patient profiles, and the need for robust multidisciplinary coordination. The Paediatric

Stem Cell Transplantation Program at King Faisal Specialist Hospital and Research Centre (KFSH&RC), Riyadh, Saudi Arabia, established a structured, outcomes-based clinical audit program as part of its JACIE accreditation and continuous quality improvement strategy. This audit focused on key early post-transplant indicators, that includes engraftment outcomes, to assess clinical performance and compliance with JACIE quality management standards.

Methods: A retrospective clinical audit was conducted to evaluate engraftment outcomes among all pediatric patients who underwent hematopoietic stem cell transplantation HSCT at the study center between 1STJan 2021 and 31ST Dec 2024. Eligible cases were identified through Data Unit of the center. Audit indicators were selected in alignment with Joint Accreditation Committee ISCT-EBMT (JACIE) quality management standards and the institution's key performance indicators to ensure consistency with internationally accepted benchmarks. The primary outcome of interest was engraftment performance. Neutrophil engraftment was defined as the first of three consecutive days with an absolute neutrophil count (ANC) ≥0.5 ×10^9/L. Platelet engraftment was defined as achieving a platelet count ≥20 ×10^9/L sustained for at least seven consecutive days in the absence of platelet transfusion support. Secondary outcome measures included the time to neutrophil and platelet engraftment, calculated from the date of stem cell infusion (day 0) to the date on which engraftment criteria were first met. Data were analyzed descriptively to assess engraftment patterns and performance over the audit period.

Results: Between 2021 and 2024 audit cycle, a total of 589 pediatric allogeneic and autologous hematopoietic stem cell transplants were performed, of which 578 cases were analyzable respectively for engraftment. Patients who died before day +28 post-transplant were excluded from engraftment analysis. During 2021,137 transplants were performed, with 134 analyzable cases; neutrophil and platelet engraftment were achieved in 98% of these patients, with a (median time to neutrophil engraftment of 18,19,20 days and platelet engraftment of 20, 21, 22 days. In 2022, 145 transplants were conducted, 143 were analyzable, and 95% reached successful engraftment (median neutrophil 18,19,20 days; platelet 21, 22, 23 days. In 2023, 151 transplants were performed with 148 analyzable cases, among which 96% achieved engraftment (median neutrophil 19, 20, 21 days; platelet 22, 23, 24 days. Finally, in 2024, 156 transplants were carried out, 153 were analyzable, and 97% achieved (median neutrophil 19, 20, 21 days; platelet 22, 23, 24 days.

Conclusions: This JACIE-aligned clinical audit of the Pediatric Stem Cell Transplantation program demonstrates that annual monitoring of engraftment outcomes through existing governance and CAPA processes enhances accreditation readiness, transparency, and ongoing quality improvement. The findings underscore the value of continuous, outcomes-driven audits in maintaining JACIE compliance and ensuring safe, high-quality transplant care.

Disclosure: Nothing to declare.

P349

IMPLEMENTING A MULTI-LEVEL DASHBOARD TO IMPROVE QUALITY, TRACEABILITY AND COMPLIANCE IN CELLULAR THERAPY PROCESSES: A BLOOD BANK'S EXPERIENCE

*Vittoria Amateis[1], **Valentino Granero**[1,2], Emanuela Gambetta[1], Cristiana Francone[1], Rebecca Ghione[1], Luisa Giaccone[1], Tiziana Francisci[1], Alessandro Busca[1]*
[1]A.O.U. Città della Salute e della Scienza, Turin, Italy, [2]ASL TO3, Collegno and Pinerolo, Italy

Background: Structured, comprehensive, and timely data management is a fundamental requirement for ensuring quality, traceability, and regulatory compliance within Tissue Establishments (TE).
To meet this need, a "*Cruscotto*" was developed—based on Project Management principles and aligned with JACIE and CNT Standards—using Microsoft Excel as an operational database designed to collect, organize, and analyse in real time all information related to cellular manipulations performed in our TE.
The tool supports both daily operational activities and serves as a reference platform during audits and inspections.
This dashboard is structured across three interconnected decision-making levels, each oriented toward specific objectives:

- Strategic Level (Leadership): aimed at assessing long-term sustainability and the competitive position of the service. The "*Cruscotto*" enables monitoring of the aggregated non-conformity rate, analysis of key performance indicators, audit success rates, and satisfaction metrics from affiliated Centers. These elements reinforce decision-making related to service expansion, resource allocation for innovation, and the maintenance of high regulatory standards.
- Tactical Level (Management and Analysis): supports operational efficiency and medium-term risk management. The system integrates analysis of process times, deviations from activity-related KPIs, distribution of root causes of non-conformities, and monitoring of critical stock levels. This allows managers to identify workflow bottlenecks, adjust personnel training investments, and implement targeted corrective actions to prevent operational issues.
- Operational Level (Daily Execution): ensures real-time verification of manipulation activities and correct application of procedures, guaranteeing immediate traceability and prompt intervention in the event of critical deviations.

Methods: Structurally, the "*Cruscotto*" includes dedicated worksheets for the main procedure categories (HPC-AUTO, HPC-ALLO, HPC-M, CAR-T, Extracorporeal Photopheresis), each designed to collect more than 40 clinical and technical variables: donor/patient data, collection parameters, quantitative outputs (CD34+, viability, WBC count), manipulation details, adverse events, and process-specific quality indicators. This organization ensures both daily operational oversight and the creation of a consistent, longitudinal database suitable for retrospective analysis and performance comparisons over time.

Results: Between 01/01/2025 and 30/11/2025, a total of 671 procedures were recorded (see Table 1), resulting in a significant improvement in data completeness and enhanced

ability to monitor collection and manipulation efficiency, operator performance, and procedural outcomes.

Jan-Nov 2025	HPC-AUTO	HPC-ALLO family	HPC-ALLO registry	CAR-T	ECP	HPC-Marrow family	HPC-Marrow Registry
number of procedures	93	31	48	29	464	2	4

Conclusions: The implementation of the "Cruscotto" proved fully compliant with regulatory and excellence standards, improving traceability, documentation consistency, data verification speed, and continuous monitoring of activities. Its flexibility allows ongoing updates, integration of new indicators, automated calculations, and graphical summaries. Moreover, it has become a central tool in preparing documentation for audits and inspections, as well as in generating quarterly reports.
In conclusion, the "Cruscotto" is not merely a data aggregator, but a transformative tool that ensures Tissue Establishments operate with maximum safety, efficiency, and full regulatory compliance.

Disclosure: None

P350

JACIE QUALITY COORDINATION IN A ADULT/PEDIATRIC HEMATOPOIETIC STEM CELL TRANSPLANTATION AND CELL THERAPY PROGRAM

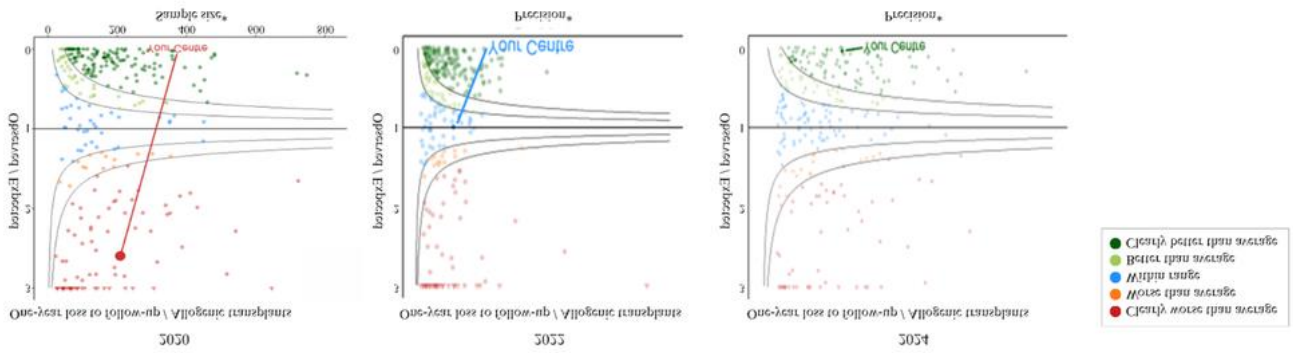
Iván López-Torija[1], *Lourdes Petriz González*[1], *José Manuel Portos Villar*[1], *Manuel Suero Haldón*[1], *Rodrigo Martino Bofarull*[1], *Javier Briones Meijide*[1]
[1]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

Background: The Joint Accreditation Committee ISCT/EBMT (JACIE) ensures that Hematopoietic Stem Cell Transplantation and Cell Therapy (HSCT-CT) programs meet established quality standards and best clinical practices. Its accreditation provides academic, professional, and managerial recognition for HSCT-CT units.
The objectives of this work are to present the experience and evolution of quality coordination toward achieving JACIE accreditation, to improve the quality management of the HSCT-CTP through the involvement of institutional leadership, and to obtain and maintain JACIE accreditation.

Methods: Compliance with JACIE standards: Hematopoietic Cellular Therapy – Accreditation Manual. Two key roles were identified: the Quality Manager (QM) and the Data Manager (DM). The QM is responsible for establishing and maintaining systems for reviewing, modifying, and approving quality policies and operational procedures aimed at monitoring and ensuring compliance with program standards. The QM must also receive ongoing training

in both cell therapy and quality management.
The DM must have sufficient staffing to collect the required data for the specific forms of the EBMT (European Society for Blood and Marrow Transplantation) international registry, as well as participate in annual specialized training.
Changes in the performance of the QM role between 2012 and 2022 were analyzed: from a position initially requiring a hematology specialist, or other (medical or non-medical) disciplines, and currently being held by nursing staff. The position evolved from part-time to full-time, merging the QM and DM roles into a single individual.

Results: As of 2025, all re-accreditations of the adult program have been maintained, CAR-T accreditation (HSCT-CT) has been achieved, the pediatric HSCT program has been accredited, and accreditation of bone marrow harvesting is ongoing.
A full update of all treated patient records has been completed in the EBMT registry. The centre's standing in the EBMT Benchmarking Report has improved substantially, rising from markedly below the average to clearly above it. (Figure1).



In addition, the progressive implementation of quality standards has permeated the entire clinical programme, strengthening multidisciplinary engagement and fostering a shared culture of continuous improvement. This has been translated into greater team confidence and reassurance, enhanced institutional positioning, strengthened document control, comprehensive and timely registry completion, systematic outcome monitoring, and sustained compliance with administrative authorisations. These gains have been accompanied by challenges, including the need for substantial investment in personnel, ongoing training, and potentially the acquisition of a dedicated document management system.

Conclusions: Achieving JACIE accreditation is not only essential to ensure high-quality care but also to avoid being at a disadvantage or risk the loss of administrative authorization to continue the HSCT-CT program.
Moreover, the combined QM–DM role has proven to be a cornerstone of the program, ensuring consistency, traceability, and integration between clinical practice quality, and data management activities. This hybrid figure has become essential for sustaining accreditation and continuous improvement.

Disclosure: No disclosure.

P351

DEVELOPING EXCELLENCE: HOW A STRATEGIC QUALITY FRAMEWORK LAUNCHED A CUTTING-EDGE CELL COLLECTION CENTRE

Hirasine Sengomona[1], *Dawn Hart*[1], *Salmah Ahmed*[1]
[1]*Anthony Nolan, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: The safe establishment of the Anthony Nolan Cell Collection Centre (CCC) required a coordinated and innovative quality framework aligned with regulatory approval (Human Tissue Authority and Care Quality Commission) and development towards JACIE accreditation.

Methods: A phased validation strategy was implemented to commission the CCC, initially focusing on Donor Lymphocyte Collections (DLCs) to prioritise donor safety. Validation was conducted across the three core processes the CCC had to implement;

1. medical assessment and clearance,
2. DLC procedures and laboratory processes, and
3. Peripheral Blood Stem Cell (PBSC) collections.

Regulatory compliance with the Human Tissue Authority (HTA) and Care Quality Commission (CQC) formed the foundation of the quality management system (QMS). Equipment underwent installation, operational and performance qualifications (IQ/OQ/PQ). Staff training required development of a competency-based framework supported by an electronic QMS. Deviations, incidents, audits, supplier qualification, and risk management were managed under established QMS governance.

Results: 42 medical assessments from volunteer donors, 26 DLCs, and 3 PBSC collections were completed for the validation of the CCC processes, which started in March 2025. To minimise donor burden throughout validation, all DLCs were conducted as reduced collections. All critical clinical and laboratory equipment, including Spectra Optia, Sysmex XN-550, BD FACS Lyric, and BD BACTEC FX®, were successfully validated during this process. Core clinical and laboratory staffing achieved full operational competency enabling the CCC to 'go live.' Donor feedback demonstrated high satisfaction with staff professionalism and environment, directly informing service improvements. The CCC was granted a HTA satellite licence for procurement and testing following a planned site visit in February 2025. CQC registration was also achieved on target. A few low-risk outstanding actions (e.g., PBSC G-CSF cold-chain validation and formal CVC service agreement) were mitigated and did not prevent operational 'go live'. The centre opened safely for both DLC and PBSC collections for allogeneic donors in July 2025.

Conclusions: A structured, phased quality management approach enabled the safe, compliant and timely opening of the new CCC while maintaining donor safety as Anthony Nolan's primary focus. Key lessons learned included the need to build in sufficient time for developing high-quality documentation, SOPs, training material and ensuring adequate time

to test these in the unique clinical and laboratory environment. This early investment in robust documentation and process testing was critical to a successful operational launch. Our audit programme and continuous improvement strategy now refine these processes further, supporting the delivery of a consistently safe donor experience and high-quality cell products for patients. This approach positions the CCC to progress effectively toward JACIE accreditation and provides a replicable model for establishing new cell collection services within a resilient and quality-driven framework.

Disclosure: Nothing to declare.

P352

VALIDATION OF EXTRACORPOREAL PHOTOPHERESIS USING THE THERAKOS™ CELLEX™ PHOTOPHERESIS SYSTEM: A MULTICENTER EUROPEAN PROJECT

Katharina Kronenberg[1], Nina Worel[2], Angelo Ostuni[3], Wolfgang Mayer[4], Anita Schmitt[5], Barbara Loconte[6], Mauro Baglioni[6], Vincenzo Iaconianni[7], James Hutchinson[1], ***Federica Zunino***[8]
[1]Universitätsklinikum Regensburg, Regensburg, Germany, [2]Medical University Vienna, Vienna, Austria, [3]Policlinico di Bari, Bari, Italy, [4]Tirol Kliniken, Innsbruck, Austria, [5]Universitätsklinikum Heidelberg, Heidelberg, Germany, [6]Ente Ospedaliero Cantonale (EOC), Bellinzona, Switzerland, [7]ICMED, Milan, Italy, [8]Therakos UK (Ltd), Staines upon Thames, United Kingdom of Great Britain and Northern Ireland (the)

Background: Extracorporeal photopheresis (ECP) is a well-established therapeutic option for cutaneous T cell lymphoma (CTCL), acute and chronic graft-versus-host disease (GvHD) and solid organ transplant rejection. ECP is an apheretic procedure that involves collecting peripheral blood leukocytes, inducing apoptosis using 8-methoxypsoralen (8-MOP) and UVA irradiation, and then returning the treated cell mixture to the patient by intravenous infusion. The growing need to ensure uniform quality standards across ECP programs underscores the importance of having a validated and reproducible process to support accreditation pathways. This study aimed to develop and evaluate a standardized validation protocol for care providers intending to validate ECP procedures performed using the THERAKOS™ CELLEX™ instrument.

Methods: This multicenter project was conducted across 6 centers in 4 European countries. An expert panel developed a comprehensive Validation Masterplan consistent with GMP and FACT–JACIE requirements, defining standardized procedures for sample collection, shipment, and laboratory testing. A total of 43 paired untreated (pre-ECP) and 8-MOP/UVA-treated (post-ECP) apheresate samples were collected using the THERAKOS™ CELLEX™ Photopheresis System. 37 patients with varying clinical indications (GvHD, systemic sclerosis, localized scleroderma or lung transplant rejection) provided samples that were shipped overnight (<24 h) to a central laboratory for harmonized analysis. Automated hematology counts and flow cytometry (Annexin-V/7-AAD staining) were used to assess product composition and apoptosis rates in $CD45^+$ leukocytes, $CD3^+$ T cells, $CD33^+$ myeloid cells, and

CD14⁺ monocytes at 0 h and 22 h. Data were evaluated with repeated-measures ANOVA, paired t-test or correlation analyses.

Results: The expert panel defined and approved the Validation Masterplan, establishing robust protocols for sample shipping and centralized analysis of photopheresates. Samples analysed upon arrival showed that early apoptotic CD3⁺ T cells predominated on day 1 (12.81±5.09 % vs. 2.35±1.95 %; p<0.0001; n=43; Fig. 1A), while late apoptotic T cells increased over 22 h culture (47.41±13.38 % vs. 12.81±5.09 %; p<0.0001; n=43; Fig. 1B). Post-ECP samples showed significantly reduced viability in CD45⁺ leukocytes (7.33±5.25 % vs. 34.84±18.06 %; p<0.0001; n=43) and CD3⁺ T cells (6.77±7.33 % vs. 57.51±27.28 %; p<0.0001; n=43) after culture for 22 h compared to pre-ECP samples. After 22 h culture, the frequency of late apoptotic T cells was significantly higher in post-ECP samples across all centers (47.41±13.38 % vs. 15.67±13.74 %; p<0.0001; n=43). Apoptosis induction in myeloid cells after 22 h culture was less consistent (viability pre-ECP: 11.55±11.84 %; viability post-ECP: 6.96±8.04 %; p=0.0039; n=43). Assay reproducibility was confirmed by strong correlation (R^2 = 0.94) between repeated samples. Variability in viability rates

appeared patient-specific rather than assay-related.

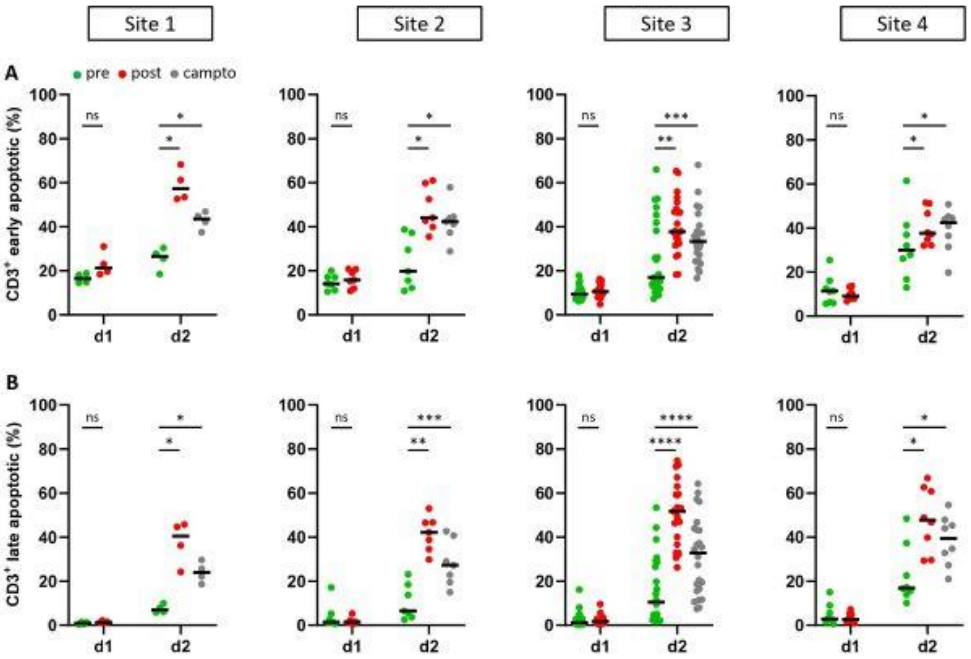


Figure 1 *8-MOP-treated and UVA-irradiated CELLEX samples contain significantly higher frequencies of late apoptotic cells.* ECP samples were stained for flow cytometry analysis before (d1) and after (d2) 22 h cell culture. Frequencies of early (A) and late (B) apoptotic T cells were determined in untreated pre (green dots) and in 8-MOP/UVA treated post samples (red dots). Camptothecin treated pre samples (grey dots) were used as positive control (results are shown as individual values (dots) and median (line); n=4 for Site 1 n=7 for Site 2, n=24 for Site 3 and n=8 for Site 4; statistical analysis was performed using RM one-way ANOVA with Geisser-Greenhouse correction and Tukey's multiple comparisions test; p values are indicated as ns=p>0.05, *=p<0.05, **=p<0.005, ***= p<0.001 and ****= p<0.0001).

Conclusions: This multicenter European validation study confirms that ECP performed with the THERAKOS™ CELLEX™ device reliably induces apoptosis in patient-derived leukocytes across a range of clinical indications. While patient-related factors and sample handling variations may influence apoptotic profiles, the validation protocol proved robustness and reproducibility, supporting its use for standardizing ECP validation procedures.

Disclosure: This study was sponsored and funded by Therakos UK Limited. Support for third-party assistance in development of the Validation Masterplan and oversight of the study was provided by ICMED and funded by Therakos UK Limited.
James A. Hutchinson received honoraria from Therakos UK Limited.
Federica Zunino is employed by Therakos UK Limited.
Nina Worel received speakers fees from BMS Celgene, Johnson & Johnson, Kite Gilead, Miltenyi Biotec, Therakos and Vertex.

P353

SUSTAINING QUALITY IN A COMBINED JACIE-ACCREDITED CENTRE: TWO DECADES OF CONTINUOUS IMPROVEMENT INCLUDING IEC ACCREDITATION

Katerina Steinerova[1], *Pavel Jindra*[1], *Daniel Lysak*[1], *Michal Karas*[1], *Jiri Sramek*[1]
[1]*Faculty Hospital Pilsen, Pilsen, Czechia*

Background: Our combined adult haematopoietic stem cell transplantation and cell therapy centre initiated preparations for JACIE (Joint Accreditation Committee ISCT-Europe & EBMT) accreditation twenty years ago. The centre is accredited for all activities except paediatric transplantation since 2008 and, at the latest reaccreditation in 2024, successfully included immune effector cell (IEC) therapy. Over time, JACIE standards have shaped not only our compliance processes but also our institutional culture of quality and safety.

Methods: A retrospective evaluation of quality management activities was performed covering the period 2004–2024. Data from internal audits, adverse event reporting, risk assessments, corrective and preventive actions (CAPA), staff education, and key performance indicators (KPIs) were analysed across clinical, collection, processing, and IEC programmes. Trends over successive accreditation cycles were compared to assess the sustainability of quality standards.

Results: Audit compliance rates remained consistently above 80%. Over the last five years, 135 deviations and adverse events were analysed using structured root cause and risk analysis, resulting in 35 corrective and 30 preventive actions. The number of high-risk events decreased by 42% compared with the previous cycle. Regular risk reviews enabled early identification of process gaps and improvement of traceability. Multidisciplinary engagement, continuous training, and strong leadership commitment proved essential for maintaining quality performance.

Conclusions: Two decades after initiating JACIE preparations, our experience confirms that sustained excellence requires embedding quality culture into everyday clinical practice. The integration of systematic risk and adverse event analysis enhanced patient safety and process reliability. The inclusion of IEC activities further strengthened our comprehensive and forward-looking quality management framework.

Disclosure: nothing to declare

P354

DISPOSAL OF HEMATOPOIETIC STEM CELLS IN A PEDIATRIC TRANSPLANT UNIT OVER 10 YEARS IN ARGENTINA: A QUALITY MANAGEMENT OPPORTUNITY FOR PROCESS OPTIMIZATION

*Marcela Varela[1], Sandra Formisano[1], **Daniela Iglesias**[1], Gisela Gonzalez[1], Gisela D Angelo[1]*
[1]Hospital de Niños Sor Maria Ludovica, La Plata, Argentina

Background: Cryopreservation of hematopoietic stem cells (HSC) is an essential practice in both autologous and allogeneic transplant programs. However, a significant proportion of the collected units remain stored unused or are ultimately discarded, posing ethical, logistical, and economic challenges. This study analyzes a decade of experience at a public pediatric transplant center, describing the magnitude and causes of discarded stem cell units (SCU) , with the aim of providing national evidence for the design of rational storage and disposal policies.

Methods: A retrospective study was conducted at a public pediatric center in Argentina, analyzing cryopreserved SCU between November 2014 and November 2024. The relationship between stored, infused, and discarded units, distribution by type of hematopoietic stem cell transplantation (HSCT), reasons for discarding, and storage duration were described.
Because the indications and kinetics of HSC use are different between autologous and allogeneic transplantation, they will be described separately.
Since 2017, our policy has been to keep backup doses for a year; however, the duration of storage for cryopreserved HSCs is a subject of debate.

Results: Over a 10-year period, 204 units corresponding to 84 patients were cryopreserved. 34.3% were discarded, predominantly in the unrelated allogeneic transplant group (54.4%), followed by autologous transplants (19%) and related haploidentical transplants (14%).

Table 1.Distribution of SCU by type of HSCT

TYPE OF HSCT	**Patients**		**Cryopreserved SCU**	**Infused** SCU	**Discarded SCU**	**Discard %**
Autologous	**37**		**107**	**85**	**20**	**18.7**
Haploidentical	**5**		**7**	**6**	**1**	**14.2**

URD	**42**		**90**	**24**	**49**	**54.4**
Total	**84**		**204**	**115**	**70**	**34.3**

HCT: Hematopoietic Cell Transplant SCU:Stem Cells Units URD: Unrelated Donor

In this 10-year retrospective series from a public pediatric transplant unit, approximately one-third of the cryopreserved units were discarded. Discarding was concentrated mainly in the unrelated transplant group, due to the practice of cryopreserving backup units that are ultimately not used. In autologous transplants, discarding was associated with disease progression or death, while in haploidentical transplants it was low.
In pediatric centers like ours, which perform allogeneic transplants with unrelated adult donors, it is common to receive apheresis products with a cellularity higher than needed to meet the target dose for the pediatric recipient. This weight difference between adult donor and pediatric recipient leads to the generation of more than one cryopreserved unit per patient. This can result in an unintentional increase in the number of units stored.
Except in cases where the patient has died, the decision to discard a cryopreserved unit is difficult to make.
Strategies for improvement include defining strict criteria for cryopreservation of backup units, establishing storage periods, and implementing disposal policies.

Conclusions: Over a 10-year period, 34% of cryopreserved units were discarded, with unrelated donor units predominating. The main reasons were: non-use of backup units, disease progression, and recipient death. Our findings are consistent with international reports and underscore the need for standardized storage and discard policies in order to optimize resources.

Disclosure: Nothing to declare

P355

THE REGULATION OF CLINICAL TRIALS WITH HEMATOPOIETIC STEM CELL PREPARATIONS: CHALLENGES AND PERSPECTIVES IN THE CONTEXT OF REGULATION (EU) NO. 536/2014

Susanne Ellinger[1], *Wolfgang Bethge*[2], *Michael Heuser*[3], *Torsten Tonn*[4], *Johannes Schetelig*[5], *Selim Corbacioglu*[1]
[1]*University Hospital Regensburg, Regensburg, Germany,* [2]*University Hospital Tuebingen, Center for Clinical Trials and Department of Hematology&Oncology, Tuebingen, Germany,* [3]*University Hospital Halle (Saale), Martin-Luther-University Halle-Wittenberg, Halle, Germany,* [4]*German Red Cross Blood Donation Service Baden-Württemberg - Hessen gGmbH Institute for Transfusion Medicine and Immunohematology, Frankfurt, Germany,* [5]*1University Hospital Dresden, 2. DKMS Group, Dresden, Dresden, Germany*

Background: The regulation of clinical trials involving hematopoietic stem cell preparations (HSCPs) is complex because it involves both European and national legal requirements.

While the EU Clinical Trials Regulation (CTR, Regulation (EU) No. 536/2014) seeks to harmonize clinical trial procedures, HSCPs are excluded from its scope since they are classified as tissue products under Directive 2004/23/EC. This creates significant regulatory differences among EU Member States, complicating the planning and execution of multinational clinical trials. The lack of harmonization particularly hinders academic research and the development of innovative cell-based therapies in Europe, a significant locational disadvantage.

Methods: A qualitative research design was used, systematically analyzing relevant European and national legal frameworks, along with conducting expert interviews. The legal analysis focused on Germany and selected EU member states, examining requirements for safety, quality, and ethics in clinical trials with HSCPs. Expert interviews with clinicians, legal professionals, and regulatory experts provided practical insights into the challenges of implementing these regulations in multinational studies.

Results: The legal framework in Germany differs significantly from that of other European countries and has notably strict rules for clinical trials involving HSCPs. These trials are classified as medicinal products under the German Medicines Act (AMG), which requires extensive manufacturing authorization, GMP compliance, and thorough documentation. In contrast, many other EU countries categorize HSCPs as tissue products, which only require ethical review for clinical trials. This difference creates substantial administrative burdens and causes delays in multinational studies, as seen in the T-Haplo for SCD trial (NCT04201210), which faced divergent regulatory pathways in Germany, Austria, and Italy. Experts confirm that the lack of harmonization poses major barriers to academic research and international collaboration. The upcoming EU SoHO Regulation (2024/1938) aims to improve harmonization, though uncertainties remain about how it will be implemented nationally and whether national regulations and laws will continue to overrule EU regulations such as SoHO.

Conclusions: Current regulatory frameworks for clinical trials with HSCPs in Europe are fragmented, with significant differences in legal classification, approval procedures, and quality requirements. Germany's particularly restrictive approach limits academic research and complicates multinational studies. Harmonization at the European level—especially through clear criteria for classifying cell preparations and streamlined approval processes—is urgently needed. The implementation of the SoHO Regulation offers an opportunity to reduce regulatory barriers, but its success will depend on consistent application across Member States and avoiding additional bureaucratic hurdles. Targeted support for academic research, including simplified procedures for low-risk studies and centralized guidance, is necessary to promote international studies and strengthen academic research.

P357

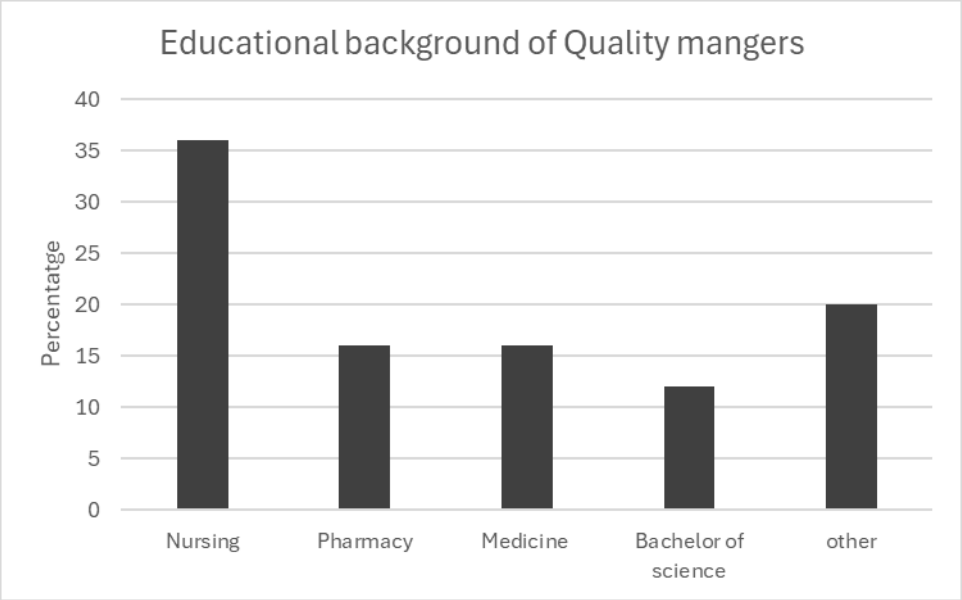
WHO IS CURRENTLY OCCUPYING THE BMT QUALITY MANGER CHAIR, MULTI-CENTER DESCRIPTIVE USING LINKEDIN® WEBSITE

*Asia Abdalla[1], Sabah Zahooruddin[1], Rosanne Makiramdam[1], Fatema Al Kaabi[1], Yendry Ventura[1], Mubasher Maqbool[1], **Dina El Mouzain**[1], Maysoon Al Karam[1]*
[1]Abu Dhabi Stem Cell Center, Abu Dhabi, United Arab Emirates (the)

Background: The FACT–JACIE HSCT Standards provide only a broad description of the qualifications required for a cellular therapy quality manager. According to the 9th Edition, the role may be fulfilled by "an individual with an undergraduate degree or equivalent in health or biological sciences, accompanied by training or experience in quality management". This broad definition allows considerable variation in the educational backgrounds of quality managers, despite their carrying out similar functions across centers operating under the same standards. The objective of this analysis is to determine the educational backgrounds of individuals currently serving as quality managers and to assess the extent of diversity in the educational qualifications of those performing quality management functions in cellular therapy and bone marrow transplantation.

Methods: A list of JACIE- and FACT-accredited centers was obtained from the respective websites. Centers were selected to achieve broad geographic representation, with up to five centers included per continent. Availability of publicly accessible information identifying the quality manager was an additional inclusion criterion. LinkedIn searches were performed to determine the educational background of cellular therapy and bone marrow transplant quality managers/ Quality assurance officers. The proportion of each educational background was calculated by dividing the number of quality managers with the same educational background by the total number of centers analyzed, multiplied by 100. For example, the percentage of nurses' representation was calculated by dividing the number of quality managers with Bachelor of Nursing, which is nine, by the total number of centers which is 25 accordingly the percentage of nurses was (9/25) *100= 36%. Diversity within each continent was calculated by dividing the number of distinct educational backgrounds by the total number of centers, multiplied by 100.

Results: A total of twenty-five centers were included in the analysis, and the educational backgrounds of their quality managers or quality assurance officers were identified. Eight distinct educational backgrounds were observed across the cohort. Notably, three quality managers held non-healthcare degrees, all of whom were senior professionals with more than 20 years of experience. Nursing was the most common educational background, followed by pharmacy and medicine, as illustrated in the accompanying graph below. The lowest diversity in educational backgrounds was observed in North America, while the highest diversity was seen in Africa, likely influenced by the smaller number of centers included from that region



Continent	%Diversity
Africa	100
Asia	80
Europe	80
Australia	75
South America	75
North America	40

Conclusions: Nurses appear to be the most common healthcare professionals assuming the quality management role, particularly in North America. As bone marrow transplantation and cellular therapy continue to advance and evolve, there is a growing need to strengthen the qualifications of quality managers and reduce variability in their educational backgrounds. Future studies are warranted to determine the most appropriate educational profile for this role and to define the certifications or requirements that should be considered essential for the position.

BUILDING A COST-EFFICIENT, JACIE-ALIGNED GMP FACILITY FOR CAR-T MANUFACTURING WITH SCALABLE EXPANSION TO CELL AND GENE THERAPIES IN AN LMIC SETTING: EXPERIENCE FROM CARTOGENE THERAPEUTICS

Anupam Chhabra[1], *Neeraj Gupta*[2], *Sumit Wadhwa*[1], *Ravindra Rathi*[1], *Aadhar Gupta*[2]
[1]*Cartogene Therapeutics, Gurgaon, India,* [2]*Genes2Me, Gurgaon, India*

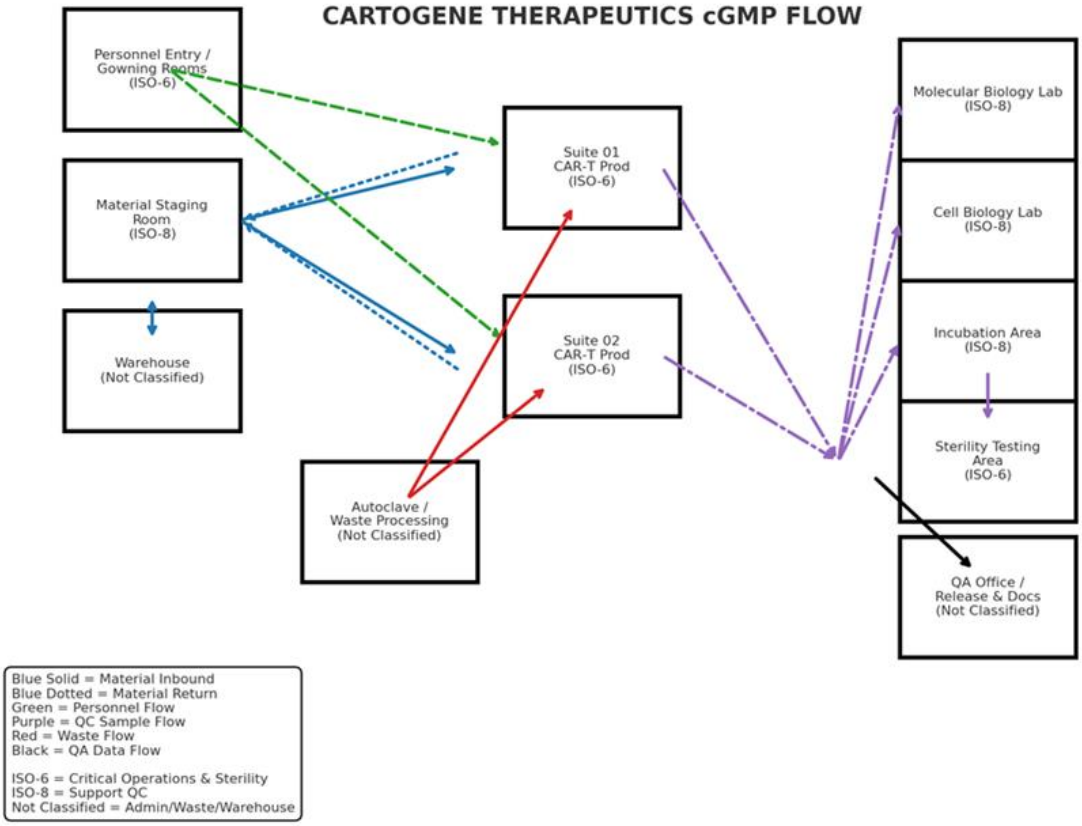
Background: CAR-T cell therapy has demonstrated curative potential in relapsed/refractory B-cell malignancies; however, access remains limited in low- and middle-income countries (LMICs), where treatment costs can exceed 10–20× the average annual income. A primary barrier is the lack of domestic GMP-compliant manufacturing aligned with recognised international accreditation frameworks such as JACIE. To sustainably expand access, infrastructure must be designed to balance global quality expectations with affordability, streamline workflows to reduce operational complexity, and incorporate modularity for future cell and gene therapy (CGT) expansion. Cartogene Therapeutics has developed a cost-optimised GMP in India to enable affordable CAR-T production and establish a scalable pathway for subsequent CGT modalities.

Methods: A manufacturing of ~3500 sq. ft. was developed using value-engineered construction principles, reducing infrastructure-related expenditure by an estimated **40–50%** relative to comparable facilities in high-income countries. The manufacturing environment includes:

- **Two independent CAR-T manufacturing core suites (ISO-6)** are designed for autologous and adaptable for other workflows.
- **Closed-system processing**, minimising open handling and controlling environmental exposure for all critical steps
- **Segregated functional areas,**including:
    1. Primary and secondary gowning zones **(CLASS-B, ISO-8 → ISO-6)**
    2. Process staging and fill-finish **(ISO-6)**
    3. Warehousing with physical separation of raw, in-process, and finished goods
    4. Defined hazardous waste handling pathways
    5. Dedicated block for Cell biology, Molecular biology, Incubation **(ISO-8**) and Sterility area **(ISO-6)**

Material and personnel movements were engineered to eliminate cross-contamination risks using independent airlocks, labelled directional flow pathways, and **dedicated dynamic pass boxes.**
A **unidirectional waste management system** ensures that all generated biohazard materials are sealed, transferred into a segregated warehouse pathway, and sterilised before removal by licensed biomedical waste handlers.
Manufacturing cleanrooms utilise **PUF-filled modular partitions**, smooth powder-coated finishes, epoxy flooring, and coving at all junctions to enable high cleanability. **Dedicated AHUs** and pressure cascade zoning provide contamination-risk-aligned environmental control and reduce downtime for maintenance.

The integrated warehouse enables centralised material control for the entire organisation while maintaining GMP segregation through a **material staging room** that prevents cross-flow between clinical and non-clinical inventory.



Results: The facility successfully meets cGMP principles and is architecturally aligned with JACIE accreditation requirements for cellular therapy facilities. Key operational outcomes include:

- **Streamlined personnel workflow,** lowering gowning-related nonproductive time and reducing facility occupancy burden while ensuring contamination prevention.
- **>30% operational manpower efficiency** achieved through simplified logistics, pass-box-driven movement.
- **Improved manufacturing**, supporting tighter vein-to-vein timelines.
- **Initial production capacity for ≥700 therapies per year**, with scalability option.
- **Robust segregation of material states**, preventing mix-ups and enabling operational excellence metrics critical for regulatory audits.
- **Cost-reduction enablement** through localised supply chain development and optimised OPEX models — positioning CAR-T as a more sustainable alternative.

The design supports **future-ready transformation**, with pathway adaptations already mapped for CGT.

Conclusions:

Cartogene Therapeutics has established a cost-efficient, globally aligned CAR-T manufacturing facility tailored for LMIC constraints without compromising quality or scalability. This JACIE-aligned infrastructure not only supports the immediate deployment of accessible autologous CAR-T programs in India but also lays the foundation for regional growth in advanced cell and gene therapies. This model offers a reproducible blueprint for LMIC healthcare readiness in next-generation biologics.

Clinical Trial Registry: Not applicable

P359

MICROBIAL CONTAMINATION OF CELLULAR THERAPY PRODUCTS: A DECADE OF SUCCESS OF SINGLE CENTER EXPERIENCE IN THE MENA REGION

Manal Yaghmour[1], *Aisha Alkaseri*[1], *Abdallah Abdallah*[1], *Dana Alasmar*[1], *Nasimeh Azadi*[1], *Jawaher Al-Emadi*[1], *Wedad S. Hamdi*[1], *Fabio Culurgioni*[1]
[1]*Hamad Medical Corporation, Doha, Qatar*

Background:

Aseptic technique is critical in Cellular Therapy Processing laboratories to ensure the safety, purity, and efficacy of cellular therapy products (CTPs). Hematopoietic stem cell products (HPSCs), used in bone marrow transplantation (BMT), are administered to immunocompromised patients who are highly vulnerable to infections. Even minimal microbial contamination can lead to severe complications, including sepsis, graft failure, and increased clinical interventions. Therefore, strict adherence to Good Manufacturing Practices (GMP) and contamination control is essential to protect patient outcomes and meet regulatory standards. Since the initiation of our BMT program in 2015, our facility has consistently maintained a 0% microbial contamination rate (bacteria and fungi) in CTPs sourced from apheresis or bone marrow harvest (BMH) and processed in a cGMP-compliant cleanroom. This study highlights the effectiveness of our comprehensive control measures implemented before, during, and after CTP processing.

Methods: Our control measures are based on Good Manufacturing Practices (GMP), JACIE standards, and our own expertise. Key measures include:

- **Access Control:** Prior authorization, controlled access, use of tacky mats and shoe covers, and limiting the number of staff in cleanrooms.
- **Personnel Hygiene:** Daily bathing, wearing clean clothes, and prohibiting smoking, makeup, nail polish, hair gel, body lotions, and accessories.

- **Personal Protective Equipment (PPE):** Use of sterile cleanroom garments.
- **Cleaning Protocols:** Regular cleaning of biosafety cabinet, processing devices and stations, with monthly deep cleaning by specialized personnel.

- **Environmental Monitoring:** Continuous surveillance of temperature, pressure, and humidity, scheduled AHU and HEPA filter changes, and monthly air sampling and particle counting.
- **Microbial Testing:** Staff finger dabs pre- and post-processing, strict aseptic techniques, and particle counting during processing.
- **Processing**: using close system under Grade A and by using strict aseptic techniques

A retrospective analysis of sterility testing was conducted on 1,603 samples, using BACTEC pediatric blood culture bottles at various stages of CTP processing. Cultures were monitored for 10 days for bacterial or fungal growth.

Results: Of the 1,603 samples analyzed, none tested positive for bacterial or fungal contamination, yielding an observed contamination rate of 0% (95% CI: 0–0.19%). Compared to the internal benchmark contamination rate of 2%, this result was highly significant (exact binomial test, $p < 0.0001$).

Conclusions: The stringent control and aseptic measures implemented at cGMP-CTL-DLMP-HMC have proven highly effective in preventing microbial contamination, achieving a 0% contamination rate compared to an internal benchmark of 2-3%. Our decade-long experience provides a reproducible model for other institutions aiming to improve safety in Cellular Therapy Processing, reduce infection risk, and optimize outcomes for immunocompromised patients undergoing BMT.

Disclosure: Nothing to declare

P360

REGULATORY MODELS FOR CAR-T CENTER QUALIFICATION IN ITALY AND SWITZERLAND: IMPLICATIONS FOR CLINICAL RESPONSIBILITIES AND QUALITY GOVERNANCE

Vincenzo Iaconianni[1], *Maria Goldaniga*[2], *Giorgia Saporiti*[2], *Francesco Passamonti*[2]
[1]*ICMED S.r.l., Sesto San Giovanni, Italy,* [2]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy*

Background: The implementation of commercial CAR-T therapies requires transplant programs to fulfill specific authorization, quality and organizational requirements. Italy and Switzerland apply distinct frameworks regarding center qualification, JACIE accreditation,

GMP responsibilities and the role of national authorities. Misinterpretations—particularly concerning Swissmedic's scope and the status of JACIE in Switzerland—can significantly affect program design.

Methods: Comparative analysis of national documents:
• Italy: State-Regions Agreement 5/5/2021, AIFA provisions for commercial CAR-T, CNT requirements;
• Switzerland: Swissmedic regulations for cell manufacturing and handling activities, SBST criteria for center recognition, LAMal provisions for reimbursement;
• FACT–JACIE standards, 8th edition.
The analysis was supplemented with direct observations regarding the qualification of CAR-T centers and transplantation in the two contexts.

Results: Italy.
In Italy, for commercial CAR-T products, qualified centers must have regional authorization identifying the centers authorized for CAR-T reimbursement, possess CNT certification, JACIE accreditation for allogeneic transplantation (clinical unit, collection, processing), and availability of intensive care. The production and handling of commercial CAR-T is carried out exclusively by pharmaceutical companies holding AIC (Novartis, Gilead, BMS, J&J), which retain GMP responsibility for the process. Hospitals are qualified for clinical management, patient care, and complications, but not as GMP sites for collection and handling.
Italian legislation does not go into detail on the requirements for non-commercial CAR-T/IEC (academic trials, compassionate use), which are not limited to allogeneic JACIE accreditation, allowing greater regulatory flexibility for trials.
Switzerland.
Swissmedic does not require centers administering commercial CAR-T to have a full GMP license, as production remains industrial, similar to Italy. Swissmedic authorizations only come into play when a center performs activities defined as manufacturing steps.
The crucial difference compared to Italy concerns JACIE: in Switzerland, it is mandatory in practice, because LAMal reimbursement of transplant activities (including CAR-T as part of the same clinical-organizational pathway) requires the center to be recognized as a transplant program.
Recognition is verified by the SBST (Swiss Society for Stem Cell Transplantation), which checks compliance with JACIE requirements and communicates the center's suitability. Without this recognition, services are not reimbursable.
SBST and Swissmedic have completely separate roles: SBST is responsible for clinical quality and eligibility for reimbursement; Swissmedic is responsible for the regulation of medicines.

Conclusions: The two models differ on key aspects.
In Italy, there is a clear separation between industrial responsibility (company holding the AIC) and clinical responsibility (hospital center).
In Switzerland, on the other hand, the system structurally links the quality of programs (JACIE) to the reimbursement of services through LAMal, with SBST as the national control body.
Misinterpretations of Swissmedic's role and the nature of GMP requirements in Switzerland can lead to an overestimation of the regulatory obligations of clinical centers. A thorough understanding of the differences is essential for designing efficient CAR-T programs, clearly defining responsibilities, and harmonizing European quality models.

Disclosure: Nothing to declare.

P361

30 YEARS OF THE NHS CORD BANK - MAINTAINING A STABLE INVENTORY

Alex Ross[1], *Rachel Pawson*[2], *Ulrike Paulus*[2], *Miguel Reyes Roque*[2], *Benjamin Cash*[2], *Clarissa Staub*[2], *Guy Parkes*[2]
[1]*NHS Blood and Transplant, Bristol, United Kingdom of Great Britain and Northern Ireland (the),* [2]*NHS Cord Bank Filton, Bristol, United Kingdom of Great Britain and Northern Ireland (the)*

Background: The NHS Cord Bank has been operational since 1996 and will celebrate both it's 30th anniversary and the provision of 1000 cord blood transplants in 2026. More than 20,000 cords with diverse HLA types have been donated to the bank since it opened. The median number of years in storage for cords provided for transplant is just under 8 years and the oldest cord issued had been in storage for over 20 years. It is of utmost importance to maintain a stable inventory and to evidence this stability as part of an accreditation programme and to maintain the confidence of transplant centres. We are building the statistical model and will present the stability data from the NHS Cord Bank and the engraftment data for cords that have been transplanted.

Methods: Data was extracted from our laboratory management system and cleaned by statisticians. The data set comprised 938 records of cords issued between 1999 and 2023, which had been donated and banked between 1996 and 2021. To analyse outcomes, a dataset was built from single cord tranplants using days to neutrophil engraftment as the primary measure of engraftment. This data was obtained from the Eurocord data, providing the main cohort of cases and all clinical outcome variables.
The effect of cord age/time in storage on viability was assessed by considering the following quality variables:
CD34+ count ($\times 10^6$): pre-freeze and post-thaw
Percentage of Viable CD34+: pre-freeze and post-thaw
TNC ($\times 10^6$): pre-freeze and post-thaw

Results: The final cohort size was 880 after data cleaning with a median storage time of 4.6 years prior to transplant and a maximum storage time of 21.8 years. Preliminary analysis has shown no statistically significant decline in CD34+ viability or TNC post-thaw related to duration in storage. The statistical model is being refined to consider changes in CD34+ enumeration and the data will be re-evaluated for CD34+ counts. Looking at patient outcomes, no evidence of difference in time to engraftment or one-year overall survival was seen based on the age of the cord.

Conclusions: This work builds on an earlier analysis of the effect of time in storage on quality parameters with a larger cohort of transplanted cords and a longer median storage time as well as cords that had been in storage over 20 years. Our initial analysis of outcomes

related to duration of storage does not indicate any difference in time to engraftment. All cords undergo thorough release testing on post thaw samples prior to release to ensure that the requested dose for the patient is available as well as viability and potency.of the cord. Cords that do not meet the release criteria are very few in number but will be included in a further analysis to determine whether there is any relationship to duration of time in storage. Our results indicate that quality parameters are unaffected regardless of the time in stable, cryogenic storage and should not be a barrier to selection.

Disclosure: Nothing to declare

P362

DISPOSAL OF AUTOLOGOUS HEMATOPOIETIC STEM CELL ALIQUOTS: A REGULATORY AND ETHICAL ANALYSIS FROM THE SAN GIOVANNI ADDOLORATA PROCESSING FACILITY

Gabriella Peluso Cassese[1], *Floriana Simonelli*[1], *Claudia Di Berto*[1], *Giovanni Ottolino*[1], *Antonio Fede*[1], *Eleonora Ceresoli*[1], *Elisabetta Campana*[1], *Donatella Pastorelli*[1], *Angela Rainaldi*[1], *Michele Cedrone*[1]
[1]*Azienda Ospedaliera San Giovanni Addolorata, Rome, Italy*

Background: The disposal of hematopoietic stem cell (HSC) products represents a critical but often overlooked phase within the lifecycle of Substances of Human Origin (SoHO). While regulatory and clinical attention traditionally focus on donor selection, collection, processing, cryopreservation, and infusion, the final step—safe, justified, and traceable disposal—has gained importance under EU Regulation 2024/1938. Disposal practices are regulated by EDQM guidelines, JACIE Standards, and the Italian CNT Guidelines, which define safety, traceability, and ethical requirements for human-derived materials. At the San Giovanni Addolorata Hospital, the transplant program serves adult patients affected by multiple myeloma, lymphomas, and acute myeloid leukemia, for whom stem cell collection and storage are integral to therapeutic pathways. In general, disposal may occur due to quality issues, loss of indication, incomplete traceability, container damage, or time-based criteria such as storage exceeding ten years. Although such thresholds exist, no time-based criterion was applied in this experience. Disposal was required only following the confirmed death of the patients.

Methods: An evaluation of disposal workflows was conducted at the SGA Processing Facility. The regulatory framework included EU Regulation 2024/1938, EDQM Guidelines, JACIE Standards and the Italian CNT Guidelines. Process mapping described each operational step from the decision to eliminate an aliquot to its final destruction, including documentation flows, biosafety procedures, authorization pathways, and record validation. An ethical assessment ensured responsible stewardship of human-derived material. A central methodological component was the use of the Regional Electronic Prescription Platform (SISMED), which enabled verification of patient vital status, retrieval of official death certificates, and the ability to trace patients who had been lost to follow-up after discharge, ensuring accurate long-term outcome confirmation. All disposal documentation, including

these certificates, was reviewed, verified, and formally validated by the Transplant Program Director and the Processing Facility Director, ensuring complete regulatory, ethical, and traceability compliance. SOPs, disposal records, biovigilance data, and staff interviews were analyzed to evaluate workflow adherence and training adequacy.

Results: in 2025 a total of 58 aliquots were eliminated, consisting of 30 stored internally and 28 stored externally at a contracted third-party facility. Disposal concerned material belonging exclusively to deceased patients. In every case, the only indication for disposal was the confirmed death of the patient; no time-based storage criterion, including thresholds beyond ten years, was applied. For each disposal event, documentation—including the death certificate—was verified and signed by the Transplant Program Director and the Processing Facility Director, guaranteeing appropriate authorization and complete traceability. Eliminating these aliquots resulted in a significant reduction in cryostorage burden, generating measurable savings in storage space and associated costs, particularly for externally stored material

Conclusions: In the SGA Transplant Program, disposal of HSC aliquots was required only due to patient death, underscoring the need for rigorous documentation, ethical oversight, and strict regulatory compliance. Adherence to EU Regulation 2024/1938, EDQM and JACIE standards, and the Italian CNT 2014 Guidelines, combined with regional information platforms such as SISMED capable of long-term patient tracing, ensures respectful, transparent, and justified disposal practices. Continuous monitoring promotes responsible stewardship and alignment with evolving European regulatory expectations.

Disclosure: Nothing to declare

P363

GLOBALIZING PSIRF

Oseyaede Eboiyehi[1]
[1]*The Christie NHS Foundation Trust, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: **What is PSIRF:** The Patient Safety Incident Response Framework (PSIRF) provides a structured approach to developing and maintaining effective systems and processes for responding to patient safety incidents, with the overarching goal of facilitating learning and driving continuous improvement in patient safety.
PSIRF was introduced by NHS England in August 2022 and implemented by The Cellular Therapy Program in March 2024.
Strategic Aims of PSIRF:
• Compassionate engagement and involvement of key staff members and patients affected by patient safety incident
• Proportionate responses to identify learning from patient safety incidents
• System-based approach to action plans and quality improvement following patient safety incidents

• Effective governance and oversight focused on strengthening response processes and systems

Methods: **PSIRF from the lens of SEIPS:** PSIRF uses SIEPS (System Engineering Initiative for Patient Safety) as a system-based approach from learning from patient safety incidents.
What does PSIRF involve:
Cultural change
Transition from the Serious Incident Framework, towards promoting a proportionate and learning focused approach to responding to patient safety incidents.
This shift has led to:
• Change in incident management systems
• Change in incident management processes and governance
• Policy update and staff training
• Change in communication, engagement and overall approach

Results: **Outcome of PSIRF Implementation**
• There has been an increase in the number of incidents reported since the introduction of PSIRF. This is viewed as a positive outcome, demonstrating that staff feel empowered to speak up when things go wrong or nearly go wrong
• Various learning responses have been implemented, leading to improvements in the program's systems, processes, and policies, with less emphasis on individual blame and more focus on systemic change.
• Confidence and satisfaction among our patient safety partners have increased, particularly due to the program's engagement with patients and next of kin (NoKs) involved in incidents. This includes fulfilling Duty of Candour obligations, providing timely feedback to queries and complaints, sharing findings from investigations, and outlining action plans to prevent recurrence.
• The quality strategy, aligned with the program's objectives, has contributed to improvements in patient safety, experience, treatment, and care. These enhancements have been driven by learning from incidents and near misses.

Conclusions: **Cellular Therapy Program Quality Strategy in-line with PSIRF:**
Quality Strategy 2026: To improve patients' health outcomes through continuous quality improvement.
Our objectives:
• Detect and review adverse events and risks across all program areas.
• Carry out system-wide learning by implementing quality improvement projects across the program.
• Implement effective actions derived from lessons learned across various quality domains.
• Monitor, evaluate, and refine processes to sustain improvements in patient safety and experience.
• Ensure adherence to established quality metrics and regulatory standards.
We aim to achieve this by:
• Maximising the utilisation of our resources (policies, processes, and systems) to support effective care delivery.
• Ensuring accountability for actions through an evidence-based approach.

• Driving continuous monitoring and improvement, supported by data-driven insights and analysis.

Disclosure: No conflict of interest.

GAPP-PRO JOINT ACTION: LATEST UPDATE

Ruth Barrio[1], *Jaume Tort*[1], *Samuel Arrabal*[2], *Fiorenza Bariani*[3], *Shubhada Bopegamage*[4], *Livia Cannata*[5], *Claudia Carella*[3], *Paola Di Ciaccio*[3], *Blandine Derycke*[2], *Ursula La Rocca*[5], *Michal Nowicki*[6], *Verena Plattner*[7], *Anna Palmieri*[5], *Simonetta Pupella*[5]
[1]*OCATT, Barcelona, Spain,* [2]*ABM, Paris, France,* [3]*ISS-CNT, Rome, Italy,* [4]*Slovenka Zdravotnicka Univerzita Bratislave, Bratislava, Slovakia,* [5]*ISS-CNS, Rome, Italy,* [6]*Uniwersytet Medyczny Im Karola Marcinkowskiego W Poznaniu, Poznan, Poland,* [7]*AGES, Vienna, Austria*

Background: The Joint Action *Piloting GAPP Model Approach for Assessing and Authorising Novel Substances of Human Origin Preparation Processes* (GAPP-PRO) was launched in February 2024 (https://gapp-pro.eu).
The GAPP-PRO Joint Action builds upon the previous European initiative GAPP, bringing together national Competent Authorities (CAs) and other stakeholders involved in the authorisation of preparation processes for Substances of Human Origin (SoHO).

Methods: A survey to collect updated information on SoHO preparation processes in Europe, categorised by different risk levels — including bedside preparations — was carried out. This survey was addressed to all European CAs.
In parallel, joint country and cross-country assessments are being conducted within pilot authorisation processes for different types of SoHO: blood, blood components, tissues, cells, reproductive cells, breast milk, and faecal microbiota. The main goal is to properly evaluate, through a set of indicators, the applicability of the GAPP methodology (https://www.gapp-ja.eu), which includes the application of a Preparation Process Dossier (PPD) as common approach.
In addition, interviews with the SoHO entities that prepared the PPDs, as well as with the experts and CAs involved in the evaluations, are planned to gather relevant insights for further consideration.

Results: The survey results will form the basis of the SoHO Preparation Compendium, which will be incorporated into the SoHO Platform as outlined in the Substance of Human Origin Regulation (Regulation (EU) 2024/1938).
The pilots using real PPDs, along with the indicators and interview findings, will support the evaluation and refinement of the GAPP methodology for different types of SoHO. The involvement of all relevant stakeholders will contribute not only to the validation of the tool, but also to the development of a harmonised procedure endorsed by both SoHO entities and CAs.
The new SoHO Regulation establishes that CAs must provide guidelines and templates for submitting applications for preparation process authorisation, as well as for designing clinical

outcome monitoring plans. The updated GAPP-PRO Guideline will be aligned with this new Regulation.

Conclusions: The GAPP-PRO Guideline will offer SoHO entities a standardised methodology for requesting authorisation of preparation processes, and provide CAs with a common framework for reviewing and approving these processes. This will enhance mutual recognition across the European Union.

Clinical Trial Registry: Not applicable.

Disclosure: No conflict of interest.

Psychological Issues

PSY4-3

A PROTOCOL FOR ASSESSING PSYCHOLOGICAL READINESS FOR HEMATOPOIETIC STEM CELL TRANSPLANT AND GENE THERAPY IN SICKLE CELL DISEASE

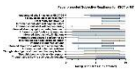
Dana Footer[1,2], *C. Nneka Nwankwo*[1,2], *Stephanie Merwin*[1,2], *Megan Connolly*[1,2], *Afsoon Gazor*[1,2], *David Jacobsohn*[1,2], *Steven Hardy*[1,2]
[1]*Children's National Hospital, Washington, United States of America (the),* [2]*George Washington University School of Medicine and Health Sciences, Washington, United States of America (the)*

Background: Recent advances in hematopoietic stem cell transplant (HSCT) and gene therapy (GT) offer increasing access to transformative therapies for sickle cell disease (SCD). These treatments offer potential life-changing benefits but also carry psychological implications. Guidance on evaluating readiness for therapy is limited. We describe our protocol for evaluating patient readiness for HSCT and GT in pediatric SCD and report characteristics of a novel patient-reported questionnaire measuring self-appraisals of readiness.

Methods: Youth with SCD ages 8-24 years being considered for HSCT or GT completed a psychological evaluation consisting of a clinical interview and brief cognitive assessment. Patients also completed a 16-item readiness survey. Respondents used a visual analog scale (range=0-10) to rate self-perceptions of knowledge and readiness for BMT or GT, with higher scores reflecting greater subjective readiness.

Results: Fifteen patients were evaluated: the mean age was 14.64 years (SD=4.55) and 60% were female. Eight patients (53%) were evaluated for a nonmyeloablative HSCT, 6 (40%) for gene therapy, and 1 (7%) for a myeloablative HSCT. Evaluations occurred 0.10-5.07 months prior to treatment (M=1.88; SD=1.32) following a median of 3 consults with the transplant team (IQR = 2-4). All patients were diagnosed with HbSS and previously

treated with hydroxyurea. Mean IQ was 99.73 (SD=19.19).
The clinical assessment involved a semi-structured interview evaluating social, emotional, academic, medical, and family histories as well as patient knowledge of and expectations for the planned treatment. Questions spanned transplant logistics, treatment trajectory, potential complications, and medication, isolation, diet, and follow-up requirements, as well as personal experiences and past coping with medical symptoms, treatments, hospitalizations, and adherence. At the conclusion of each evaluation, patients and caregivers were provided information about the availability of psychological support and recommendations to enhance readiness. Recommendations were also relayed to the medical team to incorporate into treatment planning.
Internal consistency of the readiness survey was good (Cronbach's alpha=.84). The mean composite score on the readiness survey was 6.38 (SD=1.83, range 0-10). The two highest rated items included: "How ready do you feel for transplant?" (M=8.07, SD=2.55) and "How informed do you feel about the length of time you might be in the hospital for your transplant?" (M=7.93, SD=2.43). The two lowest rated items included: "How informed do you feel about the foods you can/cannot eat during or after transplant?" (M=4.53, SD=4.03) and "How informed do you feel about the problems that might come up during transplant?" (M=4.93, SD=3.56). IQ was not significantly correlated with perceived readiness or number of consults, but older age was correlated with subjective ratings of understanding of the reason for transplant and feeling in control of the decision to pursue treatment (r=.69, CI=.27-.89 and r=.72, CI=.33-.90, respectively).



Conclusions: Patient psychological readiness is a critical component of preparation for HSCT and GT and has the potential to meaningfully enhance treatment outcomes. We described a protocol for assessing readiness that could be replicated at other institutions and reported psychometric properties and results of a novel patient-reported readiness questionnaire. Such efforts hold promise for improving patient readiness for transformative therapies as access widens globally.

Disclosure: Nothing to declare.

P375

PSYCHOSOCIAL WELL-BEING IN PATIENTS UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (ALLO-HSCT) AND THEIR CAREGIVERS: A PROSPECTIVE STUDY

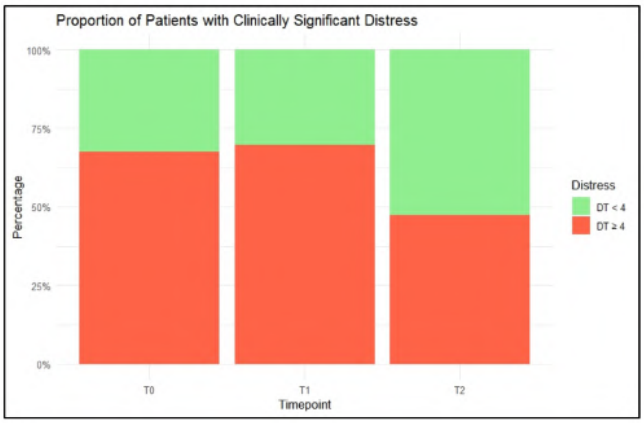
*Elsa Cavagna[1], Alessandro Leoni[1,2], Giulia Benedini[2], Giulia Brambilla[1], Daniele Avenoso[1,2], Simona Bernardi[2], **Mirko Farina**[1], Gabriele Magliano[1], Vera Radici[1,2], Domenico Russo[1,2], Michele Malagola[1,2]*
[1]ASST degli Spedali Civili di Brescia, Brescia, Italy, [2]University of Brescia, Brescia, Italy

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) can be curative for many hematologic malignancies but places a substantial psychological and emotional burden on patients and caregiver. This study assessed distress, quality of life (QoL), and unmet needs in allo-HSCT patients over 12 months using a variety of validated psychometric tools.

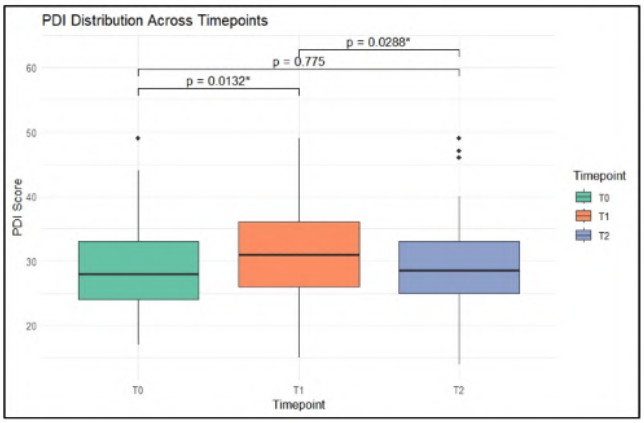
Methods: In this single-center, prospective study, between February 2020 and January 2024, 115 out of 143 screened patients were enrolled after meeting eligibility criteria, including informed consent, language comprehension, and absence of untreated psychiatric diseases. Assessment was performed at baseline (T0), 6 (T1), and 12 months after allo-HSCT (T2), using validated tools: Distress Thermometer (DT), Psychological Distress Inventory (PDI), Short Form Health Survey (SF-36), Needs Evaluation Questionnaire (NEQ), and the Family Strain Questionnaire–Short Form (FSQ-SF) for caregivers. The Psychosocial Assessment of Candidates for Transplantation (PACT) questionnaire was submitted at baseline. Repeated-measures and linear mixed-effects models were used to evaluate change over time.

Results: The median age at transplant was 56 years (IQR 48.5 -65.0), with a male-to-female ratio of 69:46. Acute Myeloid Leukemia was the most frequent diagnosis (57/115 patients, 50%), followed by Myelodysplastic Syndrome (14%), and Myelofibrosis (12%).Of the 115 enrolled patients', only 80 (70%) performed the PACT questionnaire following the initial psychological assessment. The median score was 38 (IQR 32 – 40); only 9% had a low PACT score (<29). Among them, 1 patient scored between 0-19, 2 patients between 20-24, and 6 patients between 25-29. At baseline, 67% of patients reported clinically significant distress (DT ≥ 4), increasing at 6 months (69%) and significantly decreased at 12 months (47%; p=0.0012) (Fig. 1A). PDI scores showed a similar pattern, peaking at 6 months (median: 31.4) and returning near baseline at 12 months (median: 28.5) (Fig. 1B). Female reported higher psychological distress than male at baseline (p=0.044) and 6 months (p=0.002), with the difference attenuating at 12 months.
SF-36 scores demonstrated significant improvements over time in multiple subscales, particularly between 6- and 12-months post-transplant. Notable improvements were observed in physical functioning (T0-T1 p=0.0014; T1-T2 p=0.0019), energy/fatigue (T0-T1 p=0.0007; T1-T2 p=0.0136), emotional well-being (T0-T1 and T1-T2 p=0.0382), social functioning (T1-T2 p=0.00015), pain (T1-T2 p=0.0289), and general health (T0-T1 p=0.011; T1-T2 p=0.0058).
Unmet needs assessed by NEQ were higher at 6 and 12 months than at baseline, especially regarding information clarity, future expectations, and communication with medical staff, with significant improvements over time in several items (adjusted p<0.01). Sex and age influenced perceived needs, with greater changes reported by female and younger patients (<48 years).
Regarding caregivers, moderate–high burden decries over time, while a small but persistent proportion experienced severe burden (Fig. 1C).

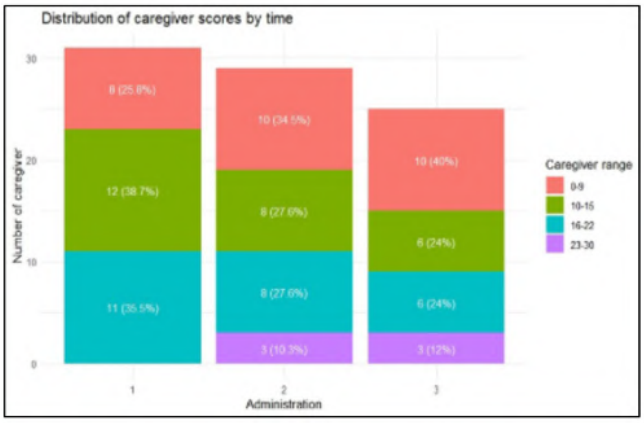
1A



1B



1C



Conclusions: This study underscores the dynamic course of psychological distress in allo-HSCT patients, with a peak at 6 months post-transplant and declines by 12 months, alongside improvements in quality of life and unmet needs. Sex- and age-related differences support personalized, time-sensitive psychological care, and integrated longitudinal assessment, underscores the value of psycho-oncology services and caregiver support into HSCT care models, with the of improving clinical outcomes.

Disclosure: Nothing to declare.

P376

LEVEL 1 PSYCHOLOGICAL SKILLS TRAINING FOR HSCT STAFF

Anna Lagerdahl[1], *Jasmine Hebden*[1]
[1]*Great Western Hospital, Swindon, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Psychological support within cancer care and HSCT services in the UK is currently understood in line with a four-level model (NICE, 2004), where support at Levels 1 and 2 is provided by healthcare professionals from a range of non-psychological professional backgrounds, and support at Levels 3 and 4 is provided by psychological specialists. Level 2 psychological skills training is widely recognised and delivered within the majority of cancer and HSCT services, with a clear consensus of what this training should cover and who should deliver it (Association of Clinical Psychologists UK, 2025). Level 1 training, on the other hand, is less developed, even though the majority of care in the aforementioned services is provided by level 1 professionals.

Methods: To address this gap, psychological specialists at Great Western Hospital have developed a half-day psychological skills package, which has been mapped against the ACCEND capabilities for the 'Supportive Workforce'. The training is provided by psychological specialists and covers:
1. Recognition of emotional distress (includes types of distress and the impact of this).
2. Responding to emotional distress (includes exploration strategies, trauma-informed care and onward referral).
3. Self-care.
Twenty-five members of staff, consisting mainly of staff nurses and healthcare assistants, have attended the training. At the end of each training session, attendees filled out an evaluation form, which enquired into the extent to which the training had been helpful and added confidence and skills in a variety of areas. Both qualitative and quantitative feedback was collected.

Results: Descriptive statistics indicated that the level 1 training increased attendees' confidence, knowledge and ability to support people with cancer who experience psychological distress. Most attendees (>82%) rated this increase at the highest possible level.
Further qualitative analysis identified 4 themes:
- '**Sufficiency of Training Conten**t': Training had met expectations and relevant comprehensive.
- '**Clinical Communication and Interpersonal Skills**': The training had improved emotional awareness and empathy for patients.
- '**Wellbeing, Emotional Awareness and Resilience**': Attendees had developed greater awareness of stress, boundaries and self-care.
- '**Applying Learning; Intentions, Challenges and Support'**. While the attendees stated that they had strong intentions to implement their learning from the training, they also identified barriers in the form of time and confidence.

Conclusions: This evaluation demonstrates the value of delivering a structured Level 1 psychological skills training package for HSCT clinical staff. Although the four-level psychological support model is well established, Level 1 training has remained underdeveloped for the workforce that provides most direct patient care. Findings from this pilot indicate that a brief, specialist-delivered programme can enhance staff confidence,

knowledge, and perceived capability in recognising and responding to distress. Quantitative feedback showed consistently high benefit, complemented by qualitative analysis which highlighted improved communication skills, greater emotional awareness, and increased recognition of the importance of self-care. Attendees also noted barriers to applying their learning, particularly limited time and confidence. These insights emphasise the need for organisational support and opportunities for ongoing skill consolidation. Overall, the training package offers a promising foundation for strengthening psychologically informed care across cancer and HSCT services.

Disclosure: None

P379

COMBINING VIRTUAL NATURE EXPOSURE AND HYPNOSIS TO IMPROVE QUALITY OF LIFE IN PATIENTS UNDERGOING HEMATOPOIETIC CELL TRANSPLANTATION: FEASIBILITY AND EFFICACY OUTCOMES

Valentyn Fournier[1,2], *Audrey Laurin*[1,2], *Floriane Rousseaux*[1,2], *Jean Roy*[2], *David Ogez*[1,2]
[1]*Maisonneuve-Rosemont Hospital Research Center, Montréal, Canada,* [2]*Université de Montréal, Montréal, Canada*

Background: Hematopoietic cell transplantation (HCT) is widely used to treat hematological malignancies but is associated with substantial adverse effects, including a reduced quality of life (QoL) exacerbated by prolonged protective isolation. There is therefore an urgent need for tailored interventions to improve patients' psychosocial well-being and QoL immediately after transplant. Nature exposure is a promising approach to support well-being. Its effects are explained by attentional mechanisms: nature facilitates the restoration of attentional resources and promotes focus on positive elements. However, protective isolation prevents direct nature exposure.
In this context, we developed a virtual reality (VR) intervention that brings natural environments (forest, beach) into the hospital room through immersive audiovisual stimuli. Given the effects of nature exposure are mediated by attentional processes, we combine it with hypnosis, a technique aiming at enhancing focus on positive elements. Following a processual methodology for the development of non-pharmacological interventions, we conducted a feasibility study including patient recommendations.

Methods: Participants were offered autonomous use of the intervention for two weeks between from Day 7 to Day 21 (±3 days) after HCT. Frequency of use, cybersickness symptoms, and compliance were monitored. Semi-structured interviews were conducted in 8 users to explore patients' suggestions for improvement. The study also included a pilot evaluation of efficacy, assessing QoL before and after the intervention using the Functional Assessment of Cancer Therapy – Bone Marrow Transplantation (FACT-BMT). Secondary outcomes included self-reported pain, anxiodepressive symptoms, and fatigue.

Results: Among the 60 participants initially approached, 18 declined participation prior to effective inclusion, citing lack of interest in hypnosis, perceived complexity of VR, or absence

of perceived need for support. Ultimately, 42 participants were included (22 control, 20 experimental group). In the intervention group, 18 underwent allogeneic HCT and 2 autologous HCT. Feasibility outcomes revealed a relatively low retention rate (60%), heterogeneous use of the headset (1 to 7 sessions), and low cybersickness. Patient feedback highlighted a preference for supervised, time-limited sessions rather than autonomous use. The pilot efficacy analysis showed no significant change in QoL between pre- and post-intervention assessments.

Conclusions: Our work represents one of the first interventions for patients undergoing HCT developed using a structured framework for non-pharmacological interventions. The absence of significant effects of the intervention on QoL may be explained by feasibility factors, including low retention, variability in VR exposure, and autonomous use of the intervention. Based on those findings and participants recommendations, we revised the protocol to design a feasible randomized controlled trial aimed at evaluating the efficacy of this non-invasive and cost-effective intervention to preserve QoL in HCT patients. The inclusion of participants started on the November 1st, 2025. To date, 9 patients (5 control and 4 intervention; all allogeneic HCT) have been included and enrolled, and preliminary results from the first 20 patients will be presented at time of the conference.

Clinical Trial Registry: NCT06817759

P380

PIONEERING PSYCHOSOCIAL SUPPORT FOR BONE MARROW TRANSPLANT PATIENTS: A DESCRIPTIVE CROSS-SECTIONAL SURVEY STUDY AT ABU DHABI BONE MARROW TRANSPLANT PROGRAM, CENTER OF EXCELLENCE

Rahma Almheiri[1], *Dina El Mouzain*[1], *Asia Ibrahim*[1], *Rouba Talih*[1], *Sabah Zahooruddin*[1], *Ardo Hassan*[1], *Cyril Buhayan*[1], *Nameer Al Saadawi*[1], *Mohamed Abu Haleeqa*[1], *Inas El Najjar*[1], *Maysoon Abdulrahman Al Karam*[1], *Fatema Al Kaabi*[1]
[1]*Abu Dhabi Stem Cell Center /Yas Clinic Khalifa City, Abu Dhabi, United Arab Emirates (the)*

Background: Psychosocial support is increasingly recognized as a critical component of comprehensive care for individuals undergoing hematopoietic stem cell transplantation. Support groups provide structured environments for patients to share lived experiences, receive emotional validation, strengthen coping strategies, and reduce the isolation commonly associated with prolonged and intensive treatment. At Abu Dhabi Stem Cell Center (ADSCC) and Yas Clinic Khalifa City (YCKC), a pioneering in-person support group for bone marrow transplant (BMT) patients was developed to address these needs. Patients are introduced to the group during their first psychosocial consultation with the clinical social worker and are encouraged to continue participation throughout their treatment journey. The group convenes monthly for two hours, with the first hour dedicated to educational content and facilitated peer discussion, followed by a second hour centered on wellness-focused

activities such as yoga, sound healing, salon pampering, cake-decorating workshops, and vision-board exercises.
Given the novelty of this program within the United Arab Emirates where there are limited psychosocial support offering to BMT patients, objective of this study was to assess participant satisfaction with the current support group structure and to collect patient perspectives on potential areas for improvement.

Methods: A descriptive cross-sectional survey was conducted using an electronic questionnaire developed through Microsoft Forms. Confidentiality was ensured through fully anonymous response collection, with no names or email addresses recorded. The survey was administered in English, as all participants were fluent in the language. A four-point Likert scale was used for multiple-choice items, and an open-ended question was included to capture suggestions on how the support group could better meet patient needs. The survey assessed the extent to which the support group met participant's need, the appropriateness of the time allocated to educational speakers versus group discussion, and participant satisfaction with the activity component of the sessions.

Results: A total of 20 participants completed the survey, with ages ranging from 19 to 65 years. Overall satisfaction was high across all program components. Detailed results are presented in the table below. Qualitative feedback highlighted opportunities to enhance the program by incorporating hybrid (virtual + in-person) participation options, improving logistical arrangements, increasing caregiver involvement, and expanding wellness focused content activities.

Table 1: Participant Satisfaction with Support Group (N = 20)

Survey Question	Response Options	N (%)
How well do you feel the support group is meeting your needs?	Extremely satisfied	19 (95%)
	Somewhat satisfied	1 (5%)
How would you rate the breakdown of time spent with speakers vs. group discussion?	Sufficient time	19 (95%)
	Need more time in group discussion	1 (5%)
How satisfied have you been with the activity session?	Very satisfied	19 (95%)
	Dissatisfied	1 (5%)

Conclusions: This initiative represents the first in-person BMT support group program in the UAE. Findings demonstrate high levels of patient satisfaction and underscore the value of a multifaceted psychosocial support model for BMT patients. The program's success led to its adoption as a hospital-funded service, with dedicated financial and manpower resources allocated for expansion in 2026. Future studies should evaluate the cost-effectiveness of this intervention and its broader impact on patient quality of life and psychosocial outcomes.

Disclosure: Nothing to declare

P381

CHRONIC FATIGUE SYNDROME AND PSYCHOSOCIAL FACTORS IN ADULT PATIENTS BEFORE HEMATOPOIETIC STEM CELL TRANSPLANTATION

*Olga Chernenko[1], Alisa Volkova[1], Olga Ushakova[1], Anna Smirnova[1], **Ivan Moiseev**[1], Tatyana Ionova[2]*
[1]Pavlov University, Saint Petersburg, Russian Federation (the), [2]State-St. Petersburg University Hospital, Saint Petersburg, Russian Federation (the)

Background: The relevance of this study is due to the high prevalence of chronic fatigue syndrome (CFS) in oncology practice and the need to identify key factors influencing its development and implementation effective rehabilitation programs. The aim of the study was to analyze the relationships between CFS severity and a number of psychological, demographic, and clinical parameters in cancer patients.

Methods: A single-center study was conducted from February to November 2025 at the Gorbacheva Research Institute of Oncology, Cancer Research, and Traumatology. Seventy-five cancer patients (37 women, 38 men) aged 19 to 68 years (mean 40.8, median 40.1) participated in the study before HSCT. The majority of patients were diagnosed with acute leukemia (n = 54, 72%), followed by chronic myeloid leukemia (n = 10, 13.3%), and other diagnoses (n = 11, 14.6%). The average disease duration in the sample was 24.5 months (median 11.5). At the time of the study, 52 patients were in remission from their underlying disease.
Structured questionnaires were used to collect data: the HADS (anxiety and depression) scale, the MMAS-8 to assess treatment adherence, and the FACIT-F questionnaire (severity of CFS). Clinical and anamnestic parameters were also recorded: duration of cancer treatment in months, body mass index (BMI), degree of protein-energy malnutrition (PEM), and the status of the underlying disease. Statistical analysis was performed using nonparametric Spearman correlation analysis (ρ). The level of statistical significance was set at $p < 0.05$.

Results: The study found that the mean CFS score for the sample was 124.5 points (median 127.1). We identified 56% (n=42) of subjects scored above the mean, while 44% (n=33) scored below. According to the FACIT-F questionnaire, the lower the score, the more severe the CFS, with the maximum score being 160 points. Correlation analysis revealed statistically significant moderate inverse relationships between the severity of chronic fatigue syndrome and psychological indicators: the higher the anxiety ($p < 0.001$) and depression ($p < 0.001$), the more severe the CFS. The relationship between CFS severity and treatment adherence (MMAS-8) was weak and did not reach statistical significance ($\rho = 0.205$, $p = 0.077$). None of the clinical and anamnestic parameters demonstrated a significant linear relationship with the severity of CFS.

Conclusions: The data obtained indicate the important role of the psychological component in the pathogenesis and clinical presentation of chronic fatigue syndrome in cancer patients. This highlights the need to include screening and treatment of anxiety and depressive disorders in comprehensive rehabilitation and maintenance therapy programs to reduce the severity of CFS. The results indicate a predominant association between chronic fatigue syndrome and the psychoemotional state of patients in this group of patients. The identified correlations confirm the importance of a bio-psycho-social approach in oncology and the need for multidisciplinary patient management.

Disclosure: Nothing to declare.

P382

CELL THERAPIES AND PSYCHOLOGICAL WELLBEING: ASSESSING IMPACTS AND IMPROVING SUPPORT IN THE UK

Nele Gewert[1], *Niamh Buckingham*[1], *Caitlin Farrow*[1], *Yasmin Sheikh*[1]
[1]*Anthony Nolan, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Cellular therapies are transformative treatments that offer hope to patients facing life-threatening conditions, but their psychological burden can be profound and pervasive. This study aimed to summarise the psychological impact and stressors patients and those close to them experience, identify any unmet needs and gaps in support provision in the UK, and understand policy interventions that could address these gaps.

Methods: We conducted a literature review of peer-reviewed journals and clinical guidelines from the last five years to understand what's already known about psychological needs and support in transplant care and gaps in UK service provision.
Using purposive sampling, we conducted semi-structured interviews with patients, caregivers, related stem cell donors and healthcare professionals about their experiences and priorities for psychological care. This was supplemented by previous survey results about patients' and carers' experiences of the financial impact of treatment and the support they were offered.
Data was coded using a thematic analysis. Emerging themes were clarified through discussion with the research team and a lived experience focus group.

Results: In total, we spoke to eight patients and carers, three stem cell donors and five healthcare professionals. Additionally, we received 48 survey responses and reviewed 40 research articles.
Patients reported feelings of anxiety, depression and PTSD, as well as struggling with their identity and social relationships throughout treatment and recovery. These effects could by exacerbated by long periods of protective isolation, the financial burden of illness and treatment, uncertainty about outcomes and relapse, and disruption to family and social lives. Children may also miss out on developmental and social milestones.
Family members and carers are also negatively impacted, reporting stress, fatigue and anticipatory grief. Financial strain and separation from other children and family members,

particularly for parents, were common stressors for poor mental health in carers.
Finally, experiences of family and sibling donors can vary greatly, with some feeling pride and gratitude, while others can feel anxiety and fear, a responsibility to donate, and guilt about unsuccessful outcomes.
While there are examples of excellent care, access to specialist psychological support is inconsistent across the UK. Participants reported that mental wellbeing support is treated as optional throughout the treatment pathway, with the biggest gaps existing in support for patients with non-malignant indications, for family members, family donors and carers, and for outpatients during post-transplant care.

Conclusions: This study reflects the intense, all-encompassing impact cell therapy can have on patients and loved ones.
Our results suggest that embedding specialist psychologists into multi-disciplinary teams can offer a lifeline to patients in their treatment journey and that, in the absence of specialist support, all patient-facing staff should be adequately trained to spot the signs of poor mental health and take appropriate action to secure support for the patient. Psychosocial support should also be extended to families and family donors.
By investing into workforce training and specialist psychologist roles, and integrating psychological care into long-term follow-up, the UK can lead the way in creating a truly holistic model of care for cell therapy patients and their families.

Disclosure: **Niamh Buckingham, Caitlin Farrow, Nele Gewert, Yasmin Sheikh – Funding**
In the FY 2023/24, Anthony Nolan received a grant of £20,000 from Aventis Pharma Limited to carry out this research.

P383

PSYCHOLOGICAL RISKS AND SUPPORT NEEDS IN HSCT: PILOT STUDY FINDINGS

Volha Mishkova[1], *Daria Volhina*[2], *Volha Vshyukova*[1], *Lubou Zherko*[1], *Inessa Grigoriyeva*[2], *Anzhalika Solntsava*[1]
[1]*Belarusian Research Center for Pediatric Oncology, Hematology and Immunology, Borovlyany, Belarus,* [2]*Republican Research and Practice Center for Mental Health, Minsk, Belarus*

Background: Hematopoietic stem cell transplantation (HSCT) is the only curative option for many severe oncological, hematological, and immunological diseases. However, it is an extremely aggressive procedure with significant toxicity, prolonged isolation, and demanding recovery. Most patients reach HSCT after multiple relapses, already experiencing physical and psychological strain. Under these conditions, assessing anxiety and adjustment disorders becomes critical for maintaining treatment adherence and improving outcomes.

Methods: The pilot phase of the project to develop and implement a method for the medical prevention of anxiety and adaptation disorders (F41, F43) in patients undergoing

hematopoietic stem cell transplantation was conducted at the Transplantation Department of the Republican Scientific and Practical Center for Pediatric Oncology, Hematology, and Immunology in close collaboration with specialists from the Republican Scientific and Practical Center for Mental Health. Clinical-psychopathological, clinical-biographical, experimental-psychological, and statistical research methods were used.

Results: In 2024-2025, the pilot project involved 43 transplant patients (26 boys, 17 girls) aged 3 to 27 years (median age 12.7 years) with cancer (neuroblastoma), oncohematological (acute lymphoblastic leukemia, acute myeloid leukemia, acquired aplastic anemia, anaplastic large cell lymphoma), hematological (myelodysplastic syndrome, Blackfan-Diamond anemia), and immunological (primary immunodeficiency) diseases, as well as the legal representatives of minor patients. To ensure an accurate comparison between the clinical and psychological studies, the patients were divided into three age subgroups: 3 to 7 years (9 patients), 8 to 17 years (26 patients), and 18 to 35 years (8 patients). To assess distress severity in patients before and after HSCT, the NCCN Distress Thermometer was administered. Symptom severity in patients before and after HSCT was evaluated using the Children's HSCT Symptom Questionnaire. Depression severity was assessed using the Children's Depression Questionnaire. A visual analog scale (VAS) was used to evaluate pain intensity before and after HSCT. Changes in quality-of-life indicators were assessed using the PedsQL 4.0 questionnaire.
Based on the analysis of these tests, data confirmed that severe distress in patients is a risk factor for reduced treatment adherence. Uncorrected distress during HSCT procedures is an additional risk factor for anxiety and adjustment disorders.
It was also shown that most parents of patients lack coping strategies to support their children during HSCT; intolerance of uncertainty (fear of death and loss of a child) is closely associated with anxiety symptoms and helplessness. The primary concern is the uncertain prognosis for survival after HSCT and the overall course of the disease.

Conclusions: These results demonstrate a high incidence of distress and adaptation disorders in patients undergoing HSCT and their immediate families. These conditions have a significant impact on treatment adherence and overall quality of life. The need for early psychoprophylactic intervention aimed at correcting anxiety disorders and supporting patients' families has been identified. The development and implementation of psychological support programs are essential for improving the effectiveness of comprehensive transplant care.

Disclosure: Nothing to declare.

P384

ASSESSING PSYCHOSOCIAL NEEDS OF RELATED STEM CELL DONORS: STAFF PERSPECTIVES FROM A UK REGIONAL STEM CELL CENTRE

Jonathan Harrold[1]
[1]*University Hospitals Birmingham, Birmingham, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Related stem cell donors may experience complex psychosocial and relational pressure; psychosocial wellbeing is critical to safe and effective donation. While psychological assessment is well established in UK renal living donor pathways, practice within stem cell donor assessment is less clearly defined.
Aim: To establish a baseline understanding of current practice, staff confidence, and perceived need for psychology input when assessing and supporting the psychosocial needs of related stem cell donors within a UK regional centre.

Methods: An exploratory online survey was distributed to medical staff involved in related donor assessment over a one-month period. Questions focused on current psychosocial assessment practices, confidence in identifying risk, and views on additional psychological support.

Results: Three responses were received. Psychosocial concerns were recognised and in some cases acted upon, including declining donation on mental health or relational grounds. However, approaches varied and largely relied on individual clinical judgement rather than structured tools or agreed pathways. Respondents expressed an appetite for clearer guidance, training, and enhanced access to specialist psychology support to enhance consistency, confidence and care.

Conclusions: This small scoping exercise suggests that psychosocial assessment of related donors is occurring but variable, with staff interest in strengthening psychosocial support. Aligning practice more closely with established UK renal living donor psychology guidance may support staff, improve consistency, and strengthen donor-centred care. Planned developments include targeted training, practical resource materials, and a psychological advice or consultation pathway. Future developments include exploration of donors psychosocial needs and experiences, and the donor-recipient dyad.

Disclosure: No conflicts of interest.

Advancing the Art of Patient Care

ENABLING MODEL INFORMED PRECISION DOSING OF BUSULFAN IN HSCT PATIENTS: AN EXTERNAL MODEL EVALUATION

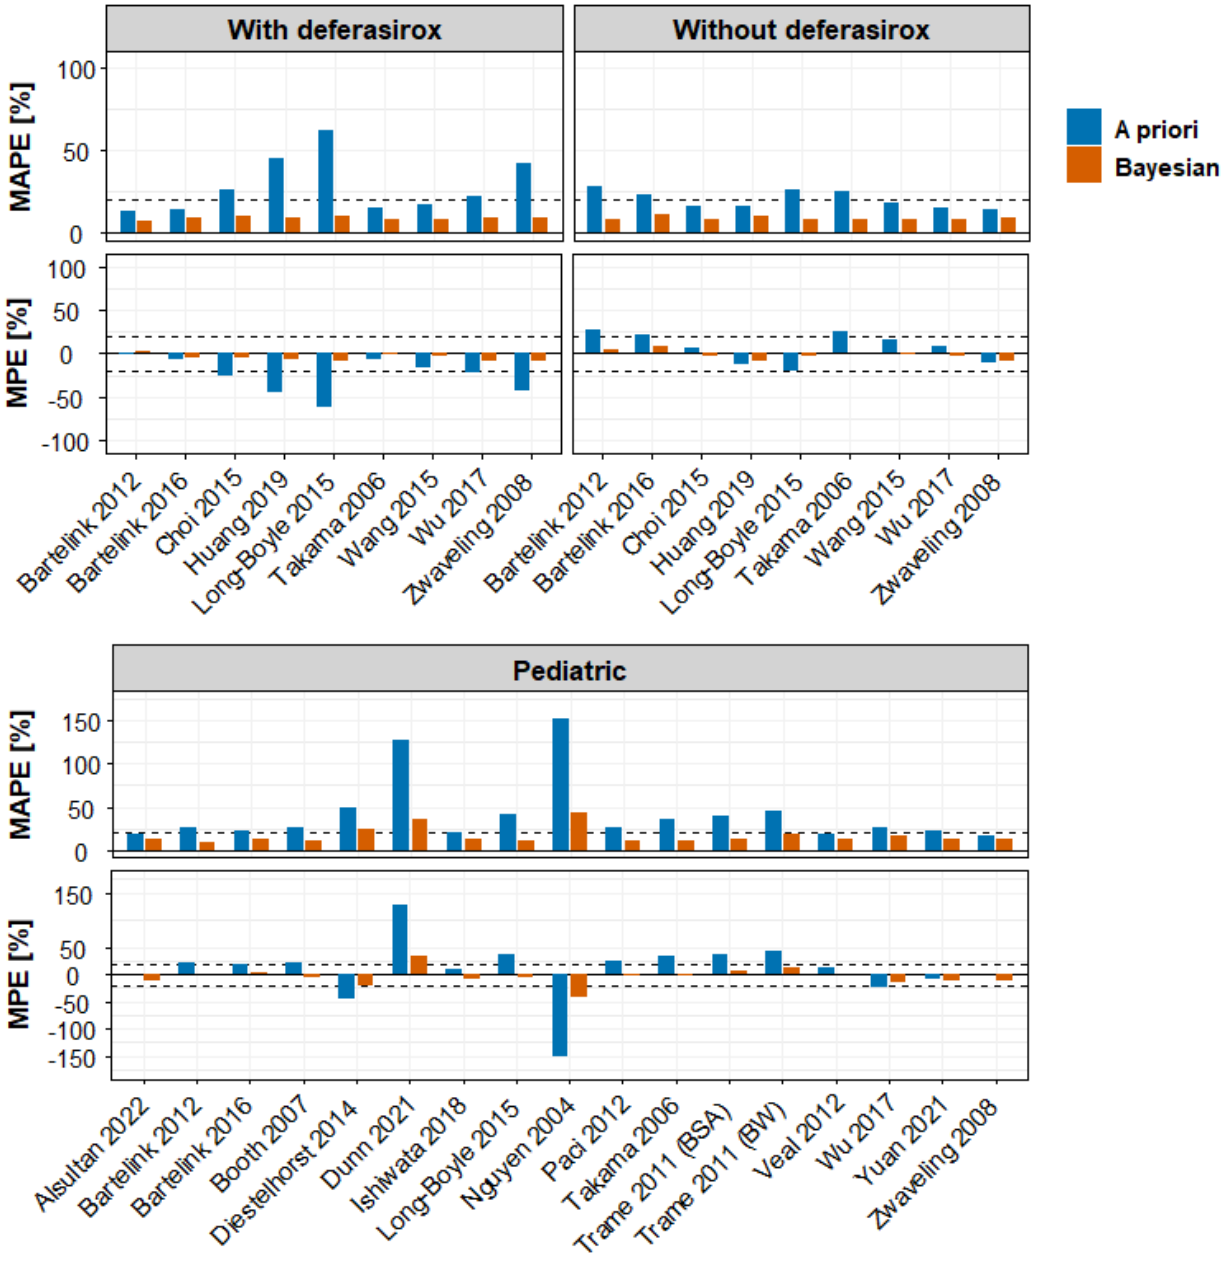
Sandra Witta[1], *Adrin Dadkhah*[2,3], *Claudia Langebrake*[2,3], *Ayuk Francis*[3], *Sebastian G. Wicha*[1]
[1]*Institute of Pharmacy, University of Hamburg, Hamburg, Germany,* [2]*Hospital Pharmacy, University Medical Center Hamburg-Eppendorf, Hamburg, Germany,* [3]*Dept. of Stem Cell Transplantation, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Busulfan is commonly used in conditioning regimens prior to allogeneic hematopoietic stem cell transplantation (allo-HSCT), however its narrow therapeutic index and high interindividual variability in patient pharmacokinetics (PK) presents clinical challenges [Seydoux et al., 2022]. The need to balance adequate busulfan exposure with the risk of toxicity has motivated progress in the adoption of therapeutic drug monitoring (TDM) for busulfan [Domingos et al., 2024; Palmer et al., 2016]. Model informed precision dosing (MIPD) leverages a mathematical model and statistical framework to integrate patient data to precisely estimate individual PK profiles and is therefore recognized as gold standard for calculating a personalized busulfan dose [Shukla et al., 2020]. However, to reliably implement a MIPD workflow, a robust external evaluation of existing population pharmacokinetic (popPK) models is necessitated. The aim of the present study was thus to assess individual model performance in both pediatric and adult patients. Additionally, model performance was compared in adults with and without deferasirox co-medication, an iron chelator indicated to decrease busulfan clearance, to identify best performing models in distinct patient subpopulations [Essmann et al, 2022].

Methods: Retrospectively collected, anonymized PK data from 419 allo-HSCT patients (81 pediatric, 338 adult) with deferasiox co-medication administered in 101 adult patients. A total of 23 published popPK models were processed in NONMEM® (version 7.5) to perform an external model evaluation. Model performance was stratified according to patient population (adult vs. pediatric) and deferasirox co-medication. Models were applied according to the population age group for which they were originally developed. Performance was assessed using *a priori* prediction of the first dosing interval and Bayesian forecasting of the second dose based on prior observations collected during TDM. PK data for a second dose were available for 246 patients. Evaluation metrics included median absolute prediction error (MAPE) and median prediction error (MPE).

Results: The models evaluated in our study varied considerably in their predictive performance in the *a priori* scenario. Bayesian forecasting substantially improved predictive performance, yielding MPE or MAPE values within ±20%, with the exception of two models for the pediatric subpopulation. Within adult patients, the deferasirox co-medication showed an effect on predictive performance in the *a priori* scenario, where the presence of the comedication resulted in predominantly underpredictions (MPE: -62.4 to 1.24%; MAPE: 12.97 to 62.4), compared to the non-deferasirox subgroup (MPE: -19.4 to 27.6%; MAPE: 14.1 to 27.8%). For children, *a priori* predictions varied more notably (MPE: -151.1 to 128.0%; MAPE: 16.5 to 151.1%).
Bayesian forecasting yielded higher accuracy and precision for adult patients with deferasirox co-medication (MPE: -8.36 to 2.71%; MAPE: 7.03 to 10.5%) and in those without the co-medication (MPE: -9.0 to 8.57%; MAPE: 7.73 to 10.9%). Performance was also improved for

children (MPE: -42.2 to 35.0%; MAPE: 9.53 to 42.5%).



Conclusions: Several models demonstrated acceptable model performance overall. As expected, *a priori* predictions were less adequate in the deferasirox co-medication subgroup; however, Bayesian forecasting minimized the impact, potentially attributed to disparities in subgroup sizes. Reliable MIPD implementation necessitates further model evaluations and a popPK model incorporating the effect of deferasirox.

Disclosure: Nothing to delcare.

Pharm2-3

HIGHER INFLIXIMAB EXPOSURE IS ASSOCIATED WITH IMPROVED RESPONSE IN PEDIATRIC STEROID-REFRACTORY GRAFT-VERSUS-HOST DISEASE: DO WE NEED THERAPEUTIC DRUG MONITORING?

Shaden Mahmmod[1,2], *Milou Meijs*[3], *Anne Verbeek*[3], *Suze Jansen*[1,3], *Emmeline Buddingh*[3], *Caroline Lindemans*[1,2], *Rick Admiraal*[1]
[1]*Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands (the),* [2]*Wilhelmina Children's Hospital University Medical Center Utrecht, Utrecht, Netherlands (the),* [3]*Willem-Alexander Children's Hospital Leiden University Medical Center, Leiden, Netherlands (the)*

Background: Steroid-refractory acute graft-versus-host disease (SR-aGvHD) after allogeneic hematopoietic stem cell transplantation (HSCT) is associated with considerable morbidity and mortality. Infliximab (IFX), a monoclonal antibody directed against tumor necrosis factor alpha, is a widely used off-label therapeutic option in SR-aGvHD. This study aims to evaluate the impact of IFX exposure on remission and survival of SR-aGvHD in a pediatric HSCT population.

Methods: This retrospective dual-center cohort study included consecutive children treated with IFX for grade II-IV SR-aGvHD between November 2012 and May 2024. IFX was initiated as standard of care according to national guidelines at 10mg/kg intravenously once weekly. Trough levels were routinely obtained and used to adjust dosing or skip administrations. For this study, IFX exposure (area under the curve; AUC) per patient was estimated using all measured concentrations and a pediatric population pharmacokinetic (popPK) model for IFX. To minimize bias in estimating the true effect of IFX, exposure was restricted to the first 28 days ($AUC_{0\text{-}28}$). The primary outcome was overall response rate (ORR; any improvement in GvHD severity) at day 28. Secondary outcomes were overall survival (OS) and event-free survival (EFS). Cox proportional hazard models and Fine-Gray competing risk analyses were used.

Results: Forty-one patients (19 female, 46.3%) with a median age at HSCT of 8 years (IQR 3.0-11.5) were included. Median follow-up among survivors was 76.5 months (IQR 45-109.3). Malignancy was the most common HSCT indication (19/41, 46.3%). Median time from HSCT to aGvHD and to IFX initiation was 33 days (IQR 25-49) and 45 days (IQR 35-102), respectively. In total, 205 IFX concentrations were available (median 3 per patient); with a median IFX $AUC_{0\text{-}28}$ of 2387 mg*days/L (IQR 1577-3143).
Twenty-five of 41 patients (61%) achieved OR by day 28, with a median time to response of 14 days (IQR 10-18.5). Although, evaluation of the log relative hazard (log HR) against $AUC_{0\text{-}28}$ showed that an $AUC_{0\text{-}28}$>2400 mg*day/L was not associated with higher response rates (figure 1a) in univariable analysis (p=0.12, figure 1b), a significant association was observed in multivariable analysis (log HR 1.015, 95% confidence interval [CI] 1.0033-1.028 for every 100 units in $AUC_{0\text{-}28}$, p=0.013). Higher IFX exposure was also associated with improved overall survival (log HR 0.93; 95%CI 0.87-0.99 for every 100 units in AUC,

p=0.036), and improved EFS (log HR 0.27, 95%CI 0.088-0.85, p=0.025 for those with AUC >2400 mg*day/L).

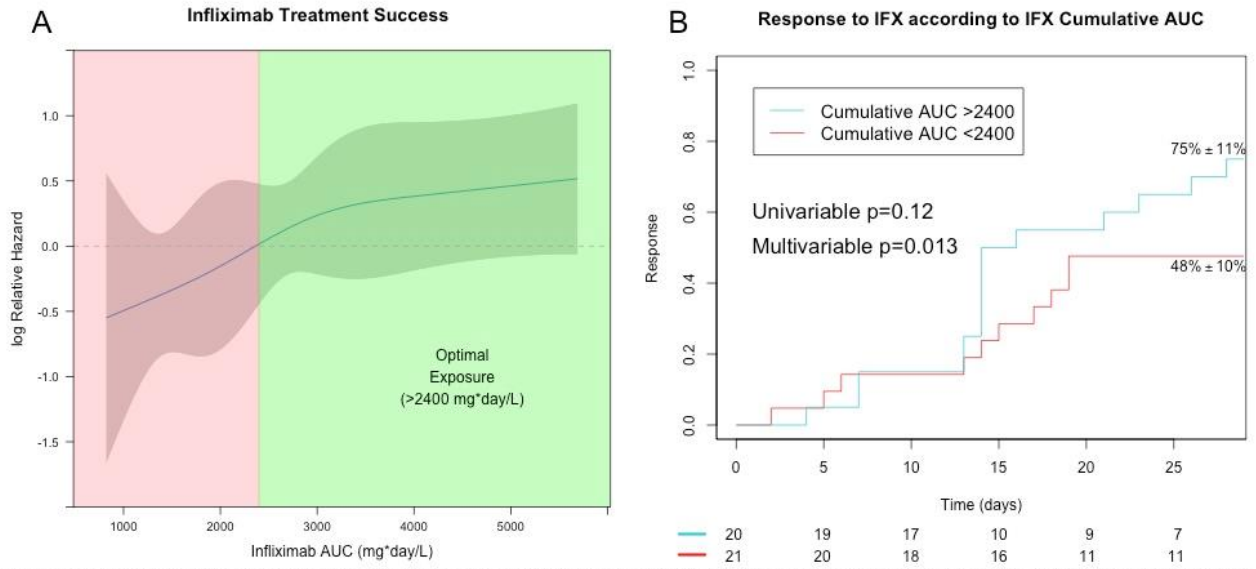


Figure 1: Panel A: Log-relative hazard for overall response rate for acute graft-versus-host-disease plotted against the area under the curve for infliximab from 0-28 days, demonstrating a positive hazard ratio with AUC 0-28 above 2400 mg*day/L. Panel B: Cumulative incidence curve of overall response rate within 28 days after startof infliximab in those with an area under the curve for infliximab from 0-28 days under and over 2400 mg*day/L.

Conclusions: This study suggests that higher IFX exposure is associated with better GvHD response, as well as improved EFS and OS in children with SR-aGvHD, within the first 28 days. These findings support a potential role for therapeutic drug monitoring (TDM) to optimize IFX AUC dosing in this population. Future prospective trials comparing TDM-guided dosing with standard care are needed to confirm these observations.

Disclosure: Nothing to declare

Pharm2-4

EVALUATING THE EXPOSURE-RESPONSE AND EXPOSURE-TOXICITY RELATIONSHIP OF RUXOLITINIB IN STEROID-REFRACTORY ACUTE GRAFT-VERSUS-HOST DISEASE

Aashal Bhavesh Shah[1]
[1]*Veer Narmad South Gujarat University, Surat, India*

Background: One of the leading causes of morbidity and mortality following allogeneic hematopoietic stem cell transplantation (HSCT) is steroid-refractory acute graft-versus-host disease (SR-aGVHD). High-dose steroids are the mainstay of treatment for GVHD; which makes SR-aGVHD life-threatening. Ruxolitinib, a Janus Kinase (JAK) inhibitor, is a critical second-line therapeutic agent for the management of SR-aGVHD, especially in a country like India, where there is limited access to advanced cellular therapies. There are certain

limitations such as baseline cytopenia, variability in patients' plasma concentration and concomitant use of azole antifungal drugs causing drug-drug interactions, may influence therapeutic outcomes in HSCT patients. Thus, this study was planned to evaluate the relationship between the plasma concentration of ruxolitinib with its clinical response and toxicity in patients with SR-aGVHD.

Methods: This was a prospective and observational study conducted at a tertiary care hospital with HSCT centre over a duration of three years. Adult patients aged 18 years or above with grade II-IV SR-aGVHD, being treated with ruxolitinib were included. The drug dose was 5-10 mg 12 hourly. Dose was modified based on drug-drug interactions and cytopenia. Liquid chromatography-mass spectrometry assays were done on days 7, 14 and 28 to measure the steady-state trough plasma concentration of drug. The primary endpoint was overall response rate (ORR) at day 28. The secondary endpoints included incidence of grade ≥3 haematologic toxicities (thrombocytopenia, neutropenia) and incidence of documented infections as well as non-relapse mortality (NRM) and overall survival (OS) at six months. For analysis, patients were categorised based on ruxolitinib trough concentration. Mann-Whitney U test and Fisher's exact test was used for group comparisons. Kaplan-Meier survival analysis was used for estimation of OS and NRM. Factors associated with overall response were identified using multivariate logistic regression models. P-value < 0.05 was considered significant statistically.

Results: Total 86 patients were included in the study. The mean age of participants was 37.53 ± 4.86 years. 63.41% patients had grade III-IV aGVHD. 76.32% patients were on concomitant azole antifungal. The median tough concentration of ruxolitinib was 57.8 ng/mL. The ORR at day-28 was 65.53%, with 33.26% patients showing complete response. Patients with higher trough concentrations (> 70 ng/mL) had significantly higher ORR compared to those with trough concentrations below 70 ng/mL (78.13% vs 53.09%, P = 0.01). Similarly, the incidence of grade ≥ 3 thrombocytopenia was more in higher exposure patients as compared to lower exposure group (28.18% vs 13.96%, P = 0.03). Overall, incidence of infection was 25.69%, the most common being viral infections (56.41%). OS at six months was 59.85% and NRM was 24.69%.

Conclusions: Thus, higher plasma concentration of ruxolitinib showed improved response rates in patients with SR-aGVHD; but also increased incidence of hematologic toxicities. Individualised dose regimens and therapeutic drug monitoring can help optimize ruxolitinib therapy by minimizing drug-drug interactions and incidence of cytopenia in susceptible patients.

OPEN WIDE: EXPLORING SALIVA AS A NON-INVASIVE TOOL FOR POSACONAZOLE LEVELS IN CHILDREN

Heather Weerdenburg[1,2,3]
[1]The University of Melbourne, Melbourne, Australia, [2]The Royal Children's Hospital, Melbourne, Australia, [3]Murdoch Children's Research Institute, Melbourne, Australia

Background: Therapeutic drug monitoring (TDM) is essential for optimising triazole antifungal therapy in immunocompromised children. Frequent blood sampling, however, is invasive and distressing, particularly for children undergoing intensive cancer treatment or haematopoietic cell transplantation (HCT). Non-invasive TDM methods, such as saliva sampling, offer a promising alternative due to ease of collection and suitability for home use. Emerging evidence supports salivary monitoring for agents such as voriconazole, but there are no published data for posaconazole despite its increasing use in children. This study aimed to determine whether posaconazole can be reliably detected in the saliva of paediatric oncology and HCT patients.

Methods: We conducted a 2-year prospective pharmacokinetic study (2023 to 2025) at The Royal Children's Hospital Melbourne. Children aged 1 to <18 years receiving posaconazole during inpatient care were eligible; those with oral mucositis, bleeding, or infection were excluded. Paired posaconazole serum levels at steady-state (5 to 7 days after initiation) and unstimulated saliva samples were collected within 15 minutes of each other using both an oral synthetic swab and passive drool (0.5–2 mL, Salimetrics®). Samples were analysed via ultra-performance liquid chromatography–tandem mass spectrometry in positive electrospray ionisation mode. Ethics approval was obtained (HREC 81867).

Results: Ten children (median age 14.1 years, range 8.1–17.8) were enrolled. A median of two serum (range 2–5) and two saliva (range 2–5) samples per child were collected, with a median sampling interval of 5 minutes (range 0–10). Posaconazole concentrations were undetectable (<0.05 mg/L) in 25/26 (96%) saliva samples, despite majority of the samples reported as therapeutic (median 1.4 mg/L, range 0.1–5.0). Only one saliva sample had detectable posaconazole (0.06 mg/L) with a paired serum concentration of 5.0 mg/L. Correlation between plasma and saliva concentrations could not be calculated.

Conclusions: This is the first prospective study assessing salivary detection of posaconazole in children. Our findings indicate that saliva sampling is unsuitable for posaconazole TDM in immunocompromised children. The minimal detection is possibly related to its high protein binding (>98%) similar to itraconazole and in contrast to voriconazole (~58%) and fluconazole (~10%), which have demonstrated reliable salivary penetration. Future work should focus on agents with proven salivary penetration, such as fluconazole and voriconazole, to reduce the burden of invasive sampling in this population.

ANTIFUNGAL PROPHYLAXIS PATTERNS AND INVASIVE FUNGAL INFECTIONS OUTCOMES IN PAEDIATRIC ALLOGENIC HCT: A MULTICENTRE COHORT STUDY

Hyatt Assafiri[1], *Aleisha Anderson*[2], *Vasant Chinnabhandar*[2], *Gabrielle Haeusler*[1], *Angelika Kimble*[2], *Kristene Rimbaldo*[1], *Heather Weerdenburg*[1], *Hannah Walker*[1], *Daniel Yeoh*[2]
[1]*The Royal Children's Hospital, Melbourne, Australia,* [2]*Perth Children's Hospital, Perth, Australia*

Background: Invasive fungal infections (IFIs) remain a significant complication after paediatric haematopoietic stem cell transplant (HCT). Evidence guiding antifungal prophylaxis selection in children is limited, particularly regarding the most appropriate mould-active strategies for children who develop IFI early post HCT. This study aimed to determine antifungal prophylaxis use and associated IFI incidence across a multicentre paediatric HCT cohort.

Methods: We conducted a retrospective review of children undergoing first allogenic HCT at two large Australian HCT centres; The Royal Children's Hospital (RCH) and Perth Children's Hospital (PCH) between 2016 and 2022. Patients who received a second HCT were excluded. Antifungal prophylaxis use was divided into two time periods based on the timing of engraftment; a pre-engraftment period (start of conditioning to Day 30) and a post-engraftment period (Day 31–100). Choice of antifungal prophylaxis was classified as non–mould-active (fluconazole), mould-active (including micafungin, liposomal amphotericin B, voriconazole and posaconazole), or mixed (both non-mould active and mould active agents). Clinical data obtained included patient demographics, transplant indication, donor type, antifungal stop date, and development of IFI defined as; proven, probable or possible IFI.

Results: A total of 239 allogeneic HCT episodes were analysed (RCH 84%; PCH 16%). Median age at day 0 was 6.9 years (IQR 3.1–12.8), and 59% of patients were male. Twenty-five patients had a history of IFI prior to HCT (10.5%); these children were older (11.5 vs 6.7 years) and more often had malignant disease (72% vs 57%), particularly AML (61% vs 29%) compared to children without a history of IFI pre-HCT. Donor types were similar between both groups.
Among children without prior-IFI pre-HCT, pre-engraftment antifungal prophylaxis used most frequently was fluconazole in 71.96% (154/214), with mould-active agents used in 21.96% (47/214) and mixed regimens in 6.07% (13/214). Children with prior-IFI pre-HCT were more likely to receive secondary prophylaxis with a mould-active agent in 60% (15/25) and fluconazole was rarely prescribed alone (2/25, 8%).
Regarding post-engraftment prophylaxis, fluconazole remained the most common in the no prior-IFI pre-HCT group (96/214, 44.85%), with mould-active (62/214, 28.97%) and mixed regimens (56/214, 26.16%) also used. Prior-IFI pre-HCT patients continued to favour mould-active (16/25, 64%) and mixed prophylaxis regimens (6/25, 24%).
IFI incidence overall occurred infrequently, in 10.46% (2+23/25+214) of the total cohort. IFI incidence was lower (2/25, 8%) in children with prior-IFI pre-HCT, compared to (23/214, 10.75%) in those with no history of IFI pre-HCT. All IFIs in prior-IFI pre-HCT patients occurred pre-engraftment (1 probable and 1 possible).
In children without prior-IFI pre-HCT, IFIs occurred more frequently in the post-engraftment

period (14/23, 60.9%) compared to pre-engraftment (9/23, 39.1%). Importantly, all proven IFIs (2/2) occurred on fluconazole monotherapy. Probable IFIs (9/23, 39.1%) occurred across fluconazole monotherapy, mould-active and mixed regimens.

Conclusions: Antifungal prophylaxis in paediatric allogenic HCT was strongly risk-adapted, with increased mould-active use in patients with prior history of IFI. IFIs occurred across all prophylaxis strategies, with all proven IFIs occurring in patients on fluconazole monotherapy. Most IFIs arose post-engraftment, highlighting the need for consistent, risk-based escalation to mould-active prophylaxis in immunosuppressed children.

P387

A UK RETROSPECTIVE ANALYSIS OF THE USE OF BELUMOSUDIL IN THE MANAGEMENT OF CHRONIC GRAFT VERSUS HOST DISEASE

Siobhan Smith[1], *Nick Duncan*[2], *Fleur Harvey*[3], *Chris Salmen*[3], *Francesca Kinsella*[2]
[1]*Cardiff and Vale University Health Board (On Behalf of the UK BMT Pharmacists Group and BSBMTCT), Cardiff, United Kingdom of Great Britain and Northern Ireland (the),* [2]*University Hospitals Birmingham NHS Foundation Trust, Birmingam, United Kingdom of Great Britain and Northern Ireland (the),* [3]*The Royal Marsden NHS Foundation Trust, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Chronic Graft versus Host Disease (cGvHD) is the leading cause of late morbidity and mortality following allogeneic stem cell transplantation. Belumosudil is licensed in the UK for the treatment of cGvhD after two or more systemic treatments. This study retrospectively assessed the delivery of Belumosudil and the available outcome data.

Methods: All UK allograft centres were invited to submit data to the UKBMT Pharmacists Group. All patients commenced on Belumosudil from July or December 2023 in Scotland, England or Wales were included, according to Scottish Medicines Consortium and NICE approvals respectively.

Results: 179 patients were included from 10 UK centres during the study period (June to November 2025 dates). Table 1 shows baseline data and prior treatments delivered.
129 (72%) of patients received Belumosudil 200mg once a day, where 20 (16%) received concomitant PPI. In contrast, 94% (46) of the 49 patients who received Belumosudil twice a day received PPI.

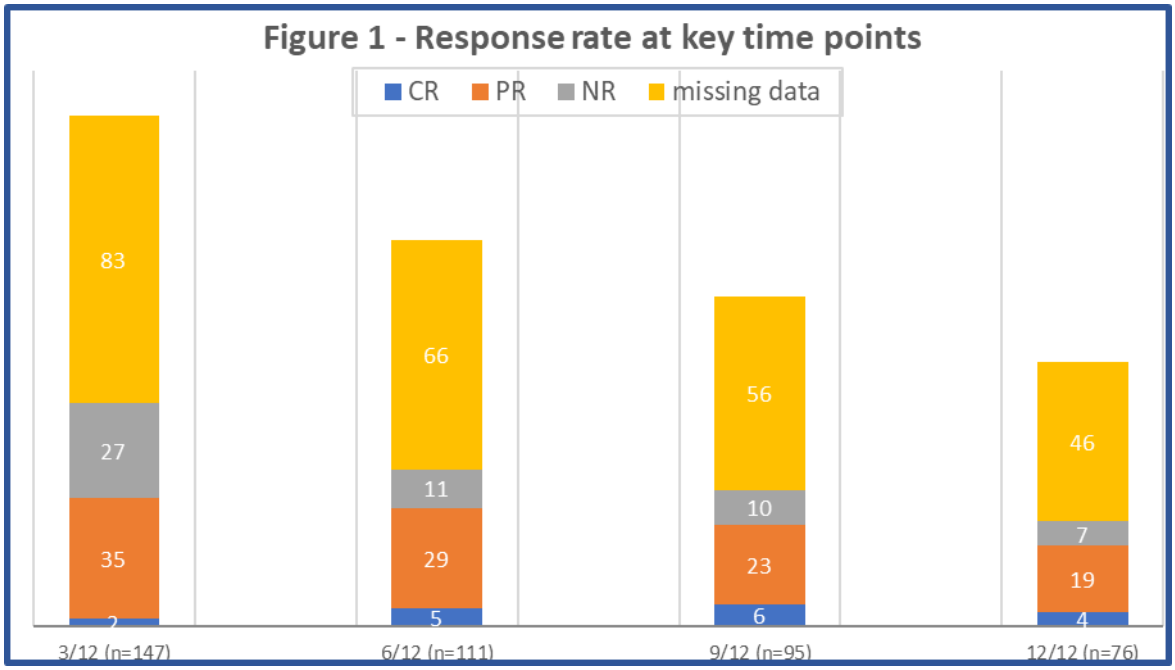
149 patients had received Belumosudil for at least 3 months to permit assessment of response. After excluding patients with missing NIH response data (n=71), the best overall response rates were as follows (n=78): CR = 9 patients (11.5%), PR = 45 patients (57.7%) and NR = 24 patients (30.8%). Response rates at specific time points are presented in figure 1.

Lee Symptom scoring was only undertaken in 3 centres and both baseline and follow-up scores were only available for 19 patients in total. 12/19 patients (63.2%) reported a clinically significant improvement in Lee symptom score (defined as a reduction in total score of at least 7 points) at some point during belumosudil treatment. When comparing baseline scores with scores at last follow-up, 7/19 patients (36.8%) reported an improvement.



Steroid reduction is an important measure of treatment efficacy. 92 (51%) patients were in receipt of steroids when starting belumosudil (33 (18%) unknown). Data recorded at 90 days for 58 of these patients shows 40 reduced their steroid dose (12 fully tapered) within 90 days. Of the 42 patients still taking belumosudil at 6 months 28 (67%) had decreased steroid doses where a further 10 (24%) tapered fully.

Belumosudil was stopped in 64 (36%) of patients over the course of the study. 5 patients

(8%) had a complete response in their cGvHD. 14 (22%) had progressive cGvHD, 15 (23%) stopped due to adverse effects, and 23 (36%) stopped due to death. 3 (5%) patients chose to stop belumosudil (3 (3%) unknown). Adverse effects included hepatotoxicity (5, 33%), Oedema (2, 13%), CNS related (4, 27%), other 4 (27%).

Conclusions: This study highlights the challenges in reporting and collecting real-world data retrospectively for cGvHD, where there can be significant missing data in response criteria and patient reported outcome measures. Where data was available, the combined overall response rate of 69.2% is comparable to that reported in the prospective ROCKstar trial, as were the reported rates of adverse events. This exemplifies the need for a dedicated prospective UK GvHD database and registry for future real-world studies.

EVALUATING THE IMPACT OF A DEDICATED OUTPATIENT PHARMACY CLINIC ON MEDICATION SAFETY AND TRANSITIONS OF CARE FOR PATIENTS UNDERGOING HAEMATOPOIETIC STEM CELL TRANSPLANTATION

Karim Ibrahim[1,2,3], *Peter Samios*[1], *Barbara Withers*[1,2,3], *Annabel Mary Horne*[1,2], *Simone Kay Jensen*[1,2], *Phoebe Jeffery*[1,2], *Sinead Keane*[1], *Bashar Alani*[1,2,3], *Amit Sen*[1,2], *Nabin Karki*[1,2,3], *Mao-Mao Yu*[1,2]
[1]*St Vincent's Hospital Sydney, Darlinghurst, Australia,* [2]*The Kinghorn Cancer Centre, Darlinghurst, Australia,* [3]*School of Medicine and Health, University of New South Wales Sydney, Kensington, Australia*

Background: Medication-related problems are common in haematopoietic stem cell transplantation (HSCT) due to complex polypharmacy, frequent dose adjustments, narrow therapeutic index medicines, and multiple care transitions. Dedicated transplant pharmacists play a vital role in improving medication safety and streamlining transitions of care, but evidence for outpatient pharmacy clinic models is limited. We established an outpatient HSCT pharmacy clinic service in May 2025 and evaluated its impact over the first six months (30th of May to 30th of November 2025). The aims were to describe services delivered, quantify pharmacist interventions and assess early process outcomes.

Methods: A prospective service evaluation was conducted for all patients attending the pharmacist-led outpatient clinic between 30th of May and 30th of November 2025. The clinic aimed to review patients 7–10 days prior to planned transplant admission and 7–14 days after discharge, each consultation was allocated 30 minutes. During each visit, the pharmacist reviewed the upcoming conditioning chemotherapy protocol, discussed key side

effects, documented allergies, completed a full medication history and medication reconciliation, identified drug interactions, reviewed relevant drug levels, screened for adherence issues, and assessed tolerability issues with prior chemotherapy. The clinic operated using trained HSCT pharmacists, aligned with FACT–JACIE standards for pharmacist competence, quality management, and record keeping. Data were obtained from the electronic medication management record and the cancer centre operational dashboard, capturing the number of visits, patient demographics, medication reconciliation activity, allergy documentation, and the number and type of pharmacist-led interventions. Interventions were categorised into four domains relevant to quality and safety: cessation or modification of inappropriate or interacting medicines, medication additions required to meet protocol-based recommendations, therapeutic drug monitoring (TDM)-guided dose changes, and chemotherapy dose optimisation based on patient-specific parameters. Descriptive statistics were used to summarise the clinic activity.

Results: Over the six-month period, 52 patients (13 autologous and 39 allogeneic transplant recipients), attended 76 outpatient visits, with 43 pre-transplant and 33 post-transplant consultations. Medication reconciliation and allergy documentation clarification were completed for all 52 patients, resulting in standardised medication lists that were directly accessible to inpatient teams. A total of 109 pharmacist interventions were recorded, of which 91 (83%) were accepted by the transplant team. This equated to an average of 2.1 interventions per patient, and 1.4 interventions per visit. The most frequent interventions involved cessation or modification of inappropriate or interacting medicines (n=57). Suggested medication additions as per transplant protocol (n=24), TDM-guided dose-change recommendations (n=20), suggested chemotherapy dose adjustments (n=8).

Conclusions: During the first six months of operation, the implementation of the outpatient pharmacy clinic enhanced medication safety, improved the accuracy and consistency of medication reconciliation and allergy documentation, and strengthened transitions of care. The high proportion of accepted pharmacist interventions highlights meaningful clinical impact, opportunities for deprescribing, and strong multidisciplinary collaboration. Ongoing data collection will focus on broader quality indicators, including reducing time to chemotherapy charting and ordering, patient and clinician satisfaction data, and reductions in readmission rates to further evaluate and quantify the clinic’s contribution to overall transplant program quality.

P390

POSACONAZOLE IN PAEDIATRICS: ARE WE HITTING THE MARK OR MISSING THE TARGET?

Heather Weerdenburg[1,2,3]
[1]The University of Melbourne, Melbourne, Australia, [2]The Royal Children's Hospital, Melbourne, Australia, [3]Murdoch Children's Research Institute, Melbourne, Australia

Background: Invasive fungal infections (IFIs) pose a significant risk to immunocompromised children undergoing cancer treatment or haematopoietic cell transplantation (HCT). Posaconazole is widely used for prophylaxis and treatment, but paediatric data on optimal dosing remain limited. This study evaluates posaconazole dosing, therapeutic drug monitoring, and clinical outcomes of prophylaxis and treatment in children.

Methods: This 8-year retrospective audit included children (≤18 years) receiving cancer therapies or HSCT at the Royal Children's Hospital, Melbourne. Data on posaconazole dosing, serum concentrations, efficacy, and adverse effects were collected. The non-parametric Mann–Whitney U-test test was used to compare continuous variables. Statistical analysis was performed using IBM SPSS Statistics for Windows, Version 29.0 (IBM Corp., Armonk, NY, USA).

Results: Eighty children (median age 12.8 years) received 106 posaconazole courses: two-thirds were for prophylaxis, and the remainder were for IFI treatment. The majority had haematological malignancies (71%), with 36% undergoing allogenic HCT. Therapeutic concentrations (prophylaxis ≥0.7µg/mL; treatment ≥1.0µg/mL) were achieved in 92% and 76% of courses, respectively. The IV formulation achieved target concentrations in all patients with a median dose of 7 mg/kg/day. For the delayed release tablet, 97% (median dose 7mg/kg/day) and 83% (median dose 10mg/kg/day) achieved the prophylaxis and treatment target, respectively. While for oral suspension, only 67% of prophylaxis courses (median dose 7mg/kg every 8 hours) and 29% of treatment courses (median dose 8 mg/kg every 8 hours) achieved target concentrations. Children receiving oral suspension via a nasogastric tube had a lower success rate compared patients receiving doses orally (median 0.9 µg/mL, range 0.4-2.2 vs. 0.6 µg/mL, range 0.1-1.2, $p < 0.05$). Treatment of proven/probable IFIs was successful in all cases (median trough concentration 1.7µg/mL). Adverse events occurred in 21% of patients with hepatotoxicity occurring in 16%.

Conclusions: Posaconazole is effective in preventing and treating IFIs in children but requires higher than recommended doses to achieve therapeutic targets for treatment.

Advancing the Art of Patient Care

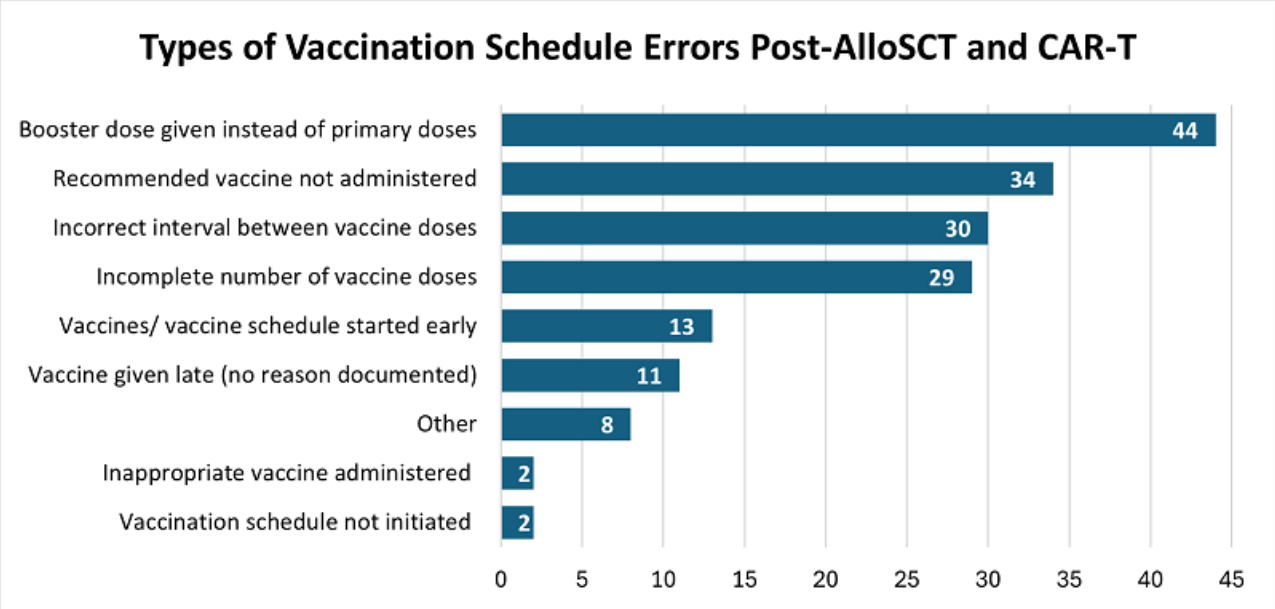
AN EVALUATION OF COMPLIANCE WITH A VACCINATION PROGRAMME FOR PATIENTS WHO HAVE UNDERGONE ALLOGENEIC STEM CELL TRANSPLANTATION OR CAR T-CELL THERAPY

Vaishali Dulobdas[1], *Simran Dhadda*[1], *Nick Duncan*[1], *Donna Walsh*[1]
[1]*University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Patients undergoing stem cell transplantation (SCT) or CAR T-cell therapy experience profound and prolonged immunosuppression, increasing the risk of severe and life-threatening infections. Additionally, there is a decline in antibody levels to vaccine-preventable diseases post-treatment, therefore patients should be considered never vaccinated. Consequently, patients should be re-vaccinated to restore antibody levels and mitigate infection-related mortality. National and international guidance recommend commencing vaccination relatively early post-treatment. Inactive vaccinations are typically advised from 3-6 months, while live vaccines are generally considered safe after two years has elapsed. Local practice at our hospital (a large tertiary haematology centre) is to ask the general practitioners (GP) of our patients to deliver the vaccination programme based on a printed schedule that we provide.
We conducted a retrospective evaluation of vaccination practices. Our primary aims were to assess compliance with the vaccine schedule and to identify common errors.

Methods: Patients who received an allogeneic SCT (AlloSCT) between January-December 2024 or CAR-T therapy between June 2019-March 2025 were eligible for inclusion. Patients who died or relapsed within 6 months, or were experiencing complications following treatment necessitating postponement of vaccinations (e.g. GvHD) were excluded. Primary Care (GP) records and clinic letters were reviewed to identify vaccine administration or documented reasons for omission. Compliance was assessed by comparing vaccine initiation and details of recorded vaccinations (including vaccine brands) with the schedules issued to patients and their GPs. Data was inputted into Microsoft Excel, and descriptive analysis was conducted.

Results: In total, 147 patients (62 AlloSCT and 85 CAR-T) were included in the evaluation. 58.5% (40 AlloSCT and 46 CAR-T) of patients were non-compliant with at least one part of their vaccination schedule. Overall, a total of 173 errors were identified, with a median of one error per patient (range 0-5). These errors were classified into nine categories, as shown in Figure 1.



The most common reason for non-compliance was booster doses given instead of the primary vaccine(s) (n=44), this included COVID-19 boosters given instead of primary doses (n=30) and Pneumovax 23® (designed to be given as a booster) being given instead of Prevenar13® (n=13). Other reasons include omission of recommended vaccinations (most commonly shingles or Pneumovax 23® vaccine) (n=34), receiving the incorrect number of vaccinations (n=29), and incorrect vaccine intervals (n=30). We found no major differences in errors between the AlloSCT and CAR-T subgroups.

Conclusions: This retrospective service evaluation has highlighted significant non-compliance with the vaccination schedule post AlloSCT and CAR-T, with 58.5% of patients identified as non-compliant. Reasons were not directly investigated but are likely to be multifactorial e.g. delayed or missing vaccine paperwork, unfamiliarity with the procedure amongst GPs or vaccine unavailability. The non-compliance issues identified could potentially lead to inadequate vaccine responses, leaving patients vulnerable to vaccine-preventable infections. To improve compliance, we introduced a vaccine passport in July 2025 which is now given to all eligible patients. We believe that enhanced communication and education, along with continued close monitoring of compliance, will be essential to optimize vaccine adherence and reduce infection-related complications in this vulnerable population.

A PROSPECTIVE STUDY EVALUATING THE ROLE OF NOVEL PLATELET-DERIVED MICRORNAS IN MEGAKARYOCYTE DIFFERENTIATION

Aashal Bhavesh Shah[1]
[1]*Veer Narmad South Gujarat University, Surat, India*

Background: Extracellular vesicles (EVs), derived from platelets, containing bioactive molecules, such as, proteins, lipids, and microRNAs (miRNAs) have emerged as critical mediators of intercellular communication. Recent evidence has suggested key influence of platelet-derived miRNAs in the fate and function of other haematopoietic cells, the role of miRNAs in megakaryocyte differentiation is not fully established. Identifying and characterising the specific miRNAs and their regulatory pathways can help reveal novel potential therapeutic targets for platelet-related disorders and bone marrow failure syndromes. Hence, this study was planned with an aim to identify and evaluate the functional role of platelet-derived miRNAs in regulating thrombopoiesis.

Methods: This was a prospective, observational study conducted at a tertiary care hospital. For the study, platelets were obtained from healthy donors after taking written informed consent. Nanoparticle tracking analysis and CD63/CD41 flow cytometry was used to characterise EVs. Next-generation sequencing (NGS) was used for global miRNA profiling after extracting total RNA from EV. Quantitative real-time polymerase chain reaction (qRT-PCR) was used to validate the candidate miRNAs with highest differential expression. Primary human megakaryocytes were co-cultured with platelet-derived EVs with identified miRNAs to evaluate their effects. Proplatelet formation, flow cytometry and immunofluorescence were conducted. CRISPR/Cas9-mediated knockout megakaryocyte progenitors were used for further exploration of specific miRNAs. Comparisons between treated and control groups were made using unpaired two-tailed t-tests or one-way ANOVA with post hoc Tukey's test where appropriate. Data were expressed as mean ± standard deviation (SD). $P<0.05$ was considered statistically significant.

Results: Platelets from 60 donors was collected. The most significantly upregulated miRNAs on NGS were miR-223-5p and miR-126-3p with fold changes of 3.8 ± 0.6 and 4.5 ± 0.7, respectively ($P \leq 0.001$) compared to control group. This was confirmed by qRT-PCR. Co-culture of megakaryocytes with EVs showed significant upregulation of CD41+ and CD42b+ cells ($P < 0.001$). There was a significant ($P < 0.01$) enhancement of proplatelet formation in megakaryocytes treated with miR-223-5p (68.7 ± 5.2) and miR-126-3p (74.2 ± 6.1) compared to untreated control (32.4 ± 4.5). The knockout experiment revealed a significant reduction in thrombopoietic potential and impaired formation of proplatelet in vitro.

Conclusions: Platelet-derived EVs act as carriers of regulatory miRNA species that influence hematopoietic cell development in a paracrine manner. miR-223-5p and miR-126-3p were identified as critical platelet-derived miRNAs enhancing thrombopoiesis. These findings provide a basis for exploring miRNA-based therapeutic strategies in thrombocytopenic disorders such as ITP and aplastic anaemia.

Disclosure: There are no conflict of interest to declare.

IMPACT OF LOW DOSE ANTI-T-LYMPHOCYTE GLOBULIN ON CLINICAL OUTCOMES IN THE ERA OF POST-TRANSPLANT CYCLOPHOSPHAMIDE

Mehmet Dokumacı[1], Derya Üstün Eroğlu[1], Elçin Erdoğan Yücel[1], Aybüke Olgun[1], Züleyha Can Erdi[1], Gökhan Sezgin[1], Zehra Narlı Özdemir[1], Cengiz Ceylan[1], ***Oktay Bilgir***[1]
[1]*Izmir City Hospital, Izmir, Turkey*

Background: Post-transplant cyclophosphamide (PT-Cy) and Anti-T-Lymphocyte Globulin (ATLG) are effective strategies for graft-versus-host disease (GVHD) prophylaxis, and are increasingly used in combination. While emerging evidence suggests association between absolute lymphocyte count (ALC) and ATLG clinial outcomes, this relationship has not yet been evaluated in the specific setting of PT-Cy-based prophylaxis. Therefore, we conducted a single-centre study to analyse the effect of the ATLG dose and ALC count on clinical outcomes in patients receiving PT-Cy.

Methods:

Patients who underwent allogenic hematopoietic stem cell transplantation (allo-HSCT) between May 2024 and October 2025 and received combined GVHD prophylaxis with pre-transplant ATLG (Grafolon®) and PT-Cy (days +3/+4, total 60-100 mg/kg) were included. Our center's protocol utilized a lower-dose ATLG regimen (cumulative <10 mg/kg). Pre-treatment ALC (cell/µL) was recorded on the day of first ATLG infusion. ATLG doses were assessed as total mg and mg/kg. Overall survival (OS), progression-free survival (PFS), Graft-versus-host-disease (GVHD)- free survival, cytomegalovirus (CMV) reactivation-free survival, and BK virus event- free survival, neutrophil, platelet, lymphocyte engraftment days were analysed. Survival probabilities were calculated using the Kaplan–Meier method (Log-rank test for comparisons). The impact of key variables, including ATLG dose and ALC, was assessed using Cox proportional hazards regression models (HR and 95% CI), with variables categorized by median cut-off. Pearson coefficients were calculated in correlation analyses with engraftment days. Statistical significance was defined as $p < 0.05$. Analyses were performed using SPSS and MedCalc (version 23.2.0)

Results: A total of 25 patients (60% female) with a median age of 53 years (range: 21–69) were included in the retrospective analysis. The demographic, clinical, and transplant characteristics of patients are listed in Table 1. The median follow-up period was 127 days (13-403). A total ATLG dose of ≥480 mg was significantly associated with a higher hazard of CMV reactivation (HR: 3.60; 95% CI: 1.29–10; p=0.01) compared to lower doses. The incidence of CMV reactivation was not significantly influenced by ALC levels or the ATLG dose when analyzed by mg/kg (p>0.05). Additionally, patients with lower ALC (<140/ µL) had significantly lower BK virus event-free survival (p=0.007). No statistically significant correlation was found between the ATLG dose (mg/kg or total mg) or the ALC and the time to neutrophil, platelet, or lymphocyte engraftment (p>0.05). Neither the ALC nor the weight-based ATLG dose (mg/kg) showed a statistically significant association with other survival endpoints.

Table 1. Distribution of demographic, clinical, and transplant characteristics of patients who underwent allogeneic hematopoietic stem cell transplantation

		Total Number n=25(100)	**Median(Min-Max)**
Year			53(21-69)
Weight (kg)			70(45-122)

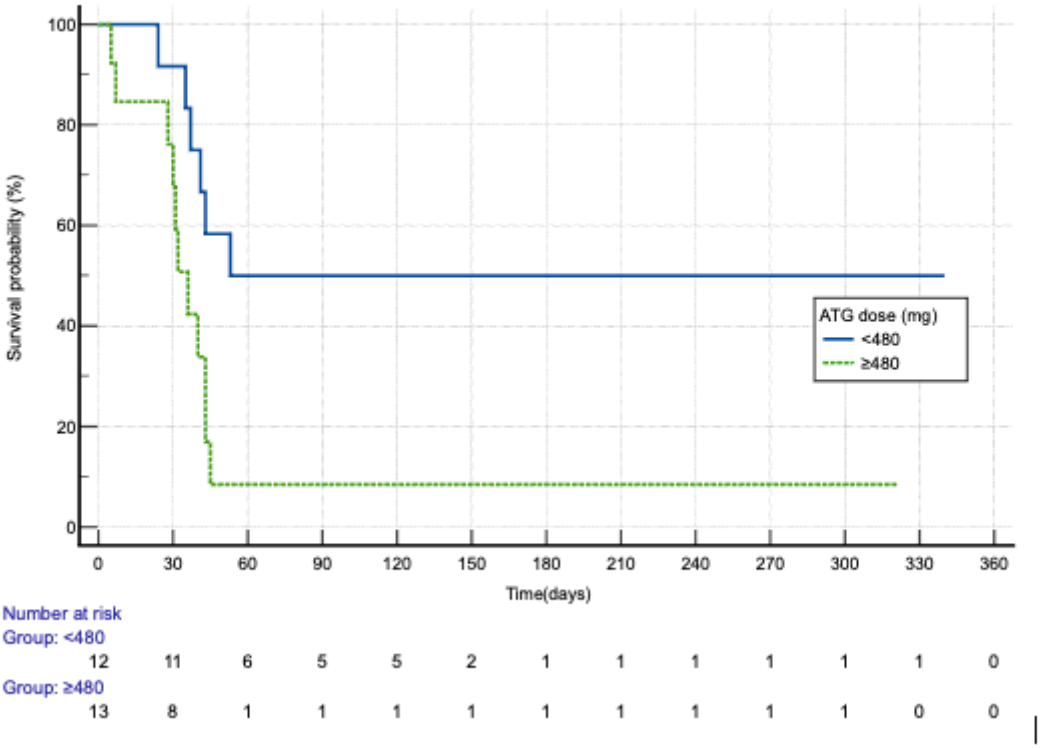
Disease progression		3(12)	
Death		5(20)	
CMV Reactivation		17(68)	
ATLG Dose <6.27 (mg/kg) ≥ 6.27 (mg/kg) <480 (mg) ≥480 (mg)		 13(52) 12(48) 12(48) 13(52)	

ALC <140/µL ≥ 140/µL		11(44) 14(56)	0.14(0-4.70)
Engrafmant days Neutrophil engraftment Platelet engrafment ALC engrafment			15(11-32) 18(11-33) 30(16-125)

AML: Acute myeloid leukemia, HLA: Human leukocyte antigen, MAC: Myeloablative conditinoing, NMA: Non-myeloabletive, RIC: Reduced intensity conditioning, MRD: Minimal residual disease, aGVHD: acute graft-versus-host-disease,
CMV: Cytomegalovirus, ATLG:Anti-T-lymphocyte globulin, ALC: Absolute lymphocyte count

Figure 1. CMV reactivation-free survival



Conclusions: Our study demonstrates that higher cumulative ATLG doses significantly increases the hazard of CMV reactivation, and ALC serve as a risk marker associated with BK virus event-free survival in patients receiving combination of PT-Cy and ATLG.
Overall, these findings, when used in combination with PT-Cy, highlight the importance of careful ATLG dose optimization rather than fixed weighted dose and support the need for

larger-scale studies to further clarify exposure-response relationships and improve personalized prophylaxis strategies.

ANTICIPATION OF PHARMACOTHERAPEUTIC PROBLEMS PRIOR TO ALLO HEMATOPOÏETIC CELL TRANSPLANTATION IN PATIENTS WITH CO-MORBIDITIES: A TWO YEARS EXPERIENCE REVIEW

*Margaux Jeanjacquot[1], Valérie Coiteux[1], Emelle Ufuksen[1], Tanguy Ayade[1], **Léonardo Magro**[1], Micha Srour[1], David Beauvais[1], Nicolas Gazeau[1], Paul Chauvet[1], Ibrahim Yakoub-Agha[1], Pacal Odou[1], Nicolas Simon[1]*
[1]Lille University Hospital, Lille, France

Background: Allogeneic hematopoietic cell transplantation (allo-HCT) frequently involves patients with multiple co-morbidities and then polymedication. This increases the risks of complications during the transplant procedure, either through the mechanism of action, the adverse reaction profile or the risk of pharmacological interactions. Since more than 2 years, some cases are discussed between an hematologist and a clinical pharmacist in order to anticipate any problem related to the patients' pharmacotherapy.
This study aimed to describe the decisions issued before the transplant procedure.

Methods: This is a monocentric and descriptive study. From January 1st, 2023 to April 30th, 2025, patients eligible to allo-HSCT were selected by a senior hematologist on the base of predetermined risks of complications. For each patient, we recorded all their medications 7-15 days before admission. As the engraftment protocol was known, the risks related by the whole pharmacotherapy were screened, leading to shared therapeutic decision before hospitalization and summarized in the patients' medical electronic file.
Pharmaceutical interventions (PI) were based on an adapted version of the Act-IP classification [1] consist in: continuing, adding, stopping or substituting drugs, dose adaptation or therapeutic drug monitoring (TDM). New PIs consist in requiring expertise from a specialist physician and anticipating a risk occurrence during hospitalization. Comparisons involved Student t test; correlations involved Kendall tau test (a=5%).

Results: The 104 patients included (55.8±11.5 years-old; gender ratio = 1.21) received allo-HCT principally for AML (47.1%), MDS (20.2%) and ALL (17.3%). Conditioning was mainly no MAC regimen (69.2%).The most frequent co-morbidities were hypertension (34.6%), dyslipidemia (21.2%) and T2 diabetes (13.5%). Most patients have more than 3 comorbidities (48.0%).
Prior to admission, patients had 5.60±2.32 medications with 3.79±2.21 for comorbidities. 294 PI were formulated (i.e. 2.82±1.30 PI/patient). Most PIs concern drug stop (29.9%, e.g. hypolipemiants, oral antidiabetics or platelets antiaggregating agents); drug maintenance (23.1%, e.g. sartans, betablockers) and prevention of drug iatrogeny (14.6%, e.g. preventing drug-drug interactions with antiepileptics such as valproate and meropenem).

There is a correlation between the number of PI and the total number of drugs (tau = 0.404; p < 0.0001) or the number of drugs for comorbidities (tau = 0.410; p < 0.0001). At the end, the number of drugs out of allo-HCT protocol is statistically different: 4.09 ± 2.21 (p < 0.0001).

Conclusions: Some drugs are inappropriate for allogeneic transplant patients. Physicians and clinical pharmacists must remain vigilant about the risk of complications during allo-HCT procedures due to co-morbidities medications.
Recommendations were recently published by the French bone marrow and cell therapy society (i.e. SFGM-TC) [2]. Further studies will confirm the clinical benefit for patients receiving allo-HCT.

Disclosure: There is no disclosure.

TACROLIMUS C/D RATIO–BASED METABOLIZER PHENOTYPE: A POTENTIAL PREDICTOR OF ACUTE KIDNEY INJURY IN HEMATOPOIETIC CELL TRANSPLANTATION RECIPIENTS

Luiz Carlos da Costa-Junior[1,2], *Rita de Cássia Barbosa da Silva Tavares*[2], *Marina Izu*[2], *Simone Cunha Maradei*[2], *Maria Claudia Rodrigues Moreira*[2,3], *Marta Colares Nogueira*[2], *Décio Lerner*[2], *Teresa de Souza Fernandez*[4], *Paulo Caleb Júnior Lima Santos*[1,5]
[1]*Postgraduate Program in Medical Sciences, Faculdade de Medicina da Universidade de São Paulo (FMUSP), São Paulo, Brazil,* [2]*Bone Marrow Transplant Center, Instituto Nacional de Câncer (INCA), Rio de Janeiro, Brazil,* [3]*Bone Marrow Transplant Program, Hospital Universitário Clementino Fraga Filho (HUCFF), Universidade Federal do Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil,* [4]*Cytogenetic Laboratory, Cell and Gene Therapy Program, Instituto Nacional de Câncer (INCA), Rio de Janeiro, Brazil,* [5]*Department of Pharmacology, Escola Paulista de Medicina, Universidade Federal de São Paulo (EPM-Unifesp), São Paulo, Brazil*

Background: Tacrolimus (TAC) is a calcineurin inhibitor (CNI) widely used for prophylaxis of graft-versus-host disease (GVHD) following allogeneic hematopoietic cell transplantation (HCT). Its pharmacokinetics exhibit substantial interindividual variability that affects both immunosuppressive exposure and toxicity. The concentration-to-dose (C/D) ratio provides a practical surrogate of intrinsic metabolic capacity, enabling patient stratification into fast and slow metabolizers. Because acute kidney injury (AKI) is a frequent early complication with major clinical impact, early identification of individuals at increased risk may support more tailored immunosuppressive management.

Methods: We conducted a retrospective single-center cohort study including allogeneic HCT recipients treated with TAC between 2014 and 2023 who had therapeutic drug monitoring available during the first 21 days of therapy. TAC was administered as a continuous 24-hour infusion (0.01–0.05 mg/kg/day) and adjusted to maintain trough concentrations of 5–15 ng/mL. The C/D ratio was calculated as follows: C/D ratio (ng/mL per mg/kg) = TAC trough concentration (ng/mL) ÷ [daily TAC dose (mg) ÷ body weight (kg)]. Patients were classified

as median: fast (<420 ng/mL·mg^{-1}·kg) or slow metabolizers (≥420). AKI was defined using KDIGO 2012 criteria, with baseline creatinine established as the lowest stable pre-TAC value over ≥5 consecutive days. Statistical analyses included chi-square or Fisher's exact tests, Mann–Whitney U tests, and cumulative incidence estimation using 1–Kaplan–Meier with comparisons by log-rank test up to day +21.

Results: Seventy-one HCT recipients were evaluated (mean age 21 years; 35.2% pediatric; 50.7% male). Fast and slow metabolizers were evenly distributed (49.3% vs. 50.7%). Underlying diagnoses included acute leukemias (52.2% collectively), bone marrow failure syndromes (22.5%), and myelodysplastic/myeloproliferative neoplasms (12.7%). Donor types (31.0% related, 36.6% haploidentical, 32.4% unrelated), graft sources (62.0% bone marrow, 38.0% peripheral blood), conditioning intensities (47.9% myeloablative), and GVHD prophylaxis regimens were similarly distributed between groups. AKI occurred in 38.0% of recipients by day +21, and 23.9% developed stage 2–3 injury. Stage 2–3 AKI was more frequent among slow metabolizers (36.1%) compared with fast metabolizers (11.4%, p = 0.015). In time-to-event analysis, slow metabolizers had a significantly increased hazard of moderate-to-severe AKI (HR 3.71; 95% CI 1.21–11.39; p = 0.0136). Slow metabolizers also required fewer TAC dose increases (50.0% vs. 96.8%) and more dose reductions (50.0% vs. 3.2%) compared with fast metabolizers.

Conclusions: The tacrolimus concentration-to-dose (C/D) ratio reliably identified metabolic variability in hematopoietic cell transplantation recipients. Slow metabolizers, characterized by higher C/D ratios, showed an independently increased risk of stage 2–3 acute kidney injury in the early post-transplant period. They also required fewer dose escalations and more dose reductions compared with fast metabolizers. These findings support the C/D ratio as a practical and accessible tool for early risk stratification and individualized tacrolimus management. By enabling early identification of patients with increased susceptibility to renal toxicity, this pharmacokinetic parameter strengthens its role as a potential predictor to guide more proactive and safer immunosuppressive strategies.

Clinical Trial Registry: Not applicable. This study is not a clinical trial.

Disclosure: The authors declare no conflicts of interest. This study was supported by Brazilian governmental research funding agencies (FAPESP, CAPES, CNPq, and FAPERJ).

Paulo (FMUSP), São Paulo, Brazil, [2]Bone Marrow Transplant Center, Instituto Nacional de Câncer (INCA), Rio de Janeiro, Brazil, [3]Afya Universidade do Grande Rio (Unigrario), Duque de Caxias, Brazil, [4]Bone Marrow Transplant Program, Hospital Universitário Clementino Fraga Filho (HUCFF), Universidade Federal do Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil, [5]Faculdade de Ciências Médicas, Universidade Estadual de Campinas (Unicamp), Campinas, Brazil, [6]Cytogenetic Laboratory, Cell and Gene Therapy Program, Instituto Nacional de Câncer (INCA), Rio de Janeiro, Brazil, [7]Department of Pharmacology, Escola Paulista de Medicina, Universidade Federal de São Paulo (EPM-Unifesp), São Paulo, Brazil

Background: Calcineurin inhibitors (CNIs), particularly cyclosporine (CSA) and tacrolimus (TAC), are essential for graft-versus-host disease (GVHD) prophylaxis after allogeneic hematopoietic cell transplantation (HCT). However, both agents exhibit substantial inter- and intra-individual pharmacokinetic variability, despite standardized dosing and routine therapeutic drug monitoring (TDM). Such variability may compromise the maintenance of therapeutic ranges required for effective GVHD prevention. Identifying clinical, laboratory, and pharmacological factors that influence CNI exposure is therefore critical, especially if these determinants are predictable or modifiable. Additionally, whether CSA and TAC differ in their susceptibility to these influences remains incompletely understood. Understanding these patterns could improve individualized dosing and early post-transplant pharmacological management.

Methods: This retrospective single-center cohort included allo-HCT recipients transplanted between 2002 and 2023, excluding umbilical cord blood grafts. Clinical, laboratory, demographic, and pharmacological data were extracted from electronic medical records. Intravenous CSA and TAC were administered according to institutional protocols with daily through monitoring. All measurements obtained from day 1 to day 21 after CNI initiation were analyzed. Separate linear mixed-effects models (LME) were developed for CSA and TAC to evaluate associations between plasma levels and key covariates: age, sex, race, body weight, creatinine, AST/TGO, ALT/TGP, albumin, hematocrit, antifungal exposure (fluconazole, micafungin, voriconazole), and day since CNI initiation. Patient unique identifier (matricula) was included as a random intercept to account for repeated observations. Models were fitted using lmer() (lme4), with Satterthwaite-adjusted inference via lmerTest. Complete case analyses were performed for each CNI group. This report presents preliminary findings; additional patients are currently being incorporated. The study was approved by the institutional ethics committee in accordance with the Declaration of Helsinki.

Results:

Hematocrit	*5.43*	*1.576*	*0.000656*		0.216	0.134	0.108

A total of 634 HCT recipients were identified in the institutional cohort. Among them, 291 CSA users and 70 TAC users had complete clinical, laboratory, and pharmacological covariates available for mixed-effects modeling, contributing 1,401 CSA and 350 TAC trough measurements between days 1 and 21 after CNI initiation. For CSA, higher levels were independently associated with later days after CNI initiation (β = +3.36/day; p < 0.001), greater body weight (β = +1.06/kg; p < 0.001), and higher hematocrit (β = +5.43; p < 0.001). No antifungal agent or hepatic biomarker showed a significant association with CSA levels. For TAC, several variables significantly influenced exposure: later days after initiation (β = +0.31/day; p < 0.001), micafungin use (β = +4.40; p = 0.009), younger age (β = −0.068; p = 0.009), male sex (β = −1.93; p = 0.030), higher body weight (β = +0.057; p

= 0.005), and lower ALT (β = −0.012; p = 0.023). Full results for all covariates are presented in Table 1.

Conclusions: CNI plasma levels are influenced by drug-specific patterns involving clinical, laboratory, and pharmacological factors. CSA exposure was primarily shaped by weight and hematocrit, whereas TAC demonstrated additional associations with age, sex, hepatic function, and micafungin use, reflecting its more complex metabolism. These findings suggest that part of the variability in CNI levels is predictable and occasionally modifiable, supporting refined, individualized TDM strategies to optimize GVHD prophylaxis.

Clinical Trial Registry: Not applicable. This study is not a clinical trial.

Background: Bloodstream infections (BSIs) remain a major cause of morbidity and mortality in children undergoing hematopoietic stem cell transplantation (HSCT). Fluoroquinolone prophylaxis has been used to prevent infectious complications; however, its overall impact remains controversial due to concerns regarding antimicrobial resistance, potential drug-related toxicities and inconsistent efficacy data.

Methods: We conducted a retrospective cohort study of pediatric HSCT recipients transplanted between October 2020 to June 2025. Patients were divided into two groups based on exposure to quinolone prophylaxis: those transplanted between October 2020–October 2022 (prophylaxis group) and those transplanted between November 2022–June 2025 (no-prophylaxis group). Demographic and clinical variables collected included sex, underlying diagnosis, age at transplant, type of HSCT, donor type and cell source. The primary outcome was the incidence of gram-negative infections within the first six months post-transplant. For each infectious episode, site of infection and causative microorganism were recorded. Data were obtained from electronic medical records. Group comparisons were performed using χ^2 or Fisher's exact test for categorical variables.

Results: A total of 42 pediatric HSCT recipients were included, with 21 patients in the prophylaxis group and 21 in the no-prophylaxis group. The cohort had a mean age of 8.73 years at the time of HSCT and 23 patients (55%) were male. Underlying diagnoses included acute lymphoblastic leukemia (ALL) in 23 patients (55%), acute myeloid leukemia (AML) in 8

patients (19%) and other conditions (non-malignant diseases) in 11 patients (26%).
In the prophylaxis group, 7 of 21 patients (33%) developed at least one gram-negative bacterial infection within the first six months post-transplant; three of these patients experienced two infectious episodes. Similarly, in the no-prophylaxis group, 7 of 21 patients (33%) developed gram-negative infections, with three patients experiencing two episodes. In the prophylaxis group, infections included 3 bloodstream infections and 4 urinary tract infections, whereas in the no-prophylaxis group, 5 bloodstream infections and 2 urinary tract infections were observed. Comparisons between groups were performed using Fisher's exact test. No statistically significant differences were observed in the incidence of gram-negative infections between groups.
Overall, the most frequently isolated microorganisms were *Klebsiella pneumoniae* (n = 5) and *Pseudomonas aeruginosa* (n = 3), followed by *Escherichia coli* (n = 2) and *Stenotrophomonas maltophilia* (n = 2). Less frequently identified pathogens included *Campylobacter jejuni* (n = 1) and *Proteus mirabilis* (n = 1).

Conclusions: In this cohort of pediatric HSCT recipients, quinolone prophylaxis was not associated with a reduction in the incidence of gram-negative infections during the first six months post-transplant. Infection rates were comparable between patients who received prophylaxis and those who did not. Although differences in infection localization were observed between groups, no statistically significant differences were identified and no clear clinical benefit of prophylaxis was demonstrated. Larger, prospective studies are needed to better define the role of antibacterial prophylaxis in preventing gram-negative infections in pediatric HSCT patients.

VANCOMYCIN PROPHYLAXIS IN PAEDIATRIC UMBILICAL CORD BLOOD TRANSPLANTS: A SINGLE CENTRE SERVICE EVALUATION

Rebecca O'Neill[1]
[1]*Great Ormond Street Hospital for Children, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Umbilical cord blood (UCB) transplants offer many advantages, including expanding access. Delayed engraftment, lack of transferred immunity and incidence of acute graft versus host disease (GvHD) increases risk of infectious complications in this cohort. Despite bacterial prophylactic regimens, the value of prophylaxis targeting a wider range of gram-positive pathogens is unknown. Experiences and reports in literature note that *Streptococcus Viridans* has accounted for a high rate of bacteraemia events in neutropenic paediatric patients. Vancomycin, a glycopeptide antibiotic with broad gram-positive coverage, is included in local institutional guidelines for UCB transplant recipients during neutropenic phase, starting at D+1. The aim of this project was to evaluate safety and appropriateness of this regimen including analysis of target level range for prophylaxis.

Methods: All patients who received a transplant using UCB as stem-cell source between January 2021 and December 2024 were included. Patient's demographics (including age and weight), treatment details (conditioning regimen, date and dose of vancomycin initiation and completion) and laboratory results (including first vancomycin levels, positive blood cultures and acute kidney injury warnings linked to creatinine) were retrospectively collected using electronic prescribing system, collated and analysed.

Results: A total of forty-nine cord blood recipients were recorded. Median age was 4.6 years (range 0-12years). Eleven patients (22%) were excluded from data collection due to contraindications to vancomycin prophylaxis (reasons including already being on treatment dose or a recorded allergy to vancomycin). Median starting dose for vancomycin was 16mg/kg BD (range 10.2 – 21.5mg/kg).
Timing to first level varied from 1 to 9 days from initiation (average 3.3 days). Average first level value was 4.6mg/L (aiming for a trough level of less than 10mg/L as per trust guideline for prophylaxis). Flags for acute kidney injury due to raise in creatinine were monitored in first week of initiation. One patient required discontinuation of prophylaxis due to high-levels (11.8mg/L) and AKI stage 3. Average duration of prophylaxis was 9.5 days (range 2-21 days). Most common reason for cessation was change to vancomycin treatment regimen due to persistent fever spikes in 61% of patients (n=23). Ten patients received vancomycin prophylaxis until Neutophils >0.2 as per policy.

Conclusions: Despite adherence to current trust policy, a large variation in time to first level and levels reported between ages outlines need for clearer guidance and needs to incorporate patient factors. In view of large proportion of patients pre-emptively moving to treatment regimens due to fever spikes, patient numbers optimally adhering to proposed prophylactic regimen were small. A previous single centre publication has outlined the safety of vancomycin prophylaxis in neutropenic Acute Myeloid Leukaemia patients, but clear guidance on dosing and target strategies in UCB transplants remain limited. Therapeutic drug monitoring for vancomycin remains essential to prevent further toxicity (particularly in early acute transplant phase), but further work is required to outline optimal strategy for prophylaxis.

RETROSPECTIVE REVIEW OF LETERMOVIR FOR CYTOMEGALOVIRUS PROPHYLAXIS IN PAEDIATRIC ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANT RECIPIENTS

Yi Xuan Chua[1], *Su-Fern Michaela Seng*[1], *Xue Fen Valerie Seah*[1], *Karen Donceras Nadua*[1], *Ah Moy Tan*[1]
[1]*KK Women's and Children's Hospital, Singapore, Singapore*

Background: Cytomegalovirus (CMV) infection remains one of the most clinically significant complication following allogeneic haematopoietic stem cell transplantation (alloHSCT). Since

its approval in 2017, letermovir prophylaxis has become standard practice in adults CMV seropositive recipients (R+). Letermovir usage in paediatrics was previously limited to retrospective case series. Recently in February 2025, the European Medicines Agency (EMA) extended the approval of letermovir to paediatrics based on pharmacokinetics and safety data from phase 2b study. At KK Women's and Children's Hospital (KKH) in Singapore, letermovir was first used in a paediatric HSCT patient for secondary prophylaxis of CMV in July 2024. We have since expanded the use of letermovir for primary prophylaxis. This review analyses letermovir usage in paediatric HSCT patients at KKH to-date.

Methods: Paediatric alloHSCT patients at KKH who received letermovir prophylaxis from July 2024 to September 2025 were included in this retrospective review. Data on letermovir indication, duration, efficacy and safety were analysed. Clinically significant CMV infection (CS-CMVi), defined as CMV disease or viraemia leading to pre-emptive treatment (PET), was used to assess efficacy of letermovir prophylaxis. Patients were dosed according to EMA label. Letermovir tablets were cut, crushed and diluted in water for paediatric administration.

Results: A total of 14 patients, median age 7.6 years (2.8 – 12.8 years), were included in this review. The median follow-up duration was 237.5 days (110-512 days).
Letermovir was used as primary prophylaxis in 12 patients, with majority (10/12) being CMV R+. Two patients who were CMV D-R- were initiated on letermovir prophylaxis—patient 3 developed detectable low copies of CMV DNAemia (<500 copies/ml) on day -3, while the haploidentical donor for patient 5 was found to be CMV IgM positive (CMV PCR and CMV IgG negative) during pre-transplant screening. Letermovir was given as secondary prophylaxis in 2 patients—patient 1 had multiple episodes of CMV reactivations requiring extended treatment with ganciclovir or foscarnet over 3 months, while patient 4 was started on letermovir after initial PET for CMV reactivation peri-engraftment.
2/14 patients developed CS-CMVi during letermovir prophylaxis. Patient 7 was started on letermovir primary prophylaxis on D+65 and was treated with 1-week course of ganciclovir when her CMV viral load increased to log 3.5 on D+70, fulfilling the criteria for CS-CMVi. She continued letermovir after PET without further episodes of CMV reactivation. In retrospect, patient 7 likely experienced a CMV blip while on letermovir prophylaxis which may not have warranted initiation of ganciclovir PET. Patient 9 developed CS-CMVi 46 days after stopping letermovir prophylaxis on D+100.
Letermovir was initiated at a median of D+14, with median duration 133 days. Reasons for extended duration of letermovir in 10 patients beyond 100 days included poor graft function, delayed immune reconstitution, multiple immunosuppressants for graft-versus-host disease treatment. Letermovir was well-tolerated without significant attributable side effects. No patients discontinued letermovir due to adverse effects.

Table 1. Clinical characteristics and outcome of paediatric patients who received letermovir prophylaxis at KK Women's and Children's Hospital.

Patient no.	Age (years)	Type of alloHSCT	Donor/ recipient CMV serostatus	Indication of letermovir	Letermovir initiation day	Letermovir duration (days)	CS-CMVi

Table 1. Clinical characteristics and outcome of paediatric patients who received letermovir prophylaxis at KK Women's and Children's Hospital.

	median: 7.6				median: D+14	median: 133	

Abbreviations: alloHSCT, allogeneic haematopoietic stem cell transplant; CS-CMVi, clinically significant CMV infection; haplo, haploidentical haematopoietic stem cell transplant; MSD, matched sibling donor; MUD, matched unrelated donor.
Note: KK Women's and Children's Hospital uses TCRαβ CD45RA depletion for T-deplete haplo.

Conclusions: Letermovir prophylaxis appears to be safe and effective in our series of paediatric alloHSCT patients. Further research is needed to better define CMV viral load thresholds for initiating PET while on letermovir prophylaxis.

Disclosure: Nothing to declare.

P400

SUBTHERAPEUTIC CYCLOSPORINE CONCENTRATIONS DESPITE STANDARD DOSING IN HSCT PRACTICE

Tsung Yu Pai[1], *Chao Hung Wei*[2], *Xavier Cheng-Hong Tsai*[1]
[1]*National Taiwan University Hospital, Taipei, Taiwan (Province of China),* [2]*National Taiwan University Cancer Center, Taipei, Taiwan (Province of China)*

Background: Cyclosporine remains a cornerstone of graft-versus-host disease (GVHD) prophylaxis following allogeneic hematopoietic stem cell transplantation (HSCT). Although current guidelines recommend an initial dose of 3 mg/kg/day, a substantial proportion of patients at our institution fail to achieve the target trough concentration of 150–250 ng/mL. Therefore, evaluating whether this standard dosing strategy provides adequate therapeutic exposure is clinically important.

Methods: This single-center, prospective observational study included patients who underwent allogeneic HSCT between January 2023 and December 2024 (NTUH REC approval number 201810058RIND). Standard GVHD prophylaxis consisted of cyclosporine 3 mg/kg/day divided twice daily, in combination with an anti-metabolite agent. Cyclosporine was dosed based on ideal body weight or total body weight, whichever was lower (the lower body weight). Steady-state trough concentrations obtained under the 3 mg/kg/day regimen were analyzed. The primary endpoint was the proportion of transplantation cases achieving the target trough concentration of 150–250 ng/mL at the first measurement.

Results: A total of 97 patients were enrolled; two patients underwent multiple allogeneic HSCTs during the study period, yielding 100 transplantation cases for analysis. The median age was 53 years (range, 20–74), and 54 patients (55%) were male. The median initial cyclosporine trough concentration was 83 ng/mL (range, 15–170). Dose adjustments were made in 70% of cases based on early drug levels. Fifty-two cases met the definition of overweight (BMI >24) and 7 were underweight (BMI <18.5). There was no significant difference in levels among patients receiving empirical dosing across body weight categories, with mean concentrations of 82.7 ng/mL in the overweight group, 86.5 ng/mL in the underweight group, and 90.2 ng/mL in those with normal body weight. ($p>0.05$)
Drug–drug interactions were identified in 21 cases receiving concurrent antifungal therapy (6 on voriconazole, 12 on isavuconazole, 3 on fluconazole). Empirically, cyclosporine was reduced by 50% when co-administered with voriconazole, whereas the standard 3 mg/kg dose was maintained with isavuconazole or fluconazole. Only 1 case (8.3%) with isavuconazole met target level.
Cyclophosphamide was included in the conditioning regimen for 96 patients; the remaining four cases involved second or later transplants, limiting the ability to assess the contribution of cyclophosphamide to cyclosporine clearance. Only 5 patients (5.2%) achieved the target concentration on initial measurement; all five involved conditioning regimens containing cyclophosphamide, with patient BMI ranging from 22–30.

Conclusions: The standard cyclosporine dose of 3 mg/kg/day frequently fails to achieve target therapeutic concentrations in HSCT patients. Despite a wide distribution of BMI in the cohort, no clear association between body size and achieving therapeutic levels was observed

when dosing was based on lower body weight. This finding suggests that using lower body weight for dosing is appropriate. Drug-drug interactions with cyclophosphamide also unlikely contribute to reduced cyclosporine exposure. However, we found that current dosing recommendations of 3 mg/kg/day may be insufficient, and early dose adjustment or higher initial dosing should be considered to optimize GVHD prophylaxis. Further studies are warranted to determine the optimal cyclosporine dosing strategy in patients undergoing HSCT.

Clinical Trial Registry: NTUH REC approval number 201810058RIND

RISK VS BENEFIT: CIPROFLOXACIN PROPHYLAXIS IN HIGH DOSE MELPHALAN AUTOLOGOUS SCT - A SINGLE CENTRE EXPERIENCE

*Helen Wilson[1], **Elizabeth Davies**[1], Mark Henry[1], Philip Crea[1], Jenna Fielding[1], Louise Sweeney[1]*
[1]Manchester University NHS Foundation Trust, Manchester, United Kingdom of Great Britain and Northern Ireland (the)

Background: Fluoroquinolone prophylaxis (FQP) is recommended in adult patients with expected neutropenia ≥7 days, aiming to reduce mortality, febrile episodes and Gram negative blood stream infections (BSI), however should be balanced against potential harmful effects. Recent UK recommendations and incidence of colonization with multi-drug resistant (MDR) bacteria, such as ESBL producing Gram negatives and vancomycin resistant enterococci in our Unit, led to a trial of discontinuing routine ciprofloxacin prophylaxis in patients undergoing high dose melphalan autologous stem cell transplant.

Methods: Retrospective review: Twenty patients (January-June 2024) receiving FQP (Group 1) were compared to 20 patients (January–June 2025) not treated with FQP (Group 2). Data obtained via hospital patient records. Patient characteristics, hospital acquired infections and antibiotic use during hospital admission was reviewed. Length of hospital stay (LoS), serious adverse reactions (SAE) to antibiotics and acquisitions of MDR bacteria detected on routine screening were also recorded.

Results: Both groups were comparable in baseline characteristics, with the exception of more transplants being commenced in the ambulatory setting in group 2, admitted to hospital in the neutropenic phase. All patients required broad spectrum antibiotics for neutropenic fever/suspicion of BSI at least once following transplant. There was no significant difference in the number of episodes of neutropenic fever in either group. There was higher incidence of BSI (twice the rate of Gram negative BSI) in the no FQP group, although no significant difference in antibiotic course length. There were no *Clostridium difficile* infections, representative of our local epidemiology.
Double the number of patients on FQP required a second course of antibiotics but patient numbers are extremely small. The total number of antibiotic days was longer in the FQP

group, 3 patients in this group required ICU admission – one for piperacillin/tazobactam anaphylaxis, one for potential infection/bleeding and one non-infection related. No patients required ICU admission in the no FPQ group. There were no deaths, all patients were discharged from hospital, with only one re-admission which was not infection related. There was no difference in ESBL Gram negative isolation – one BSI in each group. The Gram negative BSIs in the no FQP group were, largely not MDR, with the exception of one ESBL *Klebsiella*. Gram positive infections occurred in both groups which would not be prevented by ciprofloxacin prophylaxis.

	Group 1 FQP (N=20)	**Group 2 no FQP (N=20)**
Gender Male Female	 14 6	 15 5
Median Age	60	62
Diagnosis: Myeloma AL amyloidosis POEMS	 20 0 0	 18 1 1
Median Length of stay (range)	18 days (10-39)	19 days (10-27)
Hospital readmission rate within 30 days	1 (unrelated to infection)	0
Escalation of care to Intensive Care Unit (ICU)	3 (1 airway obstruction, 1 penicillin anaphylaxis, 1 ?infection/?bleed)	0
VRE Acquisition (N) CPE acquisition (N) C. *difficile* infection	4 0 0	4 0 0
BSIs (N)	6 (*E. coli* x 2 *Streptococcus mitis/oralis* x 2 *Niallia circulans* x 1 *Rothia mucilaginosa* x 1)	*9* *(E.coli x 2* *VRE x 2 (Vancomycin resistant Enterococcus faecium)* *Streptococcus mitis/oralis x 1* *Streptococcus infantarius x 1* *Pseudomonas aeruginosa x 1* *Klebsiella pneumoniae x 1* *Streptococcus gallolyticus x 1*

Patients received a single course of antibiotics (N) Patients received 2 courses of antibiotics (N)	18 2	19 1
Total antibiotic exposure (days)	227	203
SAEs	Penicillin anaphylaxis	N/A

Conclusions: Our results mirror previous studies, FQP was associated with lower rate of Gram negative BSI, higher rate of BSI including Gram negative BSI in the non FQP group, but no difference in outcome in particular mortality between the two groups.
There was no impact on LoS, broad spectrum antibiotic treatment or VRE acquisition. Gram negatives in our non FQP group were in the main, not MDR. The study involves small patient numbers therefore more data is required to draw any firm conclusions, other than the increase in BSI rate including Gram negatives in the non FQP group, but the majority were susceptible to empirical antibiotics and no patients in the no FQP group required escalation of care to ICU. It is important to consider local antimicrobial resistance epidemiology.

Disclosure: Nothing to declare

P402

AWARENESS OF EXTRAVASATION MANAGEMENT FOR CYTOSTATIC AND NON-CYTOSTATIC DRUGS AMONG HEMATOLOGISTS IN THE CZECH REPUBLIC

Jana Vedrová[1], *Petra Rozsívalová*[2,3]
[1]*Institute of Hematology and Blood Transfusion, Praha, Czechia,* [2]*University Hospital Hradec Králové, Hradec Králové, Czechia,* [3]*Charles University, Faculty of Pharmacy in Hradec Králové, Hradec Králové, Czechia*

Background: Extravasation of intravenous drugs remains a significant clinical challenge with potentially severe consequences for patient outcomes. While awareness of extravasation caused by cytotoxic agents is well established, substantial knowledge gaps persist regarding non-cytostatic drugs and the appropriate selection of antidotes among practicing hematologists—an issue that warrants urgent attention.

Methods: A cross-sectional survey using an anonymous questionnaire (Microsoft Forms) was conducted among hematologists at two major Czech centers (University Hospital Hradec Králové and Institute of Hematology and Blood Transfusion, Prague) to assess their knowledge of extravasation prevention, recognition, and management.
The 14-item questionnaire covered demographics, clinical experience, risk factors, symptom

recognition, extravasation management knowledge, high-risk agents, and awareness of antidote availability. Data were analyzed using descriptive statistics.

Results: A total of 25 hematologists completed the survey (17 from University Hospital Hradec Králové, 8 from the Institute of Hematology and Blood Transfusion).
A striking paradox emerged: although 17 out of 25 respondents (68%) had more than 10 years of clinical experience, the same proportion (68%) rated their own knowledge as merely basic—a concerning self-assessment.
Critical gaps were identified: only 15/25 (60%) were aware of institutional protocols covering both cytostatic and non-cytostatic drugs, and alarmingly, 10/25 (40%) could not identify where antidotes were stored. Knowledge of specific antidotes was inconsistent: 20/25 (80%) correctly identified DMSO 99% for anthracyclines, but only 12/25 (48%) knew the appropriate treatment for vinca alkaloid extravasation (hyaluronidase with heat compresses), while 9/25 (36%) incorrectly chose cold application. For propofol, 15/25 (60%) provided the correct answer (hyaluronidase with cold compresses), and for radio/x-ray contrast agents, 20/25 (80%) answered correctly (cold compresses).
Only 8/25 participants (32%) were able to identify all risk factors predisposing patients to extravasation and furthermore, only half of respondents 14/25 (56%) accurately recognized the clinical manifestations of extravasation. Notably, only 3/25 participants (12%) correctly classified all agents belonging to the group of vesicants. These findings highlight persistent gaps in comprehensive knowledge regarding extravasation risk assessment and management among experienced clinicians.

Conclusions: Significant and unexpected knowledge gaps persist among experienced hematologists regarding extravasation management protocols, antidote accessibility, and treatment procedures for specific agents. These findings represent a critical patient safety concern and underscore the urgent need for targeted, continuous education to standardize clinical practice and prevent potentially irreversible tissue damage.

Disclosure: Nothing to declare.

RISK ASSESSMENT OF HERPESVIRUS REACTIVATION IN CHILDREN UNDERGOING ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION WITH PROPHYLACTIC USE OF LETEMOVIR: A RETROSPECTIVE SINGLE CENTER OBSERVATIONAL STUDY

Mi Zhou[1], Qingwei Wang[1], Senlin Zhang[1], Shuwen Huang[1], Jiaxiao Dong[1], Zhe Liu[1], Lili Huang[1], Li Gao[1], Jun Lu[1], Peifang Xiao[1], Jie Li[1], ***Shaoyan Hu***[1]
[1]*Children's Hospital of Soochow University, Suzhou, China*

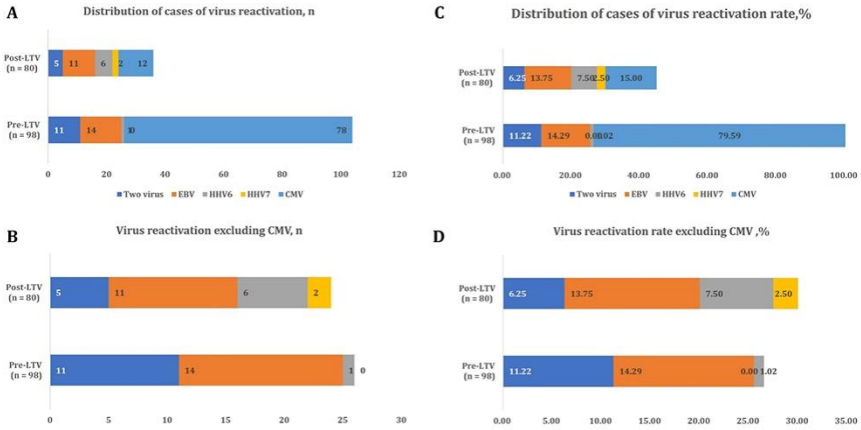
Background: Virus reactivation after allogeneic hematopoietic stem cell transplantation is a common complication that seriously affects patient prognosis. Letermovir (LTV), a novel drug for preventing cytomegalovirus (CMV) infection, significantly reduces the need for broad-spectrum antiviral drugs such as ganciclovir and foscarnet. This broad-spectrum antiviral also

exhibit inhibitory activity against other herpesviruses, such as HHV-6. Studies in adults suggest that LTV use may be associated with reactivation of HHV6. The immune reconstitution process, viral infection spectrum, and response to LTV in children may differ from those in adults. Currently, there is a lack of information on the reactivation patterns and clinical outcomes of herpesviruses in pediatric HCT patients in the context of LTV use.

Methods: A single-center retrospective study was established and approved by the Ethics Committee of Children's Hospital of Soochou University (2025CS136). Patients' data were extracted from the electronic medical record system from September 2022 to March 2024. They were divided into two groups based on whether they received LTV prevention or not. Patient demographic information was collected, including age, sex, primary disease, donor type, stem cell source, pre-treatment regimen, GVHD prevention regimen, LTV usage, and virus monitoring data.

Results: A total of 98 patients were included in the Pre-LTV group, with 80 patients in the Post-LTV group. The proportion of CMV reactivation in the Post-LTV group was significantly lower than that in the Pre-LTV group (36.2% vs 70.4%, $p < 0.001$), whereas the proportion of HHV6 and HHV7 reactivations in the Post-LTV group was higher than that in the Pre-LTV group (8 cases vs 1 case, $p < 0.015$). The neutrophil engraftment time in the Post-LTV group was longer than that in the Pre-LTV group(13.0 ± 3.5 vs. 12.2 ± 1.8 days, $p = 0.046$) (Fig 1). In addition, according to the grouping of HHV6/7 activation and without HHV6/7 activation, there was no different in neutrophil engraftment time between cases with and without HHV6/7 activation. However, the platelet engraftment time was longer in cases with HHV6/7 activation than in those without activation, at No active 13.0 ± 5.6, HHV6 27.2 ± 31.3, HHV718.0 ± 1.4 days, respectively, $p < 0.001$. No HSV-1/2, VZV was detected in all cases.

Figure1 Number and proportion of reactivated viruses



Conclusions: Prophylactic use of LTV in pediatric transplant patients can significantly reduce the risk of CMV reactivation, but these patients also experience an increased risk of HHV6 and HHV7 reactivation due to the weakened "bypass" inhibitory effect of broad-spectrum antiviral drugs, which may prolong platelet engraftment.

Disclosure: Nothing to declare.

VARIANCES IN PATIENT EXPERIENCES WITH SHARED DECISION-MAKING BY TREATMENT IN PATIENTS WITH LBCL: ANALYSIS OF LYMPHOMA COALITION'S 2024 GLOBAL PATIENT SURVEY ON LYMPHOMAS AND CLL

Lorna Warwick[1], *Natacha Bolanos*[2], *Mavis Lui*[1], *Shawn Sajkowski*[1], *Kathryn Perry*[1]
[1]*Lymphoma Coalition, Etobicoke, Canada,* [2]*Lymphoma Coalition, Madrid, Spain*

Background: Shared decision-making (SDM) is a key aspect of patient-centred care for patients with large B-cell lymphoma (LBCL), requiring patient inclusion in care decisions and healthcare providers (HCPs) understanding preferences and needs of patients. In relapsed/refractory (R/R) or high-risk LBCL, guidelines recommend stem cell transplant (SCT) or CAR-T therapy. This study investigates variances in SDM by these therapy classes.

Methods: A cross-sectional, anonymous online global survey for patients with lymphoma was deployed in 2024. This analysis focuses on people with lived experience (PWLE) with LBCL, exploring questions regarding SDM including treatment goals, perceived involvement in care decisions and patient-HCP communication. Responses were categorised by last treatment (CAR-T, SCT) for descriptive analysis and comparison of SDM experience.

Results: The study included 178 PWLE-LBCL (R/R or high-risk) from 23 countries, categorised by last treatment received: CAR-T (42.1%, n=75) or SCT (57.9%, n=103). While the CAR-T cohort was slightly older and the overall sample included more females, most patients were in remission (CAR-T: 50.7%; SCT: 61.2%).
A significant gap persists in SDM. Nearly all patients desired high involvement (CAR-T: 100%; SCT: 97%), but far fewer felt adequately involved (CAR-T: 62.5%; SCT: 49.5%). Most preferred collaborating with their doctor on decisions (around 58% in both groups), emphasising the vital need for clinic integration of SDM.
Treatment goals differed: Remission was very important to a higher proportion of PWLE-SCT (97.3% vs. 76.9% CAR-T), as was improved quality of life (80.6% vs. 66.7% CAR-T).
CAR-T patients consistently reported more positive interactions related to productive SDM clinic behaviours. They were more likely to feel their HCP always encourages questions (60.0% vs. 41.6% SCT), routinely checks understanding (57.3% vs. 40.4% SCT), experienced fewer interruptions (70.3% vs. 55.4% SCT), and perceived greater clinician kindness/sensitivity (79.7% vs. 61%) and attentive listening (76.7% vs. 61.4%).
Treatment choice was limited, particularly for SCT patients (CAR-T: 46.7% offered a choice; SCT: 27.8%). Subsequently, far more SCT patients wished they had received a different

therapy (29.5%) due to its impact of the treatment on their QOL, compared to CAR-T patients (14.6%).

	PWLE-CAR-T (n=75)	PWLE-SCT (n=103)
Biological sex	Female 57.3%	Female 68.9%
Average age	59.7 years [range 25-87]	53.5 years [range 27-76]
Patient definitely involved in care decisions as much as they want to be	62.5%	49.5%
Patient would like SDM with doctor	59.2%	57.0%
Patient would like to make care decisions alone	15.5%	15.0%

	PWLE-CAR-T (n=75)	PWLE-SCT (n=103)
Patient would like doctor to make care decisions alone	25.4%	24.0%
Factors very important to treatment choice		
Cure	78.8%	86.8%
Improved/longer survival	75.5%	89.2%
Bring about a remission or response	76.9%	97.3%
Improved quality of life	66.7%	80.6%
Fewer side effects / more tolerable side effects	35.3%	35.1%
Duration of treatment	21.2%	29.7%
Certainty of available treatment data/results	46.2%	40.5%
Patient was given a therapy choice prior to most recent treatment	46.7%	27.8%
In hindsight, patient would have chosen a different treatment option due to impact on quality of life	14.6%	29.5%

Conclusions: Suboptimal SDM persists for all PWLE-LBCL and improvements are needed for all patients. While most patients desire high involvement, just over half achieve it. Crucially, SDM is more successful in the CAR-T cohort (higher involvement, better communication, more options). This highlights the need for proactive, targeted SDM efforts to close the significant engagement gap in the SCT patient group.

P366

EXPLORING DEATH, GRIEF AND BEREAVEMENT AT ANTHONY NOLAN: THE IMPORTANCE OF STRUCTURED INVOLVEMENT TO IMPROVE SUPPORT FOR BEREAVED LOVED ONES

Liam Rooney[1], *Louise Jones*[1]
[1]*Anthony Nolan, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Death after stem cell transplant is a common reality: around half of patients do not survive beyond five years. Research shows that bereavement experiences in this community can be distinct and severe, affecting a wide range of individuals including patients' families and even unrelated donors, who may feel sadness, grief, and helplessness. Parents bereaved after a child's transplant often report higher levels of depression, anxiety, and traumatic grief than those whose children received other treatments. Despite this, bereavement support specific to stem cell transplant is limited, fragmented, and reactive, leaving staff uncertain and emotionally strained when supporting families. We wanted to know where Anthony Nolan's work and support currently sits within this, and what we could do differently and better. This led to us thinking how to best involve bereaved loved ones in such a sensitive project.

Methods: We used the Design Council's double diamond framework for involvement. We conducted 12 1 on 1 interviews with people who had been bereaved after their loved one had a stem cell transplant. We then convened as a working group to review and find themes. A survey was then created that included those themes and asked for feedback and further insight. 29 people responded to the survey, and a small group of these people are continuing their involvement, for example with user testing new resources.

Results: We found seven themes:

1. Grief is unique, even within families grieving the same person. This is connected to the next theme.

2. Isolation after isolation: the bereaved experience of isolation is compounded and connected, by them, to their loved one's experience of being in isolation for treatment.

3. Participants experience guilt about their perceived incorrect decisions, inaction or own stem cells in the case of sibling donors.

4. Bedside manner: the way the death is dealt with within healthcare teams is different and not as well received by the bereaved.

5. The gap for CYP support is larger than for adults, leading to inequality within the support of families.

6. Family dynamics change following a death, and the role of next of kin influences this.

7. This was all underpinned with an overarching theme of a need for more support in both professional intervention and peer support.

Conclusions: As we were able to carry out meaningful involvement, we have an enriched set of outcomes that are directly connected to what loved ones told us about their experience. We were able to see there is unmet need in this area, and Anthony Nolan are well placed to provide supportive interventions such as improved health information, working with healthcare professionals to provide information materials at the right time for the bereaved. We also believe that stem cell and CAR-T informed counselling services that can cater to families would address some of the need for emotional support. We will explore working with relevant organisations and loved ones to deliver peer support. All these outputs continue with involvement at the forefront of this continuing significant project.

P368

THE NEW EU REGULATION ON SOHO: STRENGTHENING THE PROTECTION OF DONORS, RECIPIENTS AND OFFSPRING

Aurélie Mahalatchimy[1], *Valentin Roby*[1], *Christian Chabannon*[2]
[1]*Aix Marseille Univ, CNRS, DICE, CERIC, Aix-en-Provence, France,* [2]*Institut Paoli-Calmettes/Center for Cell Therapy/Center for Clinical Investigation in Biotherapy, Inserm CBT-1409 AMU AP-HM IPC, Marseille, France*

Background: The European Union (EU) regulation 2024/1938 on standards of quality and safety for Substances of Human Origin (SoHO) intended for human application was adopted on 13 June 2024 in order to solve issues that were not (sufficiently) addressed by the previous EU directives on blood (Directive 2002/98/EC) and tissues and cells (Directive 2004/23/EC). Among them, an extensive evaluation of the EU legislation led by the European Commission highlighted that they were avoidable risks for donors and for children born from donated gametes, and that patients were not fully protected from avoidable risks.

Methods: This study is based on an analysis of the preparatory documents and of the final adopted version of the EU regulation on SoHO regarding the protection of SoHO donors, recipients and offspring. It combines legal and biomedical sciences approaches as well as fundamental and practical analysis in order to clarify and discuss the new EU legal measures targeting the protection of SoHO donors, recipients and offspring.

Results: The EU regulation on SoHO strengthens the protection of SoHO donors, recipients and offspring through the introduction of two dedicated chapters with detailed binding rules. First, the fundamental principles of the protection of donors are anchored within the

provisions of the EU regulation on SoHO. Not only these principles are recognised and key notions such as compensation and consent are legally defined, but conditions for their implementation are provided, especially regarding voluntary and unpaid donation of SoHO and consent.
Second, minimum standards are established and increased to ensure a high level of safety and protection of health of SoHO donors, SoHO recipients and offspring from medically assisted reproduction. It implies the data collection from SoHO donors and the mandatory use of SoHO living donors' registries to monitor their health after SoHO donation. It also implies a positive benefit/risk balance for SoHO recipients and offspring and mitigation of risks of communicable and non-communicable disease transmission (including the transmission of serious genetic conditions and cancer), and of any other avoidable risk to the health. Those risks include those: related to the protection of dignity, resulting from cross-contamination between SoHO, arising from microbial contamination of SoHO from the environment, the personnel, the equipment and the materials coming into contact with SoHO, linked to the addition or contact with any reagents and solutions, linked to the changes of the inherent properties of SoHO, and to human error.
Third, the implementation of particular standards to protect SoHO donors, recipients and offspring shall comply with additional binding rules adopted by the European Commission. In their absence and upon demonstration of relevance to SoHO competent authorities, SoHO entities shall take into account guidelines published by the ECDC, the EDQM, the Member States, or guidelines or technical methods considered compliant with EU law standards by the inspectors of SoHO establishments.

Conclusions: The EU regulation on SoHO operates a major shift from the quality and safety of SoHO to the wider protection of SoHO donors, recipients and offspring which is either strengthened or newly covered.

Disclosure: *Aurélie Mahalatchimy and Valentin Roby have no conflict of interest to declare. Christian Chabannon has received speaker honoraria and consulting fees from BMS, Gilead/Kite, Novartis, Jazz Pharmaceuticals, Janssen/J&J and Miltenyi Biotec.*
This work has been funded by the French National Agency for Research (ANR) ANR-funded I-BioLex project (ANR-20-CE26-0007-01) and by the European Union's Horizon 2020 research and innovation programme under Grant Agreement No 965241 (EuroGCT project).

P369

DESIGNING LIFE AFTER CAR-T: EXPLORING PATIENT UNCERTAINTY AND EDUCATION NEEDS IN POST-CAR-T THERAPY LIFE

Ahmed El-Naas[1]
[1]*Weill Cornell Medicine-Qatar, Doha, Qatar*

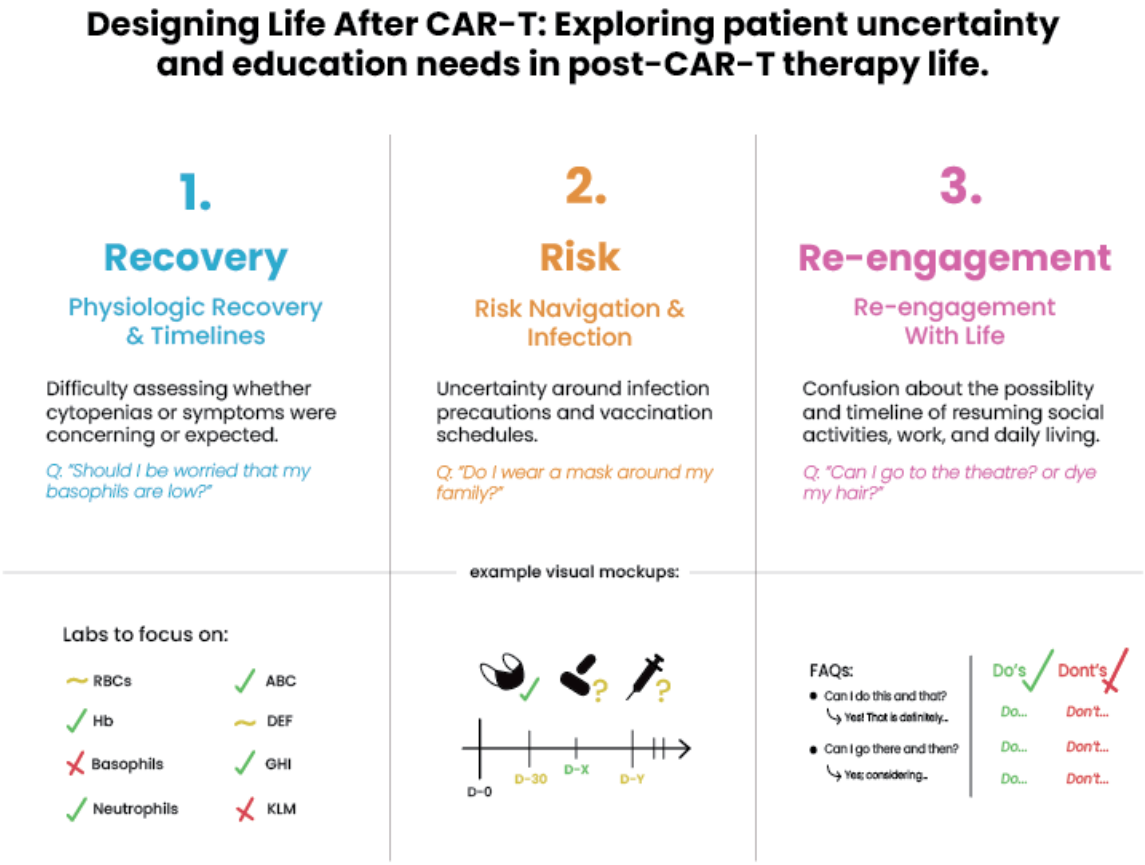
Background: CAR-T therapy patient education resources are often comprehensive when it comes to pre-treatment education; yet, far less emphasis is placed on the post-CAR-T period: when patients leave a highly-monitored inpatient environment and face confusing symptoms, fluctuating lists of lab values, and an uncertainty on their readiness for returning

to daily life. In practice, these uncertainties manifest as questions such as "Should I be worried that my basophils were low?, "Can I go to the theatre?", or "Can I swim at my family's pool party?".

Methods: This reflective analysis integrates on-the-ground clinical observations in patient encounters (focusing on recurrent questions and concerns voiced by patients during follow-up) and thematic insights from patient-reported experience literature. A design-thinking approach was then used as a lens to identify unmet needs, map out thematic domains of patient uncertainty, and translate them into proposed solutions.

Results:

Three domains emerge to represent the core categories of uncertainty that were observed and appear to influence patient confidence, behaviors, and emotional well-being: recovery, risk, and re-engagement.
Recovery (Physiologic Recovery & Timeline): Patients exhibited difficulty assessing whether changes such as fluctuating cytopenias or certain symptoms represented concerning developments or expected recovery patterns. Patient questions included "Should I be worried that my basophils are low?", and "I saw that my RBC count is low?".
Risk (Risk Navigation): Uncertainty about infection precautions, including masking, exposures, and vaccines, was a major driver of anxiety. Patient questions included "Do I wear a mask with my family?", and "What about the flu vaccine?".
Re-engagement (Re-engagement With Life): Patients expressed confusion and worry about the possibility and the timeline of resuming social activities, work, and other daily functions. Patient questions included "Can I go to the theatre?", and "So I was wondering if I could dye my hair?".
A visual post-CAR-T life guide is proposed to address these domains purposefully: incorporating simplified explanations and structured time lines to address Recovery, stratified precautions tied to immune milestones to address Risk, and scenario guidelines and FAQs to address Re-engagement.



Conclusions: Major themes of uncertainty in post-CAR-T life were recovery timelines, risk navigation, and re-engagement with daily life. This structured understanding can then inform the creation of purposeful and accessible patient education tools. Iterative design-thinking, alongside visual graphic design, emphasize clarity, usability, and co-creation: appropriate for an education tool that must be well-suited for the cognitive and emotional demands of the post-CAR-T period, and that may reduce patient anxiety, improve communication efficiency at follow-up visits, and enhance quality of life during early survivorship. Collaborative development with clinicians and patients will then support future feasability of pilot testing and implementation - whether that be as a student-led project, a clinic-based initiative, an academic center program, or a broader organizational rollout.

Disclosure: Nothing to declare.

P370

CAREGIVERS' PROXY ASSESSMENTS OF HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH HEMATOLOGIC MALIGNANCIES

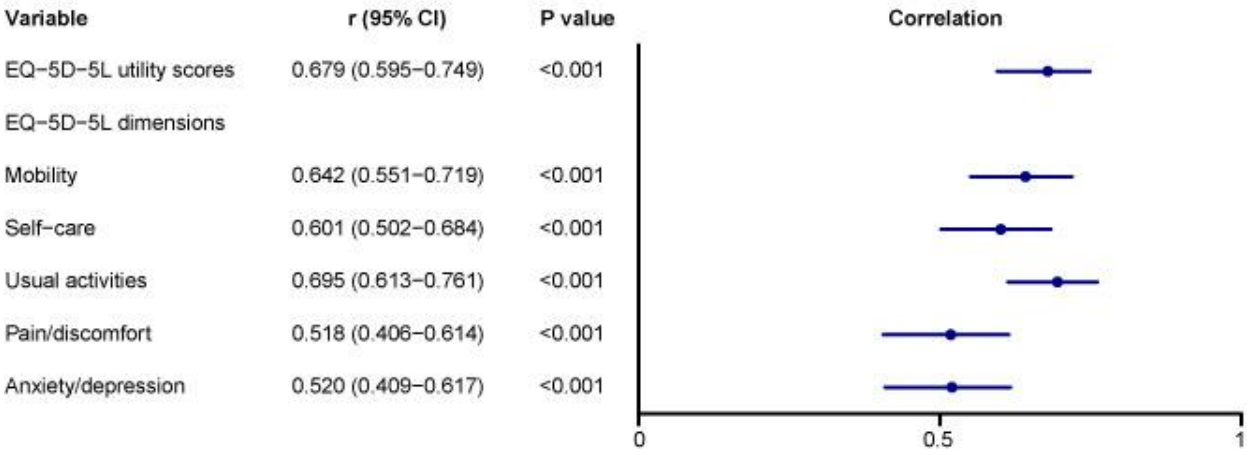
Wei Qin[1], Fenfang Tong[1], Cong Zeng[1], ***Yajing Xu***[1]
[1]*Xiangya Hospital, Central South University, Changsha, China*

Background: Patients with hematologic malignancies are commonly burdened by the disease itself as well as treatment-related side effects, which makes it difficult for them to complete the health-related quality of life (HRQoL) assessments. We aimed to investigate the reliability and influencing factors of caregivers as proxies in measuring HRQoL for patients with hematologic malignancies.

Methods: 203 patients with hematologic malignancies and their caregivers were enrolled. Both patients and caregivers independently completed the EuroQol 5-Dimensions 5-Levels questionnaire to collect patient self-rated HRQoL and caregiver proxy-rated HRQoL. Additionally, caregivers completed the Generalized Anxiety Disorder 7-Item Scale, Patient Health Questionnaire-9, and Family APGAR Index to evaluate their anxiety symptoms, depression symptoms, and perceptions of family functioning.

Results: The caregiver proxy-rated HRQoL exhibited strong correlations with patient self-rated HRQoL, in both EQ-5D-5L utility scores (r = 0.679, P < 0.001) and EQ-5D-5L dimensions (correlation coefficients from 0.518 to 0.695, all P < 0.001). Exact agreements between caregiver proxy-ratings and patient self-ratings ranged from 66.5% to 84.2% across EQ-5D-5L dimensions. Caregivers' demographic characteristics and perceptions of family functioning had no impact on the accuracy of proxy assessments, while greater anxiety symptoms (r = 0.408, P < 0.001) or depression symptoms (r = 0.288, P < 0.001) among caregivers were significantly associated with their overestimation of patients' symptom burden.

Qin et al. Figure 1



Conclusions: Caregivers are reliable proxies for assessing HRQoL in patients with hematologic malignancies. However, the anxiety or depression symptoms of caregivers may increase their overestimation in patients' symptom burden.

Disclosure: Nothing to declare.

P371

QUALITY OF LIFE TRAJECTORIES IN THE YEAR FOLLOWING ALLOGENEIC STEM CELL TRANSPLANT: A MIXED-METHODS STUDY

Christina Yiallouridou[1], *Lauren Young*[1], *Karen Dean*[1], *Dawn Hart*[1], *Rachel Miller*[1], *Robert Danby*[1,2], *Gemma Pugh*[1]
[1]*Anthony Nolan, London, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Allogeneic haematopoietic cell transplantation (allo-HCT) offers curative potential for many haematological disorders; however, patients often face physical and psychosocial challenges which affect quality-of-life (QoL). This study prospectively examined QoL trajectories and patient perspectives about change in wellbeing in the first year following allo-HCT.

Methods: This multicentre prospective cohort study used a convergent mixed-methods design. Adult (≥18 years) allo-HCT recipients from three UK centres completed questionnaires at baseline (pre-transplant), day 0, day 28, day 100, and day 365 (one-year follow-up). QoL was assessed at each timepoint using the 29-item Patient-Reported Outcomes Measurement Information System (PROMIS-29) which evaluates physical function, fatigue, sleep disturbance, anxiety, depression, pain interference, social participation, and pain intensity. Descriptive statistics were used to summarise cohort characteristics. PROMIS T-score trajectories were analysed using the Friedman test with Bonferroni-adjusted Wilcoxon post-hoc comparisons. Semi-structured interviews conducted at one-year follow-up explored patient experience of recovery and how symptom burden influenced QoL after transplant. Qualitative data were analysed using framework analysis and integrated with quantitative findings using a joint display.

Results: Sixty patients were enrolled (median age 56 years, range 21–74). Most participants were male (70%), White British (80%), and married or in civil partnerships (58%). The majority had acute myeloid leukaemia (53%) and received a matched unrelated donor transplant (67%). Over half held higher or degree-level education (57%), and most lived in the least deprived areas (upper IMD quartile, 8–10; 47%).
Physical function scores declined from baseline (45.9 ± 9.2) to day 28 (36.8 ± 8.1; $p<0.001$, $r=0.81$, 95% CI 0.72–0.86) with partial recovery by day 100 (43.5 ± 9.4; $r=0.68$, 95% CI 0.48–0.84). Fatigue scores increased from baseline (52.1 ± 9.8) to day 28 (63.6 ± 9.3; $r=0.83$, 95% CI 0.75–0.87). Social participation declined (36.4 ± 6.7; $r=0.73$, 95% CI 0.58–0.84), and sleep disturbance rose between day 0 (47.9 ± 5.1) and day 28 (53.1 ± 8.0;

r=0.72, 95% CI 0.57–0.84), all p<0.001 (Bonferroni-adjusted). Anxiety scores peaked on day 0 (57.9 ± 10.2), while depression scores were highest on day 100 (53.0 ± 10.5). By one year, most QoL domains had recovered to baseline levels, though few patients achieved population normative values.
Interviews with ten participants contextualised these trends. Five themes were identified: (1) initial decline, slow improvement, but never the same; (2) health first, social life second; (3) learning to live with fatigue; (4) evolving anxiety; and (5) the long-term burden of isolation. Participants described initial recovery as physically and emotionally demanding, characterised by weakness, fatigue, and restricted social contact leading to isolation and reduced confidence. At one year post-HCT, participants described ongoing challenges with energy, physical stamina, and anxiety about relapse and long-term health.

Conclusions: Recovery after allo-HCT is characterised by early decline and gradual, sometimes incomplete improvement in QoL during the first year. Integrating patient perspectives with PROs helps capture the real experience of recovery and guide survivorship care that better supports long-term wellbeing.

P372

SUPPORTING PATIENTS WITH LIMITED OR NO ENGLISH TO PARTICIPATE IN RESEARCH: A NATIONAL SURVEY OF LANGUAGE AND TRANSLATION SUPPORT IN UK ALLOGENEIC TRANSPLANT CENTRES

Tomos Lloyd-Roberts[1], *Christina Yiallouridou*[1], *Karen Dean*[1], *Gemma Pugh*[1]
[1]*Anthony Nolan, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Patients with limited or no English often face barriers to accessing health information and opportunities to participate in research. The purpose of this study was to investigate i) which languages other than English are most spoken by UK cell therapy patients and ii) what translation and interpretation services are available to support patients with limited or no English to participate in research.

Methods: A cross-sectional survey was distributed to health care professionals working within UK adult allogeneic transplant centres (June–September 2025). The survey captured: i) which languages other than English are most spoken; (ii) the availability and perceived quality of interpretation and written translation services; (iii) local NHS trust policies on translation and interpretation; and (iv) perceived barriers to engaging patients with limited or no English in research. Descriptive statistics were used for closed-ended questions, while inductive thematic analysis was applied to free-text responses.

Results: A response was received from 58 health professionals across 22/23 (95%) of UK adult allogeneic transplant centres. Respondents were predominantly nurses (n=38, 66%) or doctors (n=8, 14%). All respondents reported caring for patients with limited or no English.

60% of respondents reported that >5% of their patient population had limited English. There was widespread variation between respondents from different transplant centres about which languages other than English were most spoken. However, Arabic, Urdu and Polish emerged as the most frequently encountered languages nationally. There was a relatively even split between the use of in-person and video or telephone interpretation services (48% vs 52%). 36% of respondents reported that access to an interpreter often affected their ability to recruit patients to research studies. Availability of written translated materials was limited. Only one respondent could name a current study at their centre that provided translated materials for participants. 90% of respondents were unaware of, or reported the absence of, a local NHS trust policy or guideline for including patients with limited or no English in clinical trials and research studies. Within free-text comments respondents highlighted that it was often difficult to ensure patients with limited or no English fully understand study information, that taking informed consent was challenging, and that reliance on family members as informal interpreters was common.

Conclusions: This survey highlights that UK transplant centres consistently care for patients with limited or no English, yet there is limited structured translation or interpretation services to support these patients to participate in research. The findings underscore the need for language support to be included in broader strategic initiatives designed to improve diversity and inclusion in clinical research. To inform evidence-based guidance and policy recommendations, future research should seek to work directly with patients with limited or no English to understand their experience care and using translation and interpretation support.

Clinical Trial Registry: N/A

Disclosure:

Nothing to declare:

- The survey was conducted as part of routine work at Anthony Nolan
- There was no commercial funding
- No author has personal financial conflicts related to translation services or vendors

P373

SCALING SOCIOECONOMIC AND QUALITY OF LIFE DATA COLLECTION AMONG HAEMATOPOIETIC STEM CELL TRANSPLANT RECIPIENTS IN THE UK: SEQOL STUDY PROGRESS AND SAMPLE SIZE FORECAST

*Gemma Pugh[1], **Christina Yiallouridou**[1], Tomos Llyod-Roberts[1], Dawn Hart[1], Rachel Miller[1], Karen Dean[1], Diana Voiniciuc[1], Robert Danby[1,2]*
[1]Anthony Nolan, London, United Kingdom of Great Britain and Northern Ireland (the), [2]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom of Great Britain and Northern Ireland (the)

Background: The purpose of the SEQoL study is to scale the collection of socioeconomic and quality of life data among allogeneic haematopoietic cell transplant (HCT) recipients. Data from the SEQoL study will be linked with clinical outcome data and used to investigate the effect of social determinants on patient outcomes and quality of life. This abstract presents the current recruitment progress and the sample size forecast.

Methods: Within the SEQoL study, adult (>18 years) allogeneic HCT patients are invited to complete a brief demographic and quality-of-life questionnaire before conditioning, on the day of their transplant, on days 28 and 100, and at 6, 9 and 12 months post-transplant. Outcome measures include the MacArthur Ladder, The Functional Assessment of Cancer Therapy - Bone Marrow Transplantation (FACT-BMT), and Lee Symptom Scale for chronic graft-versus-host-disease. Transplant centres are responsible for participant recruitment and consent, but outcome data collection and follow-up are managed by the research team at Anthony Nolan. Each transplant centre has received a tablet computer to facilitate e-consent and electronic data collection at baseline. Patient consent to link patient-reported outcome data from the SEQoL study with clinical outcome data held by national registries is obtained at enrolment.

Results: Recruitment to the SEQoL study opened in August 2024, since then >480 patients (as of December 2025) have enrolled in the study. There are 23 NHS transplant centres in the UK which provide allogeneic HCT to adults. The SEQoL study is open in 19 of these transplant centres, the remaining centres are planned to open in 2026. To ensure sufficient statistical power to detect even small effect sizes between socioeconomic predictors and patient outcomes following HCT, an estimate of the required sample size based on an 80% power threshold and a 5% significance level was produced. Given the inclusion of up to 10 socioeconomic variables in multivariable models and accounting for an anticipated 30% dropout rate by 12 months post-transplant, it is estimated that a minimum of 1175 participants are required to retain adequate power for the final analysis. The SEQoL study recruits on average 10 new patients per week. It is forecast that 1175 patients will be recruited by March 2027 after which data linking with clinical outcomes will begin. Consistent with the pilot study, capacity and workload at transplants centres has influenced the SEQoL study recruitment rate. The research team are working with transplant centres to streamline study processes related to study monitoring to overcome issues related to workload and are actively encouraging centres to involve health professionals in the co-ordination of the study via the NIHR, Associate Principle Investigator (PI) Scheme.

Conclusions: The SEQoL study will enable investigation into the temporal change in quality-of-life outcomes post-transplant and the effect of subjective and objective socioeconomic status on patient outcomes. Without this data there is limited understanding of how a stem cell transplant affects patient quality-of-life, and the impact of social determinants of health on clinical outcomes.

Disclosure: This study is sponsored and funded by Anthony Nolan. Additional funding to support this study has been received from NIHR (205434) and Therakos.

P374

CLINICAL PROFILE AND HEALTHCARE RESOURCE UTILIZATION IN PATIENTS WITH SICKLE CELL DISEASE WHO RECEIVED HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTS IN THE UNITED STATES

*Jiahe Li[1], **Duncan Brown**[1], Arie Barlev[1], Sara Rodrigues[1], Aric Parnes[1], Kinwei Arnold Chan[2], Amanda Moore[2], Gina Giase[2], Bridget Nolan[2], Suzan Imren[1]*
[1]Vertex Pharmaceuticals Incorporated, Boston, United States of America (the), [2]TriNetX, LLC, Cambridge, United States of America (the)

Background: Sickle cell disease (SCD) is a genetic blood disorder that causes red blood cells to become abnormally shaped (sickle-shaped), leading to vaso-occlusive crises (VOCs), hemolysis, and end-organ damage. Haploidentical hematopoietic stem cell transplant (haplo-HSCT) is a type of allogeneic hematopoietic stem cell transplant (allo-HSCT). It uses stem cells from a half-matched donor, most often a close family member like a parent or sibling. It is a potential curative treatment option for patients with SCD. The use of haplo-HSCT has increased in the last decade; however, its risks such as graft-versus-host disease (GvHD), graft failure, and death can be significant. This study aims to characterize the clinical profile and healthcare resource utilization (HCRU) among patients with SCD who received haplo-HSCT in the United States (US).

Methods: This retrospective observational cohort study utilized the TriNetX Dataworks-USA National EHR Network Database. Patients with SCD were identified based on ≥1 inpatient or ≥2 outpatient records with an SCD diagnosis between June 1, 2010, and October 24, 2023 (patient identification period). Given the lack of specific ICD-10 codes for haplo-HSCT, an algorithm for patient identification was recommended by medical experts: ≥1 record of allo-HSCT on or after the first SCD diagnosis, receiving thiotepa as part of the conditioning regimen and cyclophosphamide as part of the GvHD prophylaxis care plan. Physician notes in a subset of patients were reviewed to confirm the use of haplo-HSCT. The index date was the date of the first record of haplo-HSCT procedure. Demographics were assessed on the index date. Mortality, transplant-related complications, treatments, and HCRU were summarized in the follow-up periods post haplo-HSCT.

Results: Thirty-five patients with SCD who underwent haplo-HSCT were identified. The mean age was 17.9 (SD: 7.9) years and 45.7% were female. The mean follow-up from the index date was 2.8 [SD: 1.7] years. Four patients (11.4%) died: one died during the first 100 days post haplo-HSCT and three died within 16 months after haplo-HSCT. Many patients experienced transplant-related complications: graft rejection or failure (17.1%), acute GvHD (17.1%), and/or chronic GvHD (20.0%). During the follow-up period after the first 100 days post haplo-HSCT, 76.5% of patients were prescribed opioids. About two thirds of patients (64.7%) had an emergency room (ER) visit, with an average of 2.2 (SD: 5.2) ER visits per-patient-per-year (PPPY); the mean number of inpatient visits PPPY was 3.3 (SD: 8.6) and the mean number of outpatient visits PPPY was 45.0 (SD: 31.2).

Conclusions: The results of this study demonstrate the risks and burden associated with haplo-HSCT in patients with SCD. There is a notable 11.4% mortality rate, and many patients experience burdensome complications and require enduring HCRU following haplo-HSCT. Despite advancements in transplant conditioning regimens leading to reduced graft rejection/failure rate and GvHD prevention, haplo-HSCT still poses considerable risks, highlighting the need for innovative therapies that deliver curative potential without the risks inherent to haplo-HSCT.

THE CURRENT SITUATION OF STRESS AND MENTAL HEALTH INTERVENTION OF HEMATOPOIETIC STEM CELL TRANSPLANT CAREGIVERS

Shasha Li[1], *yuqing liu*[1], *jun rao*[1], *xiaoli chen*[1], *xi zhang*[1]
[1]*Blood Disease Medicine Center, Second Affiliated Hospital of Army Medical University, Chongqing, China*

Background: **Objective:** This study systematically analyzes the current stress levels and influencing factors among HSCT caregivers, exploring mental health intervention strategies to improve caregivers 'psychological well-being, thereby enhancing treatment outcomes and family functioning.

Methods: A prospective longitudinal design was employed, with 100 pairs of HSCT patients and their primary caregivers (daily accompaniment ≥4 hours) planned for inclusion. Follow-up surveys were conducted at key time points: pre-transplantation, alogenic anemia phase, post-donor phase, and 3 months post-transplantation. The caregivers' psychological status was assessed using standardized scales, including:
1. Stress Levels: The Caregiver Stress Index (CSI) was used for qualitative screening of stress presence; 2. Burden Degree: The Zarit Caregiver Burden Inventory (ZBI) and Caregiver Burden Inventory (CBI) were employed to quantify physical, emotional, and social burdens; 3. Psychological Reactions: Negative and positive feelings were analyzed through the Caregiver Response Assessment Scale (CRA). The study combined questionnaire surveys, clinical data, and social support indicators (e.g., financial pressure, family relationships) to analyze key factors influencing psychological status using a multivariate regression model.

Results: 1. Current Stress Status: Financial Burden: 43% of families need to sell assets or borrow money, with annual out-of-pocket medical expenses exceeding 50% of household income. Caregiver Intensity: 61% of caregivers require professional nursing skills, 72% experience sleep deprivation, and postoperative daily caregiving time ≥10 hours for 3 months. 2. Psychological Issues: Anxiety (30%), depression (60%), and post-traumatic stress symptoms (PTSS, 20%-30%) significantly higher than general population; family relationship tension rate reaches 38%,83% of caregivers go out for entertainment <5 times annually. 3. Influencing Factors: Patient Factors: Allogeneic transplantation and complications (e.g., GVHD) significantly increase stress; 4. Caregiver Factors: Young age, low education level, and negative coping styles correlate with higher anxiety; 5. Social Support: Financial

pressure, information opacity, and insufficient family support exacerbate psychological burdens.

Conclusions: HSCT caregivers universally face multidimensional stress, and their mental health status directly impacts patient recovery and family stability. Future interventions should focus on: 1. Long-term monitoring: Establish a comprehensive psychological assessment system covering the entire transplant cycle, with particular attention to high-risk phases (e.g., acute phase and complication phase); 2. Personalized support: Develop digital psychological platforms (e.g., online consultation, peer support communities) and integrated intervention programs (e.g., cognitive behavioral therapy, mindfulness training); 3. Family and social support: Provide economic assistance guidelines, family communication tools, and enhance professional guidance for caregivers by medical teams. This study provides empirical evidence for optimizing mental health interventions for HSCT caregivers, emphasizing the need to integrate caregiver support into the overall management framework of hematologic disease treatment.

Disclosure: Nothing to declare.

MONITORING STRESS AND WORKLOAD IN PRIMARY CAREGIVERS OF PATIENTS UNDERGOING ALLOGENEIC HEMATOPOIETIC PROGENITOR CELL TRANSPLANTATION: A ONE-YEAR SINGLE-CENTER EXPERIENCE

Sara Marcos Asensio[1], *Lorena Hernandez Medina*[2], *Marta García Blazquez*[1], *Estefanía Perez López*[1], *Lucia López Corral*[1]
[1]*Complejo Asistencial Universitario de Salamanca, Instituto de Investigacion Biomédica de Salamanca, Salamanca, Spain,* [2]*Instituto de Investigación Biomédica de Salamanca, Salamanca, Spain*

Background: Allogeneic Hematopoietic Progenitor Cell Transplantation (allo-HSCT) is the only curative treatment for various malignant and non-malignant hematological diseases. It is a highly complex procedure with high morbidity in the early stages; therefore, the role of the primary caregiver is essential. The reviewed literature shows that these caregivers experience high levels of stress and burden, which negatively affect their quality of life.

Methods:

An observational, descriptive, cross-sectional study was designed at the University Hospital of Salamanca, conducted from July 2024 to July 2026. Caregivers were recruited in the allogeneic transplant nursing clinic during the pre-transplant assessment. All caregivers were included except those with physical or psychological disabilities and/or healthcare training.

Participants completed the Perceived Stress Scale (PSS-10), the Gijón questionnaire, and the Zarit Caregiver Burden Scale at the time of study inclusion, one month after the allogeneic transplant, at three months, and at one year. The PSS-10 questionnaire is scored from 0 to 40 points, with higher scores indicating higher stress levels. The Zarit scale ranges from 22

to 110 points and is stratified as follows: 22–46 "no burden," 47–55 "mild burden," and 56–110 "severe burden."

Clinical variables related to the patient's disease and treatment will be extracted from medical records. Statistical analysis will be performed using the SPSS v.25. Results will be presented using descriptive statistics, with frequency distributions and percentages for qualitative variables, and measures of central tendency and dispersion for quantitative variables.

Results:

39 caregivers have been recruited. All participants (100%) completed the baseline assessment and the one-month follow-up, 87% (n=34) completed the three-month follow-up; and 39.5% (n=15) completed the one-year follow-up. Six caregivers (15.4%) withdrew from the study due to the death of their relatives. Table 1 shows the characteristics of these caregivers and the mean scores on the administered scales.

Age (mean)	57,57 years (30-72)
Sex	Female: 31 (79.5%) Male: 8 (20.5%)
Caregiver's highest level of education	Primary Education: 11 (28.2%) Secundary Education: 2 (5.1%) High School: 3 (7.7%) University Degree: 8 (20.5%) Post-University Degree: 5 (12.8%) Profesional Education: 9 (23.1%) No answer: 1 (2.6%)
Caregiver's employment status at baseline	Full-time work: 12 (30.8%) Part-time work: 2 (5.1%) Household duties: 8 (20.5%) Unemployed: 8 (20.5%) Retired: 5 (12.8%) Others: 4 (10.3%)
Caregiver/patient relationship	Partner: 25 (64.1%) Sibling: 3 (7.7%) Son/Daughter: 3 (7.7%) Mother/Father: 8 (20.5%)
Living with the patient	Yes: 33 (84.6%) No: 6 (15.4%)

Other dependents under the care of the same caregiver	Yes: 10 (25.6%) No: 28 (71.8%) No answer: 1 (2.6%)
Possibility of alternating with another caregiver	Yes: 25 (64.1%) No: 14 (35.9%)
Patient and caregiver residence	Salamanca: 9 (23.1%) Castilla y León: 16 (41%) Extremadura: 12 (33.3%) Others: 1 (2.6%)
Mean baseline stress scale score Mean stress scale score at 1 month after allo-HSCT Mean stress scale score at 3 months after allo-HSCT	18.24 points (7–30) 19.25 points (7–33) 18.79 points (0–32)
Mean baseline Zarit scale score Mean Zarit scale score at 1 month after allo-HSCT Mean Zarit scale score at 3 months after allo-HSCT Mean Zarit scale score at 1 year after allo-HSCT	40.64 points (22–69) 40.44 points (26–65) 41.93 points (23–71) 40.71 points (25–59)

Table 1.

As shown in Table 1, the mean stress score remains high throughout the process due to its complexity, but it is lower during the first month while the patient is hospitalized, which may be related to the fact that care responsibilities fall mainly on healthcare professionals. Stress increases at three months, when the patient usually presents greater fragility and dependence for basic activities of daily living and decreases again at one year, as patients begin to regain part of their life prior to allo-HSCT. Regarding the Zarit scale, scores remain constant throughout the year, around 42 points, indicating an absence of caregiver burden.

Conclusions:

After one year of follow-up, we observed that caregivers of our patients experience consistently high levels of stress throughout the process; however, they do not exhibit significant caregiver burden. This finding should be interpreted with caution, as the impact of hospitalizations due to complications on caregiver burden requires further investigation. Additionally, potential bias may arise when patients complete questionnaires under stress or pressure.

Based on these findings, the next step would be to evaluate the impact of hospitalizations on caregiver burden and to determine the effectiveness of psychological interventions for caregivers.

PSYCHOSOCIAL ASSESSMENT OF PATIENTS AND CAREGIVERS UNDERGOING AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANTATION AT HOME

Ana Rodriguez Calvo-Parra[1], *Alberto Sanchez Donaire*[1], *Jesus Ignacio Merlo Luis*[1], *Irene Marquez Vita*[1], *Cristina Elez Martinez*[1], *Beatriz Gallego Diaz*[1], *Marcela Talero Garcia*[2], *Marta Escudero Iglesias*[2], *Javier Cornago Navascues*[1], *Laura Pardo Gambarte*[1], *Jose Luis Lopez Lorenzo*[1], *Elham Askari*[1], *Sergio Ramos Cillán*[1], *Juan Carlos Caballero Hernaez*[1], *Maria Angeles Perez Saenz*[1], *Elena Gonzalez Arias*[3], *Daniel Naya Errea*[3], *Alberto Velasco Valdazo*[3], *Pilar Llamas Sillero*[1], *Amalia Domingo Gonzalez*[1], *Laura Solan Blanco*[1]
[1]*Fundación Jiménez Díaz Universitary Hospital, Madrid, Spain,* [2]*Asociacion Española Contra el Cancer, Madrid, Spain,* [3]*Rey Juan Carlos Universitary Hospital, Madrid, Spain*

Background: Haematopoietic Stem Cell Transplantation (HSCT) is a procedure that has increasingly demonstrated the benefits of home-based treatment over hospitalization. In order to offer this option to patients who live far from the hospital, we collaborate with the Asociación Española Contra el Cáncer (AECC), which provides us with apartments close to the hospital.
This programme also requires the patient to have a caregiver throughout the process. The caregiver plays a crucial role in the HSCT home programme. Despite their critical role, their needs and wellbeing are often overlooked.
Currently, a psychosocial assessment of the patient is recommended to identify the most vulnerable individuals, as well as an assessment of the caregiver's wellbeing.
This study analyses, for the first time at the national level, the psychosocial risk of patients undergoing home-based HSCT using the Gijón Socio-Family (GSF) scale and the level of adverse effects on the quality of life of the primary caregiver using the Family Reported Outcome Measure (FROM-16) scale. The results of these measurements significantly help to implement holistic clinical practice.

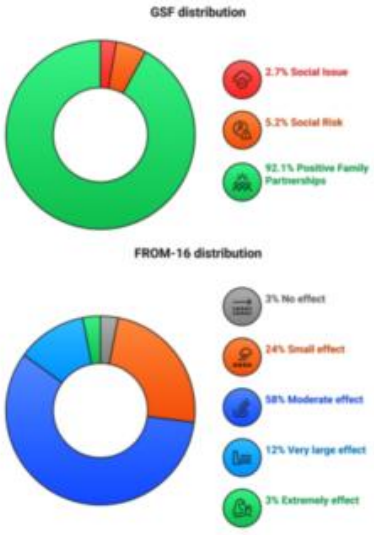
Methods: Data were collected retrospectively from March 2021 to November 2025 from all patients and their caregivers undergoing home-based HSCT in a tertiary hospital. Patients were assessed in person and systematically using the GSF, and caregivers were assessed using the FROM-16.
Statistical analyses were performed using SPSS software.

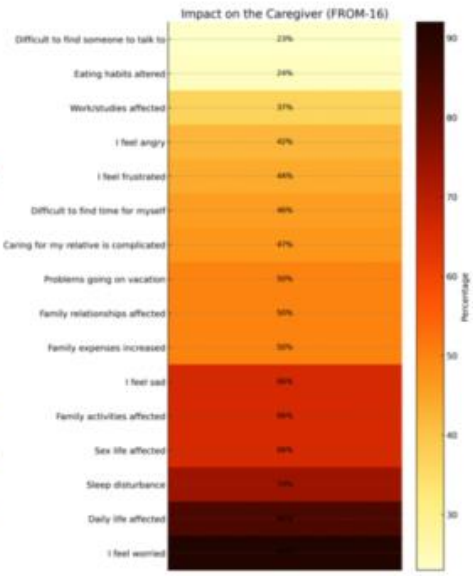
Results: Patients with data for both GSF and FROM-16 were analysed. Of a total of 46 patients transplanted at home between March 2021 and November 2025, only 38 patients and 38 caregivers could be analysed (Table 1). The GSF shows that 92.1% of patients have a

good socio-family assessment; likewise, FROM-16 shows that the home-based HSCT process has a moderate effect on the primary caregiver in 58% . Additionally, FROM-16 shows that, on an emotional level, 92% of caregivers report being somewhat or very concerned about the situation, while 66% feel sad and 42% feel angry. Only 23% find it difficult to talk about their thoughts with someone. On a personal and social level, 84% of caregivers see their daily lives as somewhat or very affected. Furthermore, 74% of them report having sleep disturbances. On the other hand, 37% of caregivers report that their work or studies have been affected and 50% report an increase in their family expenses. 47% of caregivers consider caring for their family member to be complicated. And 66% say that their sex life is affected (Image 1).Finally, the relationship between both scales and different transplant complications such as fever, diarrhoea, mucositis, and readmission was analysed, showing no direct association with them.

Table 1. Patient characteristics

Patients, n	38
Age, median (range)	55 (21-71)
Man/Female, n (%)	19 (50) /19 (50)
Caregiver, n (%)	
Couple	24 (63)
Mother/Father	6 (16)
Brother/Sister	3 (8)
Son/Daughter	3 (8)
Others	2 (5)
Primary disease, n (%)	
Multiple myeloma	22 (58)
Lymphoma	9 (24)
Cancerous tumours	7 (18)
Age-adjusted Sorror, n (%)	
0-1	11 (29)
2-3	17 (45)
4-7	10 (26)
Location HSCT, n (%)	
Patient's home	28 (74)
AECC apartment	10 (26)
Readmission, n (%)	10 (26)





Conclusions: Most patients with access to the home transplant programme are in a good socio-familial situation. Furthermore, it is clear that this transplant modality has a moderate effect on caregivers, without this affecting the outcome of the transplant. Measures need to be implemented to help minimise this effect on caregivers, with the support of professionals. The AECC has enabled us to perform this type of transplant in 26% of our patients.

DIGESTIVE AND SYSTEMIC PROPHYLAXIS IN HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT): A NATIONAL SURVEY IN FRANCE

Valentin Rinaldi[1], Sarah Benezech[1], Amandine Bertrand[1], ***Cécile RENARD***[2]
[1]Institut d'Hématologie d'Oncologie Pédiatrique, Lyon, France, [2]Institut d'Hématologie d'Oncologie Pédiatrique, lyon, France

Background: Infectious prevention in pediatric hematopoietic stem cell transplantation (HSCT) remains a critical issue. Historically, prophylactic oral digestive decontamination (PDD) aims to reduce the risk of bacterial translocation, but its effects on microbial diversity and the emergence of multidrug-resistant bacteria (MDR) are controversial. In the context of increasing antibiotic resistance and ongoing research in the prevention and treatment of acute and chronic graft-versus-host disease (GVHD), we conducted a multicenter survey to map the practices of digestive prophylaxis and empirical antibiotic therapy in pediatric allogeneic HSCT in France.

Methods: A structured questionnaire was sent to 12 French pediatric transplant centers. The collected data covered: (1) the use of PDD, (2) oral care practices, (3) microbiota surveillance, (4) nutritional modalities (oral, enteral, and parenteral), (5) antibiotic and antifungal prophylaxis, and (6) the use of fecal microbiota transplantation (FMT). Centers also estimated the annual frequency of gastrointestinal GVHD by grade.

Results: PDD practices were highly variable: one center used it systematically, two used it conditionally, while the majority did not use it. Oral care was universal but heterogeneous in composition, ranging from antifungals and/or antibiotics to simpler formulations like bicarbonate or Caphosol® (calcium phosphate). Exclusive oral nutrition was rare (<25% of patients in all centers), leading to frequent use of enteral (>50% in 4 centers) or parenteral nutrition (>50% in 3 centers). Empirical antibiotic therapy in febrile aplasia primarily relied on third-generation cephalosporins alone (50% of centers), sometimes combined with an aminoglycoside (25% either systematically or conditionally). FMT was reported in 4 centers (33.3%), exclusively for severe gastrointestinal GVHD. All centers reported an incidence of gastrointestinal GVHD grade 3–4 of less than 25%.

Conclusions: This survey represents the first national multicenter analysis describing digestive and nutritional prophylactic practices in pediatric allogeneic HSCT in France. The marked variability observed, particularly regarding PDD, nutrition, and antibiotic prophylaxis, highlights the lack of consensus and the empirical adaptation of strategies. The low reported incidence of severe gastrointestinal GVHD does not allow for a causal link to be inferred but strengthens the hypothesis of a protective role of the microbiota when preserved. These results call for prospective pediatric studies incorporating microbiological data and clinical outcomes to define harmonized recommendations.

NP96

IMPACT OF SWITCHING FROM SODIUM CITRATE AND TAUROLIDINE TO 4% TETRASODIUM EDTA AS A CATHETER LOCK SOLUTION IN HEMATOLOGY PATIENTS

Georgeta Tudor[1], *Cristina Virgi Cristea*[1], *Oana Otilia Niculita*[1]
[1]*Fundeni Clinical Institute, Bucharest, Romania*

Background: Central venous catheters (CVCs) are essential for patients undergoing autologous or allogeneic transplantation and chimeric-antigen T-cell therapy. Catheter-related infections and lumen cause treatment interruption, increased healthcare costs, and are a significant cause for morbidity. Both 4% tetrasodium EDTA and the combination of 4$ sodium citrate with taurolidine exhibit antimicrobial and anticoagulant properties and inhibit biofilm formation. Additionally, 4% tetrasodium EDTA can eradicate established biofilm.

Methods: We performed a retrospective analysis of medical records from July to October 2025. A total of 92 hematological patients requiring CVCs were included and divided into two groups, 52 patients in the citrate + taurolidine group, and 40 patients in the 4% tetrasodium EDTA group.
The group that utilized citrate+taurolidine consist of:
-20 Autotransplant
-5 MUD
-1 Sibling
-3 Haploidentical transplant
-21 Stem Cell Collection
-2 CAR-T administration.
The group in which 4% Tetrasodium EDTA was used, consists of:
-18 Autotransplant
-5 MUD
-2 Sibling
-3 Haploidentical transplant
-10 Stem Cell Collection
-2 CAR-T administration.
Statistical analysis was performed using IBM SPSS Statistics. Chi squared test was used to assess differences between groups.

Results: Switching from citrate + taurolidine to 4% EDTA resulted in a marked clinical improvement. Catheter-related infections decreased from 23.08% (n=12) to 5.00% (n=1) (p=0.017) (Figure 1a). CVC occlusions decreased from 26.92% (n=14) to 2.5% (n=1) (p=0.002) (Figure 1b).

Conclusions: Compared with other lock solutions, 4% tetrasodium EDTA significantly reduced CVC-related infections and improved CVC patency. Its superior antimicrobial and antibiofilm activity translated into meaningful clinical benefits and potential cost savings for hematology patients requiring central venous access.

Donor Care

NG12-01

CLOSING THE GAP IN DONOR CARE: A RETROSPECTIVE AUDIT OF RELATED STEM CELL DONOR FOLLOW-UP

Patricia Cardoso[1], *Monica Blasco Gomez*[1], *Alaine Rasay*[1], *Alison Pratt*[1], *Emma Davies*[1], *Sandra Anteh*[1], *Victoria Potter*[1], *Michelle Kenyon*[1]
[1]*King's College Hospital NHS Foundation Trust, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Haematopoietic Cell Transplant (HCT) practices are highly regulated, yet clear standards for post-donation care of related stem cell donors are lacking (Sanchez et al, 2023). Kisch et al (2017, 2025) emphasise the need for systematic, early, and individualized follow-up for addressing physical symptoms, psychological well-being, and social or relational factors. Anecdotal feedback from our related donors highlighted unmet needs and a sense of abandonment. In response, we implemented a related-donor follow-up telephone clinic, modelled on an unrelated-donor registry framework, safely providing structured personalised care throughout recovery. Donors are contacted by telephone 5 times (day +2, +7, month 1 ,6 and 12) after each donation (PBSC – peripheral blood stem cell or DLC-donor lymphocyte collection) regardless of recipient outcome. Each call includes structured assessment of physical psychological, and social/ relational well-being with escalation of concerns as required.

Methods: We conducted a retrospective audit of related PBSC and DLC donors attending our follow-up telephone clinic between January 2023 and November 2025. Data included donor demographics, donation type (PBSC or DLC), and follow-up outcomes (physical symptoms and emotional well-being) and were analysed using descriptive statistics.

Results: We reviewed 86 donation follow-up episodes from 71 related donors (median age 43, range 16-70; 38 male, 33 female). There was 15 additional collections (6 second PBSC, 9 DLC) from donors whose first donation was also in the audit window (n=71). Most were siblings (n=57), with parents (n=7) and children (n=7) also donating. HLA matched donors accounted for 50 relatives while the remaining 21 were haploidentical.
Of 430 scheduled follow-up calls, 114 were not completed (period of staff shortages), largely impacting the 6 and 12 month follow-up. Physical symptoms were reported in 70 of the 86 donation episodes: most commonly tiredness (n=45), bone pain (n=31), headache (n=20), and line site bruising (n=16). Most resolved within one month; though persistent adverse effects (AE) were reported after 13 donations at one month (tiredness and abnormal blood results) with AEs from 7 of these exceeding one month, largely attributable to pre-existing conditions. All were triaged and received medical review (transplant centre or general practitioner). Central venous catheter insertion (femoral line) was required for 10 collections with no associated complications reported.

Emotional recovery varied: full recovery was reported after 52 donations, with reports of feeling worse (n=7) mainly due to concern for the recipient (4/7) or feeling better (n=7) due to satisfaction in supporting their family.

Characteristic	Number of Donors (n=71)	Total donations (n=86)
Median age years (Range)	43 (16-70)	
Gender Male Female	 38 33	
Relation to recipient Sibling Parent Children	 57 7 7	
Degree HLA match Full Match Haploidentical	 50 21

Lines related side effects Infection - Femoral Line - IVC Pain - Femoral Line - IVC Bruising - Femoral Line - IVC		 0 0 0 7 1 6 16 3 12

Conclusions: This audit underscores the value of a systematic related-donor follow-up clinic in ensuring safe, effective care. While minor gaps exist due to staffing, overall compliance and donor feedback are positive. Persistent 1-month symptoms suggest a 2-month follow-up may be beneficial. Beyond tracking physical and psychological symptoms, the clinic provides emotional support and regular contact, particularly important when recipients face transplant complications, allowing timely additional support for donors.

A FAIR MATCH? AUDIT OF GEOGRAPHIC INEQUITY IN RELATIVES TISSUE TYPING TIMELINES

Monica Blasco Gomez[1], *Patricia Cardoso*[1], *Alison Pratt*[1], *Alaine Rasay*[1], *Victoria Potter*[1], *Michelle Kenyon*[1]
[1]*King's College Hospital, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Timely identification of related stem cell donors is critical in haematopoietic stem cell transplantation (HCT). Anecdotal reports suggest that HLA typing of non-UK resident (non-UK-R) related donors is frequently delayed, potentially affecting transplant decision making. Delays may arise from logistical barriers including customs clearance, incomplete documentation, shipping costs, and visa requirements, sometimes necessitating donation overseas. This audit examined whether these challenges represent isolated events or recurring systemic issue affecting transplant timelines and contributing to potential inequity for patients and their non-UK-R donors.

Methods: A 2-year retrospective audit (January 2024–December 2025) examined HLA typing and donation requests for non-UK resident (non-UK-R) related donors, with UK-resident (UK-R) donors as a comparator. Data were extracted from transplant centre records, typing centre correspondence, and electronic systems, including donor demographics, relationship to recipient, country of origin, and key timelines from typing pack dispatch to HLA report issue and sample validity. Descriptive statistics were used for analysis.

Results: A total of 122 tissue-typing packs were sent to 93 non-UK-resident (non-UK-R) and 122 to 110 UK-resident (UK-R) potential related donors. In the UK-R relative group, 52/110 were male and 58/110 female; ages 17-75; siblings (74/110), parents (9/110), children (26/110) other relative (1/110). In the non-UK-R group, 45/93 were male, 48/93 female, age 17 to 75; siblings (87/93), parents (2/93), children (2/93), other relative (3/93).
Pack receipt confirmation was lower for non-UK-R donors (99/122 vs 109/122), mainly due to address omissions and customs delays. Packs were sent to 33 countries, with recurring issues in USA (9/23), Pakistan (8/8), Nigeria (7/11), Spain (4/5), Albania (3/6), Nepal (3/4), Kenya (2/2), South Korea (2/2), Bolivia (2/2) and Brazil (2/2).
Sample return rates were also lower for non-UK-R donors (69/99 vs 96/109), often due to border controls (8/30) and dispatch costs (5/30). Median transit time was longer for non-UK-R donors (5 vs 2 days; range 2-21 vs 1-11 days), contributing to lower sample validity (53/69 vs 90/96); 17/69 non-UK-R sample dates were lacking. Failed DNA testing was the predominant reason for invalid samples; labelling errors were rare (3 vs 3).
HLA results were broadly comparable (full match UK-R 11/90 vs non-UK-R 10/53; haplo-identical 62/90 vs 31/53; not matched 17/90 vs 11/53). However, 8 UK-R donors have proceeded to cell collection, while no non-UK-R donors did, due to alternative donors, donor health, travel constraints, or pending transplant decisions. highlighting ongoing barriers and potential inequity for patients with non-UK-R related donors.

Characteristics (Non-UK-R)	**Packs Non-UK (n= 122)**	**Packs UK (n=122)**	**Relatives non-UK (n= 93)**	**Relatives UK (n=110)**

Thailand Uganda United Arab Emirates USA	3 (0 issues) 1 (0 issues) 1 (1 issue) 1 (0 issues) 4 (3 issues) 2 (0 issues 11 (7 issues) 8 (8 issues) 1 (0 issues) 2 (2 issues) 4 (2 issues) 2 (2 issues) 5 (4 issues) 3 (1 issue) 1 (0 issues) 2 (2 issues) 1 (0 issues 23 (9 issues)			

Conclusions: This audit highlights significant geographic inequity in tissue typing timelines for non-UK-R relatives and the challenges faced by all stakeholders in identifying suitable donors. Notably, none of the 10 matched non-UK-R relatives in this audit sample were invited to donate, with transplants proceeding using alternative donors. These findings reveal a systematic disadvantage for non-UK-R related donors potentially limiting donor utilisation and timely patient access and exposing clear inequities in current HCT pathways. Some deficiencies, such as customs delays and courier costs, could be addressed but this requires coordinated action among transplant teams, overseas registries, government bodies and international courier providers.

NP12

APPLICATION OF LONG PERIPHERAL CANNULA IN DONOR APHERESIS - EXPERIENCE OF ONE CENTER

Petra Vodickova[1], *Veronika Bergerova*[1], *Petra Kolerusova*[1], *Lenka Karasova*[1], *Klara Kabatova Maxova*[1]
[1]*Charles University Hospital Pilsen, Plzen, Czechia*

Background: Allogeneic peripheral hematopoietic cell (PBSC) collections place high demands on venous access while maintaining the comfort and safety of the donor. The assessment of peripheral venous access is the responsibility of the apheresis nurse. Fixed 16G and 17G (PVC) dialysis peripheral cannulas are used as standard. In case of poor quality of peripheral veins in both limbs of the donor, we insert short-term central dialysis cannulas (CVC). Since 9/2024, we have started using long peripheral venous cannulas (LPC), which are introduced under ultrasonographic control. They are used in donors who have only one good venous access on the forearm and are at risk of central dialysis catheter (CVC) insertion. The aim of this work is to present the first experiences with this access and compare them with the period before its implementation.

Methods: A retrospective single-center analysis of all allogeneic PBSC collections was performed in the period 09/2023–09/2025. The data analysis was divided into two sets: Period without LPC use 09/2023–09/2024 and period with LPC use 09/2024–09/2025. The frequency of use of individual venous accesses, flow stability during apheresis and the total duration of the collection were evaluated. When using LPC, a peripheral metal dialysis needle (PVC) was used for the collection line, and the return line was run through a long peripheral cannula (LPC). Data were drawn from the internal documentation of the apheresis center.

Results: In total, the set includes 176 allogeneic PBSC collections, of which 91 collections in the period without LPC use and 85 in the period after the insertion of LPC. Three types of venous access were compared - PVCs, CVCs, and LPCs. In the period before LPC insertion, 78% of collections were performed using PVC (71/91) and 22% using CVC (20/91). In the period after LPC insertion, 83% of collections were performed using PVC (70/85) and 8% (7/85) using CVC. LPC was used in 9% of apheresis (8/85), which represents a 65% reduction in the need for CVC. When using PVC, flow rate (72 (86-50) vs. 72 (83-50) ml/min) and collection time (235 (261-167) vs. 242 (274-197) min.) did not differ between the two periods. When using CVC, flow rate (71 (88-52) vs. 78 (83-63) ml/min) and collection time (222 (250-155) vs. 220 (229-121) min.) did not differ in both periods. When using LPC, the flow rate was (70 (73-58) ml/min.) and the collection time was (254 (259-204) min.). Compared to PVC, comparable flow rate is achieved with a discretely longer collection time.

Conclusions: Implementation of LPC led to a reduction in the need for CVC without a negative impact on flow rates or collection time. A key element is careful assessment of

venous access by the nurse during the pre-collection examination, which will allow safe and effective apheresis planning.
Given the size of the analyzed set, the results should be interpreted with some caution, however, the available data show a stable course of apheresis and support the continuation of data collection and further development of the use of LPC in clinical practice.

Disclosure: No conflict of interest.

NP73

COUNT THEM IN: RECOGNISING DUFFY NULL NEUTROPENIA IN AFRO-CARIBBEAN POPULATION WITH THE AIM TO BROADEN DONOR INCLUSION. CASE REVIEW OF A NEUTROPAENIC DONOR

James Oppong[1], *John Gillson*[1]
[1]*University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom of Great Britain and Northern Ireland (the)*

Background: In allogeneic stem cell transplants, a well-matched Human Leukocyte Antigen (HLA) donor is critical for optimal outcome. However, the likelihood of finding a suitable unrelated donor is unequal across ethnic groups. Potential donors must undergo strict medical assessments, and an unexpected blood result, like neutropaenia, might cause the donor to be placed on hold or cancelled.
Racial neutropenia is disproportionately common among people of Black and Asian backgrounds – the very groups already struggling to find well matched donors. This is associated with the Duffy Null Antigen, which is expressed by 66% of African Americans and 80% of West Africans.
The Duffy antigen, encoded by the *ACKR1* gene, gives rise to the Duffy blood group system and acts as a chemokine receptor. The Duffy null phenotype (Fy(a-) Fy(b-)) leads to abnormal neutrophil regulation and a low neutrophil count but no functional or pathological abnormality
This case involves a patient of West African background with no suitable unrelated donor but a fully matched sibling with an unexplained neutropenia during donor medical assessment.

Methods: Case Description: A West African patient, diagnosed with hepatitis associated aplastic anaemia required an allogeneic stem cell transplant. Unrelated donor search found no suitable matches, but a sibling was fully HLA-matched.
At the sibling's donor medical, she was found to be neutropaenic, with neutrophil count of 0.91 x 10^9/L. This was concerning for her own health and also the viability of using her as a donor.
Haploidentical transplant from a parent was considered, but both parents expressed donor specific antibodies (DSA) against the patient, ruling them out. With limited alternative options, the case of the matched sibling donor was revisited.
The team considered performing a bone marrow biopsy to rule out malignancy but chose to test for the Duffy Null phenotype. Blood samples were sent to NHSBT, Birmingham and the results confirmed *Duffy null* status therefore confirming the neutropaenia as racial and not

pathological. The team proceeded with her as the donor.
The sibling donor received 5 days of GCSF injections for mobilisation, followed by two days of harvesting.

Results: A CD34+ harvest dose of 7.85 x10^6/kg was obtained and patient went into transplant receiving the full dose. He engrafted on day +12 (neutrophil count of 2.1 x 10^9/L) and discharged on day +16 (neutrophil count of 2.3 x 10^9/L).

Conclusions: This case highlights the role Duffy null biomarker can play in stem cell donor selection and how lack of awareness can lead to unfair exclusion of potential donors. With Duffy null highly prevalent among the populations who are underrepresented on the global stem cell register, it is crucial that potential donors from Black/Asian background that have unexplained neutropaenia at donor medicals will be probed further by having Duffy antigen testing and not simply ruled out. 'Let us count them in'.

Disclosure: Nothing to declare.

NP87

PSYCHOLOGICAL IMPACT OF LAST MINUTE SCHEDULING CHANGES ON RELATED DONORS

Laura Baines[1]
[1]*The Christie NHS Foundation Trust, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: The Christie acts as a collection centre for registries, and for related donors. When looking at related and unrelated pathways, related donors may be identified and required to proceed to donation at very short notice, receiving less structured support. Dates can frequently change in response to the recipient's clinical condition. This unpredictability can create significant emotional and psychological strain for related donors. Related donors experience intensified stress and anxiety due to the emotional responsibility of donating to a sibling. Time pressures and uncertainty add to the psychological burden. Last minute changes can disrupt personal, professional, and family commitments, impacting donor wellbeing and overall donor experience.

Methods: We aim to highlight how last-minute changes can impact related donors experience and the psychological impact this causes. If matched its discussed in MDT. Donors are contacted to attend for medical assessment, followed by donation as soon as identified. Dates are calculated carefully with patient timeline and donor preferences.
Design: Reflecting on case studies we aim to improve future donor experience in relation to psychological impacts. Both donors were aware that donation is voluntary.
Donor 1: 20-year-old female, studying full time in Exeter (approximately 240 miles away). Initially not planned to be used as donor but due to her siblings unrelated donor withdrawing last minute, she was contacted with two day's notice to attend for a medical. Donation planned for two weeks later; however confirmatory typing was not complete. This resulted in two possible donation dates being communicated to donor considering a delay with

confirmatory typing. The donation process also coincided with the donor's 21st birthday. The short notice caused disruption to academic and personal commitments and caused long distance travel last minute. The uncertainty caused significant stress and anxiety, highlighting the psychological impact of last-minute donor scheduling.
Donor 2: 53-year-old female in full time employment. Donating for sibling. Due do pharmacy issue with patients conditioning treatment donation had to be postponed the day before the donor was due to start GCSF. No dates could be confirmed initially causing uncertainty for donor. The short notice cause stress and worry for donor. The donor had to rearrange work schedule and a family holiday that had already been postponed due to donation.

Results: Both donors donated for their siblings. However, both experienced last minute changes to plans and dates. This resulted in additional psychological burden and disruption to donor's everyday life and life events; on top of the emotional worry and sense of responsibility already associated with donating to a sibling.

Conclusions: Both donors donated to help their siblings despite the initial plan changing. As a collection centre undertaking donor medicals and harvests, we always aim to manage expectations and minimise disruption to donors. However, unforeseen last-minute changes can significantly increase the psychological burden. Ensuring clear and consistent communication between donors and the clinical team is essential in providing support throughout the process. Signposting donors to support services such as peer groups at Maggie's Centre could help further improve the donor experience.

Disclosure: Nothing to declare

Impact of New Therapies on Patient Care

NP26

FOSCARNET SODIUM ENEMA FOR REFRACTORY CMV GASTROENTERITIS AFTER HAPLOIDENTICAL HSCT: A CASE SERIES

Mengjing Li[1], *Yu Xu*[1], *Fengwei Du*[1]
[1]*The First Affiliated Hospital, Zhejiang University School of Medical, Hangzhou, China*

Background: Cytomegalovirus (CMV) gastroenteritis is a severe complication following allogeneic hematopoietic stem cell transplantation (allo-HSCT). When systemic antiviral therapy fails to effectively alleviate intestinal symptoms or clear viral loads, effective alternative management strategies are urgently needed.

Methods: We report two cases of haploidentical HSCT recipients diagnosed with CMV gastroenteritis characterized by intractable diarrhea and positive stool CMV-DNA. Following a suboptimal response to systemic antiviral regimens, both patients received foscarnet sodium retention enemas as salvage or adjunctive therapy. Clinical outcomes were longitudinally

monitored, including changes in stool/blood viral loads and improvement in gastrointestinal symptoms.

Results: Case 1 (36-year-old female, AML) presented with severe diarrhea and elevated stool CMV-DNA despite systemic treatment. Following the initiation of foscarnet sodium enema on day +63 post-transplantation, stool CMV-DNA turned negative within 5 days, accompanied by significant symptom relief. Case 2 (60-year-old female, CMML) developed severe enteritis with high viral loads on day +61. After receiving combined intravenous and rectal foscarnet therapy, stool CMV-DNA cleared by day +70, and clinical symptoms improved significantly. Both patients tolerated the local therapy well, with no observed mucosal injury or systemic toxicity.

Conclusions: Foscarnet sodium enema represents a promising, non-invasive adjunctive therapy for refractory CMV gastroenteritis after allo-HSCT. It can effectively reduce local viral burden and accelerate symptom resolution when systemic drug penetration is insufficient.

Disclosure: Nothing to declare.

IMPACT OF THE ETAPES-ONCO PEER SUPPORT PROGRAM ON THE NEEDS OF HEMATOLOGY-ONCOLOGY PATIENTS WHO HAVE UNDERGONE CELLULAR THERAPY: PRELIMINARY RESULTS

Catherine Paquette-Gascon[1,2], *Pegah Torabi*[2], *Ludovic Tamaro*[2], *Sandie Oberoi*[3], *Deborah Pascale*[3], *Kelley Kilpatrick*[4], *David Ogez*[1], *Marie-Pascale Pomey*[5], *Katia Dumont*[2], *Israel Fortin*[3], *Imran Ahmad*[2], *Karine Bilodeau*[1,2]
[1]*University of Montreal, Montreal, Canada,* [2]*Maisonneuve-Rosemont Hospital Research Centre, Montreal, Canada,* [3]*Centre Intégré Universitaire de Santé et de Services Sociaux de l'Est-de-l'Île-de-Montréal, Montreal, Canada,* [4]*McGill University, Montreal, Canada,* [5]*CHUM Research Centre, Montreal, Canada*

Background: In Canada, hematological cancers represent roughly 10% of all cancer cases. Although their incidence is growing each year, survival rates of hematological cancer are also on the rise. The recent therapeutic advances, particularly hematopoietic stem cell transplantation (HCT) and CAR-T cell therapy, are playing a big role in the survival outcomes. However, these therapies are complex and have the potential to generate side effects as well as creating isolation, uncertainty, and emotional distress: they often create unmet needs in patient's lives. Peer-support programs have shown promise in oncology, but none have been specifically designed for hematology-oncology patients undergoing cellular therapies in Canada. To address this gap, the ETAPES-Onco project was developed to create a structured peer-support program tailored to their needs. This poster aims to present preliminary findings on the perceptions of patients with hematological cancer who underwent cellular therapies and were paired with a patient partner through the ETAPES-Onco peer-support program, focusing on how this support addressed their needs.

Methods: For this study, a qualitative descriptive approach was adopted (Thorne, 2016). We are currently recruiting patients over 18 years old who have undergone cellular therapies (allograft or CAR-T) and agreed to be paired as part of the study. Individual interviews are planned three months after peer pairing, using an interview guide based on a supportive care framework (Fitch, 2008) and a conceptual peer support framework (Dennis, 2003). Qualitative data analysis is ongoing and is being conducted using a three-step iterative content analysis approach, which includes data condensation, data display, and conclusion drawing (Miles et al., 2014).

Results: The preliminary findings (3 interviews on 10) inform that peer support addressed seven main domains of patient needs (emotional, informational, psychological, physical, informational, practical and spiritual), with the greatest positive impact perceived on emotional, psychological, and informational needs. The results also highlight that peer support helps motivate and reassure patients, making them feel valued and more secure throughout their care trajectory. Data collection and analysis are still ongoing.

Conclusions: This study has potential to highlight the key role that patient partners can play in reducing unmet needs among patient undergoing cellular therapies. The insights can inform nursing practice and support the broader implementation of structured peer support pathways in oncology care.

Disclosure: Nothing to declare.

NP39

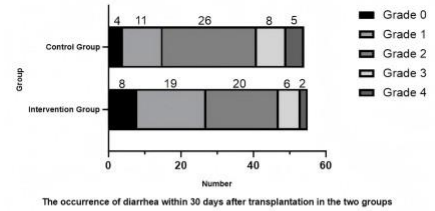
EFFICACY OF ACUPOINT APPLICATION COMBINED WITH HERBAL FUMIGATION AND WASH IN PREVENTING DIARRHEA AND PERIANAL INFECTION IN PATIENTS WITH ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Liyuan Qin[1], *Chuanhe Jiang*[1], *Lin Liu*[1], *Yang He*[1], *Xiaoxia Hu*[1]
[1]*Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: Diarrhea is a common and serious complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT), often leading to perianal infection, severity of hemorrhoidal disease, systemic complications, and impaired recovery. While current treatments focuses on symptomatic management, mucosal repair, infection prevention, and electrolyte balance, its preventive efficacy remains limited. Traditional Chinese medicine (TCM), guided by holistic and syndrome differentiation principles, has shown potential in regulating intestinal immunity, reducing inflammation, and protecting mucosal integrity. This randomized controlled trial aimed to evaluate whether these TCM interventions could reduce diarrhea duration, prevent perianal infection, and improve quality of life in allo-HSCT patients.

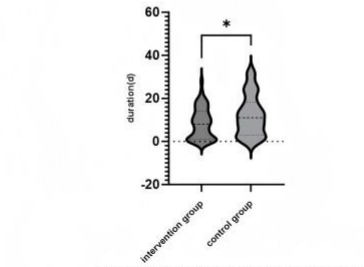
Methods: In this single-center, randomized, controlled, open-label trial, 116 patients scheduled for allo-HSCT were randomly assigned to either the intervention group (n=61) or

the control group (n=61) from March to August in 2025. The intervention group received daily herbal fumigation of the perianal area twice daily starting 24 hours before conditioning, along with acupoint application at Shenque (CV8), Tianshu (ST25), and bilateral Zusanli (ST36) for 4 hours daily. The control group received povidone-iodine warm water fumigation of the perianal area twice daily. The primary endpoints were the incidence of diarrhea and perianal infection within 30 days post-transplant. Secondary endpoints included diarrhea duration, the severity of hemorrhoidal disease within 30 days after transplantation, incidence of intestinal aGVHD, non-relapse mortality (NRM) within 100 days, and patient-reported symptom burden and quality of life.

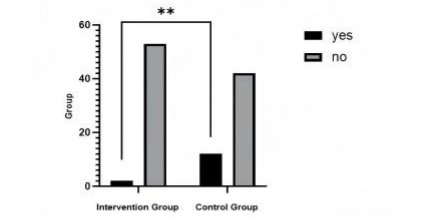


The occurrence of diarrhea within 30 days after transplantation in the two groups

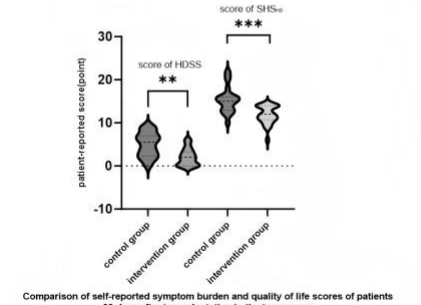
Grade 0: No diarrhea
Grade 1: 2–3 loose stools per day above baseline
Grade 2: 4–6 loose stools per day above baseline
Grade 3: 7–9 loose stools per day above baseline
Grade 4: ≥10 loose stools per day above baseline with dehydration or requiring parenteral nutrition



Comparison of the number of days with persistent diarrhea within 30 days after transplantation in the two groups



Comparison of new perianal infections within 30 days after transplantation in the two groups



Comparison of self-reported symptom burden and quality of life scores of patients 30 days after transplantation in the two groups

HDSS:Hemorrhoidal Disease Symptom Score
SHS-e:Short health scale adapted for hemorrhoidal disease

Results: A total of 109 patients (57 male, 52 female) completed the study (54 in the intervention group, 55 in the control group). There was no significant difference in the overall incidence of diarrhea between the two groups. However, the incidence of diarrhea with grade ≥2 in the intervention group was significantly lower than that in the control group (50.9% vs 72.2%,P=0.023). The duration of diarrhea in the intervention group(IQR:3,13) was significantly shorter than that in the control group(IQR:3,22) (P =0.038).
The new perianal infection rate within 30 days post-transplant was significantly lower in the intervention group (3.6% vs 22.2%, p=0.004).
No significant differences were observed between groups in the severity of hemorrhoidal disease within 30 days after transplantation (P=0.414), 100-day incidence of intestinal aGVHD (P=0.115) or NRM (P=0.494).
Patient-reported symptom burden (P=0.006) and quality of life (P<0.0001)were significantly better in the intervention group based on patient self-reports.

Conclusions: The combination of herbal fumigation and acupoint application significantly reduce the incidence of diarrhea with grade ≥2 and shortened diarrhea duration and reduced perianal infections in allo-HSCT patients. These TCM interventions were safe, well-tolerated,

and associated with improved patient-reported quality of life. This integrative approach may serve as a supportive strategy to mitigate diarrhea-related complications and enhance recovery in transplant recipients, demonstrating the potential of TCM external therapies to enhance standard supportive care protocols and improve patient recovery outcomes.

NURSE-LED INITIATIVE SKIN CARE GUIDELINE TO MINIMIZE TREOSULFAN RELATED SKIN TOXICITY AMONG PAEDIATRIC PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANT IN NATIONAL UNIVERSITY HOSPITAL, SINGAPORE

Cing Khan Lian[1], *Lai Xiaoling*[1], *Clara Su Yanling*[1], *Frances Yeap*[2], *Tan Poh Lin*[2]
[1]*National University Hospital, Singapore, Singapore,* [2]*National University Singapore, Singapore, Singapore*

Background: Treosulfan-based conditioning regimens are commonly used in pediatric allogeneic hematopoietic stem cell transplantation (HSCT). However, they can cause significant skin toxicity, including erythematous patches, hyperpigmentation, and erosions. A skin care guideline (Treosulfan) was formulated in year 2020 to minimize these effects.

Methods: The guideline included twice daily showers (hypoallergic bath oil), regular moisturizer application (3 times a day), loose-fitting clothing, frequent diaper changes (every 2 hourly), specific central line care (cleaning solution as sterile non-alcohol based povidone iodine, follow by 0.9% normal saline and covered with non-occlusive dressing), and eye care (tear natural eye drop 4 times a day). Nursing assessments documented skin changes using CTCAE Grading for rashes and Lund and Browder chart was used to calculate body surface area. Skin assessment was performed per shift and documented on electronic medical record.

Results: From year 2020 to 2025, 47 patients (median age 8.27 years) received Treosulfan-based conditioning. Treosulfan skin care regime was delivered to all the 47 patients. Grade 1-2 erythematous rashes were commonly observed in skin folds and diaper areas. Pruritus and rashes peaked between days 9-14 post-transplant and resolved by day 21. None of the child age>10 years old do not have grade 2 skin toxicity. Hyperpigmentation persisted up to 60 days post-transplant. No patients required dermatologist referral for skin excoriation or dressing for skin excoriation.

Conclusions: Skin toxicity related to Treosulfan can be significantly reduced through increased shower frequency, moisturizer application, frequent diaper changes, avoiding thick clothing, and using non-occlusive dressings. This guideline appears effective in minimizing severe skin complications associated with Treosulfan-based conditioning in paediatrics HSCT patients.

Disclosure: Nothing to declare.

NP115

PLATELET-RICH GEL PROMOTES RAPID WOUND HEALING IN SEVERE CUTANEOUS GRAFT-VERSUS-HOST DISEASE

Veronica Fernandez Angulo[1], *Amalia Ortega Caballero*[1], *Laia Seguer Cabre*[1], *Laura Romero Rodriguez*[1], *Estefania Camara Morales*[1], *Ariadna Suarez Cerezo*[1], *David Gomez-Vives*[2], *Juan Manuel Porras Paradas*[2]
[1]*Hospital Infantil Vall d'Hebron, Barcelona, Spain,* [2]*Blood and Tissue Bank of Catalonia, Vall d'Hebron Hospital, Barcelona, Spain*

Background: Graft-versus-host disease (GVHD) remains a major cause of morbidity and mortality following allogeneic haematopoietic stem cell transplantation. Chronic GVHD is a frequent long-term complication, with cutaneous manifestations being the most common sign. Skin lesions are often associated with pain, risk of infection, and a significant reduction in quality of life. Skin complications include ulcerations and scleroderma, typically associated with pruritus, dysesthesia, and pain. Despite the burden on patients, caregivers, and the healthcare system, there is still a gap in evidence-based guidelines for wound management in these cases.
Platelet-rich plasma (PRP) has emerged as a promising regenerative therapy. The theoretical basis is that PRP accelerates the repair process by providing platelet and protein concentrations above physiological levels. Moreover, reinforcement of the fibrin mesh supports healing by maintaining the viability and sustained release of bioactive molecules.

Methods:

- Comprehensive skin assessment: evaluation of skin integrity and wound dimensions.
- Implementation of regenerative therapy**,** using **Platelet-Rich Gel (PRG)** on persistent, non-healing ulcerated lesions after standard topical treatments failed.
- Serial weekly applications of PRG, combined with appropriate cleansing and protection of the perilesional skin.

Results: Overall improvement in skin lesions on the lower limbs was achieved, along with a notable reduction in pruritus, dryness, and pain, allowing better mobility and comfort.
Lesion 1: After 5 applications, wound size reduced from 15mm to 3mm, indicating accelerated tissue regeneration.
Treatment was extended onto 2 additional lesions. Lesions 2 & 3: In just 5 weeks the diameter decreased from 38mm to 6mm, showing a faster granulation process and wound closure.
No treatment-related adverse effects were reported. Consequently, a rehabilitation program could be successfully started.

Conclusions: Familiarity with the National Institutes of Health (NIH) assessment criteria for chronic GVHD is highly recommended.

The inclusion of Platelet-Rich Gel in the multidisciplinary management of cutaneous GVHD proved effective in reducing wound size and promoting healing in extensive and complex ulcerations.
It is vital to identify and implement evidence-based practices, such as advanced wound care therapies, to provide symptom relief and promote effective healing, ultimately improving functional outcomes and quality of life in patients with severe cutaneous GVHD.

NP116

COMPLEXITIES IN GENE THERAPY- MANUFACTURING DELAYS AND THE IMPACTS OF THIS ON THE PATIENTS AND THEIR FAMILIES

Kiera Whitworth[1]
[1]*Royal Manchester Children's Hospital, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Royal Manchester Children's Hospital is a centre at the forefront of gene therapy research and treatment. Here, we offer both licensed treatments and conduct several clinical trials, treating a vast patient caseload that ranges from rare metabolic conditions to haemoglobinopathies. The successes of these new treatments are groundbreaking and exciting; however, all new medicines come with their own challenges. We have looked at the ranging complexities of these gene therapy treatments and how the delays in manufacturing and treatment have impacted patients and their families both physically and emotionally.

Methods: We looked at all factors leading to delays and complications, and how this impacted the patient. The biggest reasons for delays included poor mobilisation and stem cell collection counts, issues with manufacturing itself, as well as the availability of manufacturing slots and long wait times for manufacturing the final product.
We reviewed patient data from neurocognitive assessments from our metabolic patients and clinical treatment requirements from our haemoglobinopathy patients, such as additional red cell transfusions and red cell exchanges. We collected qualitative data through speaking to patients and their families to try to understand the first-hand experiences of these treatments and how the delays have impacted their patient journey. With the majority of these treatments, we receive patient referrals globally, and so the burden of treatment is already exponential for families coming to our site.

Results: We reviewed our clinical data as well as direct patient experiences to conclude our findings. We have looked at the neurocognitive testing in our metabolic patients and have seen with some patients a decrease in this whilst waiting for treatment. This has meant a decrease in the development of the patient, potentially reducing the efficacy of the treatment being offered.
The emotional impacts of families were also looked at. With our hemoglobinopathy gene therapy patients, the difficult mobilisation regimes were identified as a challenge for both

patients and families, especially sickle cell patients, due to the multiple cell cycles requiring hospital admissions, extra central line access and vigorous pain management plans.
It was found that being open and honest with the realistic timeframes of treatment helped families prepare themselves for the expected burden. Psychology input and frequent meetings with the consultants and specialist nurses, both virtually and face-to-face, have also helped with understanding the complex treatment journey.

Conclusions: We are hoping that with more experience in gene therapy, delays and manufacturing times will be minimised, which will contribute to the overall experience of the patient and their family.
It has become apparent that, as nurses, we often have no control over the delays identified; however, we can have a direct impact on the patient and family experience going forward, despite the challenges faced as highlighted above.

Clinical Trial Registry: Not applicable

NP126

SIDE EFFECTS AND LONG-TERM EFFECTS – THE EXPERIENCES OF PATIENTS WITH CAR T-CELL THERAPY. A SCOPING REVIEW

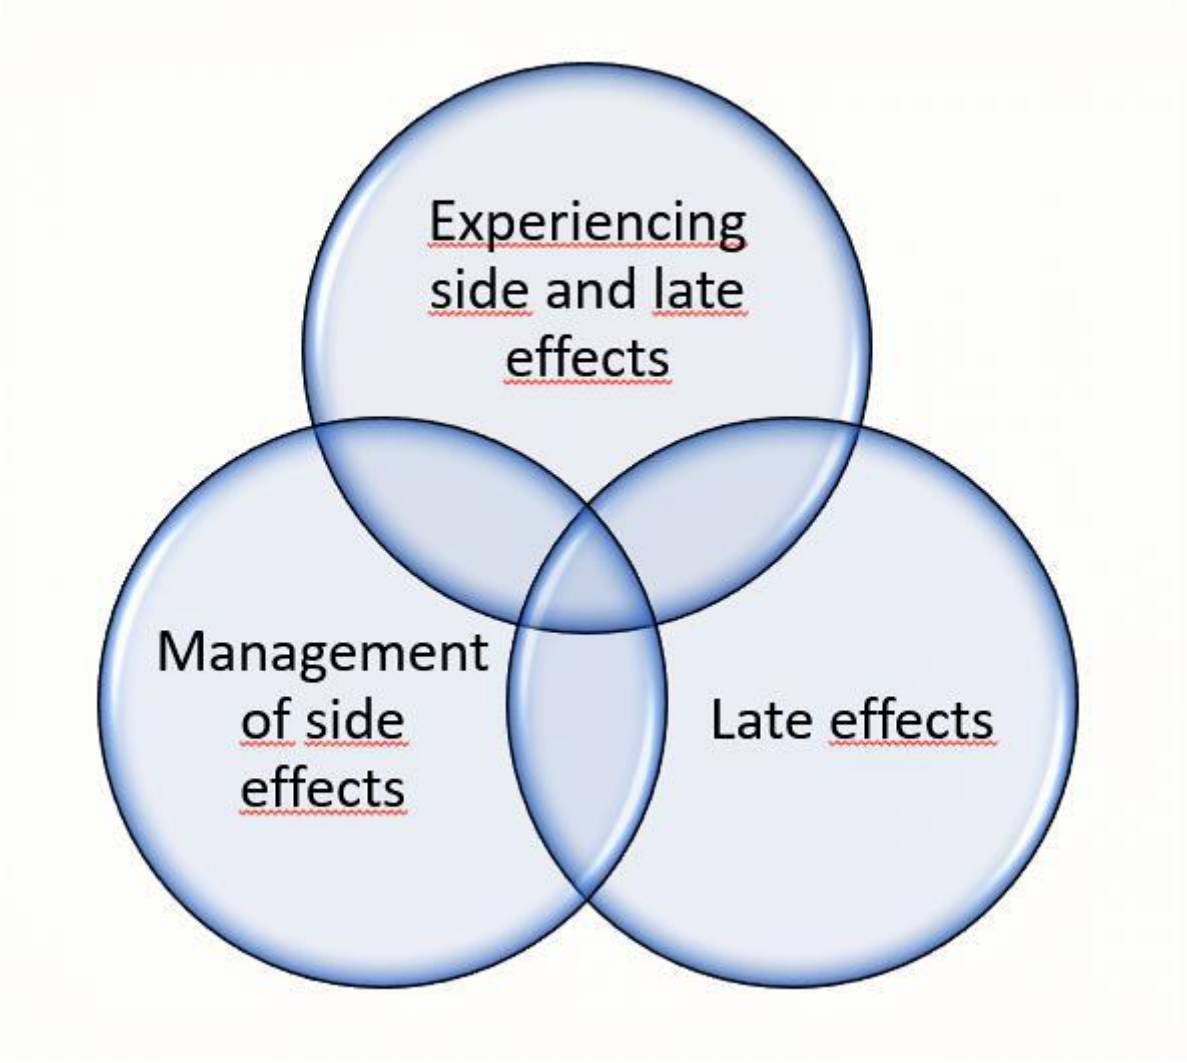
Verena Leinemann[1], *Christine Dunger*[1]
[1]*Paracelsus Medical University, Salzburg, Austria*

Background: Worldwide, the number of people with cancer is increasing. For patients with haematopoietic/oncological cancers, CAR T-cell therapy offers new chances of surviving their disease. The potentially life-threatening side effects of CAR T-cell therapy, such as cytokine release syndrome and neurotoxicity, require close monitoring of patients. Persistent cytopenia and delayed neurotoxicity may occur after CAR T-cell therapy. These symptoms present challenges for patients and nurses in the provision of care. The aim of the scoping review was to provide an overview of the current esearch regarding the side effects and long-term effects of CAR T-cell therapy in order to identify research gaps. The review focused on how patients experience the side effects and long-term effects and how they are managed by nurses.

Methods: A scoping review was carried out according to Arksey and O'Malley (2005) and the recommendations of the Joanna Briggs Institute for Scoping Reviews (Peters et al, 2020). The databases PubMed, CINAHL, LIVIVO, Cochrane Library and Web of Science were searched using keywords. The study selection was performed independently by both researchers.

Results: The search led to 15 publications that were included in the final analysis (see table 1). A majority of the included publications were scientific articles on the management of side effects and long-term effects, a smaller group were qualitative studies on patient experiences, and one was a quantitative study on the occurrence of long-term effects. The

following result categories were identified: 'Experience of side effects and late effects', 'Management of side effects' and 'Late effects' (see Figure 1). Regarding the management of side effects, the studies indicated a consensus on the importance of monitoring patients in order to be able to react quickly when side effects occur. Patients experienced CAR T-cell therapy as safe and felt prepared for the side effects, while they were often unaware of possible long-term effects.



Authors, Year	Country	Study Design	Aim	Study Population
Baer et al., 2019	USA	Scientific article	Current recommendations for the care of	Non applicable

			patients with CRS and ICANS	
Beaupierre et al., 2019	USA	Scientific article	Patient care during CAR T-cell therapy	Non applicable

Buitrago et al., 2019	USA	Scientific article	Overview of CAR T-cell therapy late effects	Non applicable
Delforge et al., 2023	USA	Qualitative study	Long-term patient experience after CAR T- cell therapy	45 patients with multiple myeloma after CAR T-cell therapy
Halton et al., 2017	USA	Scientific article	Development of standards for the care of patients during CAR T-cell therapy	Non applicable
He et al., 2023	China	Qualitative study	Skills of nurses caring for patients during CAR T-cell therapy	15 nurses
McConville et al., 2017	USA	Scientific article	Education of patients and their caregivers by nurses during CAR T-cell therapy	Non applicable
Neelapu, 2019	USA	Review	Monitoring and management of CRS + ICANS	Non applicable
Puckrin et al., 2023	Canada	Review	Management of long-term late effects of CAR T-cell therapy in adults	Non applicable

Ruark et al., 2020	USA	Quantitative study	Examination of neuropsychiatric and other long-term effects after CAR T-cell therapy	40 patients after CAR T-cell therapy
Shah et al., 2022	USA	Qualitative study	Patients' experiences with CAR T-cell therapy	47 patients before and 58 after CAR T-cell therapy
Stenson et al., 2023	UK	Qualitative study	Patients' and caregivers' experiences with CAR T-cell therapy	10 patients and 4 caregivers
Tang et al., 2023	China	Case study	Role of nurses in the early detection of side-effects	One patient during CAR T-cell therapy
Taylor et al., 2019	USA	Scientific article	Overview of CAR-T cell therapy and side-effects management and nurses training	Non applicable

Conclusions: Nurses play an important role in the care of patients before, during and after CAR-T cell therapy. So far, there has been little research on how patients experience the side effects and long-term consequences. Studies in which CAR-T cell therapy is examined in the context of the patients' life world can provide more in-depth insights.

Disclosure: The authors have nothing to disclose.

NP74

NEW THERAPIES, NEW DEMANDS: A NURSING PERSPECTIVE ON PATIENT CARE TRANSFORMATION

Zvonimir Kralj[1], *Ankica Šepak*[1]
[1]*University Hospital Centre Zagreb, Zagreb, Croatia*

Background:

The rapid introduction of novel therapies including cellular therapies (notably CAR-T), targeted small molecules and reduced-intensity conditioning regimens are reshaping delivery of care across all forms of hematology services. Nurses are central to safe implementation of these new therapies, yet the practical implications for workflows, patient education, toxicity monitoring and health-service organization are incompletely described in the literature. Our objective was to synthesize how recent therapeutic advances affect patient care delivery, nursing workload, patient outcomes and to identify priority areas for nursing practice development.

Methods:

A structured literature synthesis was performed (2018–2025) using guideline documents, systematic reviews, narrative reviews and original studies addressing cellular therapies, targeted agents and conditioning changes.

Results:

Three consistent impacts emerged. 1. Increased clinical complexity. Novel agents produce characteristic toxicities (cytokine-release and neurotoxic syndromes) requiring early recognition, standardized grading, rapid escalation pathways and placing high demands on bedside assessment and urgent multidisciplinary action. 2. Shifts in care settings. Accumulating experience supports outpatient and early-discharge models for some cellular therapies; these models improve patient experience and resource use but require robust ambulatory monitoring, clear escalation routes and integrated community links. 3. Workforce, education and governance implications. The literature highlights gaps in formal competency frameworks, the need for targeted training, revised staffing models and clear local protocols to maintain safety as application of therapies decentralizes and need for highly skilled nurses rises.

Conclusions:

Emerging therapies have shifted care in three key ways. 1. Increased clinical complexity. Novel agents produce characteristic toxicities (cytokine-release and neurotoxic syndromes) requiring early recognition, standardized grading, rapid escalation pathways and placing high demands on bedside assessment and urgent multidisciplinary action. 2. Shifts in care settings. Accumulating experience supports outpatient and early-discharge models for some cellular therapies; these models improve patient experience and resource use but require robust ambulatory monitoring, clear escalation routes and integrated community links. 3. Workforce, education and governance implications. The literature highlights gaps in formal competency frameworks, the need for targeted training, revised staffing models and clear local protocols to maintain safety as application of therapies decentralizes and need for highly skilled nurses rises.

NG27-02

BRIDGING THE EDUCATIONAL GAP: A NATIONAL, NURSE-LED ONLINE APHERESIS COURSE TO ENHANCE QUALITY IN HSCT AND CELLULAR THERAPY

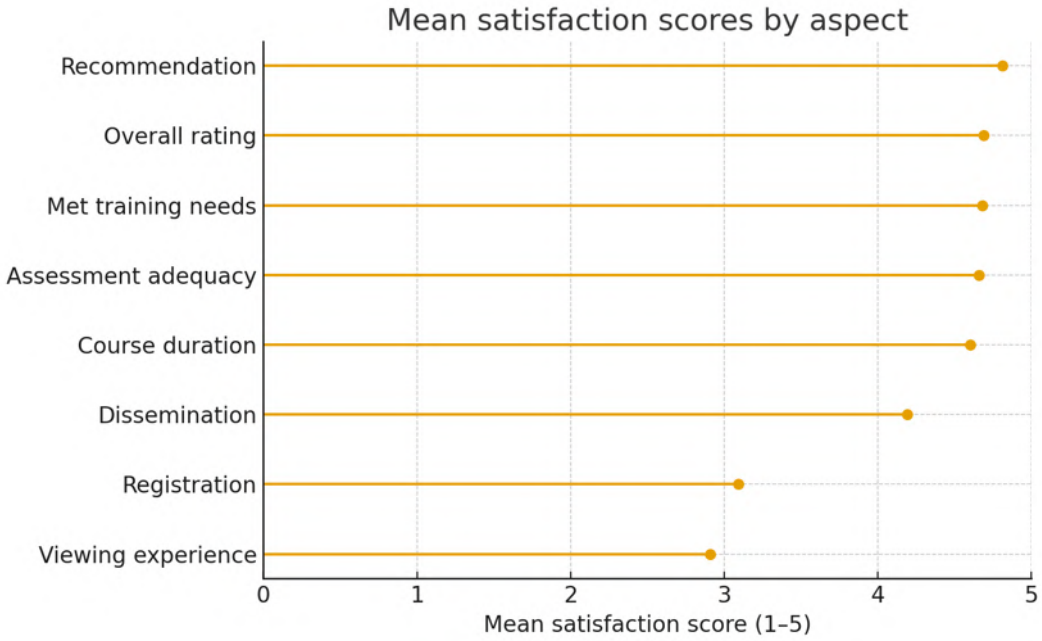
Natalia Lorente Del Río[1,2], *Isabel María Fernández Morales*[3], *Mercedes Jiménez Meoro*[3], *Rocío Rodríguez Álvarez*[3], *Adriana Zapata Arcís*[3], *Inmaculada Martinez Muñoz*[3], *Alberto Ros Miguel*[3], *Cintia Chacón Guardia*[4], *Ana García de León Cerrillo*[5], *Ana Belén Romero Herrera*[6], *María Pilar Tapia Bermejo*[6], *Elena García Astudillo*[6], *Isabel Bujedo Cuesta*[6], *Laura Cristina Bibiloni Martínez*[7], *María Jesús Mustieles Ezquerra*[8], *Jesús Zalvide Torrente*[9], *Marta Vela Garicano*[9], *Ana Isabel Torre Polo*[10], *Josefa Navarrete Ruiz*[10], *Francisca Carrasco Berlanga*[11]
[1]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [2]Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain, [3]Hospital C.U. Virgen Arrixaca, Murcia, Spain, [4]Hospital Universitario Reina Sofía, Córdoba, Spain, [5]Hospital Universitario Puerta de Hierro, Madrid, Spain, [6]Hospital Universitario La Paz, Madrid, Spain, [7]Hospital Universitario Son Espases, Palma de Mallorca, Spain, [8]Hospital Clinic, Barcelona, Spain, [9]Hospital Álvaro Cunqueiro, Vigo, Spain, [10]Hospital Universitario Infantil Niño Jesús, Madrid, Spain, [11]Hospital Regional Universitario de Málaga, Málaga, Spain

Background: Apheresis is the essential first step for cell collection, directly influencing treatment success and patient safety. Traditionally, nurse training relied on informal mentorship and fragmented courses, lacking consistency and depth. This gap compromises quality across the hematopoietic stem cell transplantation (HSCT) and cellular therapy chain—including emerging therapies such as chimeric antigen receptor T-cell (CAR-T) therapy. To overcome this, the Nurses Apheresis Group from the Spanish Group for Hematopoietic Transplantation and Advanced Therapies (GETH-TC) developed a comprehensive free online program.

Methods: group of 20 apheresis nurses representing ten hospitals from across Spain developed a curriculum of 17 topics organized into four modules:
(1) fundamentals of apheresis and vascular access;
(2) hematopoietic stem cell collection, photoapheresis, CAR-T lymphocyte apheresis, and quality systems;
(3) therapeutic procedures such as erythroapheresis, platelet/leukocyte depletion, and plasma treatments; and
(4) pediatric apheresis. Content was delivered through the GETH-TC Virtual Campus, an accessible e-learning platform, via short pre-recorded videos (max 20 minutes each), enabling flexible, self-paced learning over six months. Participants were required to achieve ≥60% on multiple-choice assessments, with two attempts available for each exam. At the end of the course, participants completed a mixed-methods evaluation survey (eight Likert-scale items and three open-ended questions) to assess satisfaction, relevance, and areas for improvement.

Results:

In its first edition, 189 nurses enrolled. Quantitative data showed high overall satisfaction, with a mean rating of 4.2/5. The highest scores were observed for overall course quality and recommendation to peers (Figure 1), whereas registration and viewing experience received slightly lower ratings, highlighting areas for future improvement. Thematic analysis of over 200 qualitative comments emphasized key strengths: expert nurse-led teaching, clinical relevance, and inclusion of real cases, including pediatric scenarios. Suggested improvements included downloadable materials (PDFs/slides), technical platform refinements, more dynamic video formats, expanded content on advanced topics (CAR-T, central lines), and interactive elements such as forums or live Q&A sessions.



Conclusions: The first national standardized apheresis course in Spain—created by nurses for nurses—successfully established a standardized, accessible, and highly valued training program that strengthens the foundation of HSCT and cellular therapy care in Spain. By equipping nurses with consistent, evidence-based competencies in apheresis—a pivotal procedure for cell collection—the course enhances quality and safety in this rapidly evolving field. The model is scalable and reproducible for other regions and offers a framework for continuous professional development. Future editions will integrate participant feedback, focusing on downloadable.

GLOBAL COLLABORATION AND AI-ENHANCED ONLINE EDUCATION FOR UKRAINIAN HCT NURSES IN WARTIME

Oleksandr Istomin[1,2], *Oleksandr Lysytsia*[1,2,3], *Irina Korenkova*[3], *Damiano Rondelli*[4], *Dietger Niederwieser*[4], *Reggie Belkhedim*[5], *Carole Charley*[5], *Catherine Gutierrez*[5], *Eugenia Trigoso*[5], *Nouf Shwikan*[5], *Paola Viveros*[5]
[1]*National Specialized Children's Hospital "Okhmatdyt", Kyiv, Ukraine,* [2]*Ukrainian Professional Society for Pediatric Oncology/Hematology, Kyiv, Ukraine,* [3]*Ukrainian Association for Blood and Marrow Transplantation, Kyiv, Ukraine,* [4]*WBMT Organization, Liebefeld, Switzerland,* [5]*WBMT Nursing Group - Committee Officers, Liebefeld, Switzerland*

Background: Hematopoietic cell transplantation (HCT) capacity in Ukraine has continued to expand despite nearly four years of full-scale war. National transplant activity increased from 223 in 2022 to 404 in 2024, with 343 procedures performed by September 2025. The number of transplant centers rose from 9 to 11, and pediatric HCT volume nearly doubled (31 to 59).
A well-prepared nursing workforce is essential for further HCT advancement, as nurses play a crucial role in patient management and care. In high-income countries, nurses routinely undertake patient education, psychological support, transplant coordination, quality management, and infection control. In contrast, Ukrainian nursing education does not address the unique requirements of HCT, and limited English proficiency restricts access to international guidelines and training. These factors, combined with the psycho-social burden of war, place HCT nurses among the most vulnerable members of the healthcare workforce in our country.
To respond to these gaps, the Ukrainian Professional Society for Pediatric Oncology and Hematology (UkrPSPOH) and the Ukrainian Association for Blood and Marrow Transplantation (UABMT), in collaboration with the Worldwide Network for BMT Nurses Group (WBMT-NG), launched a national hybrid educational course.

Methods: Preparatory work began in 2023 with a survey assessing skills and educational needs among HCT nurses at the National Specialized Children's Hospital. Results revealed strong demand for competency improvement and identified language barriers as a major limitation. In 2024, UkrPSPOH and UABMT requested WBMT-NG support in developing a national training initiative.
Curriculum development involved more than 15 WBMT-NG contributors. 5 modules program covered HCT fundamentals, donor selection, apheresis, GVHD, complications, supportive therapy, and quality management. In total 540 minutes of English-language educational content was produced, translated and voice-dubbed into Ukrainian using open-access artificial intelligence (AI) and natural language processing tools, with expert post-review ensuring accuracy. This helped reduce production costs approximately 4.5-fold, allowing redirection of funds toward the hands-on workshop.
Between April and June 2025 each module was delivered weekly via Zoom plus one in-person simulation workshop on central venous line care in Kyiv. Modules were moderated by HCT hematologists, while a messenger group supported communication and peer networking. Session recordings were uploaded to an open-access YouTube channel, ensuring

continuous access despite wartime disruptions and after course completion.
Enrollment was open to all healthcare professionals, requiring only a 42-item pre/post Multiple-Choice Question test on HCT topics alongside with a brief self-assessment survey.

Results:

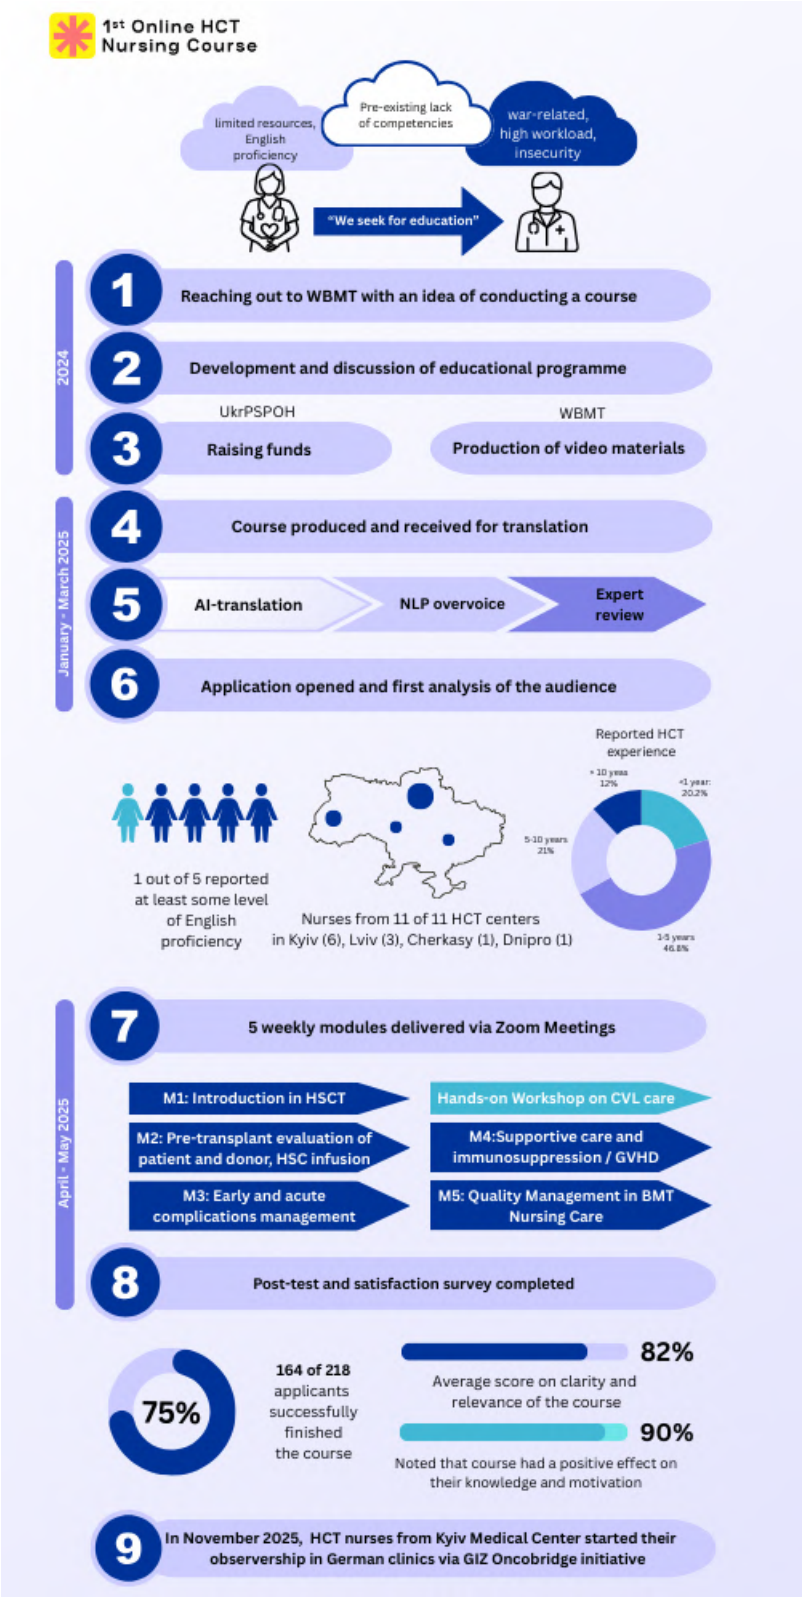
Course outcomes and metrics described in the table.

Parameter	Enrolled	Completed
# HCT centers represented	11	11
# of applicants (%)	218	164 (75,2%)
# of nurses (%)	181 (83%)	153 (93%)
# of interns, physicians, non-medical (%)	37 (17%)	11 (7%)
# of correct answers on a test (mean)	33 / 42 (78,6%)	39 / 42 (92,9%)

Satisfaction with the AI-translated course remained high: clarity (mean 4.2/5), relevance (4.3/5), and accessibility (4.7/5). 154 (90%) participants noted that course had a positive effect on their knowledge and motivation.

Conclusions:

This initiative demonstrates a major unmet need for structured HCT nursing education. Despite Ukraine's UMIC status, wartime conditions restrict opportunities for self-education and professional growth among nurses. By combining efforts with global network, expert-developed content with AI-assisted translation, this program offers a scalable model for expanding access to high-quality HCT education. The framework has been adapted by WBMT-NG for implementation in Mongolia and other countries with low or without HCT activities.



1st Online HCT Nursing Course
limited resources, English proficiency
Pre-existing lack of competencies
war-related, high workload, insecurity
"We seek for education"
2024
1 Reaching out to WBMT with an idea of conducting a course
2 Development and discussion of educational programme
UkrPSPOH

3 Raising funds
Production of video materials
January - March 2025
4 Course produced and received for translation
5 AI-translation
NLP overvoice
Expert review
6 Application opened and first analysis of the audience
Reported HCT experience
1 out of 5 reported at least some level of English proficiency
Nurses from 11 of 11 HCT centers in Kyiv (6), Lviv (3), Cherkasy (1), Dnipro (1)
April - May 2025
7 5 weekly modules delivered via Zoom Meetings
M1: Introduction in HSCT
Hands-on Workshop on CVL care
M2: Pre-transplant evaluation of patient and donor, HSC infusion
M4:Supportive care and immunosuppression / GVHD
M3: Early and acute complications management
M5: Quality Management in BMT Nursing Care
8 Post-test and satisfaction survey completed
75%
164 of 218 applicants successfully finished the course
82%
Average score on clarity and relevance of the course
90%
Noted that course had a positive effect on their knowledge and motivation
9 In November 2025, HCT nurses from Kyiv Medical Center started their observership in German clinics via GIZ Oncobridge initiative

Disclosure:

The project concept and implementation were led jointly by the Ukrainian Professional Society for Pediatric Oncology and Hematology (UkrPSPOH), the Ukrainian Association for Blood and Marrow Transplantation (UABMT) and the Worldwide Network for Blood and Marrow Transplantation (WBMT). WBMT Nursing Group provided presentations and educational video materials free of charge. The offline component of the program, (the hands-on workshop), was funded by the Charitable Foundation "Tabletochki" (Ukraine), UkrPSPOH and National Specialized Children's Hospital "Okhmatdyt". The online component was supported by "SERVIER-Ukraine", LLC Biopharma Plasma (Ukraine), and L'Oréal Ukraine. The funders (except UkrPSPOH) had no role in the design, content development, data collection, analysis, or reporting of the project.

NP02

BUILDING A SKILLED AND CONFIDENT CAR-T NURSING WORKFORCE: ASSESSING THE IMPACT OF NURSE-LED CAR-T EDUCATION

Cassandra Abbott[1], *Pippin Ellis*[1], *Olivia Cook*[1,2], *Ty Simpson*[1], *Georgina Lea*[1], *Caitlin Wesols*[1], *Madeleine Sloane*[1], *Yumei Lew*[1], *Elli Foley*[1], *Aaron Hill*[1], *Christina Kazzi*[2,1], *Miriam Wronski*[2,1], *Katherine Ko*[2,1], *Elizabeth Cole*[2,1], *Akshay Bapat*[1], *Nermen Tawfik*[1], *Jian Li*[1], *Shu Min Wong*[1], *Shafqat Inam*[1], *Shevon Fernando*[1], *Michael Swain*[1], *Mastura Monif*[2,1], *Danielle Lee*[1], *Ellen Heywood*[1], *Constantine Tam*[1,2], *Andrew Spencer*[1,2]
[1]*Alfred Health, Melbourne, Australia,* [2]*Monash University, Melbourne, Australia*

Background: Chimeric Antigen Receptor T-Cell (CAR-T) therapy is a highly specialised treatment that re-engineers' patients' own immune cells to treat malignant and selected autoimmune diseases. While it can be highly effective, CAR-T therapy is associated with potentially life-threatening toxicities. A skilled and knowledgeable nursing workforce is critical for early recognition of patient deterioration and the delivery of timely and specialised care. To address this need, a comprehensive nurse-led CAR-T education program was developed specifically for nurses and other health professionals. The aim of this abstract is to evaluate the impact of a nurse-led CAR-T education day on participants' knowledge and confidence in caring for patients receiving CAR-T Cell therapy.

Methods: A multidisciplinary curriculum was developed to encompass the CAR T-Cell treatment pathway, from the initial patient assessment through to post-treatment recovery. Key topics included CAR-T mechanisms of action; leukapheresis and cell processing; clinical signs and management of Immune Effector Cell Associated Neurotoxicity (ICANS) and Cytokine Release Syndrome (CRS); emerging clinical trials; and medication management. A pre- and post-education survey design was used to assess changes in self-reported knowledge and confidence. Knowledge was rated on a 5-point Likert scale (1='Very poor understanding' to 5='Very good understanding') and confidence rated on a 10-point scale (0='Not at all confident'' to 10= 'Extremely confident'). Descriptive statistics were used to summarise participants' response, and independent samples t-tests were performed to compare pre- and post- education scores, with a statistical significance set at 0.05.

Results: Nine CAR-T education days were facilitated from March 2023 to November 2025, with a total of 255 participants. Pre-education surveys were completed by 239 participants, and post-education survey by 218 participants. Attendees included registered nurses (47.1%), clinical trial coordinators (21%), nurse managers (9.2%), clinical nurse specialists (6.2%), clinical nurse consultants (5%), nurse educators (2.5%), ICU liaison nurses (2.5%), scientists (1.5%), and others unspecified health professionals (5%).
An increase in self-reported knowledge and confidence scale after the education program were observed in all domains: CAR-T Cell mechanisms of action (median 3.04 to 4.49, $p<0.001$); patient eligibility criteria, workup, and apheresis (median 2.54 to 4.30, $p<0.001$); role of the cellular therapies unit (median 2.64 to 4.32, $p<0.001$); daily nursing care (median 3.17 to 4.53, $p<0.001$); CRS assessment and management (median 3.32 to 4.57, $p<0.001$); ICANS assessment and management (median 3.24 to 4.58, $p<0.001$); CAR-T medications (median 2.77 to 4.44, $p<0.001$); Discharge planning and patient education (median 2.73 to 4.39, $p<0.001$); and Outpatient nursing care (median 2.66 to 4.36, $p<0.001$). Confidence levels in caring for patients receiving CAR-T cell therapy improved significantly (median 5.20 to 8.18, $p<0.001$).

Conclusions: A structured, nurse-led CAR-T education program significantly improves nursing knowledge and confidence, directly supporting safe and effective CAR-T patient care. As CAR-T therapies continue to expand, ongoing specialised nursing education will be essential to optimise patient outcomes and maintain service excellence.

Constantine S Tam has received honoraria from AbbVie, BeiGene, Janssen, AstraZeneca, Novartis and Lilly

NP06

WHEN KNOWLEDGE AND ATTITUDES DO NOT TRANSLATE INTO PRACTICE: PILOT INSIGHTS FROM HEMATOLOGY AND HEMATOPOIETIC STEM CELL TRANSPLANTATION NURSES' SEXUAL HEALTH CARE

Meng-Kuan Chiang[1]
[1]*Koo Foundation Sun-Yat Sen Cancer Center, Taipei, Taiwan (Province of China)*

Background: Sexual health is a critical yet often neglected component of survivorship care for patients with hematologic malignancies and those undergoing hematopoietic stem cell transplantation (HSCT). Despite their central role in holistic cancer care, hematology and HSCT nurses frequently encounter barriers such as cultural taboos, limited training, and the absence of clear clinical guidelines. To date, little is known about their attitudes, knowledge, and practices in this specialized field, underscoring the need for exploratory evidence. This

pilot study aimed to provide preliminary insights into the sexual health care attitudes, knowledge, and practices of hematology-oncology and HSCT nurses, to identify variations across demographic and professional characteristics, and to examine interrelationships among these domains.

Methods: A cross-sectional survey was conducted with 36 nurses working in hematology-oncology and HSCT units at a medical center. Validated instruments—the Sexual Health Care Attitudes Scale (SHC-A), Sexual Health Care Knowledge Scale (SHC-K), and Sexual Health Care Practice Scale (SHC-P)—were administered. Data were analyzed using descriptive statistics, independent-sample t-tests, one-way ANOVA, and Pearson's correlation coefficients.

Results: The mean SHC-A score was 32.9, and the mean SHC-K score was 43.4, both indicating relatively higher levels compared to previously reported ranges. The SHC-P score averaged 6.4, suggesting higher practice levels than in earlier studies, yet representing only 30.1% of SHC items implemented. Group comparisons showed that nurses with prior SHC-related training had significantly higher practice scores ($t = 2.07$, $p = .046$). Age was significantly associated with knowledge scores ($F = 5.01$, $p = .013$), and nurse professional role showed a borderline association with attitudes ($F = 3.28$, $p = .050$). Correlation analysis revealed a significant positive association between knowledge of consultation and documentation and overall attitudes scores ($r = 0.46$, $p = .004$). In contrast, negative associations emerged between attitude subdomain: concerns about colleagues' negative perceptions and practice in sexual and fertility preservation ($r = -0.42$, $p = .022$), as well as between practice in fertility preservation and knowledge of psychosocial aspects ($r = -0.38$, $p = .045$) and communication skills ($r = -0.39$, $p = .037$).

Conclusions: This pilot study highlights both the strengths and limitations in hematology-oncology and HSCT nurses' readiness to provide sexual health care. While nurses demonstrated relatively positive attitudes and knowledge, these were not consistently translated into practice, with less than one-third of care items implemented. The findings underscore the urgent need for targeted education, structured training, and institutional support to bridge the gap between knowledge, attitudes, and practice. Future studies should incorporate qualitative approaches to explore the underlying reasons for this disconnect—such as cultural taboos, workplace dynamics, and role boundaries—and conduct larger-scale surveys to validate these preliminary results. Strengthening sexual health care within survivorship models has the potential to enhance both the quality of care and the quality of life for patients undergoing hematologic malignancy treatment and HSCT.

NP16

IMPLEMENTING STRUCTURED EDUCATION IN APHERESIS: A COMPARATIVE EVALUATION OF TRAINING EFFICIENCY AND LEARNER PERCEPTIONS

Cara Cunningham[1]
[1]*University Hospitals Birmingham, Birmingham, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Apheresis services require a highly skilled workforce capable of delivering complex procedures safely and efficiently. Historically, training within our unit followed an ad-hoc, sequential model where learners progressed through procedures as opportunities arose. Plasma exchange (PEX) and white cell depletion (WCD) training occurred only when suitable patients were available, and no dedicated study time was provided for theoretical learning. As a result, staff required an average of **62 weeks** to become fully competent, often reporting uncertainty when managing alarms or troubleshooting during complex procedures. These limitations highlighted the need for a structured, standardised education pathway to strengthen competency, improve confidence, and support service efficiency.

Methods: Two apheresis team leaders completed the Terumo Spectra Optia Expert Trainer Courses for TPE, MNC and CMNC, enabling them to design a comprehensive, competency-based education programme integrated with enhanced teaching on optimisation, troubleshooting and citrate management. The pathway incorporated protected study days, staged learning outcomes and supervised practical sessions, mapped directly to the Terumo MNC/CMNC, TPE and WCD programmes, and the Therakos ECP learning pathway. Structured feedback was collected at key points - after completion of Terumo and again after Therakos training, to evaluate clarity, pacing, readiness and confidence. Training duration, confidence and preparedness were compared across cohorts before and after pathway implementation.

Results: The first cohort (n=3), all with haematology experience, achieved full competency in a median of **25 weeks**, representing a **60% reduction** in training time. The buddy-based on-call model enabled earlier rota participation and enhanced clinical exposure. Staff reported that the structured sequence, theory/practice integration and stepwise development from machine components to optimisation supported confidence and knowledge retention. The second cohort (n=3), with only one member having haematology experience, achieved full competency in an average of **26 weeks**. A consolidation period (mean 17 weeks) between Terumo and Therakos training, supported knowledge embedding while accommodating capacity pressures.
Feedback from this cohort was consistently positive: learners valued instructor support, accessible materials, and the interactive nature of the training, as seen in evaluation forms from the Terumo and ECP programmes. Constructive feedback highlighted the need for pacing adjustments, ensuring uninterrupted consolidation, and limiting the number of concurrent Terumo trainees to preserve focus. Some learners felt more confident in the modality they trained on first, recommending sequencing refinement.

Conclusions: Implementing a structured apheresis education pathway substantially reduced training duration while improving learner confidence, competence and service

responsiveness. Faster sign-off enables earlier contribution to the on-call rota, supporting workforce capacity and meeting service demand. Enhanced theoretical grounding and optimisation skills have the potential to improve procedural quality, collection efficiency and, ultimately, patient outcomes.
Going forward, learner feedback will guide refinement of the programme. All new trainees will begin with ECP to provide a supportive introduction to the specialty; consolidation periods will be protected and paced according to individual progression; and assessment timelines will be adapted to ensure learners achieve competency within a structure that reflects their needs and supports safe, confident practice.

NP28

IMPLEMENTATION OF A MENTORSHIP PROGRAMME FOR NEWLY HIRED NURSES IN ONCO-HEMATOLOGY AND BONE MARROW TRANSPLANT UNIT AT SAN RAFFAELE HOSPITAL, MILAN

Davide Bonomi[1], *Silvia Gnecchi*[2,3], *Anna Carmagnola*[2,3], *Fabio Ciceri*[2,3]
[1]*IRCCS San Raffaele Scientific Institute/ Vita-Salute San Raffaele University, Milan, Italy,* [2]*IRCCS San Raffaele Scientific Institute, Milan, Italy,* [3]*Vita-Salute San Raffaele University, Milan, Italy*

Background: Nurse turnover is a global issue, with a significant impact on the quality of care, organizational costs, and staff well-being. Young nurses and new hires are particularly vulnerable to the risk of leaving, especially in highly complex clinical settings such as the Hematology and Bone Marrow Transplant Unit (UOE-TMO). The stress associated with entering the professional world, feelings of inadequacy, gaps in training, and difficulties in managing complex clinical situations are documented risk factors. In this scenario, structured mentoring programs have proven effective in improving job satisfaction, promoting professional growth, and reducing turnover. In light of this evidence, the UOE-TMO at San Raffaele Hospital has developed a structured induction program for newly hired nurses, based on 1:1 mentoring with a clinical tutor and a mentoring program lasting up to six months.

Methods: A standardized operating procedure was implemented that defines roles, responsibilities, training tools, and evaluation methods for the induction program. The program consists of three main phases:

1. 1:1 Tutoring (first month): the clinical tutor accompanies the new hire for twelve hours shifts for a total of 12-14 days, helping them acquire the skills outlined in the job description and progressively monitoring their autonomy.
2. Mentoring (1st-6th month): the mentor guides the nurse in consolidating clinical, organizational, and interpersonal knowledge, tailoring the content to the mentee's training needs.

3. Pediatric tutoring (after at least 6 months): dedicated to the management of patients in the developmental age, with expert tutors and the progressive assignment of responsibilities.

The program is supported by structured tools such as: a theoretical-practical guide for new hires, mandatory distance learning courses, theoretical tests, skills assessment checklists, and periodic feedback meetings with mentors, tutors, and coordinators. Assessments are carried out at the end of the first month, the third month, and the sixth month, with dedicated interviews and the completion of formal tools.

Results: The adoption of the program has made it possible to structure a uniform, progressive, and personalized path for new hires, reducing the risk of overload and promoting the gradual acquisition of clinical and organizational skills. Direct tutoring ensured patient safety and facilitated on-the-job learning, while mentoring supported professional growth, critical thinking development, responsibility management, and team integration. The assessment tools allowed for the early identification of critical areas, supporting targeted training interventions. Greater continuity of care and better adaptation of new hires to the UOE-TMO context were observed, helping to strengthen their sense of belonging and job satisfaction.

Conclusions: The mentoring and coaching program for newly hired nurses in UOE-TMO is an effective strategy for supporting the transition from training to clinical practice in a highly complex setting. The structuring of clear roles, dedicated teaching tools, and assessment stages promotes autonomy, safety, competence, and professional well-being. The integrated clinical tutor-mentor approach is an organizational investment that can improve the quality of care, reduce turnover, and enhance the potential of the new generation of nurses.

Disclosure: Nothing to declare.

ESTABLISHING THE FIRST PEDIATRIC BONE MARROW TRANSPLANT NURSING PROGRAM IN THE UAE: A MODEL FOR COMPETENCY BASED EDUCATION AND INTERNATIONAL COLLABORATION

Dina El Mouzain[1], *Ciba Raphael*[1], *Mary Ann Monica Reyes*[1], *JoEllen Edson*[2], *Robyn Blacken*[2], *Lisa Morrissey*[2], *Gladilyn Bakil*[1], *Ehab Bawadi*[1], *Mansi Sachdev*[1], *Jayakumar David Dennison*[1], *Leslie Lehmann*[2], *Sabah Zahooruddin*[1], *Nameer Al Saadawi*[1], *Maysoon Abdulrahman Al Karam*[1], *Fatema Al Kaabi*[1]
[1]*Abu Dhabi Stem Cell Center /Yas Clinic Khalifa City, Abu Dhabi, United Arab Emirates (the),* [2]*Boston Children Hospital, Boston, United States of America (the)*

Background: The Abu Dhabi Bone Marrow Transplant (AD-BMT) Program, a joint initiative between Abu Dhabi Stem Cells Center and Yas Clinic Khalifa City, was commissioned in 2021 to establish a national and regional benchmark for stem cell transplant care. In 2023, the program achieved Center of Excellence (COE) status for Bone Marrow Transplant, the first in

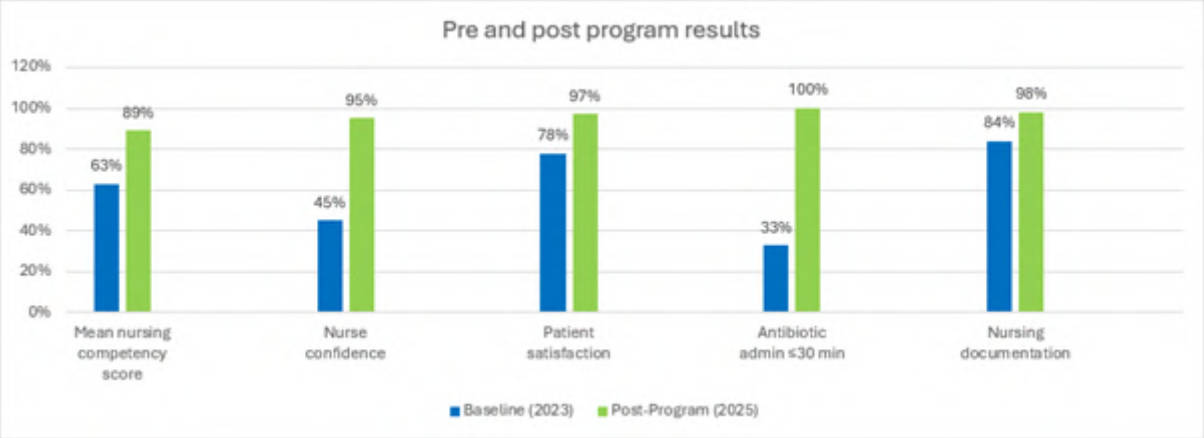
the UAE, and attained FACT accreditation in 2025, aligning with international quality and safety standards. Rapid program expansion highlighted the need to prepare newly hired nurses for the specialized pediatric BMT workforce. The aim was to create a sustainable framework for nursing excellence through structured education, competency validation, and mentorship. A three-year collaboration with Boston Children's Hospital (BCH) supported nursing education, competency assessment, policy development, mentorship, and program capacity building.

Methods: A multimodal nursing education program was developed and implemented across the pediatric BMT unit and inpatient hematology unit in collaboration with BCH and AD-BMT nursing educators. The program incorporated didactic instruction (30%), simulation-based training (25%), bedside mentorship (30%), and structured competency validation (15%). The APHON Chemotherapy and Biotherapy Provider Course was introduced to strengthen oncology nursing skills, targeting 100% completion for pediatric BMT nurses and 50% for inpatient nurses. The program educator achieved APHON Instructor status, enabling independent local and regional delivery of standardized oncology nursing education. BCH nurse experts conducted in-person visits every four months and monthly virtual meetings to evaluate competencies, identify practice gaps, guide policy alignment, and support implementation. Learning outcomes were assessed through pre- and post-tests, direct observation, and formal six-month revalidation cycles.

Results: Following implementation, significant improvements were observed across all measured indicators for the 30 participating nurses. Mean nursing competency scores increased from 63% to 89%, and self-reported confidence improved from 45% to 95%. Timely antibiotic administration within 30 minutes increased from 33% to 100%. Patient satisfaction rose from 78% to 97%, and nursing documentation accuracy improved from 84% to 98%. The central line associated bloodstream infection rate remained at zero per 1,000 catheter days throughout the program. Two APHON Courses were delivered. In the first course, 100% (n=13) passed the exam under BCH instruction. In the second locally delivered course, 100% (n=12) passed under the YCKC instructor, demonstrating sustainability and strengthening internal capacity. Qualitative feedback highlighted stronger communication between nurses and families, improved interdisciplinary collaboration, enhanced confidence in managing complex BMT cases, and greater autonomy in decision making. Establishing a locally APHON competent workforce and an in-country instructor created a sustainable framework for continued professional development and laid the foundation for a regional pediatric oncology nursing education hub.

Indicator	Baseline (2023)	Post-Program (2025)	Mean	Mean Difference	Std. Deviation
Nursing Competency score	0.63	0.89	0.76	26% ↑	0.427

Nurse Confidence	0.45	0.95	0.7	50% ↑	0.459
Patient Satisfaction	0.78	0.97	0.88	19% ↑	0.325
Antibiotic admin ≤30 min	0.33	1	0.67	67% ↑	0.471
Nursing documentation	0.84	0.98	0.91	14% ↑	0.286



Conclusions: Through structured education, mentorship, and capacity building, the AD-BMT Program established the UAE's first pediatric BMT nursing program, achieving COE and FACT accreditation within three years of inception. Collaboration with BCH and implementation of the APHON framework resulted in measurable improvements in competency, safety, and patient centered care. The development of local instructor capacity ensures sustainability, knowledge transfer, and scalability. This model provides a reproducible approach for advancing pediatric BMT nursing excellence in emerging healthcare systems across the world.

Disclosure: Nothing to declare

NP32

GLOBAL NURSING EXCHANGE: EXPERIENCES FROM THE "HOW DO YOU DO IT" ONLINE SESSIONS BY THE EBMT NURSES GROUP PAEDIATRIC COMMITTEE

Ida Bremer Ophorst[1], *Maria Finch*[2], *Salla Lehvonen*[3], *Marjola Gjergji*[4], *Michelle Kenyon*[5], *Elin Ovferberg*[6], *Hilda Mekelenkamp*[7]
[1]*Princess Maxima Center for Paediatric Oncology, Utrecht, Netherlands (the),* [2]*Great Ormond Street Hospital, London, United Kingdom of Great Britain and Northern Ireland (the),* [3]*Helsinki University Hospital, Helsinki, Finland,* [4]*Ospedale Pediatrico Bambino Gesu, Rome, Italy,* [5]*King's College Hospital NHS Foundation Trust, Departement of Haematology, London, United Kingdom of Great Britain and Northern Ireland (the),* [6]*Queen Silvia Childrens Hospital, Sahlgrenska University Hospital, Gotenburg, Sweden,* [7]*Willem-Alexander Children's Hospital, department of pediatrics, Leiden University Medical Center, Leiden, Netherlands (the)*

Background: In 2024, the EBMT Nurses Group Paediatric Committee initiated in 2024 a series of online, interactive sessions titled *"How Do You Do It…"* to facilitate the exchange of practical skills among paediatric nurses within and outside Europe. The aim of these sessions was to provide an accessible platform for sharing knowledge and clinical experiences, thereby contributing to improved quality of care. The online sessions also helped identify gaps and variations in nursing practices that may require further attention or harmonization. Since its launched, the committee organized 4 one-hour interactive online meetings using an digital tool for interactive presentations with real-time audience participation, addressing topics such as isolation rules, discharge after HSCT, central line care, and pain management. Summaries of each meeting were shared on the EBMT website in the form of infographics. An evaluation was conducted to understand the perceived value of these sessions and identify needs and collate topics for future sessions.

Methods: To evaluate participant experiences, a web-based survey was distributed by email in October and November 2025 to all those who had attended at least one session. One reminder was send after three weeks. The survey consisted of nine closed-ended and four open questions. Responses were collected using a five-point Likert scale ranging from "strongly agree" to "strongly disagree" and freetext. Results were analyzed using descriptive statistics.

Results: A total of 24 nurses from 14 countries responded to the survey (Europe 17, non-Europe 7). Seventy percent indicated that the content of the sessions was relevant to their daily practice. Approximately 55% reported learning about new practices or gaining ideas that could be implemented in their own centers. Several responders highlighted that the sessions provided valuable insights into new procedures, materials, and effective strategies to enhance clinical collaboration. Moreover, 75% believed that these sessions could contribute to the development of shared guidelines.
Most participants learned about the sessions through the EBMT website (27%), the EBMT newsletter (33%), or the paediatric committee's mailing list (27%). Overall, the online format was considered easy to access (69%), and 66% found the session duration appropriate. Around 75% reported that they would recommend the *How Do You Do It*

sessions to colleagues. Overall, participants enjoyed participation and comments included: *"It's not easy for us, nurses, to have a place to share. That's why I enjoyed it the most."* and *"Exchanging ideas with colleagues in other countries in a low-threshold format is very valuable."*
Up to three respondents disagreed on the closed-ended questions, although the survey did not provide sufficient information to identify the underlying reasons.

Conclusions: The EBMT Nurses Group Paediatric Committee's *"How Do You Do It…"* online sessions were generally perceived as a valuable means of sharing information, exchanging practical skills, and fostering connections among paediatric nurses within and outside Europe. Based on the positive evaluation, the committee will continue offering these sessions and will integrate suggested future topics such as gene therapy, GvHD, skin care, apheresis, and cultural differences.

Disclosure: None

NP119

DEVELOPMENT AND USABILITY TESTING OF A CAR-T THERAPY E-LEARNING RESOURCE FOR HEALTHCARE PROFESSIONALS: A QUALITATIVE THINK-ALOUD STUDY

Emily John[1,2], *Lauren Young*[1], *Rachel Miller*[1], *Karen Dean*[1], *Gemma Pugh*[1]
[1]*Anthony Nolan, London, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Cardiff and Vale University Health Board, Cardiff, United Kingdom of Great Britain and Northern Ireland (the)*

Background: As demand for CAR-T and other advanced cellular therapies increases, there is a growing need for healthcare professionals (HCPs) to receive the appropriate training and education on this topic. Scoping work led by the Cellular Therapy Clinical Nurse Specialist (CNS) at Anthony Nolan along with an established focus group, identified limited UK-focused, multi-professional educational resources on CAR T-cell therapy, particularly inclusive of paediatric care. A CAR-T e-learning resource was developed by Anthony Nolan. The aim of this project was to address this gap through the development, implementation and evaluation of a comprehensive e-learning resource. Alongside development, a qualitative usability study was embedded to formally evaluate user experience and learning design, recognising the importance of conducting research into digital education in this area.

Methods: HCPs were invited to take part in a qualitative think-aloud interview. During the first part of the interview HCPs were asked about their views on e-learning and their CAR-T education needs. During the second part of the interview, they completed the think-aloud task using the CAR-T e-learning resource as a prompt. Content analysis was conducted to identify emerging themes and topics. Findings from the interviews were incorporated into the development of the final e-learning resource. Participants were then sent a link to access the final resource and asked to complete it in their own time, as well as a feedback survey to share their thoughts on the entire e-learning resource.

Results: HCPs were positive about the use of e-learning due to its flexibility. Participants felt e-learning is most effective when the content is relevant to their role and when there is opportunity to contribute to Continuing Professional Development (CPD). However, participants shared that e-learning is not always accessible and barriers to its use include time, access to resources and funding. Participants stressed the importance of keeping education up to date with the rapidly evolving field of CAR-T therapy. HCPs want to feel educated on the entire CAR-T pathway, from patient eligibility through to late effects, with neurotoxicity and long-term effects being a key priority. Participants were positive about the content, design and usability of the e-learning resource developed by Anthony Nolan. Overall, they felt the content was detailed and relevant to HCPs with varying levels of knowledge on the CAR-T pathway. Participants felt the design of the resource was engaging and visually appealing and reported smooth navigation and accessibility. Small improvements suggested during user testing were implemented in the build of the final modules.

Conclusions: E-learning is viewed by health care professionals as a valuable and accessible resource for training, particularly in a rapidly evolving treatment such as CAR-T. The collaborative approach undertaken in the development of this resource and think aloud methodology utilised has ensured that the learning objectives have been clearly addressed for the workforce accessing the training and as such has provided a robust introduction into the CAR-T pathway for UK HCPs.

NP71

HAEMATOPOIETIC, CELL THERAPY AND TRANSPLANT PREPARATIVE TRAINING FOR REGISTERED NURSES IN SINGHEALTH, SINGAPORE

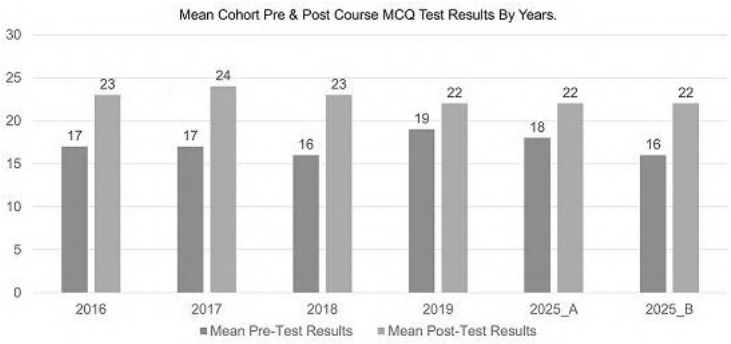
Chung Cheng Jordan Hwang[1], *Yan Yin Lim*[2], *Yew Leng Aloysius Ho*[1]
[1]*Singapore General Hospital, Singapore, Singapore,* [2]*KK Women's and Children's Hospital, Singapore, Singapore*

Background: SingHealth has the largest public Haematopoietic Stem Cell Transplant (HSCT) and cell therapy programme in Singapore. The adult service is provided in Singapore General Hospital (SGH) while the paediatric programme is housed off site at the KK Women's and Children's Hospital (KKH). Annually, close to 170 HSCTs and CAR-T cell treatments are performed across these two sites. The training and competence preparation of HSCT nurses were decentralized and organized independently prior to year 2015.

Methods: To standardize the HSCT preparative training of our nurses, the SingHealth HSCT course for Registered Nurses (RNs) was conceptualized in year 2016. The 35 hours in-person theoretical training curriculum was developed to conform with the standards of the 6th edition of the Foundation for the Accreditation of Cellular Therapy (FACT)-Joint Accreditation Committee ISCT-Europe & EBMT (JACIE) international standards for haematopoietic cellular therapy product collection, processing, and administration. The 5-day course enrolled RNs who had at least 2 years of working experience in the haemato-oncology units. The course

was taught by the staff members of the multi-disciplinary HSCT teams from both SGH and KKH. To ensure rigor for the course, assessment methodologies of pre-post course MCQ testing, case-based discussion and group presentations, stem cell infusion competency assessment, and individual post course reflective journaling were instituted.

Results: From year 2016 to 2025, a total of 8 runs of the HSCT course was conducted. A virtual edition was organized in year 2021 due to the COVID-19 pandemic restriction orders imposed in Singapore. A total of 132 participants (112 SingHealth nurses, 15 non-SingHealth nurses, and 5 HSC transplant coordinators) attended the course. Upon completion of the course, participants were presented with the certificate of completion and continuing nursing education points awarded by the Singapore Nursing Board. Paired pre and post course multiple choice questions (MCQ) tests were administered for 6 of the 8 cohorts. All 6 cohorts showed improvements in post course MCQ test results, reflecting the positive impact of the course curriculum.
Qualitative accounts from participants reported good satisfaction with the course curriculum. Two recurring themes that surfaced from participants were 'gaining confidence' and 'showing empathy'. Participants felt more confident and competent to care for these patients with their increased knowledge and understanding of HSCT management and treatment principles. Participants were better able to empathize and journey with these patients during their treatment.



Conclusions: The SingHealth Haematopoietic Stem Cell Transplant course continues to be the main HSCT preparative programme for registered nurses working within SingHealth group of hospitals and nurses working with the private stem cell transplant services in Singapore.
The course curriculum was revised in year 2020 and incorporated management and care of patients undergoing chimeric antigen receptor T cell therapy.

Clinical Trial Registry: Not Applicable

BUILDING INCLUSIVE CLINICAL CULTURES: SUPPORTING NEURODIVERSE STAFF IN A SPECIALIST HAEMATOLOGY AND TRANSPLANT SETTING

Amy Tyrrell-Marsh[1], Annie Hamilton[1], Sara Rush[1], Meryl Tebb[1], ***Arlene Bamforth***[1]
[1]*The Christie NHS Foundation Trust, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Transplant and cellular therapy is a dynamic and complex speciality that needs to nurture and support staff. Neurodiversity is an umbrella term, used to describe natural differences in how individuals' brains' think and process information. It's estimated that around 1 in 7 people in the UK have neurodevelopmental differences (Keeping Well, 2024) In 2023 the NHS published its first equality, diversity and inclusion (EDI) improvement plan. By recognising and valuing unique contributions of neurodivergent individuals, organisations can build stronger, more innovative and inclusive teams as people from different backgrounds bring different experiences, perspectives and skills.
The Clinical Educator team work closely with new staff, preparing them to care for transplant patients. During their induction, staff have disclosed they are neurodivergent or require additional learning support. Some of the established staff have also shared they are neurodivergent. Recognising an importance to adapt our teaching styles; we explored safe and non-judgemental ways that gave staff an opportunity to highlight any learning needs. "This is Us and You" was developed.

Methods: 'This is us and you' is intended to establish a setting for an inclusive and welcoming culture.
By providing the new staff member with a little information about each of us, we then invite them to tell us about themselves, including any information they think would be useful for us, as educators, to know.
Some staff have disclosed information using the document. However, the hope is that even if they do not feel comfortable disclosing via the document, they will feel the team is a welcoming, safe space where we aim to treat everyone as individuals and try to tailor the learning to them.

Results: Since September 2024, 45 new starters within the Haematology directorate have received the 'This is Us & You' document. It was completed by 19 members of staff and 2 disclosed learning needs or diagnoses within the document. 8 out of 19 informed us of their preferred style of learning.
It is important to emphasise that staff do not need a formal diagnosis to access support or reasonable adjustments. We aim to update our learning programme and materials, implementing learning approaches that are inclusive and therefore benefit all staff.
As an educator team, we are growing a culture to normalise and accept learning differences and encourage established staff to feel comfortable disclosing any issues that may be affecting them. We are developing confidence in our ability to provide inclusive education to all our haematology nursing staff.

Conclusions: So, What Now? Still lots to do!
It's the beginning of an extensive project involving the wider nursing team. One of the findings is lack of education and training to raise awareness of neurodiversity in the workplace. As educators, we found it difficult to access practical support and guidance in clinical practice.
Therefore, it's understandable why staff do not want to disclose their challenges to managers and colleagues for fear of being labelled. As a result, neurodivergent nurses can be seen as underperforming and requiring improvement plans.

Disclosure: Nothing to Declare.

NP94

IMPROVING DELIVERY AND DOCUMENTATION OF JACIE-REQUIRED EDUCATION AND COMPETENCIES IN AN ADULT AUTOLOGOUS TRANSPLANT SERVICE

Hayley Aplin[1], *Nicola Knightly*[2,2]
[1]*Great Western Hospital, Swindon, United Kingdom of Great Britain and Northern Ireland (the),* [2]*hayley.aplin, Swindon, United Kingdom of Great Britain and Northern Ireland (the)*

Background: High-quality care for patients undergoing autologous stem cell transplantation relies on a nursing workforce that is knowledgeable, competent, and fully compliant with JACIE Standards. Within our 10-bedded haematology unit, autologous transplant activity represents a small proportion of overall admissions, averaging approximately 16 patients per year. As a result, nurses did not perceive JACIE education requirements as integral to their clinical practice, and the implications of non-compliance were poorly understood. In addition, the service faced longstanding challenges with education delivery, inconsistent attendance at training sessions, and inadequate systems to evidence compliance and track competency renewal.
Historically, the service delivered supplementary JACIE training through evening sessions via Microsoft Teams. Attendance and presenter engagement were low, as staff were reluctant to undertake education in their personal time. Competency records were limited: documentation captured only the date of completion, with no mechanism to monitor or prompt renewal. Staff often overlooked expiring competencies, including critical haematology nursing skills, jeopardising compliance with JACIE and hospital-mandated nursing requirements.

Methods: A structured and sustainable intervention was therefore developed to redesign how JACIE-required education and competencies were delivered, monitored, and evidenced. Evening training was discontinued entirely. At the start of each year, a detailed education plan was created, aligning topics to relevant JACIE Standards and distributing content between face-to-face JACIE Away Days. All monthly education was pre-recorded, uploaded to YouTube, and accessible during protected work hours. On completion of the training staff received an attendance certificate; participation was logged on a central spreadsheet. Standard operating procedures were updated to embed the process, clarify expectations, and

outline consequences of non-compliance. Reminders were issued to staff who had missed required training, copied to nurse managers to reinforce accountability.
To address competency renewal, the existing matrix was redesigned to include an expiry date column with a red-amber-green status system: red for expired, amber for competencies due within three months, and green for those in date. Nurses received monthly reminders prompting them to schedule assessments well before expiry. A new end-of-year CPD record, signed by the Programme Director, further formalised individual accountability. Where training remained incomplete, a deviation was raised in accordance with the training SOP.

Results: The redesigned education model led to demonstrable improvements in compliance, engagement, and documentation. Pre-recorded content provided predictability and flexibility, while explicit links to JACIE Standards improved staff understanding of its importance. Knowledge quizzes strengthened learning, and attendance certificates supported appraisal and revalidation. By year end, all nurses achieved full compliance with required JACIE training, and 95% of clinical competencies were in date.

Conclusions: This initiative highlights the need for proactive, structured, and well-governed approaches to clinical education in transplant services. Embedding protected learning time, reminders, and clear accountability supports staff engagement and ensures ongoing compliance with JACIE and NMC requirements. Continuous review and involvement of frontline staff including a registered nurse and healthcare assistant in planning future training for 2026 will help ensure the programme remains relevant, engaging, and sustainable.

Disclosure: Nothing to declare

NP95

IN HOUSE EDUCATION PROGRAMME 15 YEARS LATER: WHERE ARE WE NOW?

Hannah Kenyon-Smith[1], *Marie Jones*[1]
[1]*Manchester Royal Infirmary, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: In 2011 a weekly education programme was introduced within our haematology and transplant unit to support nurses and allied health professionals (AHPs) in maintaining competence and meeting regulatory requirements. Advances in medicine, treatments and evolving healthcare delivery demand continuous professional development. Evidence shows that structured education improves staff retention, job satisfaction, and patient care (Pashmena et al, 2024). JACIE standards further highlight the need for specialist education in haematology and transplant services, this includes maintaining evidence of competence and assessment in clinical skills such as cell infusion, line care and treatment delivery (EBMT, 2025). We have had to adapt our education provision due to the introduction of complex treatments such as CAR-T cell, gene therapy and new clinical trials. In addition, changes to workforce and overseas recruitment has led to additional hurdles such as

language barriers and varying standards of clinical skills and education.
Original objectives:

- Deliver regular, accessible transplant-focused education
- Provide informal, 30-minute sessions
- Offer attendance certificates for portfolios/revalidation
- Ensure compliance with JACIE standards
- Make resources available via platforms such as QPULSE
- Utilise multidisciplinary team expertise
- Share presentations on request

Methods: **Then:**

- 2011, weekly were sessions introduced, covering transplant and haematology topics
- 2013, appointment of a practice educator (3 days/week)- the practice educator ensured mandatory training and haematology/ transplant knowledge, skills and competency were maintained
- 2019, full time practice educator (5 days/week)
- 2022, expansion of the transplant unit
- 2022, dedicated education room established

Now:

- Weekly sessions continue to include:
  - Attendance registers and certificates
  - Evaluation forms for feedback and topic suggestions
  - 30-minute duration to maximize participation
  - Use of extended MDT to deliver teaching
- Additional initiatives introduced:
  - Appointment of additional practice educator to cover 7-day service
  - "Tiny Teaching" (10-minute sessions with tip sheets)
  - Daily handover quizzes
  - Biannual haematology study days with protected time
  - 1:1 patient-focused teaching
  - support staff to attend training days outside of the hospital

Results:

- 60 nurse questionnaires assessed barriers to education
- 60 evaluation forms reviewed for attendance and engagement
- Findings confirm sessions are relevant, well-received, and appropriately timed.
- Findings highlight reasons for non-attendance of sessions such as workload and staffing

Conclusions: The in-house education programme remains valuable and effective since introduction 15 years ago. Feedback suggests staffing pressures and limited protected time still hinder participation. To address these barriers, diverse educational formats have been implemented to ensure consistent access to updates and sharing of key messages. The practice educator team, now fully embedded, continues to grow and recognise that they

must be adaptable in their teaching style to meet the needs of the service and team whilst ensuring the department meet regulatory requirements. We plan to update and adapt our education pack to include a learning passport.

EXPERIENCES OF AT-HOME AUTOLOGOUS STEM CELL TRANSPLANTATION IN SPAIN: CURRENT OVERVIEW AND IMPROVEMENT AREAS

Cristina Gallego Miralles[1], *Soledad Jiménez Picazo*[2], *Laura Romero García*[2], *Mercedes Cumplido*[2], *Andrea Luque Guirval*[3], *Esther Manotas Piñero*[3], *Carmen Quintela González*[4], *Jesus Ignacio Merlo Luis*[5], *Isabel Garrido Muñoz*[6], *Silvia Lucia Carles*[6], *Noelia Gómez*[7], *Nuria Ballestar Dot*[1]
[1]*Hospital Clínic of Barcelona, Institute of Cancer and Blood Diseases, Barcelona, Spain,* [2]*Hospital Universitario Reina Sofia, Córdoba, Spain,* [3]*Hospital Universitario Regional, Málaga, Spain,* [4]*Hospital Alvaro Cunqueiro, Vigo, Spain,* [5]*Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain,* [6]*Hospital Clínic Universitari, Valencia, Spain,* [7]*Hospital Universitario Marqués de Valdecilla, Santander, Spain*

Background: Management of Autologous Stem Cell Transplant (ASCT) in a Homecare Units (HCU) or an Ambulatory Setting (AS) is a growing trend. In Spain, the first experiences began before 2000; however, it was in the last decade that they started to expand. In 2023, the GETH Spanish Nurses Group (GETH-SNG), established the Homecare Group (HCG) with the following main objectives: 1. To have a general overview of the Spanish HCU, 2. To understand the impact of ASCT programmes 3.To identify common aspects to develop multicentre studies.

Methods: Nurses from various HCUs were identified through GETH-SNG and invited to participate in the HCG. A data base was created to collect information about: inclusion criteria, non clinical reasons for patients' exclusion, HCU models, resources, patients included (over the last 3 years), readmissions, other programmes for complex haematology patients and educational programmes to patients and caregivers. Methodologies related to

educational programmes were exposed in the regular HCG on-line meetings. Data were also collected from literature published by some of the units.

Results: Of the 9 HCUs invited, 8 had ASCT programmes, and 7 HCUs reported data. Across all units, the inclusion criteria were: ECOG ≤ 2, home-hospital distance of 30-60 min, a 24/7 caregiver and voluntary acceptance. The two main exclusion criteria for candidates who met the clinical conditions were long distance from the hospital and lack of a caregiver. Some hospitals reported alliances with foundations to help cover a part of these social needs.
All ASCT HCUs provided care 365 days a year during daytime hours, only one reported 24h availability of homecare. Most had a special circuit for managing emergencies at the hospital.
Between January 2023 and September 2025, a total of 1241 SCT patients were treated across 5 hospitals. The following table has the results for each hospital regarding the number of patients included, readmissions, reasons for readmission, patients who returned home to complete the process and alternative complex programmes for haematology patients. (table1)
All HCU reported educational programmes prior to discharge for patients and caregivers to ensure adequate management and safety at home. They also agreed on the importance of ongoing home-based training to support proper adherence to the recommendations, adapted to each patient's tools and abilities. None reported formal evaluations to measure the effectiveness of these interventions.

Table 1: HCU characteristics and activities Jan-2023 to Sep-25

Hospitals	**At-home Visits**	**HCU model (TASP)**	**1ST ASCT**	**N. SCT (2023-25)**	**N (%) ASCT (2023-25)**	**N (%) ASCT at HCU**	**N (%) Readmission Return home**	**Reassons**	**Port-folio Complex programs**

Álvaro Cunqueiro (Vigo)	Nurse	No							Ramp up Venetoclax Chemotherapy.

*Results obtained of a published series between 1997 to 2019

Conclusions: Social resources are needed to improve equity and increase the recruitment to HCUs for all patients who meet the clinical criteria, despite the alliances with foundations. The number of patients attended and efficiency reported by the different HCUs are high, enabling the hospitals to increase the capacity to manage complex cases.
Accurate health training programmes are essential for managing ASCT patients prior to discharge and during at home follow-up. Formal evaluations to collect feedback on these interventions are needed in order to improve the programmes.

Disclosure: Nothing to declare.

TRANSPLANT @ HOME: A SINGLE CENTRE EXPERIENCE IN HOME-BASED CARE FOR AUTOLOGOUS STEM CELL TRANSPLANTATION

Hui Li Lim[1], *Grace Cham*[1], *Foong Gwan Lee*[1], *Jedidah Lieow*[1], *Yanan Wang*[2], *Sandra Tan*[2], *Hazel Teng*[2], *Liang Piu Koh*[1], *Lip Kun Tan*[1], *Victor Ling*[1], *Joanne Lee*[3], *Michelle Poon*[1], *Esther Chan*[1], *Belinda Tan*[1], *Edwin Thong*[1]
[1]*National University Cancer Institute of Singapore, National University Health System, Singapore, Singapore,* [2]*NUHS@Home, National University Health System, Singapore, Singapore,* [3]*Centre for Clinical Haematology, Singapore, Singapore*

Background: Autologous stem cell transplantation (ASCT) for multiple myeloma has traditionally been carried out in the inpatient setting. Post COVID-19, many centers globally have shifted to home-based transplantation with safe follow-up and comparable outcomes. However, data on healthcare economics, acceptability and safety of this care model in the Asian setting are lacking. In Singapore, the Hospital-at-Home (HaH) model has become mainstream in public healthcare institutions. Since 2024, we started a pilot program with HaH (NUHS@Home) to offer home-based ASCT for myeloma.
Our pilot program aimed to evaluate the safety, feasibility, and impact on patients' quality of life of a home-based ASCT strategy in Singapore.

BMT Coordinator Assessment & Education for Home Transplant		
This assessment is to be completed before patient is enrolled into the NCIS Home Monitoring & Treatment Program. This helps identify patients and caregivers, who meet both the clinical and home assessment criteria for the program. The assessment will ensure that the safety of patients, caregivers and healthcare professionals is maintained at every stage of the Home Transplant Program.		
Pre-Transplant Assessment		**Assessor's comments for transplant physician review**
Patient Assessment	Medical History assessed and reviewed ☐ Age <65 (if ≥65 years old but fit, for individual case basis consideration) ☐ ADL independent ☐ Availability of dedicated caregiver ☐ Patient has good understanding of treatment ☐ Patient has good history of compliance ☐ Organ functions within acceptable limits	Special mention ☐ Others
	Psychosocial assessment There are identified issues that needs special highlight to the referred MSW ☐ Yes [add remarks] ☐ NIL concerns	
	Home within reasonable distance ☐ YES, ≤ 45 mins by car from NUH ☐ NO, ≥ 45 mins by car from NUH	
	Home environment brief assessment Following area [ticked] that requires special mention to transplant physician and/or OT ☐ Bathroom/Toilet ☐ Pets ☐ Plants ☐ Young children ☐ Renovation in progress at home or nearby ☐ NIL concerns	Special mention ☐ Others
Caregiver Assessment	Identified caregiver screening Following eligibility criteria met ☐ Physically available 24/7 to provide care ☐ Able to remain contactable 24/7 ☐ Able to bring patient back for treatment ☐ Able and willing to learn subcutaneous injection technique ☐ Steadfast/ Observant/ Resilient	Special mention ☐ Others
Conclusion	Passed Assessment. ☐ YES, proceed to plan and engage for Home Transplant ☐ NO, will discuss with primary transplant physician [remarks]	
Additional Remarks		
Transplant Education		
Patient & Caregiver Education	Before and Throughout Transplant period up till D+100 ☐ Nutrition ☐ Intake-Output and Body weight self-charting ☐ Exercises/ Activities to prevent boredom ☐ Personal Hygiene, Oral care ☐ Fall Prevention (home environment risks) ☐ Infection Prevention measures ☐ Blood test monitoring (pancytopenia precautions) ☐ D0 preparation: ice cubes, soft chewy candies ☐ Daily video call with NUHS@Home and BMT team ☐ Vital signs frequency & reportable values ☐ Symptoms charting & reportable adverse events ☐ CVAD care ☐ Medication management - reinforce adherence ☐ Given Patient Information Leaflet ☐ Given Emergency contact information ☐ Route to ward 58HD/ Ward 8A – Patient walkabout	
	Upon Discharge, up till D+100 ☐ TCU compliance - short- and long-term follow-up ☐ Long-term recovery expectations ☐ Travelling clearance by transplant physician	
Additional Remarks		

Methods:

Suitable myeloma patients undergoing ASCT could enrol into the home transplant program based on eligibility criteria including patients' age, functional status, medical comorbidities, caregiver availability and social situation (Refer to Image). Eligible patients received pre-transplant conditioning and stem cell infusion in the outpatient setting then returned home under the care of the HaH team. Daily video consults involving the patient/ caregiver, transplant team and HaH team were conducted. The HaH team also conducted home visits on alternate days, including blood-taking. Patients and caregivers were trained to monitor vital signs, record intake and output, and administer subcutaneous granulocyte colony stimulating factor injections. Ad-hoc interventions, including intravenous hydration or

medications were provided as needed. Patients had access to a 24-hour emergency hotline, with protocols for an expedient return to hospital where necessary. For febrile episodes, patients were admitted directly to a pre-booked bed in the transplant ward for investigations and intravenous antibiotics. For transfusions, patients were transfused in the hospital before returning home. Clinical charts were reviewed for transplant outcomes, and quality of life (QoL) was assessed with the Functional Assessment of Cancer Therapy-Bone Marrow Transplant scale (FACT-BMT version 4) pre-transplant and Day 30 post-transplant.

Results: We report our initial experience with the first 12 patients in the pilot program from September 2024 to November 2025. Median age was 62 (range: 45-67) with 5 females and 7 males. No unexpected toxicities occurred. Eight patients were returned to hospital, as per a pre-planned workflow, on a median of day +8 of transplant (range Day +7 to +15). All patients who required a return to the hospital managed to do so expediently, within our predetermined cutoff of 45 minutes. There were no ICU admissions or deaths. A median of 12 bed-days was saved (9-21) per patient, totalling 172 bed-days saved.
Overall, the program was well accepted by patients and their caregivers, with positive feedback on exit interviews. Quality of life was well-preserved as assessed by FACT-BMT scores improving from a median of 99 at baseline (range 81-136) to 116 post-transplant (range 87-126), and all but 3 patients showing improved scores post-transplant.

Conclusions: Our pilot results suggest that with careful patient selection, and protocolized treatment workflows in close collaboration with HaH, home-based ASCT is safe, feasible and accepted by patients. Our model of care allows for significant bed-savings, while maintaining patients' QoL.

Disclosure: Nothing to declare

NP19

A NURSING ROLE IN IMPROVING OPERATIONAL EFFICIENCY IN CELLULAR THERAPY CLINICAL TRIALS

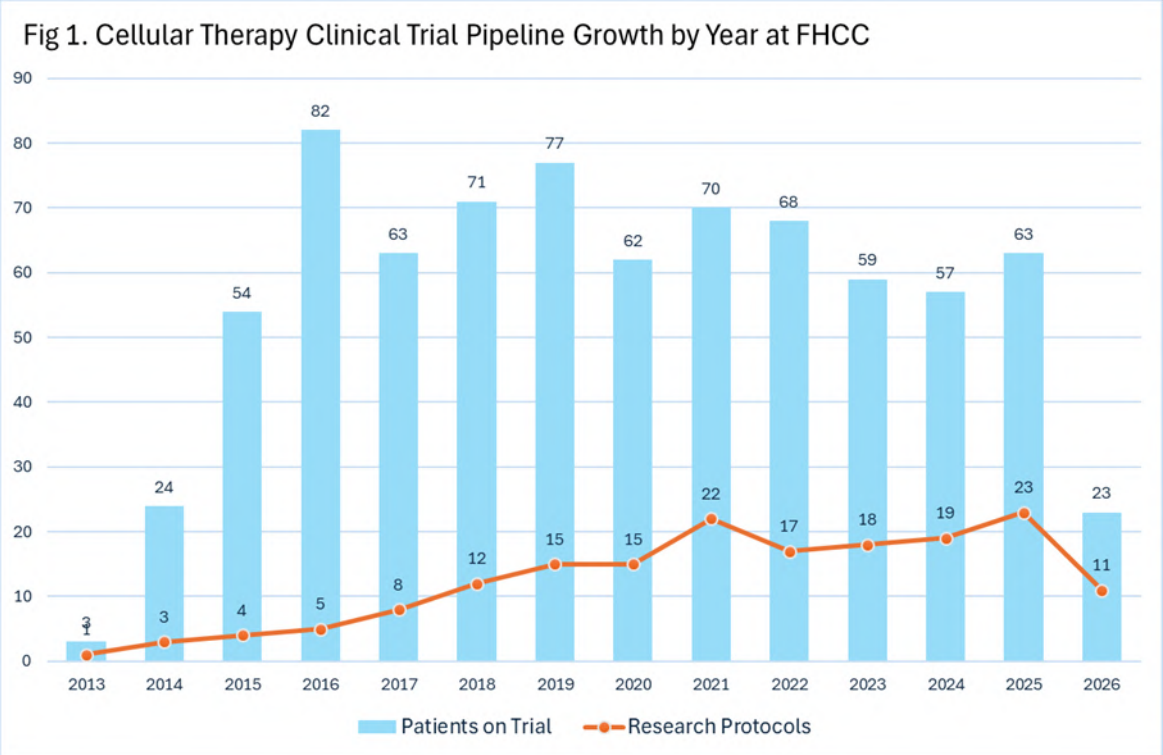
Soyoung Park[1], *Dwight Macero*[1]
[1]*Fred Hutch Cancer Center, Seattle, United States of America (the)*

Background: Cellular therapies including chimeric antigen receptor T-cell (CAR-T), T-cell receptor (TCR), and tumor infiltrating lymphocytes (TIL) therapies have transformed cancer care. Clinical trials now span autologous, allogeneic and in-vivo constructs and are expanding into disease states beyond hematologic malignancies including solid tumors and autoimmune disorders. Translating these protocols into the clinic is complex and requires coordination across multiple disciplines. Despite having multidisciplinary teams with significant experience, planning and executing trials often reveal gaps between the research and clinical teams. While the clinical research nurse role is not new, they are often embedded within clinical research teams and support specific protocols. Here we describe a unique clinical trial coordinator research nurse (CTCRN) role supporting our cellular therapy clinical trial pipeline within a centralized cell therapy service (IMTX) with a rotational physician and advanced

practice provider model at Fred Hutchinson Cancer Center (FHCC) in Seattle, Washington, USA.

Methods: The CTCRN role was introduced in 2017. We identified stakeholders and key elements supported by the CTCRN. We analyzed quality metrics from patients who received cellular therapy from July 2013 through October 2025 at FHCC.

Results: As of October 2025, we have treated 1260 patients with cellular therapy products at FHCC IMTX, of which 776 patients were treated on a clinical trial protocol. The FHCC IMTX clinical trial pipeline has grown from one research protocol to 56 unique clinical trial protocols that accrued patients with a range of 1- 195 patients per study. The number of protocols that accrued patients by year ranged from 1 to 23 protocols. Prior to 2017, there were a maximum of 5 protocols that accrued patients per year. Fig. 1 shows program growth over time.



We identified 14 stakeholders supported by the CTCRN role across several multidisciplinary teams from planning through trial activation and accrual. Key elements supported by the CTCRN role included clinical trial planning, education, and clinical support and are described in Table 1.

Table 1. Key Elements Supported by CTCRN Role Span Planning, Education and Clinical Support

Key Elements	Details
Clinical Trial Operations Planning	• Supports Feasibility of Operations Meetings • Clinical Research Protocol Roadmap Review • Patient Journey Review • Validation of Clinical Order Sets • Sponsor Site Initiation Visit (SIV)
Education	• Coordinates Clinical In-Service with PI and Clinical Trial RN – recorded and curated as on-demand enduring content • OnCore (Clinical Trial Management System) • Creates Clinical Trial Fact Sheets (high level overview of clinical trial flow)
Clinical Team Support	• Validated Order Sets and EMR (EPIC) Checklists • Clinical scheduling guidelines per protocol • Coordinates dissemination of protocol updates and amendments • Maintains high level reference for open protocols ("Cellular Immunotherapy Snapshot") • Creation of job aids for highly complex studies • 1:1 Clinical support for first-patient-in per protocol, and as needed

Conclusions: There is high added value in a clinic focused CTCRN role in an expanding centralized cell therapy service administering both investigational products and commercial therapies concurrently. We have been able to expand our clinical research portfolio and have supported >60% of patients treated at FHCC IMTX on a clinical research protocol. Focused surveys are planned to measure staff perspectives on key elements supported by the CTCRN role to identify gaps and further improve clinical trial integrity at FHCC.

Disclosure: Nothing to declare

NP22

CONTINUOUS CARE UNIT: A FEASIBLE MODEL TO OPTIMIZE URGENT MANAGEMENT IN HAEMATOLOGICAL MALIGNANCIES, TRANSPLANTATION AND CAR-T PATIENTS

Renato Luna Liendo[1], *Arianna Rosich-Soteras*[1], *Mª Lourdes Corominas*[1], *Beatriz Merchan*[1], *Pilar Fafian*[1], *Selene Falcon*[1], *Laura Villa Rodriguez*[1], *Irene Casablanca*[1], *Carol Cristina*[1], *Francesc Fernández Avilés*[1], *Ariadna Domenech*[1]
[1]*Hospital Clinic Barcelona, Barcelona, Spain*

Background: The increasing number of patients undergoing active treatment, coupled with improved survival rates and growing therapeutic complexity, has led to a rise in acute complications among cancer patients, resulting in greater utilization of emergency departments (ED). In hematologic malignancies, the rapid management of febrile neutropenia remains particularly critical. Effective triage, early symptom recognition, and timely implementation of evidence-based clinical algorithms are essential to optimize patient outcomes.
We aimed to describe the utilization of a Continuous Care Unit (CCU) by haematology patients. A secondary objective was to analyse CCU use among hematopoietic stem cell transplant (HSCT) and CAR-T recipients.

Methods: Prospective data were collected from haematology patients requiring CCU care between November 13, 2023, and November 14, 2024. The CCU operates from 9:00 a.m. to 5:00 p.m., staffed by two internists and one nurse, with five beds dedicated to urgent care. Outside these hours, patients follow standard care pathways. A descriptive analysis of clinical and demographic variables was performed.

Results: The CCU received 2,454 cancer-related evaluation requests, of which 2,189 (89%) were accepted; the main reason for non-acceptance was lack of capacity (11%). Among accepted cases, 629 (29%) involved haematological malignancies (mean age 60.4 years, SD 17.3). The most frequent diagnoses were lymphoproliferative disorders (42%), HSCT recipients (17%), and multiple myeloma (16%). Fifty-four CAR-T patients (9%) were attended. Triage classified 49% of haematology patients as urgency level 3 and 40% as level 4. For HSCT patients, level 3 predominated (61%), while CAR-T patients were mainly level 4 (36%). Infections were the leading reason for consultation across all groups: haematology (50%), HSCT (63%), and CAR-T (50%). Disease-related symptoms accounted for 29% of HSCT visits, while 31% of CAR-T patients required management of infusion reactions. Hospital admission was necessary for 58 haematology patients (9%), and 19 (3%) received home hospitalization. Among HSCT patients, 6.5% were hospitalized and 4% managed at home; for CAR-T patients, 6% were hospitalized and one received home care. After discharge, 58% of haematology patients continued routine follow-up, while 29% required CCU re-evaluation within 24–48 hours. Similar patterns were observed in HSCT (45% routine follow-up; 41% re-evaluation) and CAR-T patients (72% routine follow-up; 20% re-evaluation), respectively.

Conclusions: A part-time CCU significantly improves urgent care for haematology patients, providing timely, specialized management and reducing ED burden. The high acceptance rate and predominance of intermediate triage levels highlight its role in optimizing care for immunocompromised patients. This model is safe, feasible, and enhances continuity of care through protocol-driven management, the knowledge and skills of specialist nurses and structured ambulatory follow-up.

NP62

REDUCING INPATIENT BED UTILISATION BY DELIVERING CAR-T LYMPHODEPLETION CHEMOTHERAPY IN AN AMBULATORY SETTING AT SHEFFIELD TEACHING HOSPITALS

Alexandra Bamford[1], *Bethany Colton*[1], *Daveen Kay*[1], *Nicola Rodwell*[1], *Catherine Ellin*[1], *Amy Kent*[1], *Paul O'Connor*[1], *Nick Morley*[1]
[1]*Sheffield Teaching Hospitals, Sheffield, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Chimeric Antigen Receptor T-cell (CAR-T) therapy normally requires hospitalisation for lymphodepletion chemotherapy due to the intensity of treatment and the need for close monitoring. Increasing demand for cellular therapies has placed pressure on inpatient beds, prompting exploration of safe outpatient approaches. In January 2024, Sheffield Teaching Hospitals (STH) introduced ambulatory delivery of lymphodepletion for eligible CAR-T patients to reduce inpatient stay and enhance patient experience. STH has a well-established emergency assessment and admission pathway for haematology patients. Any patient developing symptoms or complications during ambulatory lymphodepletion are reviewed immediately in the day unit by experienced haematology staff, with direct admission to the haematology ward when required. This supports rapid clinical assessment, continuity of specialist care, and minimised treatment delays.

Methods: A multidisciplinary working group, comprising haematology nurses, medical staff, and ambulatory care teams implemented a pathway enabling CAR-T patients to receive lymphodepletion chemotherapy (Day −5, −4, −3) in the ambulatory unit. Patients were then permitted to rest at home or in ambulatory accommodation (Day −2, −1) before returning on Day 0 for their CAR-T infusion and subsequent planned inpatient admission for post infusion monitoring. Eligibility criteria included patient preference, proximity to hospital, and availability of a home carer or access to ambulatory flats.

Results: Between January 2024 and the time of reporting, 24 patients received lymphodepletion chemotherapy via the ambulatory pathway. Within this group, four patients required admission during lymphodepletion, primarily due to fevers or hypotension. A further three patients were managed as inpatients from Day −5 because a home carer was not available. These three were not included in the 24 ambulatory cases.
The ambulatory pathway saved 100 inpatient bed nights, averaging approximately four days saved per ambulatory patient. Four patients used ambulatory accommodation, while the remainder returned home between treatments. Patients reported valuing the shorter hospital stay, increased comfort, greater independence, and positive effects on mental and physical wellbeing.
There were no unplanned admissions and no complications beyond those expected, indicating that the pathway is feasible and functions effectively when supported by established emergency assessment processes. At the time of reporting, five additional patients were preparing for ambulatory lymphodepletion, demonstrating continued sustainability and confidence in the model.

Conclusions: Introducing ambulatory lymphodepletion chemotherapy for CAR-T patients significantly reduced inpatient bed usage while maintaining effective clinical care and improving patient experience. This innovative model supports more efficient use of hospital resources, shortens inpatient stays, and aligns with wider efforts to expand outpatient cellular therapy care. The pathway is reproducible for other centres seeking to optimise capacity while maintaining high quality patient centred care.

CHALLENGES OF LAUNCHING AN AT-HOME HOSPITALIZATION PROGRAM: THE "SANT PAU A CASA" HOSPITAL-AT-HOME EXPERIENCE

Alba Pla Bou[1], *Marta Yusta Arnal*[1], *Elisabet Pérez Toral*[1], *Mercè Triquell Garrell*[1], *J. M. Portos Villar*[1], *Olga Aso Ferreras*[1], *Aina Papell Penetró*[1], *Laia Alloza Crespo*[1], *Noelia Arranz Padilla*[1], *Núria Font Díaz*[1], *Sara Redondo Velao*[1], *Albert Esquirol Sanfeliu*[1], *Mª Estela Moreno Martinez*[2], *Rodrigo Martino Bufarull*[1], *Irene Garcia-Cadenas*[1], *Javier Briones Meijide*[1], *Annalisa Paviglianiti*[1]
[1]*Hematology Department, IR-Sant Pau and José Carreras Leukemia Research Institutes, Barcelona, Spain,* [2]*Pharmacy Department, IR-Sant Pau and José Carreras Leukemia Research Institutes, Barcelona, Spain*

Background: At-home hospitalization (AHH) is an increasingly used care model for selected hematological patients. Accurate estimation of census and enrollment is essential for its successful implementation. Furthermore, because a proportion of patients develop complications requiring urgent hospital transfer, dedicated pathways must be established to ensure timely management. We aimed to assess the challenges encountered during the implementation of a new single center AHH program and to describe the process involved.

Methods: Since April 2024, all consecutive adults undergoing autologous stem cell transplantation (ASCT) were evaluated for potential eligibility in the AHH program. Inclusion criteria were defined as follows: ECOG ≤ 2, travel time from home to the hospital within one hour by public transportation, availability of a suitable 24-hour caregiver, adequate cultural level and cognitive capacity to collaborate with the nursing team, and a suitable home environment. Exclusion criteria were: refractoriness to platelet transfusion, decompensated psychiatric disorders, and previous infection from multi-drug resistant organisms. In case of urgent transfers, a dedicated protocol was established in collaboration with the Barcelona Emergency Medical Service. Patients were instructed to contact the on-call hematologist or AHH physician if they experienced warning symptoms. Non-urgent transfers were arranged through the standard ambulance services coordinated by the AHH team.

Results: Since the program started, 15/81 (18’52%) consecutive patients assessed as potential referrals were enrolled. Diagnosis among enrolled patients included Multiple Myeloma (n=5), non-Hodgkin Lymphoma (n=8) and Hodgkin Lymphoma (n=3).
Among the 65 ineligible pts, reasons included: lack of a 24-hour caregiver (n=24, 30%), living >1h from the hospital (n=17, 21%), comorbidities (n=13, 16%), inadequate cultural level (n=1, 1%) and the temporary program closure in August (n=10, 12%). One patient discontinued the program on day+1 due to severe early toxicity.
Among the 15 enrolled patients, the median age was 54 years (range 27-71) and 67% were male. A total of 2 patients (13’3%) received 3 red blood cell transfusions and 6 patients (40%) 9 platelet transfusions at home, none of which were associated with transfusion reactions.
Five (33’3%) patients were discharged from AHH without complications after a median of 14 days (range 11-16). Ten patients required readmission (HL n=2, NHL n=5, MM n=3), most commonly due to fever (9/10), including one case of influenza A and one case of *Giardia intestinalis* colitis; one patient was readmitted for atrial fibrillation. Barcelona Emergency Medical Service activation was required in 7 cases (35%), while conventional transfers were used in 13 occasions (65%). Readmitted patients remained hospitalized for a median of 8 days (range 1-17), and one subsequently returned to AHH without complications.

Conclusions: Our initial experience with the AHH program in ASCT recipients highlights that a minority were eligible. Some barriers, such as the need for a 24-hour caregiver or living far from the hospital, could be mitigated with additional social resources. While several patients completed the program successfully, readmissions-mainly due to infections- were common. Close coordination with emergency services and thorough patient and caregiver education are essential for safe program implementation.

NG07-02

VITAMIN D MONITORING AND REPLACEMENT IN HAEMATOPOIETIC STEM CELL TRANSPLANTATION: A CLINICAL AUDIT OF PRACTICE AGAINST REGIONAL GUIDELINES

Maeve O'Shea[1], *Victoria Potter*[1], *Michelle Kenyon*[1]
[1]*Kings College Hospital, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Vitamin D deficiency is highly prevalent among haematopoietic stem cell transplantation (HSCT) recipients, driven by prolonged hospitalisation, limited sunlight exposure and treatment-related factors. Increasing evidence suggests that suboptimal vitamin D status is not only common but clinically significant, being linked with poorer bone health, delayed immune recovery and a greater risk and severity of graft-versus-host disease (GvHD) (Mancin et al., 2024). As a modifiable factor, vitamin D represents an important yet under-recognised aspect of supportive transplant care. The South East London (SEL) Clinical Guideline for the Management of Vitamin D Deficiency and Insufficiency in Adults (2023) recommends routine screening and treatment using defined loading and maintenance regimens. This audit evaluated local practice against these standards to identify gaps and opportunities to improve patient outcomes.

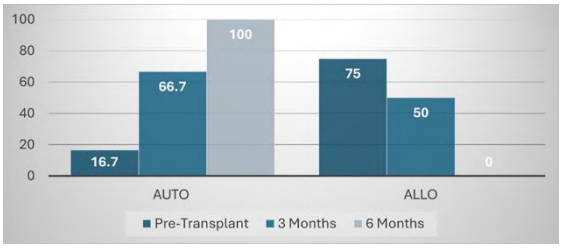
Methods: A retrospective review was undertaken of all patients who underwent HSCT between October 2023 and October 2024 at King's College Hospital. Of 255 patients, 10 who died within six months post-transplant were excluded, leaving 245 evaluable cases (151 autologous, 94 allogeneic). Patient age ranged from 17 to 75 years (mean 55.2). Data were extracted from the electronic patient record (EPIC) at three timepoints: pre-transplant, three months and six months post-transplant. Vitamin D status was classified as deficient (<25 nmol/L), insufficient (25–50 nmol/L) or sufficient (>50 nmol/L). Prescribing of loading or maintenance vitamin D was compared with SEL guideline recommendations.

Results: Vitamin D was tested in 18.3 % of patients pre-transplant, 15.6 % at three months, and 16.0 % at six months, well below the ≥90 % target for high-risk populations. Among those tested, 62.8 % were deficient or insufficient pre-transplant, 55.2 % at three months and 45.0 % at six months. Of the total cohort, 50.6 % received any vitamin D prescription, but prescribing was largely empirical and often unrelated to measured status. Among 20 patients with confirmed deficiency, only 9 (45 %) received an appropriate loading dose. Of 36 patients with insufficiency, 15 (42 %) received maintenance supplementation. Allogeneic recipients were marginally more likely to be tested (20.2 % vs 17.2 % autologous) but were less consistently treated at six months, when none of 3 deficient patients received a loading dose.

Table 1. Vitamin D testing and Deficiency Rates by Timepoint

Timepoint	Patients tested n (%)	Deficient n (%)	Insufficient n (%)
Pre-transplant	45 (18.3)	10 (23.3)	17 (39.5)
3 months	38 (15.6)	5 (10.5)	17 (44.7)
6 months	39 (16.0)	5 (12.5)	13 (32.5)

Figure 1. Appropriate Vitamin D Loading-Dose Prescription in Deficient HSCT Patients



Conclusions: Vitamin D monitoring and replacement in HSCT patients at our centre are inconsistent and substantially below guideline recommendations. Testing occurred in fewer than one in five patients, and only 45 % of those with deficiency received the recommended loading regimen. These results reflect international variation in practice (Ros-Soto et al., 2019; Kenny et al., 2019) and highlight a need for systematic improvement.
Following presentation of these findings to the haematology consultant group, work is underway to introduce automatic vitamin D testing at defined HSCT milestones and implement a standard operating procedure (SOP) for supplementation. A re-audit is planned within 12 months to evaluate improvement in compliance and patient outcomes.

NG27-07

PREPPING WITH PREHAB: A PHYSICAL ACTIVITY FOCUSED "PREHABILITATION" PILOT WITHIN THE ALLOGENEIC BMT PATHWAY

Katie Booth[1]
[1]*Queen Elizabeth University Hospital, Glasgow, United Kingdom of Great Britain and Northern Ireland (the)*

Background: To enhance the care pathway for patients undergoing allogeneic Bone Marrow Transplant (BMT), the Physiotherapy (PT) and Occupational Therapy (OT) team piloted an improvement project to enhance the existing pre-transplant assessment. This initiative aligns

with current evidence supporting early intervention and prehabilitation to improve patient outcomes and Quality of Life (QoL).

Methods: Fifty-nine patients were screened within the pilot, between April and November 2025. 35 completed the "prehabilitation" process, and 29 were admitted for transplant. Patients completed Outcome Measures (OM's)(see Table 1.) during a pre-assessment video consultation and were stratified into Specialist, Targeted, or Universal pathways for tailored follow-up over a six-week period (pre-transplant). OM's were repeated on admission, and functional performance (30-second chair stand test (30s CST)) was reassessed at discharge. Results were compared to those from a 2016–2018 project (N=148) where a virtual pre-transplant assessment was introduced without follow-up. Hospital length of stay (LOS) was used as a secondary OM. The pilot was conducted within the PT/OT team, though it was largely PT-led. As part of standard care, patients also received input from the wider Multi-Disciplinary Team (MDT), including dietetics and psychology.

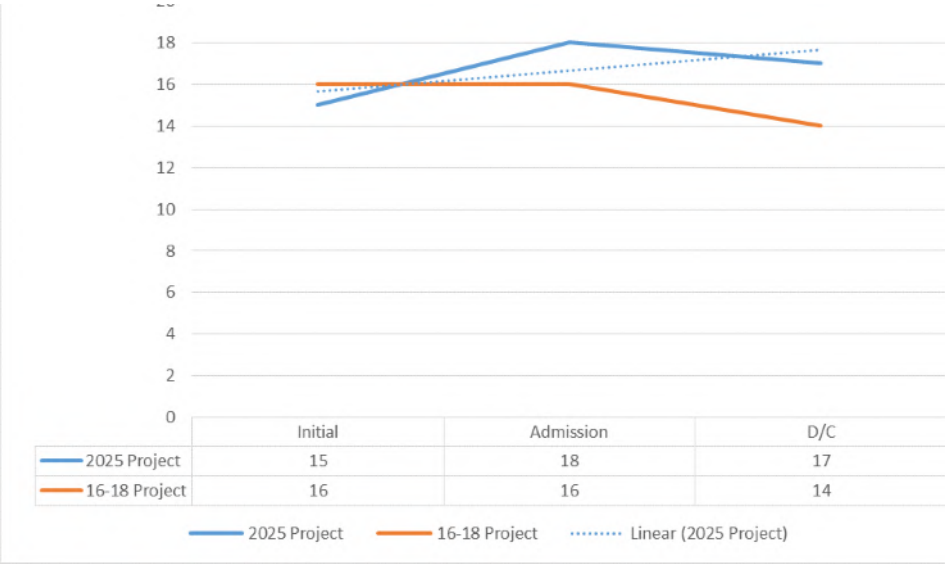
Table 1. Outcome Measures

Time Point	Primary Outcomes	Secondary Outcomes
Pre-transplant Assessment (Initial)	EORTC QLC-C30 30-Second Chair Stand Test Godin Leisure-Time Exercise Questionnaire	-
Hospital Admission for Transplant (Admission)	EORTC QLC-C30 30-Second Chair Stand Test Godin Leisure-Time Exercise Questionnaire	-
Hospital Discharge (Discharge)	30-Second Chair Stand Test	Length of Stay

Caption: *Outcome measures collected at three key time points: pre-transplant assessment, hospital admission, and discharge. Primary outcomes included quality of life (EORTC QLQ-C30), functional performance (30-Second Chair Stand Test), and physical activity (GLTEQ). Secondary outcome of length of stay was recorded at discharge.*

Results: Over half of patients (54%) required Specialist PA support. Functional outcomes improved significantly from initial assessment to discharge (30s CST, $p = 0.0018$), with Universal patients showing the greatest relative gains and Specialist patients showing meaningful improvement from a lower baseline. Targeted patients declined slightly despite similar baseline scores to the Universal group. PA levels increased significantly, with inactivity dropping from 48% to 16% and mean GLTEQ scores rising from 17 to 37 ($p < 0.05$). QoL domains showed no statistically significant change, though physical and role function showed positive trends. Mean LOS was 4 weeks, shorter than the typical 4–6 weeks, with 68% discharged within 4 weeks.

Graph 1. 30s CST Change



Caption: *Physical activity scores improved in the 2025 Project from initial assessment (15) to admission (18), with a slight decline at discharge (17), indicating sustained benefit. In contrast, the 16–18 Project showed minimal change at admission (16) and declined to 14 at discharge, suggesting reduced long-term impact.*

Conclusions: Introducing a PA based prehabilitation approach to the allogeneic BMT pathway shows promise for improving functional outcomes, with improvements maintained throughout treatment. Targeted patients demonstrated the least functional improvement and may require an adapted approach. QOL scores did not demonstrate significant change which could suggest the need for further OT and wider MDT involvement. Although there is some evidence correlating with reduced LOS, further investigation is required to evaluate this and explore associated cost-effectiveness.

NP14

GUIDING NURSING-LED STRATEGIES TO PREVENT CATHETER-RELATED BLOODSTREAM INFECTIONS DURING ALLOGENEIC HSCT: INFLUENCE OF CATHETER TYPE AND TIMING

Maria Teran-Diaz[1], *Juan Manuel Cerezo-Martin*[1], *Olga Zamanillo-Algorri*[1], *Patricia Maria Retuerta-Agudo*[1], *Esther Lopez-Ramos*[1], *Elba Velez-Blanco*[1], *Irene Fernandez-Bardon*[1], *Irene Gorostidi-Alvarez*[1], *Jose Antonio Flores-Garcia*[1], *M. Aranzazu Bermudez-Rodriguez*[2], *Lucrecia Yañez-San Segundo*[2]

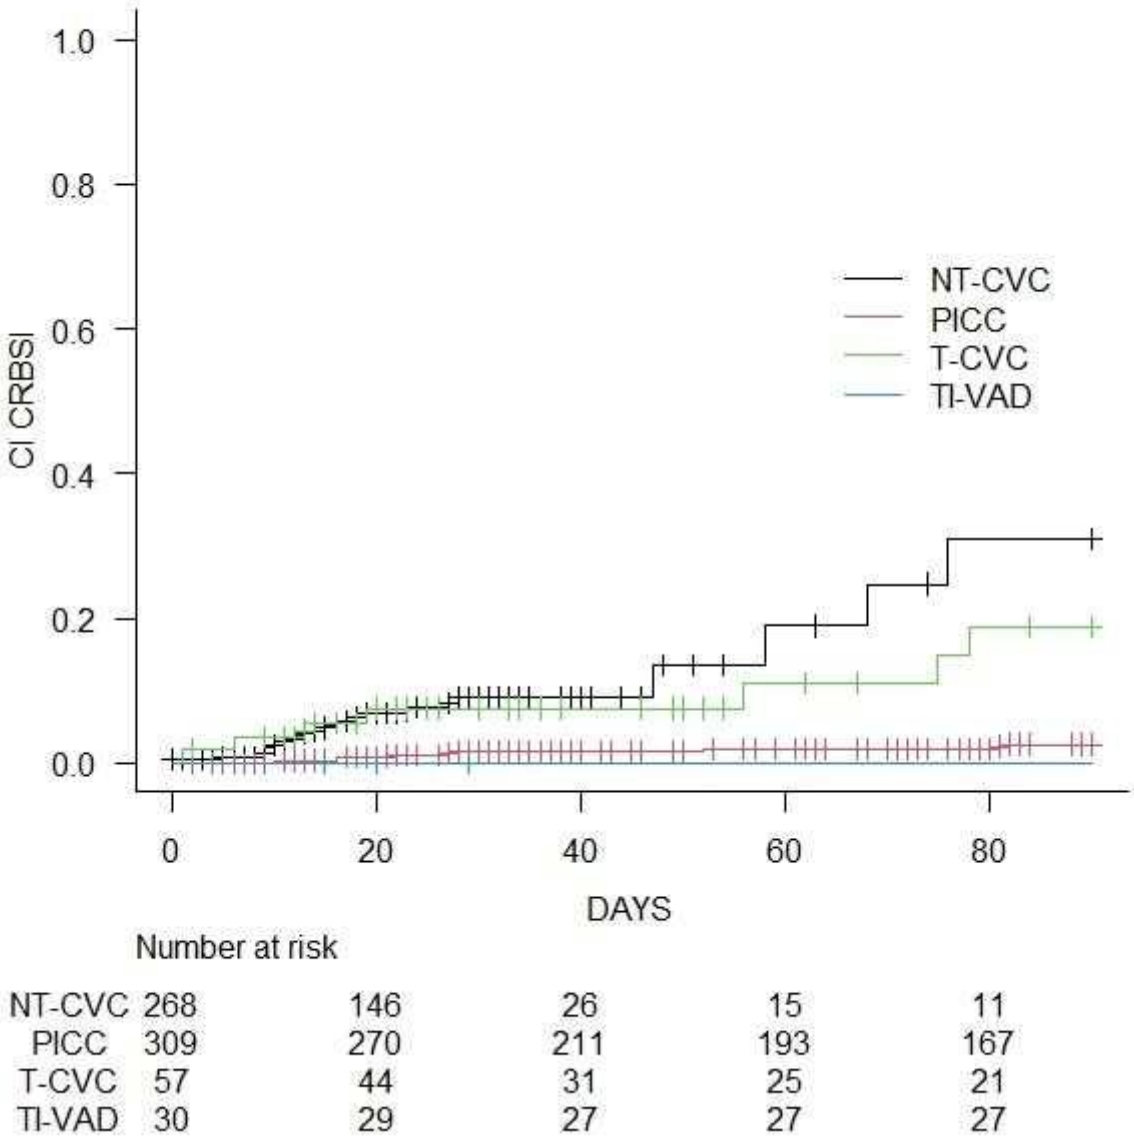
[1]Hospital Universitario Marques de Valdecilla, Santander, Spain, [2]Hospital Universitario Marques de Valdecilla, Universidad de Cantabria, Santander, Spain

Background: Catheter-related bloodstream infections (CRBSI) during allogeneic transplantation (Allo-HSCT) represent a critical factor influencing patient morbidity and mortality. Proper use and maintenance of central venous catheters (CVC) throughout the transplantation process are essential to minimize infection risk. There are only a few reports describing how catheter type and timing influence CRBSI incidence and how this information can guide nursing interventions. This study aims to evaluate it, providing insights into their chronological development and potential preventive strategies.

Methods: We performed a single-center, retrospective, descriptive study of patients who underwent Allo-HSCT at our institution between 2015 and 2024. The catheters included in the analysis were: PICC (peripherally inserted central catheter), NT-CVC (non-tunneled central venous catheter: jugular, subclavian, and femoral), T-CVC (tunneled central line catheter), and TIVAD (totally implantable venous access device). Catheter-related infections were defined according to the EBMT IDWP 2025. Cumulative incidences (CI) were calculated from catheter insertion to removal.

Results: We analyzed 432 patients. The median age was 56 years, and 62.3% of the patients were male. The most frequent diagnoses were AML (37.5%).
A total of 694 catheters were reported. Of these, 32% (n=225) were the first catheter for a patient, 35% (n=241) were the second, and 33% (n=228) were third or subsequent. The most frequent catheter types were PICCs (44%; n=311), NT-CVCs (39%; n=271), T-CVCs (8%; n=58), TIVADs (6%; n=42), and unspecified CVCs (2%; n=12).
Median catheter durations were: PICCs 98 days (IQR 33–175), NT-CVCs 21 days (IQR 13–27), T-CVCs 51 days (IQR 20–180), and TIVADs 654 days (IQR 298–981). We identified 190 bacteremia episodes in 132 patients, of which 47 were classified as definite CRBSI. Among these, 68% (n=32) were caused by Gram-positive cocci, 23% (n=11) by Gram-negative bacilli, and 9% (n=4) by other pathogens. The most commonly identified species was *S. epidermidis* (38%; n=18).
Median time to CRBSI was 88 days (IQR 29–160) for PICCs, 21 days (IQR 14–27) for NT-CVCs, 32 days (IQR 15–109) for T-CVCs, and 685 days (IQR 218-981) for TIVADs. The CI of CRBSI at days 7, 15, 30, and 90 was 1% / 2.4% / 4.7% / 8%. CI at days 7, 15, and 30 for PICCs was 0 / 0.3% / 1.5%, for NT-CVCs 0.8% / 4.3% / 8.9%, for T-CVCs 3.5% / 5.4% /

7.5%, and no CRBSI was observed at day 30 for TIVADs (p<0.01). (Figure 1).



Conclusions: Time to infection varies by catheter type, emphasizing the need for nursing-led monitoring and preventive interventions to reduce infection risk.
T-CVCs and NT-CVCs present the highest early risk of infection, reinforcing the need for intensive monitoring during the first weeks after insertion. In our center, PICCs are the preferred catheter for Allo-HSCT due to their safety and ease of use, although their infection risk increases over the long term, underscoring the importance of ongoing vigilance. TIVADs

remain the safest option for prolonged use.
Infections occur predominantly due to Gram-positive cocci, particularly *S. epidermidis*, highlighting the critical role of strict hand hygiene and aseptic handling by nursing staff.

Disclosure: No disclosure.

NP23

HEALTHCARE PROFESSIONALS' AND MANAGERS' EXPERIENCES AND PERCEPTIONS OF IMPLEMENTING CHANGE – IN THE CONTEXT OF ALLOGENEIC STEMCELL TRANSPLANTATION

Anna O'Sullivan[1,2], *Carina Lundh Hagelin*[1,3], *Jeanette Winterling*[3,4], *Annika M Kisch*[5,6], *Karin Bergkvist*[7]
[1]*Department of Health Care Sciences, Marie Cederschiöld University, Stockholm, Sweden,* [2]*Department of Nursing, Sophiahemmet University, Stockholm, Sweden,* [3]*Department of Neurobiology, Care Sciences and Society, Division of Nursing, Karolinska Institutet, Stockholm, Sweden,* [4]*Karolinska Comprehensive Cancer Centre, Medical unit HHLH, Karolinska University Hospital, Stockholm, Sweden,* [5]*Department of Health Sciences, Lund university, Lund, Sweden,* [6]*Department of Hematology, Oncology and Radiation Physics, Skåne University Hospital, Lund, Sweden,* [7]*Department of Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden*

Background: A successful introduction of new work practices and them becoming routine work depends on the context, healthcare professionals' response to the intervention and the prevailing culture and climate. Therefore assessing the organisation's readiness for change early in the process is crucial to create a sustainable implementation. This knowledge can inform implementation strategies, support that the new way of working remains over time at the site, as well as guidance for future implementations in other contexts. The aim of this study was to investigate the organisations' readiness for change and prerequisites for implementing a new way of working in a highly specialised hospital care setting.

Methods: A cross-sectional survey with 94 participating health care professionals (HCP) and mangers from two centres for allogeneic hematopoietic stem cell transplantation (allo-HCT) in Sweden was employed to investigate their experiences of working with change and organisational readiness for change (ORC). HCPs' and mangers' experiences of working with change and readiness for change was further investigated through nine individual and four focus group interviews at the two centres. The ORC instrument has four factors with sum scores *Motivation for change, Resources, Staff Attributes* and *Organisational climate.* The four factors are made up by twenty subscales and in total 113 items, with responses on a Likert scale and sum scores ranging between 10-50. A score of 30 is considered a neutral midpoint, reflecting neither overall agreement nor disagreement. Scores closer to 50 reflect strong agreement, and scores closer to 10 reflect strong disagreement.

Results: The overall organisational readiness for change scored a neutral average (36.6), with the four factors mean sum scores ranging between 32.59 – 41.75 and subscale mean

sum scores ranging from 31.16-43.68 (Table 1), indicating that no area requires major development before implementing new practices. While staff generally reported good working climate, trust, leadership, and openness to change, time constraints and stress were significant barriers (50% lacked time; 90% reported stress). Most staff felt capable of adapting to change, though 67% expressed concern about future workplace conditions. There was a significant positive association between being a woman and the factor *Motivation for change,* with women being more likely to have higher scores for motivation to change (B=5.30; CI: 1.19-9.42; p=0.01). The interviews supported the findings from the quantitative data and indicated that HCPs and managers perceive change initiatives as complex, often shaped by previous experiences where projects were launched, but failed to achieve long-term impact. Preference was expressed for bottom-up approaches, and the importance of communication, preparation, and a clear purpose. Barriers included time and resources; facilitators included ambassadors, leadership, and support. The context allo-HCT was posed as highly specialised oncology care characterised by high workload.

Table 1. Results for the four factors of organisational readiness for change

FACTOR	SUBSCALES (Factor)	Mean sum score (SD)*	Range
Motivation for Change	Program needs	32.98 (8.41)	12-47
	Training needs	32.26 (7.15)	10-50
	Pressures for change	31.89 (6.06)	13-45
Resources	Workplace	33.42 (11.50)	10-50
	Staffing	31.16 (6.50)	17-43
	Training	35.22 (6.32)	20-48
	Equipment	38.84 (4.75)	27-47
	Internet	43.62 (3.64)	35-50
Staff Attributes	Growth	38.13 (7.97)	12-50
	Efficacy	43.68 (4.79)	30-50
	Influence	43.31 (5.32)	30-50
	Adaptability	40.98 (4.36)	30-50
	Satisfaction	41.99 (5.85)	25-50
Organisational climate	Mission	34.29 (7.29)	18-50
	Cohesion	38.90 (6.56)	15-50
	Autonomy	35.84 (3.61)	28-48
	Communication	36.67 (6.56)	16-48
	Stress	38.03 (7.42)	20-50
	Change	35.81 (4.33)	26-44
	Leadership	35.34 (4.75)	24-46

*A score of 30 is considered a neutral midpoint, reflecting neither overall agreement nor disagreement. Scores closer to 50 reflect strong agreement, and scores closer to 10 reflect strong disagreement.

Conclusions: In the context of specialised allo-HCT care, the organisation demonstrates moderate readiness for change; however, successful implementation of new work practices will depend on balancing workload demands with adequate resources. Findings from ORC surveys and staff interviews provide critical insights to guide planning and support prior to integrating new interventions into routine practice.

Disclosure: Nothing to declare.

NP31

IMPLEMENTATION OF NEUTROPENIA PATHWAY TO IMPROVE ANTIBIOTIC TURNAROUND TIME IN PEDIATRIC BMT PATIENTS AT ABU DHABI BONE MARROW TRANSPLANT PROGRAM, CENTER OF EXCELLENCE (UAE)

Mary Ann Monica Reyes[1], Gladilyn Bakil[1], Roselle Del Rosario[1], Asia Abdalla Ibr[1], Ciba Raphael[1], Sabah Zahooruddin[1], Rafik Karam Fadl Allah[1], Rasha Wahdan[1], Nameer Al Saadawi[1], Jayakumar David Dennison[1], Mansi Sachdev[1], Mohamed Abu Haleeqa[1], Sakher Obeidat[1], Maysoon Al Karam[1], Fatema Al Kaabi[1], ***Dina El Mouzain***[1]
[1]*Yas Clinic Khalifa City/Abu Dhabi Stem Cell Center, Abu Dhabi, United Arab Emirates (the)*

Background: Pediatric patients undergoing bone marrow transplants are highly immunocompromised and at significant risk for life-threatening infections due to intensive chemotherapy, conditioning regimens, and prolonged neutropenia. Fever is often the earliest sign of sepsis or bacteremia, and even brief delays in empiric antibiotic therapy can lead to rapid deterioration. Early antibiotic administration is consistently linked to reduced morbidity and mortality. Historically, our center in the United Arab Emirates lacked a standardized neutropenia pathway, resulting in variable clinical responses and delayed antibiotic initiation. To address this, the pediatric BMT team implemented a quality improvement project to develop a standardized pathway aimed at improving the timeliness and consistency of antibiotic administration while aligning care with international standards. The primary aim was to reduce the mean antibiotic turnaround time from physician order to medication administration by 30 minutes or less for febrile neutropenic pediatric BMT.

Methods: A multidisciplinary team of physicians, nurses, and pharmacists developed and implemented the neutropenia pathway, outlining clear step by step actions with defined nursing and pharmacy responsibilities. Education was central to rollout, with nursing staff receiving targeted training through in-service sessions, case-based discussions, unit huddles, electronically distributed materials, and ongoing competency validation to ensure adherence. Operational changes were also introduced to support timely antibiotic administration, including stocking key empiric antibiotics on the unit to eliminate pharmacy dispensing delays and requiring all antibiotics to be ordered as STAT in the electronic medical record to ensure prioritization. Following implementation, an audit was conducted to assess nursing compliance through a retrospective chart review of 40 febrile neutropenic episodes over a 10-month period in pediatric BMT. Three timepoints were collected for each episode: fever identification, antibiotic prescription, and antibiotic administration. Antibiotic turnaround time (TAT) was defined as the interval in minutes between prescription and administration. Compliance was calculated as (episodes with TAT ≤ 30 minutes ÷ total analyzed episodes) × 100, and monthly performance trends were assessed using mean, median, and interquartile range (IQR).

Results: The quality improvement project was Initiated in January 2025 until October 2025. Compliance improved steadily, reaching 100% by July and was maintained up to October.

Across all audited episodes, the mean TAT was above 30 minutes between February and April which improved May forward. Monthly trends demonstrated early delays, with the highest mean TAT in February (76.7 minutes), followed by progressive improvement beginning in May (26.0 minutes), and the lowest mean TAT achieved in September (7.5 minutes).

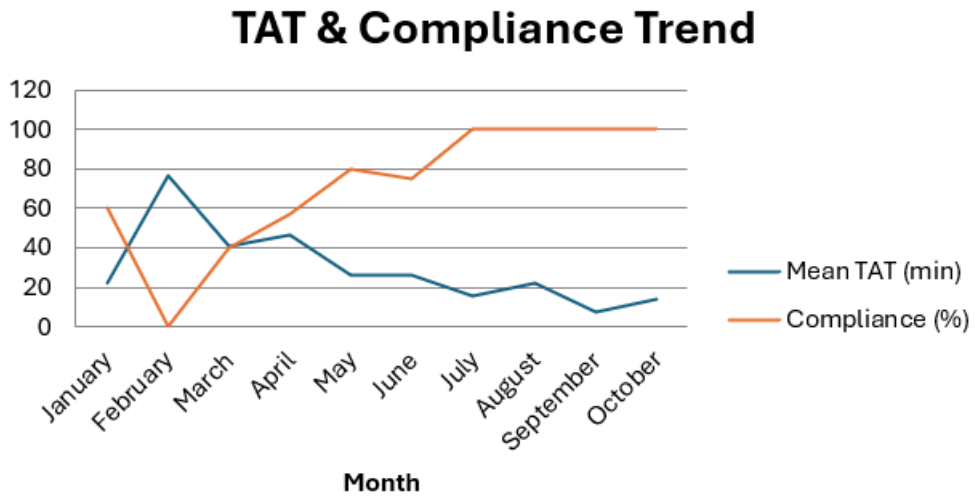


Table1.Monthly Antibiotic Turnaround Time (TAT) Performance, Jan-Oct.2025

Month	Total Episodes (n)	Mean TAT (min)	Median (min)	TAT ≤30 min (n=episodes)	Compliance (%)
January	5	21.8	21.0	3	60%
February	3	76.7	71.0	0	0%
March	5	40.8	47.0	2	40%
April	7	46.9	29.0	4	57%
May	5	26.0	26.0	4	80%
June	4	26.0	28.5	3	75%
July	5	15.6	15.0	5	100%
August	3	22.3	20.0	3	100%
September	2	7.5	7.5	2	100%
October	1	14.0	14.0	1	100%

OVERALL	40	32.0	25.5	27	67.5%

Conclusions: The developed neutropenia pathway significantly improved timely antibiotic administration in febrile neutropenic paediatrics BMT. Enhanced nursing compliance, interdisciplinary communication, and reduced care variability were achieved through structured workflow. Sustained improvement demonstrates the value of structured clinical pathways in promoting patient safety and optimizing outcomes.

NP41

READINESS FOR DISCHARGE – HOLISTIC UNDERSTANDING OF THE PATIENT JOURNEY FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION

Deeb Azaiza[1], Julia Basin-Radin[1], Cristina Salameh[1], Tatiana Litvinov[1], ***Lubna Khatib***[1]
[1]Rambam Health Care Campus, Haifa, Israel

Background: Allogeneic stem cell transplantation (allo-SCT), a life-saving treatment for multiple hemato-oncological patients, is characterized by a complex hospitalization and discharge process. The post-transplant transition from hospital to home is a critical stage associated with increased risk of morbidities, particularly, infections, and the development of acute graft-versus-host disease (aGVHD), all requiring hospital readmissions. Therefore, thorough and structured discharge preparation, encompassing patient education for self-management and timely recognition of early signs of complications, is essential and should be initiated early during the inpatient phase. SCT coordinators and nursing staff, providing continuous clinical patient-centered support throughout the transplantation course, play a pivotal role in planning, implementation, and optimization of the discharge process. The current study, conducted by the multilingual SCT nursing team at a tertiary-care medical center, aimed to identify the principal determinants of patients' discharge readiness and to establish the basis for targeted, evidence-based interventions, designed to improve patient safety, ensure care continuity, and reduce post-transplant complications and hospital readmissions.

Methods: In this quantitative observational study, validated questionnaires in Hebrew, Arabic, and Russian were used to evaluate patient's discharge readiness in key domains, including illness perception, language and communication barriers, compliance to treatment, medication management and discharge instructions comprehension. The questionnaires were distributed by nurses on the discharge day with request to be completed within the next 24-48 hours. Independent samples t-tests and Pearson correlation coefficients were applied to examine relationships between language characteristics, illness perception, treatment compliance, and discharge readiness. SPSS was used.

Results: The study included 60 post-allo-SCT patients [65% males, median age 54.1 (range, 20-77) years]. The study population was multicultural (46.7% Muslim, 40.0%

Jewish, 8.3% Christian, 5.0% Druze), showing substantial linguistic diversity (40% native Hebrew and 40% Arabic speakers, 10% Russian speakers, 10% speakers of other languages). A total of 83% of participants preferred receiving medical information and instructions in their native language. Approximately one-third of patients indicated low/insufficient proficiency in Hebrew. While oral explanations were provided by multilingual nurses, written discharge recommendations were given in Hebrew (primary official language). Overall discharge readiness levels were moderate to high (mean 3.1, SD=0.89), but varied significantly: highest for Hebrew-speakers (median 3.32) and lowest for Russian-speakers (median 2.28). Statistically significant differences were revealed in instructions comprehension ($p < 0.001$) and medication management ($p=0.005$). Significant positive correlations were found between discharge readiness and illness perception ($r=0.353$, $p < 0.01$), Hebrew proficiency ($r=0.470$, $p < 0.01$), and treatment compliance ($r=0.483$, $p < 0.01$). While overall readiness did not differ by the native language, native Hebrew speakers showed significantly higher readiness regarding medication management [$t(58) = -2.558$, $p=0.013$].

Conclusions: Post-allo-SCT discharge readiness is found to be influenced not only by clinical parameters, but also by psychological and communicative factors, illness perception, comprehension of instructions and treatment compliance. These findings highlight the need to incorporate culturally and linguistically tailored education into discharge planning. The study supports the development of a holistic, ward-based model emphasizing adaptive illness perception, patient-centered communication, and individualized preparation for home care, with the potential to reduce complications, prevent readmissions, and promote health equity.

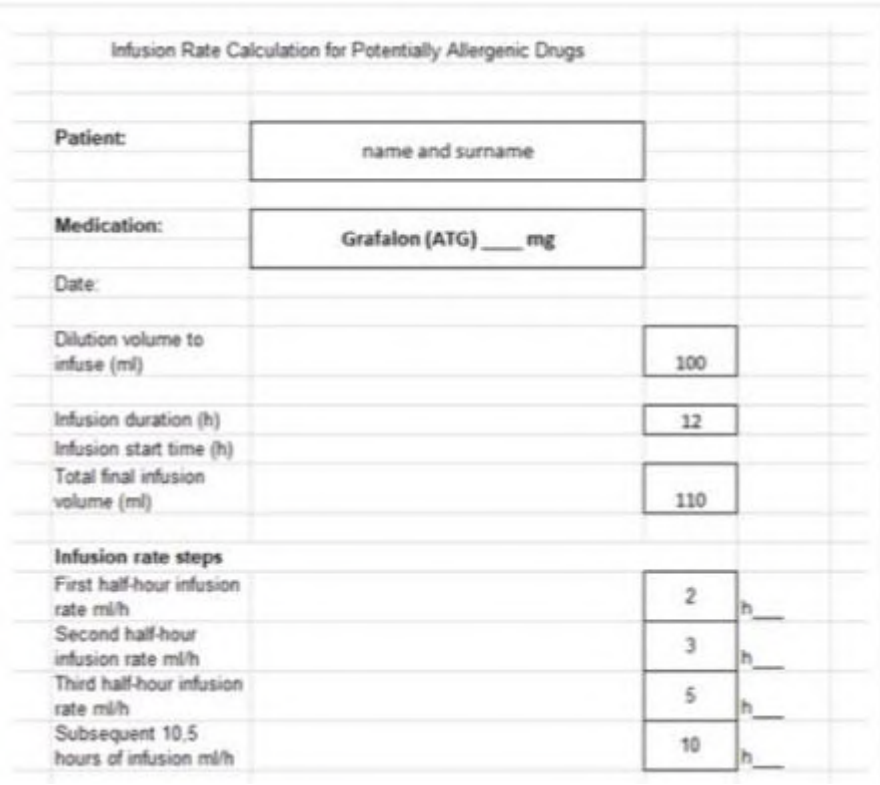
ADMINISTRATION OF GRAFALON® (ATLG) WITH A GRADUALLY INCREASING INFUSION RATE: IMPACT ON TOLERABILITY IN PEDIATRIC PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION

Giulia Pessina[1], Cyriaque Ndayishimiye[1], Raffaella Garbarino[1], Evelina Olcese[1], Alessia Salvatore[1], Tiziana Pastorino[1], Benedetta Pezza[1], Sonia Bianchi[1], ***Simona Calza***[1]*, Maura Faraci[1]*
[1]IRCCS Istituto Giannina Gaslini, Genoa, Italy

Background: Grafalon® (ATLG, anti-T-lymphocyte globulin) is a polyclonal immunoglobulin widely included in the preparatory regimen before allogeneic hematopoietic stem cell transplantation (HSCT), aimed at preventing graft rejection and graft-versus-host disease (GvHD). However, infusion-related reactions are frequent adverse events, potentially dependent on dose or infusion duration. At our HSCT unit, a procedure involving a

progressively increasing infusion rate was introduced to improve drug tolerability and reduce the severity of infusion reactions.



Infusion Rate Calculation for Potentially Allergenic Drugs

Patient:	name and surname	
Medication:	**Grafalon (ATG) ____ mg**	
Date:		
Dilution volume to infuse (ml)		100
Infusion duration (h)		12
Infusion start time (h)		
Total final infusion volume (ml)		110
Infusion rate steps		
First half-hour infusion rate ml/h		2 h___
Second half-hour infusion rate ml/h		3 h___
Third half-hour infusion rate ml/h		5 h___
Subsequent 10,5 hours of infusion ml/h		10 h___

Methods:

A retrospective observational study was conducted on 69 pediatric patients who received allogeneic HSCT at Istituto G.Gaslini, between April 2019 and May 2023. Data were collected on demographic characteristics, underlying disease, conditioning regimen, GvHD prophylaxis, Grafalon® dosage, and infusion modality and reactions. The drug was administered in 12 hours according to a gradually increasing infusion rate (Figure 1) with increments every 30 minutes for the first 1.5 hours until reaching the final rate, maintained for the remaining hours. All infusion reactions, management strategies, and infectious complications (CMV reactivation) were recorded.

Results: A total of 39 patients (56.5%) experienced at least one reaction during Grafalon® infusion, most commonly fever (n=31), chills or malaise (n=13), and tachycardia (n=11). Among these, 11 patients (28.2%) developed a second reaction and 2 (5.1%) a third, all of which were successfully managed through temporary suspension and supportive therapy, without requiring permanent discontinuation. The average infusion duration in cases with multiple reactions was prolonged (up to 14 hours), but overall tolerability was good. CMV reactivation occurred in 26 patients (37.7%), consistent with expected rates in the transplant population.

Conclusions: The adoption of a progressively increasing infusion rate for Grafalon® administration proved effective in reducing the severity of infusion reactions, ensuring better

tolerability and treatment continuity. This experience highlights that a standardized and shared nursing protocol for drug administration and monitoring represents a safe and reproducible strategy, with potential benefits for the quality of care in pediatric HSCT patients.

Clinical Trial Registry: not apply

AN OBJECTIVE PATIENT NEEDS-BASED ACUITY TOOL FOR THE STEM CELL TRANSPLANT PATIENT POPULATION

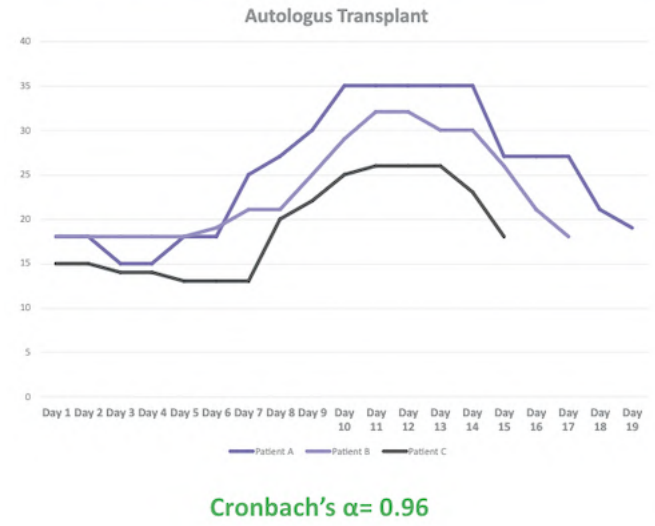
Jill Trzaska[1]
[1]*Northwestern Memorial Hospital, Chicago, United States of America (the)*

Background: Correctly identifying patient care needs per shift and equally balancing nursing workload increases nurse satisfaction and optimizes resources needed to provide appropriate levels of care on an inpatient stem cell transplant (SCT) unit. There also is not a standardized objective acuity tool for the SCT patient population and literature supports the use of tailored acuity tools for speciality patient populations. Since the SCT patient population comes with its own specific set of needs that creates complexity in care, it is vital that they are accurately represented to provide the safest and highest quality nursing care.

Methods: Observation and pre-implementation feedback on the existing process supported the need for a defined grading approach. Utilizing the DMAIC (Define, Measure, Analyze, Improve, Control) methodology, an objective acuity tool was designed to the needs of the SCT population through literature search and staff input. Each nurse filled out one acuity tool per shift, turned it into the charge nurse, and the total acuity number for each patient was utilized to equally balance workload between all nurses. When determining the reliability and accuracy of the tool, the acuity sheets were collected from day shift and night shift across a 4 month period. Patients were randomly selected from different time frames to determine acuity trends from time of transplant to discharge. This data was then streamlined into a spreadsheet and the data was graphed for visual trends in the different stem cell transplant types. Cronbach's alpha was calculated utilizing the data and scores that were input into the spreadsheet.

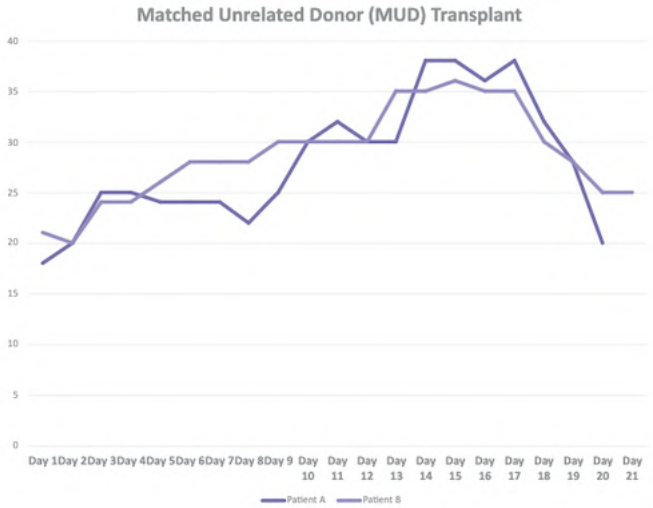
Results: The development and implementation of the objective acuity tool was successful, with a 61% increase in accurately grading patient acuity, a 48% increase in balanced nursing workloads, and a 45% increase in satisfaction with patient acuity in nursing assignments. The tool is reliable with **α=**0.93, and 97% of staff feel the implementation was beneficial.

Results



Cronbach's α= 0.96

Cronbach's α= 0.91



Conclusions: Overall, the development and implementation of an objective patient needs-based acuity tool has been successful on the SCT unit at a large urban academic medical center. The consensus from the nurses on the unit is that the implementation of the tool has been beneficial, and staff have noticed a more balanced workload between each nurse on shift. The nursing staff also feel that the tool accurately reflects the care their patients are requiring per shift, helping them to better identify their total patient acuity and nursing workflow. This tool can be adopted and adapted to other institutions' needs as well as when novel treatments arise, which may warrant new categories to be added utilizing the reliable basic framework of the tool to improve quality of nursing and patient care.

Clinical Trial Registry: Not a clinical trial

CENTRAL VENOUS CATHETER MANAGEMENT AND REMOVAL PATTERNS IN ALLOGENEIC HSCT: INSIGHTS FOR NURSING PRACTICE

Maria Teran Diaz[1], *Patricia M. Retuerta Agudo*[1], *Esther Lopez Ramos*[1], *Olga Zamanillo Algorri*[1], *Irene Fernandez Bardon*[1], *Elba Velez Blanco*[1], *Irene Gorostidi Alvarez*[1], *Jose Antonio Flores Garcia*[1], *M. Aranzazu Bermudez Rodriguez*[1,2], *Lucrecia Yañez San Segundo*[1,2], *Juan Manuel Cerezo Martin*[1]
[1]*Hospital Universitario Marques de Valdecilla, Santander, Spain,* [2]*Universidad de Cantabria, Santander, Spain*

Background: Central venous catheters (CVCs) are fundamental in allogeneic hematopoietic stem cell transplantation (Allo-HSCT), providing access for treatment and supportive care. Nursing staff play a key role in catheter management and complication detection. This study evaluates the reasons for catheter removal and aims to identify areas for improvement.

Methods: We performed a single-center, retrospective, descriptive study of patients who underwent Allo-HSCT at our institution between 2015 and 2024. The catheters included in the analysis were of the following types: PICC (peripherally inserted central catheter), NT-CVC (non-tunneled central venous catheter), T-CVC (tunneled central venous catheter), and TIVAD (totally implantable venous access device).
The reasons for catheter removal were recorded, including catheters placed during the transplant or those already in place at the time of transplantation. Subsequent catheters per patient were also included.

Results: We analyzed 432 patients. The median age was 56 years, and 62.3% were male. The most frequent diagnoses were AML (37.5%) and MDS (13.4%).
A total of 694 catheters were analyzed. The most frequent catheter types were PICCs (44%; n=311), NT-CVCs (39%; n=271), T-CVCs (8%; n=58), TIVADs (6%; n=42), and unspecified CVCs (2%; n=12).
Median catheter duration varied by type: NT-CVCs 22 days (IQR 13–28), T-CVCs 51 days (IQR 20–180), PICCs 98 days (IQR 33–175), and TIVADs 654 days (IQR 298–981).
Catheter removal occurred in 97% of cases. The indications for removal were end of treatment (49% n=335), exitus (13% n=93), persistent fever (10% n=70), signs of local infection (9% n=58), persistent bacteremia (5% n=36), pathogen-directed removal (4% n=27), sepsis/septic shock (3% n=19), thrombosis (1% n=7) and other or unknown reasons (6% n=49).
When indications for catheter removal were analyzed by catheter type, a relevant proportion of infection-related withdrawals was observed, particularly in NT-CVCs (37%, n=100). Within this group, subclavian CVCs showed the highest proportion of infection-related removals (44%, n=26). Infection-related withdrawal was also observed in T-CVCs (34%, n=20), PICCs (25%, n=77), and TIVADs (17%, n=7). In contrast, removal due to end of treatment was the most frequent indication for PICCs (69%, n=215), NT-CVCs (56%, n=152), T-CVCs (35%, n=60), and TIVADs (48%, n=20). Thrombosis was an uncommon indication across all catheter types.
A total of 210 catheters were removed for infection-related reasons (persistent fever, signs of local infection, persistent bacteremia, pathogen-directed removal and sepsis/septic shock).

Regarding catheter tip, 44 (21%) were not sent for culture. The remaining 166 tips (79%) were analyzed, of which 115 (55%) were negative. Details of catheter tip culture submissions are shown in Table 1.

Reason for removal (suspected infection related to catheter)	PERSISTENT FEVER n=70	SIGNS OF LOCAL INFECTION n=58	PERSISTENT BATEREMIA n=36	INDICATED BY PATHOGEN n=27	SEPSIS/SEPTIC SHOCK n=19
Catheter tip not sent	15 (21%)	14 (24%)	11 (31%)	2 (7%)	2 (11%)
Catheter tip sent	55 (79%)	44 (76%)	25 (69%)	25 (93%)	17 (89%)
Cultive negative	48 (69%)	28 (48%)	17 (47%)	11 (41%)	11 (58%)

Conclusions: Most catheter removals in this Allo-HSCT cohort were planned, while infection-related withdrawals were less frequent. Non-tunneled central venous catheters, particularly those placed in the subclavian vein, showed a higher proportion of infection-related removals.
Among the catheters removed at our center, a proportion of catheter tips were not sent for culture. Implementing a protocol to encourage systematic submission of catheter tip samples at the time of removal may help improve monitoring of catheter-related infections.

Disclosure: Nothing to declare.

A NURSING LED QUALITY IMPROVEMENT INITIATIVE SUSTAINING ZERO CLABSI IN A ABU DHABI BONE MARROW TRANSPLANT PROGRAM, CENTER OF EXCELLENCE IN THE UNITED ARAB EMIRATES

Ciba Raphael[1], Asia Ibrahim[1], Mary Ann Monica Reyes[1], Hernito Bernaldez[1], Theresa Combista[1], Jan Michael Tanchia[1], Shayma Alblooshi[1], Karthika Prakash[1], Ehab Bawadi[1], Nameer Al Saadawi[1], Mansi Sachdev[1], Sabah Zahooruddin[1], Maysoon Abdulrahman Al Karam[1], Fatema Al Kaabi[1], ***Dina El Mouzain***[1]
[1]Abu Dhabi Stem Cell Center /Yas Clinic Khalifa City, Abu Dhabi, United Arab Emirates (the)*

Background: Central line associated bloodstream infections (CLABSIs) remain among the most serious yet preventable complications in hematopoietic stem cell transplant (HSCT) recipients. Profound immunosuppression in bone marrow transplant (BMT) patients necessitates strict adherence to evidence-based infection prevention practices to reduce morbidity, mortality, and healthcare burden. Between 2023 and 2025, a series of nursing led CLABSI prevention interventions were implemented in the BMT Unit under the Abu Dhabi BMT (AD-BMT) Program. This initiative was aligned with FACT/JACIE accreditation

requirements and CDC/NHSN surveillance standards to support safe, high-quality care for an expanding adult and pediatric transplant population.

Methods: This observational quality-improvement study assessed CLABSI rates, adherence to central line care bundles, and key nursing performance indicators in the BMT Unit from January 2023 to October 2025. A total of 190 BMT patients were managed by 30 BMT nurses, with 4,335 central line days recorded through retrospective chart review from line insertion date to removal.
CLABSI surveillance followed CDC/NHSN laboratory-confirmed BSI definitions, and central line days were counted by NHSN methodology. The CLABSI rate was calculated as the number of CLABSI events divided by the total number of central line days, multiplied by 1,000; during the study period, zero CLABSI events over 4,335 central line days resulted in a CLABSI rate of 0 per 1,000 central line days
A multidisciplinary infection prevention framework was implemented in response to increased patient volume. The intervention included standardized central line insertion and maintenance bundles aligned with CDC, INS, and ONS guidelines. All patients received the full central line care bundle, and 100% of nurses completed structured onboarding and annual competency validation covering aseptic technique, hub disinfection, dressing change protocol, catheter access procedures, and maintenance of sterility.
Daily line necessity audits, real-time adherence monitoring, hand hygiene surveillance and daily safety huddles supported continuous quality assurance. Simulation-based training, bedside coaching, and a one-to-one preceptorship model were used to reinforce nursing practice. Patient and family engagement was integrated into central line education to promote shared accountability in infection prevention.
Performance data including Central line bundle compliance, hand hygiene adherence, and line-days were reported to the ADBMT program Quality Department and the Department of Health (DOH) for validation and regulatory KPI reporting.

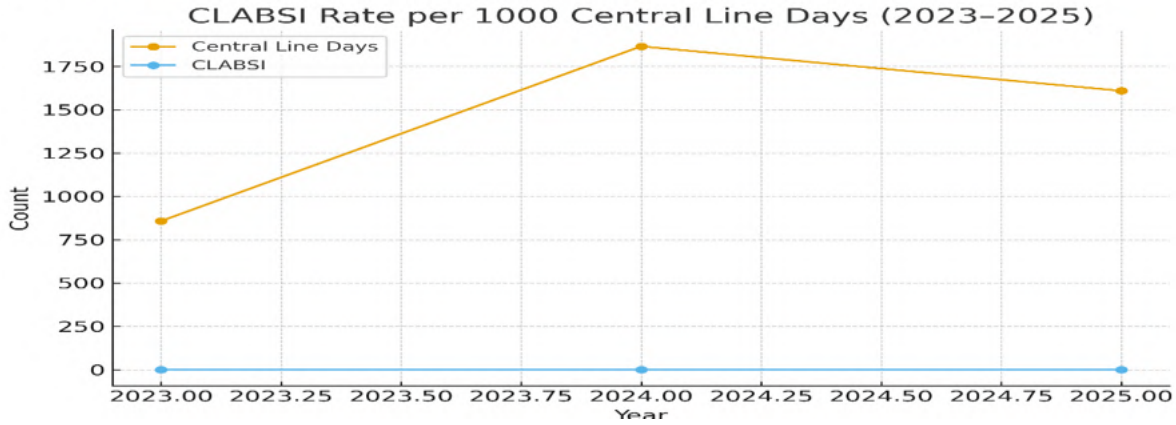
Results: From January 2023 to October 2025, the BMT Unit sustained a CLABSI rate of 0 infections per 1,000 central line days despite high central line utilization rates among BMT patients. Central line care bundle adherence remained at 100%, verified through real-time audits and 100% yearly validation of competencies for all BMT Staff

Table1: CLABSI Performance Indicators in the BMT unit

Indicator	Result	FACT/JACIE Relevance
Study period	January 2023 – October 2025 (34 months)	Continuous quality monitoring
HSCT patients (adult & pediatric)	190	Program activity volume
Specialized BMT nurses	30	Qualified staffing
Total central line days	4,335	NHSN surveillance denominator

CLABSI rate	0 per 1,000 central line days	Infection prevention outcome
Central line utilization rate	100%	High-risk population
Central line bundle adherence	100%	Evidence-based practice compliance
Nursing competency validation	100% annually	FACT/JACIE competency standards
Hand hygiene compliance	100%	Infection control KPI
Patient & family education	100% participation	Patient engagement standard

Figure 1. CLABSI Rate per 1,000 Central Line Days (Jan 2023 – Oct 2025)



Conclusions: Sustaining zero CLABSI over nearly three years in a high-risk BMT population demonstrates the effectiveness of nursing-led, evidence-based practice supported by interdisciplinary collaboration and a robust safety culture. This quality initiative highlights AD-BMT program as a regional leader in infection prevention and reinforces the critical role of nursing leadership in meeting FACT/JACIE standards, advancing patient safety, and achieving sustained quality outcomes. These findings confirm that zero CLABSI is achievable and maintainable through structured education, continuous monitoring, and strong clinical governance.

NP77

IMPLEMENTATION OF THE INCIDENTS NEWSLETTER "LEARNING SHARE TO IMPROVE CARE" IN HAEMATOLOGY AND DAY UNIT TRANSPLANT (HTDU) AND IN AMBULATORY CARE/ WITHINGTON WARD (WW)

Irina Pitacas[1]
[1]*The Christie NHS Foundation Trust, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Incident reporting is a cornerstone of patient safety and it's widely recognised as an important method for improving safety in healthcare (Leistikow et al, 2016). Effective incident reporting, coupled with systematic learning from incidents are essential components of patient safety and quality improvement (Macrae,2025). Sharing incidents with staff - alongside feedback, learning and solutions – not only prevents recurrence of the same or similar incidents, but also fosters an environment for open reporting, learning and improvement (Care Quality Commision, 2016). As part of the Christie CODE Quality Scheme, incidents should be reviewed timely, feedback and learning shared with staff and celebrating success implemented in the units. So, in January 2025, a monthly incident newsletter titled Learning Share to Improve Care was implemented in HTDU and Ambulatory Care/ WW. Designed as concise, one-page resource, the newsletter idea was focused on learning together from incidents, sharing knowledge and improving the nursing care to haematology patients, including patients pre and post autologous and allogenic haemopoietic stem cell in both units. By May 2025, the incident newsletter was formally adopted within the Christie CODE Quality Scheme as a model across the Trust to disseminate learning and reinforce safety culture.

Methods: It is used a qualitative investigation, employing the qualitative content analysis approach. Data collected from the incident newsletters in HTDU and Ambulatory Care/WW from January to August 2025, which was organised and interpreter to elicit themes present in the Newsletter.

Results: A qualitative thematic analysis identified four overarching themes, each with its own set of subthemes, consistently present across Incident Newsletter in HTDU and Ambulatory Care/ WW: (1) incidents and learning, captured the incidents investigated monthly and the sharing learning from them; (2) good practice, highlighted situations where incidents were either unavoidable but managed appropriately through adherence to protocols and SOPs (e.g., transfusion reactions), or potentially avoidable but mitigated by exemplary nursing practice (e.g., ensuring patient safety despite missing consent documentation prior to SACT administration); (3) implementation of new clinical practices reflected proactive measures introduced to reduce recurrence of incidents and enhance patient safety, such as transfusion observation checklist in HTDU or Ambi SACT checklist in Ambulatory Care/WW; and (4) sharing general information, presented in the form of "Did you know?" segments to broaden staff awareness on diverse incident-related topics including duty of candour, cross-match guidelines or extravasation management. Within Ambulatory Care/WW, a recurring feature across all newsletters was the inclusion of inpatient Mini-CODE feedback,

encompassing patient perspectives, staff experiences, and sustainable action plan to maintain gold.

Conclusions: These findings demonstrate how Incident Newsletter *Learning Share to Improve Care* can serve as vehicle for share the learning from incidents, dissemination of best practices, and reinforcement of safety culture. By integrating incident-based learning with staff, the newsletters not only foster transparency but also contribute to embedding sustainable learning culture for improvements.
While this research provides valuable insights of the incident newsletters, future initiatives should incorporate structured staff feedback to ensure a more comprehensive understanding of their impact and to further enhance the effectiveness of the learning share process.

Disclosure: Nothing to declare.

NP79

PATIENT INFORMATION VIDEOS: ENHANCING EXPERIENCE IN AUTOLOGOUS STEM CELL TRANSPLANTATION

Ellie Bonser[1], ***Claire Wood***[1]
[1]*Sheffield Teaching Hospitals, Sheffield, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Effective patient information is essential to empower individuals to make informed decisions, improve health care outcomes, and strengthens communication between patients and healthcare providers (Coulter and Ellins 2007). The Sheffield Teaching hospital Stem Cell Transplant CNS team (STH CNST) conducted a service evaluation audit to offer patients the option to view a series of short videos covering the pathway from Peripheral blood stem cell harvest (PBSCH) to Autologous stem cell transplantation (ASCT). The aim was to improve patient and family satisfaction and experience, and enable a more time effective and efficient patient preparation for someone undergoing ASCT.

Methods: Project funding was successfully sought from the hospital innovation ideas team, this enabled collaboration with the media company with expertise re: how to deliver the content incorporating the recommended optimal length of the videos to support attention span and information retention and engagement (O'Connor A et al 2014). five different videos were created to cover the pathway were created.
The project was evaluated 10 months after the introduction of the videos using a qualitive approach. Patients that had undergone an ASCT were offered the option to complete a questionnaire for video feedback. A QR code was forwarded onto the patients who gave consent to take part. Data was also obtained from the media company to give the results of how many time each individual section had been viewed.

Results: The Videos were watched a total of 800 times, this dose not account for patient and family watching the videos multiple times. Of this introduction the stem cell transplants had the most views.
32 people was contacted received ACST in the last 10 months. 2 people had not watched the

videos, one declined as this was their 2nd ASCT and the remaining 29 had questionnaires sent out to complete. 14 have responded with the highest number of responses coming from the over 55 and male categories.
100% of the patients agreed that the content and the way the information was delivered had a positive impact in their understanding the process of harvest and ASCT, with a 9.6/10 rating for patients understanding of the process of a stem cell harvest and ASCT.
100% of patients found this resource aided them in delivering the information to friends and family effectively.

Conclusions: The implementation of patient information videos for individuals undergoing Autologous Stem Cell Transplantation has demonstrated clear benefits in enhancing patient understanding and engagement. Feedback indicates that the videos support improved health literacy, greater confidence in decision-making, and a more positive overall patient experience. This digital approach has also contributed to improved communication between patients, families, and the multidisciplinary team, promoting shared decision-making and patient empowerment.
By providing accessible and consistent information, the videos have the potential to improve safety, reduce errors, and streamline the patient journey ,delivering both patient-centred and economic benefits for the Bone Marrow Transplant team. Future plans include ongoing evaluation and expansion of the video series to other transplant pathways to further embed digital education within routine care.

NP84

CONFIDENCE IN A BOX: NURSE-SUPPORTED MEDICATION SELF-MANAGEMENT FOR PATIENTS AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

Constance Klaasse[1], *Alien Stevens*[1], *Christien Oudbier*[1], *Rita Verschuur*[1], *Loes Boelens*[1]
[1]*UMC Utrecht, Utrecht, Netherlands (the)*

Background: Patients discharged after allogeneic stem cell transplantation face substantial, complex and frequently changing medication regimens. These medications are critical for this patient group to prevent complications such as infections and graft-versus-host disease (Amonoo et al, 2025). In the outpatient clinic, concerns were raised about the accuracy of patients' self-reported medication adherence. Incomplete medication summaries and limited patient education at discharge increase the risk of medication errors, unplanned readmissions, and preventable adverse effects (Becker et al, 2021).

Methods: Medication adherence was primarily supported by clinician involvement, patients' prior experience with medication management, and the use of organizational aids such as pill boxes and phone timers to help structure doses and ensure consistent timing across the day

(Amonoo et al., 2023). A pilot at the hematology ward was designed and implemented whereby allogeneic stem cell transplantation patients take responsibility for managing their own medication administration during the final phase of their inpatient admission.
A multidisciplinary approach was essential, with nurses, a pharmacist and a physician ensuring clinical accuracy and safe implementation. To ensure consistency, nurses follow a protocol with clear instructions for supporting medication self-management. In the last days of admission, patients receive a pill organizer that can be filled with three days of medication. From that point forward, they take the lead in preparing and administering their own medication while still in the hospital. Nurses play a key role by providing tailored support: they supervise medication rounds, guide patients through the steps, and intervene when uncertainties arise. This supervised practice helps patients gradually develop confidence, understand their treatment better, and recognize potential risks (Dalari et al, 2019).

Results: A patient survey was conducted to evaluate their experience with the intervention. Early results also showed that they felt more confident in managing their medication regimen and appreciated being given greater autonomy prior to discharge. Furthermore, patients described gaining a better understanding of their medication regimen and the correct administration of each drug, consistent with findings by Polito et al. (2021).
Although the intervention requires additional nursing time during hospitalization, it is expected to contribute to improved long-term outcomes, higher patient satisfaction, and potentially reduced medication-related complications or hospital readmissions following patient discharge.

Conclusions: The intervention demonstrates a feasible and scalable approach to promoting medication self-management within inpatient hematology and transplant care. The requirements are low-cost and minimally resource-intensive, enabling straightforward implementation in similar clinical settings. Other units can use this quality improvement project to help patients become more involved and increase medication safety after discharge.

Disclosure: No disclosures.

NP99

WHEN INFECTION DELAYS TRANSPLANTATION – A CASE REPORT OF A PATIENT WITH NECK WOUND INFECTION AND SEPSIS

Ajna Džanić[1], *Nikolina Žinić*[1], *Josipa Belev*[1]
[1]*Clinical Hospital Center Zagreb, Zagreb, Croatia*

Background: Patients undergoing chemotherapy and preparation for allogeneic hematopoietic stem cell transplantation (HSCT) are at high risk of severe infectious complications due to deep immunosuppression. Local infections, such as dental sources, can rapidly progress and jeopardize patient safety, delay treatment, and compromise transplant eligibility. Early recognition of infection and adherence to high standards of nursing care—

particularly through continuous assessment, timely intervention, and vigilant monitoring by specialized nurses—are essential to prevent life-threatening outcomes. This case highlights how infection progression can significantly affect clinical decision-making and the success of hematologic therapy.

Methods: This case report is based on a retrospective review of medical and nursing documentation, clinical observations, and multidisciplinary management during hospitalization, surgical treatment, and follow-up in a patient preparing for HSCT. Particular focus was placed on infection progression, surgical complications, and the scope of nursing interventions required.

Results: A patient with acute lymphoblastic leukemia (ALL) developed progressive infectious complications following an initial dental infection, which worsened during post-chemotherapy aplasia and resulted in gram-negative sepsis caused by Pseudomonas aeruginosa. The infection spread to the soft tissues of the face, requiring surgical incision, removal of necrotic tissue, and later reconstruction with a pectoral flap. Intensive nursing monitoring was required due to swelling, pain, fever, and hemodynamic instability. Postoperatively, continuous pain management, twice-daily wound care, monitoring for secretion and infection, and supervision of Penrose drains were essential. Fifteen days after the initial surgical debridement and removal of necrotic tissue, purulent discharge, necrosis, and a fistulous opening with passage of food developed. The patient refused nasogastric feeding, making enhanced oral hygiene, assisted feeding, and patient-family education crucial components of nursing care. Due to progressive local and systemic deterioration, a second reconstructive surgery was performed. Postoperatively, the patient required intensive monitoring of vital signs, laboratory values, drain output, and hemodynamic stability, including treatment in the intensive care unit during sepsis and aplasia. Nursing care played a central role throughout all phases of treatment: detailed wound assessment, documentation of changes, pain monitoring, administration of analgesics, mobilization support, nutritional assistance, and extensive education on hygiene and home care. After discharge, the patient was followed through home care and community nursing services. Two weeks later, deterioration of general condition, wound worsening, and relapse of the underlying disease resulted in a fatal outcome.

Conclusions: This case highlights how a localized dental infection can rapidly progress into life-threatening complications in immunocompromised patients and delay HSCT eligibility. It underscores the essential role of continuous, highly specialized nursing care in recognizing deterioration, managing complex wounds, preventing complications, and ensuring patient safety. Severe infections, despite preventive measures, remain a major threat to survival and may significantly impact the success of hematologic treatment.

Disclosure: Nothing to declare.

NG07-01

JOURNEY MAPPING AS A METHOD TO EXPLORE THE ADOPTIVE CELL THERAPY EXPERIENCE OF PATIENTS, INFORMAL CAREGIVERS, AND HEALTHCARE PROFESSIONALS

Nina Canova[1,2,3], *Nils Graber*[4], *Noémie Stienne*[1], *Geneviève Natarajan*[1], *Tourane Corbière*[1], *Manuela Eicher*[1,2], *Sara Colomer-Lahiguera*[1,2]
[1]*University of Lausanne (UNIL), Lausanne, Switzerland,* [2]*Lausanne University Hospital (CHUV), Lausanne, Switzerland,* [3]*School of Management and Engineering Vaud (HEIG-VD), HES-SO University of Applied Sciences and Arts of Western Switzerland, Yverdon-les-Bains, Switzerland,* [4]*Humboldt University, Berlin, Germany*

Background: Adoptive Cell Therapy (ACT) is a personalized immuno-oncology approach for hematologic and solid malignancies, increasingly delivered in clinical trial and standard-of-care settings. Current modalities include tumor-infiltrating lymphocyte (TIL) therapy and chimeric antigen receptor T-cell (CAR-T) therapy. The ACT pathway is lengthy and complex, posing unique challenges for patients, informal caregivers (ICs), and healthcare professionals (HCPs). Understanding their psychosocial experiences is essential for providing timely, tailored support. Journey mapping, originally developed in marketing research, is increasingly applied in healthcare to capture how individuals navigate and experience care. As part of a broader service improvement co-design study involving patients, ICs, and HCPs, this project used journey maps to examine shared and distinct psychosocial experiences across ACT care settings, including HCPs' perceptions of patient experiences.

Methods: A qualitative exploratory design with purposive, pragmatic sampling was employed. Participants included patients receiving standard-of-care CAR-T (n=10) or TIL through clinical trial (n=11), their ICs (CAR-T n=7, TIL n=6), and HCPs (n=10; nurses, oncologists, a psycho-oncologist, and research coordinators/associates). Journey mapping was conducted at the end of interviews. Participants received a visual timeline and an optional list of emotions, feelings, and perceptions. They validated key steps, indicated predominant psychological processes at each stage, and reflected on their meaning, co-creating a depiction of the ACT pathway. HCPs completed two maps: one reflecting professional experience and one representing their perceptions of patient experiences. All interviews were audio-recorded and transcribed. Maps were analyzed using a content approach, organizing emotions, perceived social support and control, and coping strategies across care phases (therapy presentation, pre-treatment, treatment, post-treatment). Contextual information was extracted from interviews and findings were triangulated across participant groups and settings to identify convergent and divergent experiences.

Results: Fifty-three maps were analyzed, revealing the ACT pathway as emotionally intense and ambivalent, with actor and setting-specific psychosocial challenges. In general, for patients and ICs, during therapy presentation, hope for a potentially life-extending option

coexisted with fear of complexity, severe toxicities and possible non-efficacy. Pre-treatment stress increased due to diagnostic procedures, logistics, and anticipated hospitalization, while clear communication and preparation enhanced trust. During treatment, relief and hope upon receiving therapy coexisted with fear and surprise at toxicity intensity. Post-treatment trajectories diverged: positive outcomes brought joy, gratitude, and cautious optimism, whereas poor outcomes elicited sadness or anger. Across phases, participants reported periods of high social support, episodes of loneliness, and fluctuating perceived control, ranging from manageability to feeling overwhelmed. Coping strategies spanned emotion-, problem-, and meaning-focused approaches. Notably, HCPs underestimated the emotional impact of care coordination during pre-treatment and physical debilitation during post-treatment, highlighting these two phases as periods with the greatest unmet psychosocial needs and highest priority for targeted interventions.

Conclusions: This study identifies critical psychosocial pressure points across the ACT pathway. Discrepancies between HCP perceptions and lived experiences highlight the importance of proactive, structured psychosocial assessment and the need for targeted support interventions at key moments. Journey mapping proved valuable in capturing emotional shifts and revealing unmet needs that are less evident in traditional interviews, offering actionable insights to strengthen person-centered care across ACT services.

Disclosure: This study was supported by the ISREC Foundation, the Swiss Cancer Research Foundation (KFS-5649-08-2022), and the Ligue Vaudoise contre le Cancer. The authors declare no conflicts of interest related to this work.

GENDER MATTERS: UNDERSTANDING RETURN-TO-WORK EXPERIENCES AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Karine Bilodeau[1,2], *Asma Fadhaloui*[1,2], *Tete Norbert Wilson*[3], *Imran Ahmad*[4,2], *Bertrand Porro*[5,3]
[1]*University of Montreal, Montreal, Canada,* [2]*Maisonneuve-Rosemont Hospital Research Center, Montreal, Canada,* [3]*Université d'Angers, Angers, France,* [4]*Maisonneuve-Rosemont Hospital, Montreal, Canada,* [5]*Institut de Cancérologie de l'Ouest, Angers, France*

Background: Hematopoietic cell transplantation (HCT) is a common treatment for individuals diagnosed with hematologic cancers. However, HCT can lead to side effects that significantly impact work participation. Recent reviews highlight that gender may influence the return-to-work (RTW) experience. As hematologic cancers affect both men and women, it is important to contrast their RTW experiences to better understand how to support them. The aim of this study was to explore and describe similarities and differences between men and women affected by hematologic cancer regarding factors influencing RTW after allogeneic hematopoietic stem cell transplantation (allo-HCT) in Canada.

Methods: This study is part of a larger mixed-method project exploring RTW after allo-HCT. We used a convergent mixed-method design combining quantitative and qualitative approaches to examine gender-based similarities and differences in RTW factors. Quantitative data included a retrospective review of medical records and an electronic vocational survey completed by eligible patients aged 18–60 who underwent allo-HCT between 2016 and 2022 in Montreal (Canada). Qualitative data were collected through semi-structured Zoom™ interviews with purposively sampled survey participants reporting RTW challenges. The categories of determinants for RTW identified by the REWORK framework (Porro et al., 2021) informed the design of the survey and interview guide. Data integration provided a comprehensive understanding of medical, psychosocial, and work-related influences on RTW.

Results: Among 89 participants, a total of 61 patients were included in the survey analysis. Of these, 22 participants took part in a qualitative interview: 9 identified as women and 13 identified as men. Both men and women shared common challenges such as financial insecurity, fear of losing disability benefits, and decreased importance of work post-transplant, alongside medical complications like chronic GVHD and fatigue. However, women reported greater income loss (41% vs. 27%), a slightly lower perception of the importance of work post-transplant, and were more likely to remain in the same job (72% vs. 47%), whereas men experienced more job changes. Men reported greater support for RTW (p=0.011), while women more frequently requested task adjustments (p=0.005) and described struggles to regain previous responsibilities. Fatigue intensity differed (p=0.012), with men reporting high-intensity fatigue and women moderate-intensity fatigue, compounded by increased mental workload for women. Additional contrasts included men's positive perception of family support versus women's negative perception, and women's tendency to seek complementary medical support.

Conclusions: Overall, men and women experienced similar RTW challenges, but notable gender differences emerged. Greater attention is needed to address women's financial losses after allo-HCT and workplace reintegration issues. Assessing social support remains essential, as women may experience less support than men. These findings underscore the need for gender-sensitive RTW interventions tailored to financial, psychosocial, and workplace challenges. Future studies should explore long-term RTW trajectories and evaluate interventions addressing gender-specific barriers.

PERCEIVED BURDEN IN PRIMARY CAREGIVERS FOR AT-HOME HOSPITALIZATION AFTER AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION: A SINGLE CENTER EXPERIENCE

Marta Yusta Arnal[1], *Alba Pla Bou*[1], *Elisabet Pérez Toral*[1], *Mercè Triquell Garrell*[1], *J. M. Portos Villar*[1], *Olga Aso Ferreras*[1], *Aina Papell Penetró*[1], *Laia Alloza Crespo*[1], *Noelia Arranz Padilla*[1], *Núria Font Díaz*[1], *Sara Redondo Velao*[1], *Albert Esquirol Sanfeliu*[1], *Rodrigo Martino*

Bufarull[1], Irene Garcia-Cadenas[1], Javier Briones Meijide[1], Annalisa Paviglianiti[1]
[1]Hematology Department, IR-Sant Pau and José Carreras Leukemia Research Institutes, Barcelona, Spain

Background: At-Home hospitalization (AHH) offers multiple benefits for participating patients, such as greater comfort and a potential reduction in the risk of nosocomial infections. However, its implementation requires intensive participation from the primary caregiver, whose physical, emotional, and social involvement is still poorly known. The aim of this study is to evaluate the perceived burden of primary caregivers of patients undergoing autologous HSCT in an AHH program, by using a structured questionnaire.

Methods: From May 2024 to November 2025, 15 patients underwent autologous HSCT in AHH. All caregivers completed the Modified Caregiver Strain Index (MCSI), a tool that assesses the pressure associated with caregiving for adults of any age. The questionnaire consists of 13 items evaluating the perceived burden of caregiving, with five main domains assessed by at least one item: Financial, Physical, Psychological, Social, and Personal. Each item is scored with 2 points ("yes, on a regular basis"), 1 point ("yes sometimes"), or 0 points ("no"), generating a total score between 0 and 26, where higher values indicate a greater level of burden. The questionnaire was completed once the patients were medically discharged and completed the AHH process.

Results: The primary caregiver were: 9 spouses (60%), 3 siblings (20%), 2 daughters (13%) or 1 parent (7%). They were women in 13 (87%) and men in 2 cases (13%). The Caregiving was provided full-time in 9 cases (60%) and combined with another caregiver in the remaining 6 (40%). The mean overall MSCI score was 9.06/26, being 1/26 the lowest score and 24/26 the highest.
The most frequent low scoring items were "Caregiving is a physical strain" (73% "no"), "Some behaviour is upsetting" (67% no), "There have been other demands on my time" (67% no) and "Caregiving is a financial strain" (67% no) suggesting a very limited physical and financial burden, although a small subgroup reported significant economic strain (27% "yes, on a regular basis"). The subjective feeling of being overwhelmed showed a moderate impact (13% "yes, on a regular basis" and 47% "yes, sometimes"). Among the highest score ("yes on a regular basis") we observed a punctuation for "Caregiving is confining", "There have been changes in personal plans." and "There have been family adjustments," each reported by four caregivers (27%), reflecting a predominantly emotional and organizational burden. Sleep disturbance was frequent (73% reporting "yes, on a regular basis" or "yes, sometimes"), while work-related impact was intermediate (20% and 40% respectively). Overall, the results suggest a moderate caregiver burden with substantial variability across domains.

	YES on a regular basis *2 points*	**YES sometimes** *1 point*	**NO** *0 points*

My sleep is disturbed	2	9	4
Caregiving is inconvenient	2	5	8
Caregiving is a physical strain	1	3	11
Caregiving is confining	4	7	4
There have been family adjustments	4	5	6
There have been changes in personal plans	4	7	4
There have been other demands on my time	2	3	10
There have been emotional adjustments	3	7	5
Some behaviour is upsetting	0	5	10
It is upsetting to find the person I care for has changed so much from his / her former self	1	7	7

There have been work adjustments	3	6	6
Caregiving is a financial strain	4	1	10
I feel completely overwhelmed	2	7	6

Conclusions: Personal limitations, changes in family life, and sleep disturbances were the most significant aspects. In contrast, the physical and financial burden was lower, although a significant impact on employment was identified for some caregivers. These findings underscore the need to incorporate psychological and emotional support interventions, assistance with family reorganization, and resources aimed at reducing caregiver burden in ASCT programs in hematology.

Disclosure: Nothing to declare.

NURSE LED HOLISTIC NEEDS REVIEW CLINIC 100 DAYS POST ALLOGENEIC STEM CELL TRANSPLANT: A SERVICE EVALUATION

Aileen Nield[1]
[1]*Sheffield Teaching Hospitals NHS Trust, Sheffield, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Patients are at risk of significant complications in the early phase of recovery post allogeneic haematopoietic stem cell transplantation (AHSCT). These include infections, acute graft versus host disease (GVHD), and graft failure. Intensive follow-up post discharge focuses on:

- maintaining therapeutic immunosuppression levels
- screening for, treatment and monitoring of acute GVHD
- screening and treatment of infection
- observation of chimerism and disease response

Clinically focussed care is imperative to reduce mortality and morbidity post AHSCT. However, this intensive treatment may have psychosocial and/or spiritual consequences that are not discussed or addressed in standard post-transplant follow up reviews.
A nurse-led holistic needs review clinic at 100 days post AHSCT (HNR100) was established to offer patients the opportunity to share and discuss their concerns, psychological impact and to signpost to places for relevant support.

A 12-month review of the clinic looked at themes of outcomes to establish the relevance and shape future clinic development to best serve patient need.

Methods: Patients were offered an appointment with the post AHSCT clinical nurse specialist at around 100 days post-transplant. This was optional by telephone or in person. Patients were invited to bring a person of significant support to the clinic review.
A clinic proforma was used to standardise and document conversations and outcomes. The proforma was uploaded onto the patient's clinical record with patient consent.
The discussion centred around:

- patient and family expectations in early phase post ASCT recovery
- post ASCT vaccinations
- diet and exercise
- psychological impact
- sex function/contraception
- potential premature ovarian insufficiency (POI)
- work and employment/financial issues
- managing fatigue

The service evaluation gathered 12-month data on the patient population, type of AHSCT, outcomes of holistic review by themes.

Results: 36 (male 58% ,female 42%) patients in 12 month period attended the HNR100 clinic. Median age 53 yrs (range 18-74 years). Telephone was preference for 14%, in person preference for majority (86%).
14% myeloablative, 86% reduced intensity conditioning.
Questions re financial impact (14%) and psychological impact (14%) was joint lead for patients' concerns resulting in referral to benefits advisor or clinical psychology support.
Sex function (8%) and discussions and potential POI (8%) was identified as an outcome of the clinic. This resulted in referrals to finance advisor, clinical psychology, gynaecology, erectile dysfunction clinic as appropriate. All patients given contact details re post-transplant nurse specialist, and signposting information re how to access support and advice post-transplant from relevant charity organisations.
All patients evaluated the clinic as helpful, and welcomed the opportunity to discuss worries and concerns that regular medically led reviews did not always offer.

Conclusions: The HNA100 has been a well-evaluated clinic for both patients and family support members. There is evidence that concerns re financial impact and sex function/POI has been identified at an earlier timepoint by direct questioning in a holistic review, with prompt referral to access help and support. There is an opportunity to formally evaluate psychological impact using an evaluated tool, this is the next phase of the clinic development.

Disclosure: Nothing to declare.

NP89

POST-TRAUMATIC STRESS DISORDER SCREENING FOR PRE-HEMATOPOIETIC STEM CELL TRANSPLANT PATIENTS

Keiko Wahlin[1]
[1]*Mount Sinai Hoslital, New York City, United States of America (the)*

Background: Global Hematopoietic Stem Cell Transplant (HSCT) are increasing in frequency. Research has shown that ~40% of HSCT patients develop a clinically significant psychiatric disorder during and after treatment. Anxiety and depression are common during HSCT, affecting 15-40% of patients. In addition, 6.6-26% of HSCT patients meet the criteria for Post-Traumatic Stress Disorder (PTSD), which peaks at 6 months post-transplant, affecting 28% of transplant recipients. No recommended psychosocial screening currently exists. Known risk factors for PTSD among HSCT patients include limited social support, pre-existing psychological distress, and poor coping skills. These factors are crucial to recognize prior to HSCT to minimize psychological sequelae and improve post-transplant outcome. The PTSD Checklist for DSM-5 (PCL-5) is a validated, reliable tool useful for assessing PTSD symptom severity. This project assessed how PCL-5 screening affected coping support referrals for pre-HSCT patients with PTSD symptoms.

Methods: **Setting:** Conducted at the outpatient Multiple Myeloma (MM) and Bone Marrow Transplant (BMT) clinics at an academic center in an urban city.
Participants: Adult participants with a diagnosis of hematological malignancies. Scheduled for Auto or Allo- HSCT hospitalization (N=18).
Objectives:
To implement a standardized PTSD screening process using the PCL-5, a validated 20-item questionnaire, during pre-transplant evaluations to identify patients at risk for PTSD. At an early stage to identify patients at risk for PTSD via implementing PTSD screening (PCL-5, a validated 20-item self-administered questionnaire) during pre-HSCT evaluations.
To facilitate timely psychosocial intervention by ensuring that all screening results are communicated to the Social Worker (SW), who then addresses positive scores by providing individualized coping support, including psychotherapy or referral to psycho-onc.
PCL-5 score calculation method:
The PCL-5 could determine a provisional diagnosis of PTSD in two ways:
Sum Score Method**:** Total score > 31-33 (range: 0-80) (See Figure 1) or
Symptom-Based Method: Endorse at least:
Re-experiencing: 1 from B (Q1-5)
Avoidance: 1 from C (Q6-7)
Negative cognition/mood: 2 from D (Q8-14)
Hyper-arousal: 2 from E (Q15-20) (See Figure 2)

Demographic and medical characteristics

Sociodemographic Characteristics of Participants (n=18)

Characteristic	Description	
	n	%
Gender		
Female	6	33.3%
Male	12	66.7%
Relationship status		
Married/ Partnered	14	78.2%
Single/separated/divorced/widowed	4	22.2%
Race		
Black or African American	2	11.1%
White	14	77.8%
More than one race	2	11.1%
Diagnosis		
AML/MDS/MPL/MF	6	33.3%
ALL	1	5.6%
Multiple Myeloma	10	55.6%
Lymphoma (Non-Hodgkin)	1	5.6%
Transplant Type		
Autologous	11	61.1%
Allogenic-RIC (Reduced Intensity Conditioning)	5	27.8%
Allogenic-MAC (Myeloablative Conditioning)	2	11.1%
Psychiatric Disorder		
None	14	77.8%
Anxiety	2	11.1%
Depression	1	5.6%
Anxiety/Depression	1	5.6%
Psychosocial support pre HSCT		
Took a prescription drug for anxiety or depression	1	5.6%
Seen Psychologist or Psychiatrist	1	5.6%
Seen by SWs	13	72.2%
None	3	16.7%

*AML (Acute Myeloid Leukemia)
MDS (Myelodysplastic Syndrome)
MPL (Myeloproliferative neoplasms)
MF (Myelofibrosis)
ALL (Acute Lymphoid Leukemia)

Results:

2 patients were positive for PCL-5

A:

Score 35

DSM-5 4 symptoms +

SW made aware to patient's A's Psychiatrist since already seen by Psychiatrist for Dx. Depression & Anxiety

B:

Score 28

DSM-5 4 Symptoms +

No Psychiatric History. SW did not refer to Psych-Onc. SW followed closely during hospitalization

Q. Can positive PCL-5 affect coping support referral?

A total of 18 out of 2 patients were positive for PCL-5 +

1) PCL-5 score positive = 2/18 x 100 = 11.1% →2 patients **(11.1%)** were positive for PTSD

2) The rate of positive screened referrals = 1/2 x 100 = 50% → 1 patient **(50%)** was referred to Psychiatry.

Fisher's exact test (p = 0.111)

The relationship between screening PCL-5 and referral for coping support was not statistically significant (p = 0.111)

Conclusions: Pre-Allo and Auto HSCT patients, both females and males, are equally experiencing provisional PTSD
There was no statistical significance between the frequency of PTSD and psychosocial referrals **(p= 0.111).**
Pre-HSCT patients reported experiencing insomnia, feeling distant, and recurring repeated disturbing memories, highlighting the need for psycho-oncologist evaluation.

Disclosure: Nothing to declare.

NURSE-DRIVEN INTERVENTIONS LEAD TO NEAR-ZERO CENTRAL LINE-ASSOCIATED BLOODSTREAM INFECTION RATES IN ADULT STEM CELL TRANSPLANT PATIENTS: A RETROSPECTIVE OBSERVATIONAL STUDY

Michael Sunga[1], Jan Miko Aaron Baybay[1], ***Francisco Vicente Lopez***[1]
[1]St Luke's Medical Center-Global City, Taguig City, Philippines (the)

Background: Central line–associated bloodstream infections (CLABSIs) remain a major cause of morbidity and mortality in hematopoietic stem cell transplant (HSCT) patients, who are uniquely vulnerable due to prolonged neutropenia and intensive central venous catheter (CVC) use. Evidence from prior research consistently demonstrates that nurse-driven central line maintenance bundles significantly reduce CLABSI rates in high-risk populations. Studies by Pronovost et al. and subsequent bundle-based interventions have shown reductions of 60–70% or more in CLABSI incidence when consistent nursing practices, chlorhexidine (CHG) dressings, and access port disinfection devices (e.g., Curos caps) are implemented. Similarly, multiple HSCT-specific studies have reported substantial decreases in CLABSI when standardized nursing-driven protocols are adopted, with some centers achieving near-zero rates.

Methods: A retrospective observational study was conducted involving 22 adult HSCT patients (autologous and allogeneic). Data extracted included line insertion and removal dates, duration of CVC use, type of line dressing (CHG vs non-CHG), and use of Curos port protection. The primary outcome was CLABSI occurrence during stem cell infusion and the subsequent inpatient transplant period. All patients received nurse-driven standardized line care, including CHG Tegaderm dressings and mandatory Curos cap use.

Results: Across 22 patients with central line durations ranging from 19 to 50 days, zero CLABSI events were documented (0 CLABSI per 1,000 CVC-days). All patients received CHG

dressings and Curos caps, with 100% adherence to the nurse-driven bundle elements. These findings are consistent with previous literature demonstrating that rigorous nursing-led maintenance practices can achieve near-zero CLABSI incidence in high-risk cohorts.

Conclusions: Implementation of standardized nurse-driven interventions, including CHG dressings, Curos disinfecting port protectors, and consistent daily maintenance practices, was associated with near-zero CLABSI rates in adult HSCT patients. The results reinforce existing evidence that nurse-led care bundles are among the most effective strategies for CLABSI prevention. Sustained adherence and nursing empowerment appear critical for maintaining low infection rates in stem cell transplant populations.

Disclosure: Nothing to declare

Quality of Life, Late Effects, Survivorship Care and Health Promotion

NG07-03

ENHANCING PREPAREDNESS AND WELL-BEING IN ALLOGENEIC STEM CELL TRANSPLANTATION: A MIXED-METHODS EVALUATION AND OPTIMISATION OF THE NURSE-LED ANIMO SUPPORT NETWORK

*Diana Skraback[1], **Alexandra Iosif**[1], Andrea Ellermeyer[1], Johanna Müller[1], Christine Boldt[1,2]*
[1]TUM University Hospital, Munich, Germany, [2]Hochschule München University of Applied Sciences, Munich, Germany

Background: Patients undergoing allogeneic stem cell transplantation (allo-SCT) and their caregivers face profound physical and psychological challenges across the pre-, peri- and post-transplantation trajectory. Despite advances in clinical standardisation, many still experience fragmented, insufficient or non-individualised information, which increases uncertainty, fear and difficulty navigating the transplant process. To address these gaps, the nurse-led ANIMO Network, a monthly, hybrid, support programme, was established at TUM Klinikum Rechts der Isar with the aim of strengthening preparedness, safety and well-being through the allo-SCT continuum. This study systematically evaluated informational needs and perceived informational quality to guide a structured optimisation of the programme using Step 4 of the PEPPA Framework.

Methods: A mixed-methods design integrated quantitative and qualitative approaches. In the quantitative component, twenty-one adult allo-SCT patients completed the EORTC QLQ-INFO25 questionnaire (response rate 95%). Data were analysed descriptively following EORTC guidelines, using linear transformation of raw scores (0–100) and calculation of a Global Score representing overall informational quality. The qualitative component consisted of twelve semi-structured interviews with patients and caregivers (5h 02min total duration),

analysed using Mayring's summarising content analysis. Deductive were expanded inductively. Triangulated findings informed targeted optimisation strategies within the ANIMO Network.

Results: Quantitative analysis revealed substantial variation across the four official INFO25 scales. Information about the medical tests received the highest ratings (mean 3.49), with all participants selecting "quite a bit" or "very much". Information about the disease was also rated positively (mean 3.11), though items concerning causes and mechanisms showed substantial variability.
Information about the treatment indicated moderately high satisfaction (mean 3.09), yet important gaps emerged in sensitive areas. The lowest-rated item concerned the impact of treatment on sexual activity, with 76.2% reporting "not at all" or "a little" information. The lowest overall ratings appeared in Information about other services (mean 2.84). Items related to self-help groups (mean 2.48) and rehabilitation services (mean 2.76) showed limited awareness of supportive resources.
The transformed Global Score ranged from 50.67 to 76.00 (mean 59.33), reflecting moderate overall informational quality. Despite strengths in several areas, 61.9% of respondents expressed a wish for more information, signalling the need for programme optimisation.
Qualitative findings mirrored the quantitative results. Early, personalised and clearly structured information was described as reducing anxiety and enhancing preparedness. Recurrent unmet needs concerned long-term effects of transplantation, daily self-management, psychosocial support and navigation of supportive services. Peer-to-peer exchange emerged as uniquely validating and an essential complement to professional education. Following optimisation measures, interviewees described improved clarity, emotional stability and a stronger sense of safety.

Conclusions: This mixed-methods evaluation identified significant informational gaps among allo-SCT patients, particularly regarding supportive services, long-term implications and sexual health. Using the PEPPA Framework, the ANIMO Network was systematically optimised, leading to qualitative improvements in perceived preparedness, confidence and emotional well-being. These findings offer a scalable model for supportive care in allo-SCT and underline the strategic value of advanced nursing practice in high-complexity haematology settings.

Disclosure: Nothing to declare.

NG07-05

IMPACT OF A STRUCTURED PRE-TRANSPLANT NUTRITION PROGRAM WITHIN A FRAILTY-PREHABILITATION STRATEGY IN ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

Maria Cancio-Solé[1], *Raquel Salinas*[1], *María Suárez-Lledó*[1], *Laia Guardia*[1], *Berta Sole*[1], *Adriana Cuartas*[1], *Carla Mestre-Reina*[1], *Enric Carreras*[2], *Laura Rosiñol*[1], *Maite Antonio*[1], *Carmen Martínez*[1], *Francesc Fernández-Avilés*[1], *Concepción Closa*[1], *Montserrat Rovira*[1], *María*

Queralt Salas[1]
[1]Hospital Clínic de Barcelona, Barcelona, Spain, [2]Fundació Josep Carreras Contra la Leucèmia, Barcelona, Spain

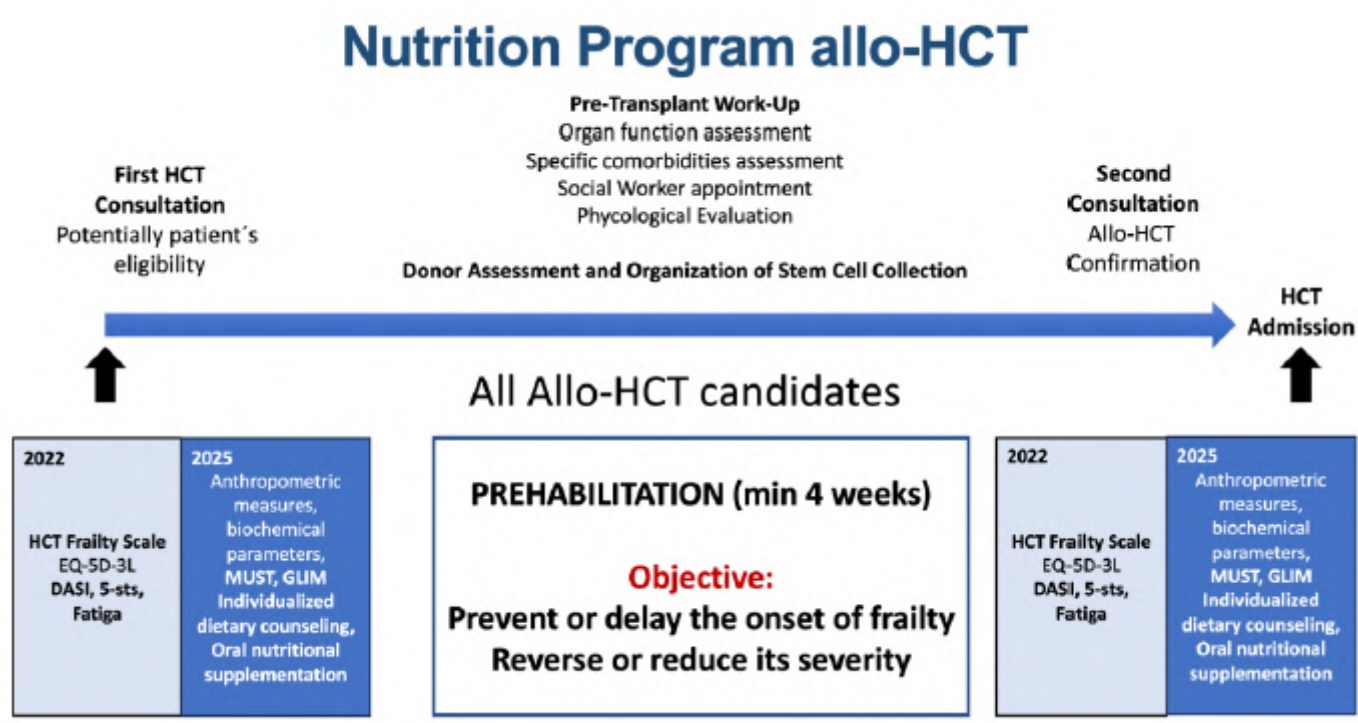
Background: Nutritional status is a critical determinant of transplant tolerance and outcomes in allogeneic hematopoietic cell transplantation (allo-HCT). Malnutrition and inadequate intake are frequent among candidates and contribute to frailty, functional decline, and impaired transplant readiness.
Since 2022, our institution has implemented a Frailty Program for all adult allo-HCT candidates, combining frailty assessments with physical prehabilitation. In 2025, a structured Nutrition Program was integrated to optimize nutritional status prior to allo-HCT, enhance prehabilitation effectiveness, and reduce nutritional-related complications. This study reports preliminary results on the feasibility and impact of this intervention during the pre-transplant period.

Methods: All adult allo-HCT candidates were prospectively enrolled in the Frailty Program and subsequently included in the Nutrition Program. The intervention comprised **(Figure 1)**:

- Comprehensive in-person nutritional assessment by a specialized team.
- Individualized dietary counseling.
- Oral nutritional supplementation when indicated.
- Close follow-up until HCT admission (in-person or telemedicine).

Effectiveness was evaluated by longitudinal changes in nutritional risk (Malnutrition Universal Screening Tool [MUST] and Global Leadership Initiative on Malnutrition [GLIM] criteria), anthropometric and biochemical parameters, and frailty status between first consultation and

HCT admission.



Results: Twenty-five patients were analyzed (median age 52 years, range 18–73; 28% ≥65 years). At baseline, frailty status was: fit 28%, pre-frail 68%, frail 4% according to the HCT Frailty Scale. Nutritional risk (MUST) was identified in 28% of patients; 71.4% met GLIM criteria for malnutrition, mainly due to >5% weight loss in <6 months and insufficient intake **(Table 1)**. Patients at nutritional risk were more often ≥65 years (57.1% vs. 16.7%) and showed higher rates of underweight (Body Mass Index [BMI] <18.5 kg/m²; 14.3% vs. 0%) and clinically relevant weight loss (71.4% vs. 0%).
Insufficient oral intake was universal (100%), prompting individualized dietary counseling and supplementation. Adherence was 100% with no gastrointestinal intolerance or aversion reported.
At HCT admission: fit 40%, pre-frail 56%, frail 4%. BMI remained stable, with an increase in patients within healthy range (from 32% to 40%). Nutritional risk decreased (from 28% to 24%), and only one patient (4%) lost weight during follow-up. Severe hypoalbuminemia remained rare (4%), suggesting overall nutritional stabilization.

Baseline Characteristics	**All patients N = 25 (100%)**	**Normal MUST N = 18 (72%)**	**Anormal MUST N = 7 (28%)**

Median Age **≥65 years**	52 (18-73) 7 (28.0)	52 (18-73) 3 (16.7)	53 (26-71) 4 (57.1)
Sex Male Female	 15 (60.0) 10 (40.0)	 10 (55.6) 8 (44.4)	 5 (71.4) 2 (28.6)

BMI Underweight <18.5 kg/m2 Healthy 18.5-24.9 kg/m2 Overweight >25 kg/m2	 1 (4.0) 8 (32.0) 16 (64.0)	 0 4 (22.2) 14 (77.8)	 1 (14.3) 4 (57.1) 2 (28.6)
Laboratory Markers Proteins < 63 g/L	3 (12.0)	2 (11.1)	1 (14.3)

Albumin < 34 g/L Pre-albumin < 0.200 g/L	0 7 (28.0)	0 5 (27.8)	0 2 (28.6)
GLIM: malnutrition diagnosis (moderate and severe)	5 (20.0)	0	5 (71.4)
Significant Weight Loss (>5% in <6 months)	5 (20.0)	0	5 (71.4)
Insufficient oral intake	25 (100.0)	18 (100.0)	7 (100.0)
HCT Admission (Post Intervention)			
BMI Underweight <18.5 kg/m2 Healthy 18.5-24.9 kg/m2 Overweight >25 kg/m2	 1 (4.0) 10 (40.0) 14 (56.0)	 0 6 (33.3) 12 (66.7)	 1 (14.3) 4 (57.1) 2 (28.6)
Laboratory Markers Proteins < 63 g/L Albumin < 34 g/L Pre-albumin < 0.200 g/L	 11 (44.0) 1 (4.0) 4 (16.0)	 8 (44.4) 0 3 (16.7)	 3 (42.9) 1 (14.3) 1 (14.3)
MUST: risk of malnutrition (medium and high)	6 (24.0)	1 (5.6)	5 (71.4)
Significant Weight Loss (>5% during the pre-transplant period)	1 (4.0)	1 (5.6)	0

Conclusions: Nutritional vulnerability was common and associated with adverse baseline profiles. Preliminary data indicate that individualized pre-transplant nutritional intervention is feasible, well-tolerated, and contributes to stabilizing nutritional status before allo-HCT, supporting its integration into pre-transplant care pathways.

HIGH LEVELS OF SYMPTOMS ARE LINKED TO STRONGER SELF-CARE MANAGEMENT IN ALLO-HCT SURVIVORS

Cecilia Engberg de Carvalho[1,2], *Anna O'Sullivan*[3,4], *Carina Lundh Hagelin*[3,5], *Annika M Kisch*[1,2], *Jeanette Winterling*[5,6]
[1]*Lund University, Lund, Sweden,* [2]*Skåne University Hospital, Lund, Sweden,* [3]*Marie Cederschiöld University, Stockholm, Sweden,* [4]*Sophiahemmet University, Stockholm, Sweden,* [5]*Karolinska Institutet, Stockholm, Sweden,* [6]*Karolinska University Hospital, Stockholm, Sweden*

Background: Long-term survivors after allogeneic hematopoietic stem cell transplantation (allo-HCT) often live with persistent symptoms that require ongoing self-care. Empirical knowledge about self-care management post-transplant is limited. This study examined self-care management, levels of symptoms and associated factors among allo-HCT survivors.

Methods: This retrospective cross-sectional survey study included allo-HCT survivors 1-4 years post-transplant (n=126). Data were collected using the Self-Care Management Scale (0-100) from the SC-CII questionnaire, based on the middle-range theory of self-care of chronic illness, as well as the global health item and the nine symptom scales from the EORTC QLQ-C30, which assess the occurrence and levels of common cancer-related symptoms. Scores were dichotomized into a "high-symptom group" and a "low-symptom group". A high-symptom score was defined as ≥66 on any EORTC QLQ-C30 symptom scale (0-100). Differences at the group level were analyzed with t-tests, and predictors of self-care management were examined using multivariable linear regression. The significance level was set to $p \leq 0.05$.

Results: The sum score for the self-care management scale showed a mean value of 57.8 (SD 20.1), indicating that self-care management varied among participants. A distributional plot showed marked heterogeneity within the high-symptom group, with a median self-care management score of 60 (range 25-100) (Figure 1). 10% reported no symptoms, while 72% reported at least three different symptoms of any level on the EORTC QLQ-C30 symptom scales.Survivors with high levels of fatigue, pain or dyspnea reported statistically significantly higher levels of self-care management compared with those with no or low levels of symptoms. When summarizing symptom levels across the nine sub-scales, the high-symptom group reported higher self-care management than the low-symptom group (mean 63.6 versus 54.2, p=0.012).

Younger survivors reported higher self-care management. In multivariable linear regression, younger age (β ≈ −0.37 per year, p=0.011) and high symptom levels (β ≈ 8.65, p=0.020) were independently associated with higher self-care management, while global health showed no association. The model explained 13% of the variance in self-care management.

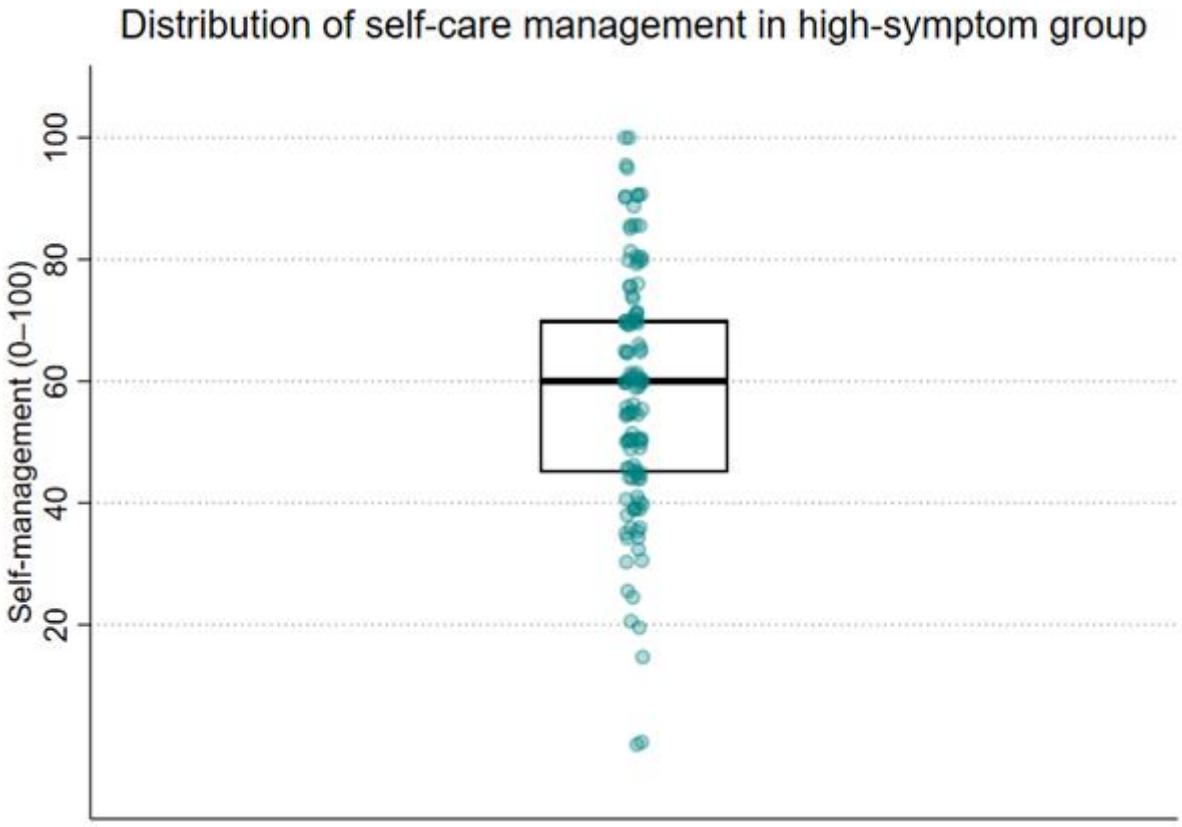

Figure 1. Distribution of self-care management scores among allo-HCT survivors classified in the high-symptom group (n=57).

Conclusions: Self-care management among allo-HCT survivors varied, with survivors with high levels of symptoms reporting higher self-care management. The associations suggest that higher levels of symptoms may prompt self-care management efforts but do not fully explain the variation observed between individuals. These findings add to current knowledge of long-term survivorship after allo-HCT and indicate that considering both symptom levels and self-care management patterns in structured follow-up may better reflect survivors' ongoing needs.

LONGITUDINAL ASSESSMENT OF STRENGTH, FITNESS, NUTRITION AND QUALITY OF LIFE IN ADULTS UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION: CALL FOR MULTIMODAL AHP CLINICS ACROSS TRANSPLANT CONTINUUM

Dale Bayquen[1], *Lauren Blackburn*[1], *Katie Taylor-English*[1], *Siobhan Cowan-Dickie*[1], *Lucy Dean*[1]
[1]*The Royal Marsden NHS, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Allogeneic haematopoietic stem cell transplantation (allo-HSCT) is a potentially curative for haematological cancers but is accompanied by treatment-related toxicities and prolonged inactivity that drive deconditioning, fatigue and reduced quality of life (QoL). Evidence for routine prehabilitation in allo-HSCT remains limited in real-world practice, and longitudinal datasets capturing objective function alongside patient-reported outcomes across admission, discharge and early survivorship are scarce. Objective pre-transplant function and nutritional impairment are clinically relevant, yet serial multimodal assessment is inconsistently embedded across the transplant continuum, limiting benchmarking and timely allied health professional (AHP) input. We embedded a pragmatic minimum dataset to characterise trajectories from pre-transplant to early survivorship and identify delivery barriers to inform multimodal AHP clinic development.

Methods: Following Royal Marsden Quality Improvement Committee approval, outcome measures were embedded using Plan-Do-Study-Act (PDSA) methodology and ASCT candidates were recruited (April 2024-September 2025). Assessments occurred pre-transplant (T1), on admission (T2), pre-discharge during (T3), and 12 weeks post-discharge (T4). Outcomes measured were BMI as pragmatic nutritional indicator, 30-second sit-to-stand (30-STS), grip strength, peak power output (PPO) and estimated VO_2peak (T1/T4 only, for safety and logistical reasons), Functional Status Score-ICU (FSS-ICU), FACIT-Fatigue, and EQ5D-5L. Data was summarized descriptively and contextualised to age-related norms. Reasons for missed assessments were prospectively recorded; usual-care AHP input occurred but was not standardised for evaluation.

Results: Eighteen patients were recruited (mean age 59.8 years; 77.8% male) over 16 months versus a forecast of 20 completing within 6 months. Completeness decreased across time points (T1 n=18; T2 n=16; T3 n=15; T4 n=13–15) due to intercurrent illness, competing appointments, travel burden and variable transplant timelines. BMI declined from 26.7 to 23.9 kg/m². 30-STS remained sub-normative from baseline median 11.5 (IQR 9.8–14.3) to 11.0 (IQR 7.8–15) at T4, with 69–80% below an age-expected threshold across time points. Handgrip strength fell from 33.8 kg to 25kg (left) and 33.1 kg to 26.3 (right). Aerobic capacity was low and worsened: PPO 1.37±0.38 to 1.20±0.51 W/kg and estimated VO2peak 17.7±4.1 to 15.2±5.2 mL·kg−1·min−1, remaining below conservative age-expected values in nearly all participants indicating reduced physical capacity and endurance. Mean FACIT-Fatigue dropped from 39.9 to 29.1 before partial recovery to 36.5 with scores <43 occurring in 50% at T1 and 93.3% at T3. EQ-5D-5L VAS declined from 74.4 to 52.0 with

partial recovery to 66.8 and drop of index score from 0.88 (T1) to 0.78 (T4). FSS-ICU declined from 35.0±0.0 (T1) to 32.0±5.3 (T4), with 35.7% <35 at T4 despite inpatient rehabilitation.

Outcome Measure	Baseline (4-8 weeks) (n=17-18)	Admission (n=16)	Pre-DC (n=15)	12-weeks Post-DC (n=13-15)	Normative Values (Age 60)
BMI	26.7 (SD 5.2)	26.5 (SD 4.6)	25.3 (SD 4.8)	24.0 (SD 4.5)	18.5–24.9 (healthy)
30-STS (reps)	11.5 (IQR 9.8–14.3)	12.5 (IQR 9.3–17.3)	13.0 (IQR 9–14)	11.0 (IQR 7.8–15.0)	Male: >14 Female: >12
Left Grip Strength	33.8 (SD 8.0)	31.6 (SD 7.5)	28.7 (SD 8.4)	25.0 (SD 8.1)	Male: 37.25kg Female: 23.47kg
Right Grip Strength	33.1 (SD 9.0)	33.0 (SD 8.9)	30.2 (SD 9.4)	26.3 (SD 7.2)	Male: 37.25kg Female: 23.47kg
Peak Power Output (W/kg)	1.37 (SD 0.38)	N/A	N/A	1.20 (SD 0.51)	1.5
Estimated VO_2peak (ml/kg/min)	17.7 (SD 4.1)	N/A	N/A	15.2 (SD 5.2)	Male: 26 Female: 18
FACIT-Fatigue	39.9 (SD 9.9)	37.8 (SD 10.9)	29.1 (SD 12.3)	36.5 (SD 13.4)	43-50
EQ-5D-5L VAS	74.4 (SD 16.4)	66.9 (SD 17.9)	52.0 (SD 22.3)	66.8 (SD 15.4)	N/A 100 (perfect state)
EQ-5D-5L Health Index State	0.88 (SD 0.14)	0.89 (SD 0.12)	0.75 (SD 0.26)	0.78 (SD 0.24)	N/A 1.0 (perfect state)
FSS-ICU	35 (SD 0)	34 (SD 2.2)	34 (SD 1.82)	32.0 (SD 5.3)	35 (ceiling)

Conclusions: Allo-HSCT recipients demonstrated prevalent baseline impairment, predictable inpatient deterioration and incomplete recovery by 12 weeks post-discharge across strength, fitness, fatigue, QoL and independence. A PDSA-embedded multimodal dataset can standardise longitudinal assessment, but access constraints and measurement limitations require further iterative refinement. These data provide a strong rationale to design and prospectively evaluate structured multimodal AHP-led clinics spanning prehabilitation, early survivorship and late effects. Limitations include generalizability of findings due to small sample size and data sets changes due to scheduling constraints, geography and agile transplant timelines.

Disclosure: Nothing to declare.

NG16-01

LATE EFFECTS AND SYMPTOM BURDEN AMONG LONG-TERM SURVIVORS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A NATIONWIDE CROSS-SECTIONAL STUDY

Mette Schaufuss Engedal[1,2], *Kristina Nørskov*[3,4], *Anders Tolver*[5], *Lea Brandt Kristensen*[6], *Astrid Lindman*[6], *Gitte Olesen*[6], *Brian Kornblit*[1], *Christoffer Johansen*[7,2], *Mary Jarden*[1,2]
[1]*Department of Haematology, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark,* [2]*University of Copenhagen, Copenhagen, Denmark,* [3]*Department of Haematology, Zealand University Hospital, Roskilde, Denmark,* [4]*University of Southern Denmark, Odense, Denmark,* [5]*Danish Cancer Institute, Copenhagen, Denmark,* [6]*Department of Haematology, Aarhus University Hospital, Aarhus, Denmark,* [7]*Department of Oncology, Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark*

Background: Survival after allogeneic hematopoietic stem cell transplantation (allo-HSCT) has improved substantially, resulting in an expanding population of long-term survivors who might be expected to have quality-of-life levels comparable to the general population. However, many remain at risk of late effects, prolonged immunosuppression, and chronic graft-versus-host disease (cGvHD), which may impair functioning and overall well-being. Despite this, long-term outcomes from the survivor perspective are insufficiently described, and large multicenter studies using patient-reported outcomes (PROs) are limited. This study aimed to assess symptom burden, functional outcomes, and survivorship-related quality of life among Danish allo-HSCT survivors, including comparisons with population norms.

Methods: We conducted a nationwide, multicenter cross-sectional study including all adults (≥18 years) who received a first allo-HSCT at Copenhagen University Hospital, Rigshospitalet (since 1973) or Aarhus University Hospital (since 2009). Eligible participants resided in Denmark or Greenland at survey initiation (May 2024).
PROs were assessed using the validated European Organization for Research and Treatment of Cancer Quality of Life Cancer Survivorship Core Questionnaire (EORTC QLQ-SURV100), which captures survivorship-specific domains and allows calculation of EORTC QLQ-C30 scores, and the Modified 7-Day Lee cGvHD Symptom Scale (MLSS). Clinical data included diagnosis, comorbidity, treatment characteristics, and cGvHD status. The study was approved by the Danish Data Protection Agency (P-2022-391) and the ethics committee.

Results: Of 2.701 patients who underwent allo-HSCT, 1.341 were eligible, and 895 responded (66.7%). The median age at survey was 55 years, with a median time since transplantation of 6.2 years; 34.6% of participants were ≥10 years post-HSCT.
The most frequently reported symptoms were joint pain (31%), fatigue (27%), muscle weakness (25%), and sexual problems (25%). Psychosocial strain was common, with 37% reporting moderate-to-severe problems related to loss of income. Survivors reported a significantly higher symptom burden compared with Danish population norms, including fatigue (mean diff 14.7, $p < 0.0001$), pain (mean diff 5.1, $p < 0.0001$) and financial

difficulties (mean diff 10.6, p < 0.0001). Across functional domains, survivors consistently scored lower than the general population, including physical functioning (mean diff −15.7, p < 0.0001), role functioning (mean diff −16.0, p < 0.0001), emotional functioning (mean diff 4.8, p < 0.0001), cognitive functioning (mean diff −11.7, p < 0.0001), and social functioning (diff −18.4, p < 0.0001). Overall, survivors reported significantly reduced global health scores compared to population norms (mean diff −5.1, p < 0.001).
Employment status indicated that 36% were employed, while 14% received disability pensions despite a median age of 55 years. Fertility concerns were reported by a subset of participants (n=187), with 52% indicating a severe impact. Approximately 60% had documented cGvHD, which was associated with higher MLSS symptom scores.

Conclusions: This nationwide study highlights the substantial symptom burden, functional impairments, and psychosocial challenges experienced by allo-HSCT survivors. The findings underscore the need for structured survivorship care, including routine PRO monitoring and targeted interventions to address fatigue, pain, sexual health, psychosocial concerns, and socioeconomic vulnerability. These insights can inform the development of nurse-led, individualized survivorship programs aimed at optimizing long-term quality of life in this population.

EMOTIONAL BURDEN PREDICTS MORTALITY 5 YEARS AFTER ADULT HEMATOPOIETIC CELL TRANSPLANTATION: THE PROSPECTIVE SWISS TRANSPLANT COHORT STUDY

Sabine Valenta[1,2], *Kris Denhaerynck*[1], *Janette Ribaut*[1], *Sabine Gerull*[3], *Jörg Halter*[2], *Dominik Schneidawind*[4], *Yves Chalandon*[5], *Sabina De Geest*[1,6]
[1]*University of Basel, Basel, Switzerland,* [2]*University Hospital Basel, Basel, Switzerland,* [3]*Cantonal Hospital of Aarau, Aarau, Switzerland,* [4]*University Hospital Zurich, Zurich, Switzerland,* [5]*University of Geneva, Geneva, Switzerland,* [6]*KU Leuven, Leuven, Belgium*

Background: Emotional burden (EB)—including depressive symptomatology, anxiety, and stress—can occur independently of a clinical diagnosis and is assessed via Patient-Reported Outcomes (PROs). EB affects a substantial proportion of hematopoietic cell transplantation (HCT) recipients and may influence survival. However, prior studies often lacked longitudinal assessments and adjustment for critical clinical predictors such as relapse or graft-versus-host disease (GvHD). This study aimed to
(1) describe EB trajectories from pre- to 5-years post-HCT and
(2) to evaluate the impact of EB on 5-year overall survival (OS).

Methods: We conducted a secondary data analysis of the Swiss Transplant Cohort Study (STCS), a multicentre prospective open cohort study. We analyzed adult HCT recipients (≥18 years) from Zurich, Geneva and Basel enrolled in the STCS from 2013–2018, linked to the EBMT-Registry for clinical data (demographic and clinical outcome data). Datasets were deterministically linked using core identifiers. In the STCS, EB (depressive symptomatology, anxiety, stress) is assessed using HADS-D, one EQ-5D-5L anxiety item, and a single-item stress scale at ~3 months pre-HCT, 6 and 12 months post-transplant, and annually thereafter. Primary outcome was OS at 5 years. Aim 1 used descriptive statistics and alluvial (Sankey-style) diagrams to characterize trajectories. Aim 2 employed Cox proportional hazards models with time-dependent EB measures. Models were adjusted for baseline sociodemographic and clinical covariates (age, sex, education, diagnosis, conditioning regimen, graft source, donor type, remission status, and GvHD) to estimate hazard ratios (HRs). Synergistic effects were tested by averaging our three standardized outcomes into one single score. Analyses were conducted in SAS 9.4 (two-sided α=0.05).

Results: The cohort included 1,028 HCT recipients (mean age 51.7 years; 61.6% male, Table 1)

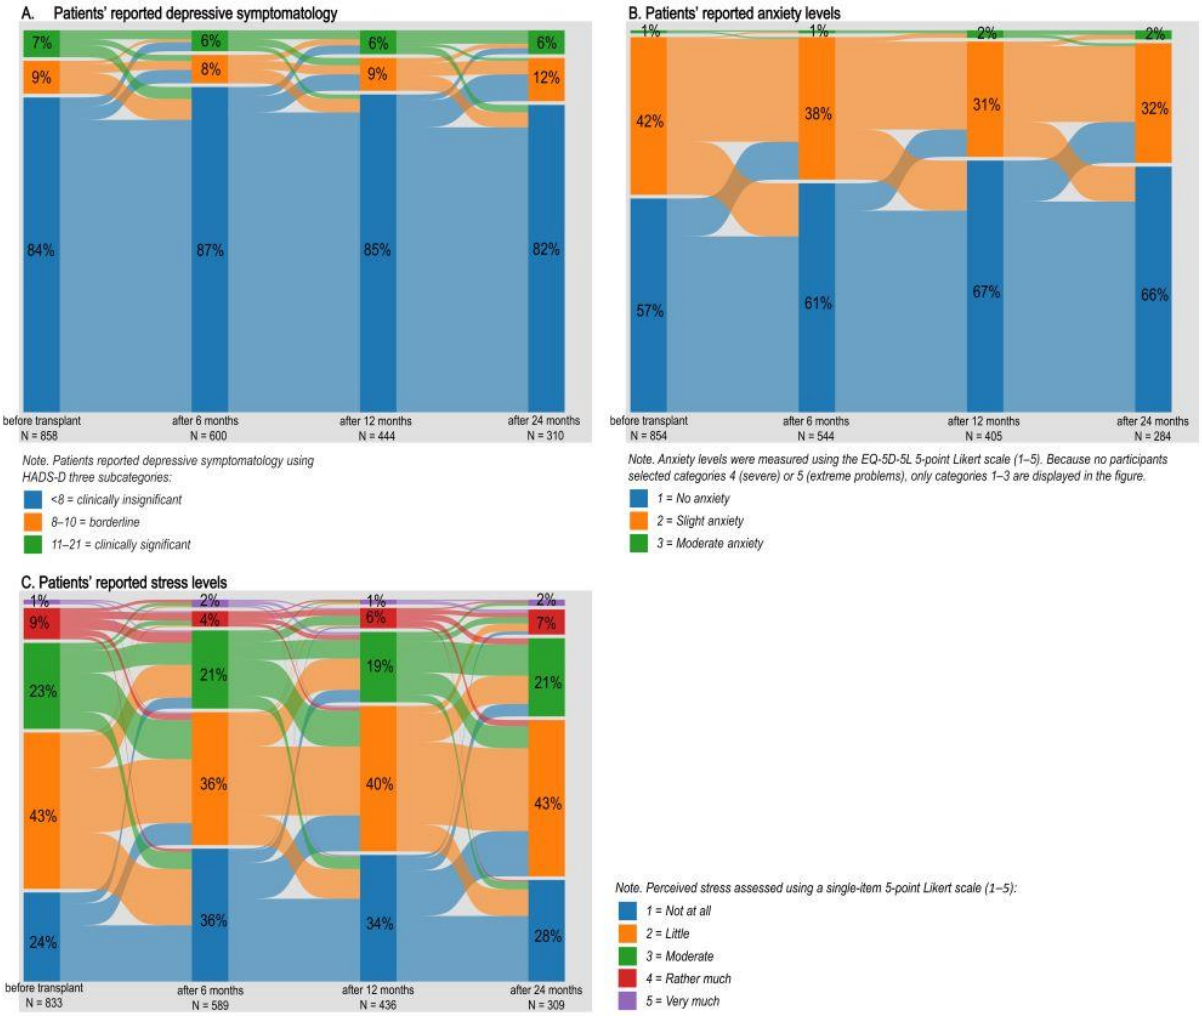
Table 1. Sociodemographic and clinical characteristics of the study population (N = 1028)

Characteristic	**Value**
Sex, male	633 (61.6%)
Age (years)	Mean = 51.7 (SD 13)
Living alone	264 (29%)
Underlying diagnosis	
– Acute leukemia	530 (53%)
– Myelodysplastic syndrome	231 (23%)
– Lymphoma	108 (11%)
Time from diagnosis	Median = 7 months (IQR 17)
Donor type	
– Sibling	346 (34%)
– Unrelated	499 (50%)
Remission at transplant	577 (59%)
Acute GvHD (Grade I–II)	322 (32%)
Chronic GvHD	202 (21%)

Note. Values are presented as n (%), mean (SD), or median (IQR).

As shown in the alluvial diagram (Fig. 1A–C), depicting the first two years post-HCT, EB remained relatively stable over time. However, across all measurement timepoints, 6–7% reported clinically relevant depressive symptomatology, about one-third anxiety, and up to 9% very high stress levels.

Figure 1A-C. Emotional burden (depressive symptomatology, anxiety & stress) from pre- to 2 years post HCT



EB significantly predicted 5year-OS: Each one-point increase in depressive symptoms was associated with a 7% higher mortality risk (HR 1.07, 95% CI 1.04–1.10, $p < 0.0001$). Higher anxiety levels conferred a 35% increased risk (HR 1.35, 95% CI 1.09–1.68, $p = 0.0069$). Elevated stress predicted an 18% higher risk (HR 1.18, 95% CI 1.05–1.33, $p = 0.0071$). Importantly, all EB associations remained significant after adjusting for the clinical and demographic variables, i.e. they did not attenuate the effect of depressive symptomatology, anxiety, or stress on OS, suggesting an independent prognostic role of EB. The combined EB

score showed a 29% higher mortality risk than any single dimension, suggesting synergistic effects.

Conclusions: EB independently and robustly predicted poorer 5-year OS in HCT recipients, even when accounting for key clinical risk factors such as relapse and GvHD. These findings highlight the clinical relevance of systematically assessing EB and integrating timely psychosocial support into post-HCT care to potentially improve long-term outcomes.

A MULTIMODAL APPROACH TO SEXUAL FUNCTION FOLLOWING ALLOGENEIC STEM CELL TRANSPLANTATION: A RANDOMIZED CONTROLLED STUDY

Kristina Holmegaard Nørskov[1,2], *Sofie Dorthea Andersen*[1], *Nicklas Lybaek*[3], *Andreas Røder*[1], *Mikael Aagaard*[1], *Gitte Ørtoft*[1], *Mette Karen Guldbrandsen*[1], *Pernille Ravn*[4], *Nicolaj Brandt*[4], *Maria Stevenson*[4], *Duruta Weber*[4], *Lars Lund*[4], *Ida Schjoedt*[1], *Mary Jarden*[1]
[1]*Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark,* [2]*University of Southern Denmark/, Odense, Denmark,* [3]*Sanos, Copenhagen, Denmark,* [4]*Odense University Hospital, Odense, Denmark*

Background: Improved survival after allogeneic HSCT has led to a growing population of long-term survivors who frequently experience sexual dysfunction. Genital chronic GVHD (cGVHD) is a key contributor, with reported prevalence of 19–66% in women and 5–20% in men, yet it remains underdiagnosed due to nonspecific symptoms and limited routine screening. Sexual function may be further affected by GVHD in other organs, medication effects, body image concerns, and psychological distress. Although guidelines recommend systematic assessment, sexual health is often insufficiently addressed in clinical practice. This study investigated the feasibility and effect of a multimodal randomized intervention targeting sexual function in HSCT recipients.

Methods: This multicenter, prospective randomized controlled trial was conducted at two Danish transplant centers from 2022–2025. Adults scheduled for allogeneic HSCT were enrolled before transplantation and randomized 1:1 to a multimodal intervention or usual care. The intervention comprised six assessments over 18 months, including sexual health questionnaires (EORTC QLQ-SH22), specialist genital evaluations, and nurse-led consultations guided by a standardized protocol. Usual care involved symptom-driven evaluation only. Sexual function was measured using the Female Sexual Function Index (FSFI) for women and the International Index of Erectile Function (IIEF-15) for men.

Secondary outcomes included broader sexual health indicators, levels of sexual distress, and feasibility measures related to intervention implementation and participant adherence.

Results: Of 135 eligible patients, 117 (86.7%) were enrolled and randomized; 41 discontinued by 18 months due to relapse, death, or withdrawal. Overall sexual function did not differ significantly between groups for women (difference 3.3, P=0.391) or men (difference 0.9, P=0 .761). Significant improvements favoring the intervention group were observed in women's sexual pain (diff -2.1, P=0.019) and, for both genders, in sexual pain (diff -13.6, P=0.030), communication with professionals (diff -15.5, P=0.017), and partnership quality (diff -22.8, P=0.040). Genital cGVHD occurred in 17.1%, with earlier detection in the intervention group. In the control group, only three cases were identified outside protocolized assessments. Median onset occurred earlier in the intervention group (365 vs. 547 days). Most cases were mild. Adherence to questionnaires, genital assessments, and nurse-led consultations was high. Across 205 counseling sessions, common concerns among women included vaginal dryness, low desire, and internal pain; men most frequently reported erectile difficulties and reduced desire.

Conclusions: We conclude that the multimodal intervention was feasible with improved sexual health, and facilitated earlier recognition of genital cGVHD, supporting the integration of interdisciplinary sexual health assessments into routine post-HSCT care.

QUALITY OF LIFE AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ADOLESCENTS AND YOUNG ADULTS: INSIGHTS FROM A DANISH CROSS-SECTIONAL STUDY USING THE EORTC QLQ AYA QUESTIONNAIRE

Nanna Randrup Madsen[1], *Kristina Holmegaard Nørskov*[1], *Niels Smedegaard Andersen*[1], *Helle Pappot*[2,3]
[1]*Department of Hematology, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark,* [2]*Department of Oncology, Copenhagen University Hospital - Rigshospitalet, Copenhagen, Denmark,* [3]*Institute of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark*

Background: In Denmark, approximately 1,400 adolescents and young adults (AYAs) are diagnosed with cancer each year, with hematological malignancies accounting for around 30% of cases. Hematopoietic stem cell transplantation (HSCT) is a well-established curative treatment for a subgroup of these patients. Advances in transplantation procedures, supportive care, and post-transplant monitoring have significantly improved survival outcomes for AYA's. Nevertheless, survivors remain at increased risk of late complications and premature mortality, highlighting the need to better understand their long-term quality

of life (QoL) and supportive care needs in this population. Notably, the recently developed and validated EORTC QLQ-AYA questionnaire provides a comprehensive, AYA specific assessment of quality QoL, complementing existing generic instruments. The aim of this study is to investigate QoL, symptom burden and sexual health in Danish AYAs following HSCT, using the newly validated EORTC QLQ-AYA, to inform strategies for optimizing long-term outcomes.

Methods: This nationwide cross-sectional study includes AYA's aged 18–29 years at transplantation who underwent a HSCT for a hematologic malignancy in Denmark, and who were ≤39 years at study participation. Participants completed four electronically administered validated questionnaires; The European Organization for Research and Treatment of Cancer Quality of Life Questionnaire - Adolescents and Young Adults (EORTC QLQ AYA27), EORTC QLQ-C30, EORTC Sexual Health Questionnaire 22 (EORTC QLQ-SHQ22), and the Lee Symptom Scale.

Results: A total of 48 participants completed the survey (45,3 %), with a mean age of 31.1 years and an equal gender distribution. Overall QoL was generally high, however women reported lower QoL than men with significantly lower scores on global health ($p = 0.04$), emotional functioning ($p < 0.001$), and cognitive functioning ($p < 0.001$). Participants reported positive personal changes (mean: 53.1 ± 27.5) but also notable concerns regarding future worry (mean: 32.2 ± 24.6) self-esteem (mean: 31.0 ± 31.9), and sexual life (mean: 32.5 ± 35.9). Compared with existing reference data, participants scored lower on emotional functioning, cognitive functioning, and financial difficulties than other hematological patient groups and Danish population norms.
Sexual health assessment revealed that 44.7% of participants had never been asked about their sexual wellbeing. Gender-specific symptom patterns were evident as women reported high levels of vaginal dryness, whereas men expressed notable concerns regarding confidence in erection. Importantly, women also reported substantially poorer body image, scoring approximately twice as poorly as men, underscoring a marked gender disparity in body-related wellbeing.

Conclusions: This study, employing the newly validated EORTC QLQ-AYA, provides a detailed assessment of QoL, symptom burden, and sexual health in AYA HSCT survivors. Findings highlight significant gender disparities and unmet supportive care needs, emphasizing the importance of tailored interventions and follow-up strategies to optimize long-term QoL in this population.

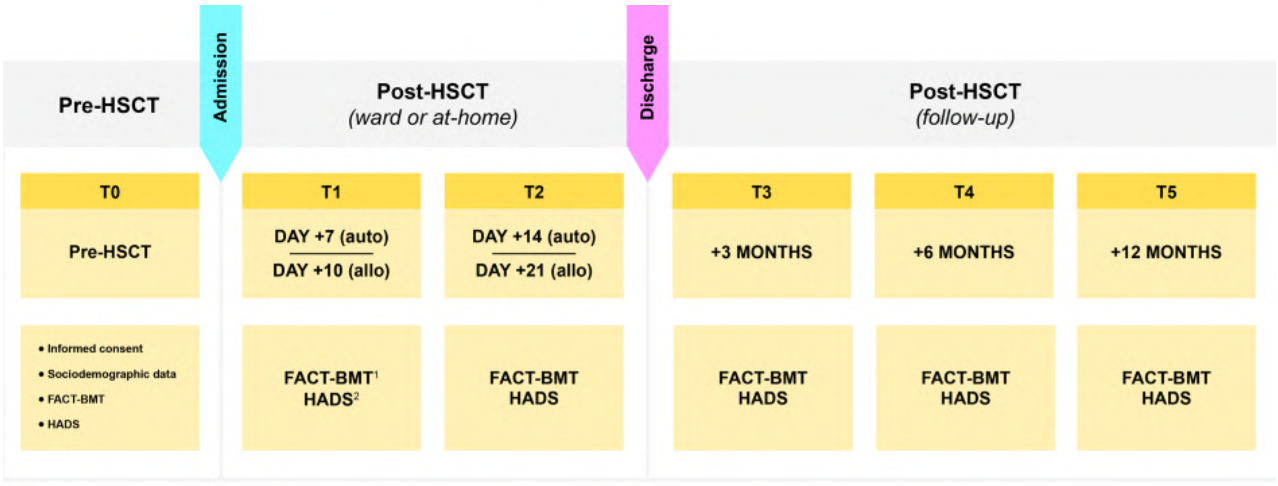
QUALITY OF LIFE, ANXIETY AND DEPRESSION IN HSCT RECIPIENTS. A 12-MONTH LONGITUDINAL STUDY

Arianna Rosich Soteras[1,2], *Anna Serrahima-Mackay*[1,3], *Carla Ramos-Serrano*[1], *Cristina Gallego Miralles*[1], *Teresa Solano Moliner*[1,4], *Núria Jaramillo Forcada*[1], *Laia Guardia Roca*[1], *Estel Güell Porteros*[1], *Ariadna Domenech*[1], *Adelaida Zabalegui*[1,2]

[1]Hospital Clinic Barcelona, Barcelona, Spain, [2]Universitat de Barcelona, Barcelona, Spain, [3]Institut Català d'Oncologia, Girona, Spain, [4]Fundació Kalida, Barcelona, Spain

Background: Receiving an HSCT has been associated with impaired quality of life (QoL) and mental health. Our aim is to describe the evolution of QoL, anxiety and depression, in HSCT recipients from pre-HSCT to 1-year post-HSCT.

Methods: An observational prospective longitudinal study was conducted between October 2019 and February 2022. Participants were recruited through consecutive sampling. FACT-BMT and the Hospital Anxiety Depression Scale were administered in 6 time points (Figure 1) to evaluate QoL and anxiety and depression, respectively. Instrument score changes over time were analyzed using an adjusted linear mixed model.



Results: 72 patients were included, 63.9% of whom were men, with mean age 52 (SD 12.6). 52.8% HSCTs were allogeneic and 50% were conducted in an at-home programme. The main reasons for HSCT were a diagnosis of leukaemia (36.1%), multiple myeloma (31.9%) and lymphoma (20.8%).
A significant decrease in QoL was observed, with a drop of 8.93 points on the FACT-BMT scale (p.0.01) during admission (T1). Results gradually recovered and improved baseline outcomes at 6 and 12 months post-HSCT. The most affected QoL domains during the acute period (T1) were physical (loss of 4.68 points, p <0.001) and functional (loss of 4.16 points, p <0.001). In contrast, the social domain remained stable through all the trajectory, while the emotional domain presented a slight, gradual improvement in values up to six months post-HSCT (p. 0.01).
Regarding anxiety, 32.4% of participants met anxiety criteria at pre-HSCT. Results didn't change during admission (T1) but decreased to 18.7% as discharge approached (T2). Results worsened when achieving 3 months post-HSCT, with 31.1% of participants meeting anxiety criteria, and results dropped to 24.1% at 12 months. For depression, we observed

12.5% incidence prior to HSCT. Patients with depression increased to 36.5% during the acute period (T1 and T2) but then progressively fell to 16.7% at 12 months.
Allogeneic recipients scored 2.51 points lower in physical well-being (p = 0.001) but 1.91 points higher in social well-being (p = 0.011) than autologous recipients. Patients receiving homecare HSCT scored 1.91 points lower in social well-being (p = 0.011) than hospitalised patients, with no other differences observed.

Conclusions: Patients' QoL declined during the acute phase but improved in the medium term. Heightened psychological distress at all time-points was observed, but values improve during follow-up. Admission proved critical for early detection and treatment of depression, while anxiety was lowest at T2 (+14 days post-autoHSCT, +21 days post-alloHSCT). Except for social well-being, QoL outcomes were similar between hospitalised and homecare patients, supporting at-home HSCT programmes as a safe and feasible option.
Understanding QoL and mental health trajectories is key to refining interventions that enhance physical, functional, and psychological wellbeing, specifically during the acute HSCT period.

Clinical Trial Registry: Not applicable.

COULD PROPHYLACTIC NASOGASTRIC TUBE FEEDING REDUCE WEIGHT LOSS FOR PATIENTS UNDERGOING HIGH-TOXICITY CONDITIONING REGIMENS DURING AUTOLOGOUS STEM CELL TRANSPLANT?

Hannah van Tromp[1], *Amber Bastian Jeronimo*[2], *James Evans*[1]
[1]*University College Hospital, London, United Kingdom of Great Britain and Northern Ireland (the),* [2]*University College London, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Autologous stem cell transplant (auto-SCT) patients are vulnerable to malnutrition due to reduced oral intake from conditioning-related gastrointestinal toxicities. Identifying which conditioning regimens place patients at highest risk may help determine who could benefit most from prophylactic nasogastric tube feeding.

Methods: A retrospective, quantitative, single-centre study of adult haematological cancer patients who received auto-SCT at University College London Hospital from April 2023 to March 2025 was undertaken. Data including weight change, mode of nutritional support and length of stay were collected from the centre's electronic patient records and compared between different conditioning regimens using appropriate parametric and nonparametric statistics.

Results: Three hundred and eighty four patient were included, 60% male, median age 58 years, 69% had multiple myeloma, 21% Non-Hodgkin lymphoma, 51% were conditioned

with melphalan 200, 20% with L(B)EAM (lomustine or carmustine with cytarabine, etoposide and melphalan), 19% with melphalan 140, 10% with TT-BNCU (thiotepa and carmustine). From day 0 to day 11-13 there was a significantly greater percentage weight loss in those who received conditioning with TT-BNCU compared to those who received melphalan 200 (mean ±SD, -4.22% ±4.20 v -1.46% ±4.04, p=0.0008) and melphalan 140 (0.55% ±3.88, p=0.0001). Patients who had L(B)EAM had a significantly longer length of hospital stay (24.76 days ±20.67) than those who had melphalan 200 (18.65 days ±6.10, p<0.001) and melphalan 140 (20.52 days ±9.63, p=0.0016), as did those who had TT-BNCU (45.10 days ±52.21) compared to melphalan 200 (p<0.001) and melphalan 140 (p<0.001). Those who did not receive nasogastric tube feeding (92%, 352/384) lost significantly more weight than those who did (8%, 32/384), -2.06% ±3.91 v -0.93% ±4.98, p=0.000064. There was a significantly greater frequency of early neutrophil engraftment (<13 days) in those who received nasogastric tube feeding than those who did not (100% vs 85.5%, p=0.021).

Conclusions: Haematological cancer patients undergoing auto-SCT with TT-BNCU or L(B)EAM conditioning regimens are at significantly higher risk of early weight loss and longer hospital stay compared to those receiving melphalan 200 and 140. These results highlight a potential role for prophylactic nasogastric tube feeding in patients receiving high-toxicity regimens to minimise unintentional weight loss and support nutritional recovery throughout auto-SCT to reduce length of stay. Further prospective research is warranted to evaluate the feasibility, safety and long-term impact of prophylactic nasogastric tube feeding in patients receiving high-toxicity regimens.

Disclosure: Nothing to declare.

LATE TOXICITIES AND QUALITY OF LIFE AFTER VARNIMCABTAGENE AUTOLEUCEL (VAR-CEL): THE ROLE OF ADVANCED PRACTICE NURSING

Mercedes Montoro-Lorite[1], *Anna Garcia*[1], *Carla Ramos*[1], *Cristina Moreno-García*[1], *Carolina Bonilla-Serrano*[1], *Nuria Martínez-Cibrian*[1], *Nil Albiol*[1], *Aina Oliver-Caldes*[1], *Natalia Tovar*[1], *Ana Triguero*[1], *Valentín Ortíz-Maldonado*[1], *Carlos Fernández de Larrea*[1], *Julio Delgado*[1], *Ariadna Domènech*[1], *Pilar Ayora*[1]
[1]*Hospital Clínic Barcelona, Barcelona, Spain*

Background: As long-term survival after CAR-T therapy increases, late toxicities and health-related quality of life (QoL) have become a priority. Current evidence highlights immune dysfunctions, recurrent infections, and neurocognitive, emotional, and social challenges. However, findings remain limited, and structured frameworks for the care of long-term survivors are lacking. This study aims to evaluate late toxicities and QoL among Varnimcabtagene Autoleucel® (var-cel) survivors and to examine the contribution of advanced practice nursing (APNCART) in longitudinal follow-up.

Methods: We conducted a cross-sectional observational study between October and December 2025. Eligible participants were adults treated with var-cel (an autologous CD19-directed CAR-T) between 2017 and 2022. Sociodemographic, clinical, and occupational data were extracted from electronic medical records. QoL was assessed using the EORTC QLQ C100 instrument. Descriptive statistics were used to summarise functional and symptom scales, and exploratory analyses identified areas for potential supportive care intervention.

Results: Forty-four survivors treated with var-cel were included. The median age was 52 years (range 27 to 80). Acute lymphoblastic leukaemia was the most common indication (64%), and 57% had prior haematopoietic stem cell transplantation (HSCT). Following var-cel, 72%Seventy-two percent developed cytokine release syndrome, 36% suffered any-grade infections, and no cases of ICANS were reported.
Regarding QoL, most survivors reported preserved functioning: Eighty-six percent maintained physical functioning (86%), and preserved functional status (91%), with stable emotional functioning (80%), and cognitive performance (82%).Social relationships were satisfactory in 82%, and 64% reported improved interactions. Half of the individuals noted a positive body image, and 50% a greater sense of purpose following treatment Healthier habits were adopted by 75%, 73% expressed a positive outlook, and 57% reported enhanced social relationships. Additionally, 41% reported strengthened romantic partnerships. Sexual satisfaction was maintained in 50%, while 34% experienced sexual difficulties, and 70% reported fertility problems. The most frequent symptoms were fatigue (75%), sleep disturbances (73%) and general discomfort (66%). Severe pain was reported by fewer than 9%. Financial stress was mild to moderate in most cases (83%).
In terms of late toxicities, recurrent infections were experienced in 75%, with 59% requiring immunoglobulin supplementation, and 11% developed chronic graft-versus-host disease (all related to prior HSCT). Almost all survivors (98%) adhered to vaccination and preventive screening programs. In employment status, 39% were working; the remainder were retired or pensioners.

Conclusions: Adult long-term survivors treated with var-cel generally maintain functional status and psychosocial resilience. However, fatigue, sleep disturbances, sexual/fertility issues, and immune vulnerability remain prevalent, alongside moderate financial stress. These findings underscore the importance of APNCART in designing and implementing structured survivorship programs. Through long-term follow-up, APNCART coordinates comprehensive care by monitoring symptom, ensures adherence to vaccination and preventive measures, and supports symptom management. Direct involvement in fatigue control, sexual health counselling, and psychosocial support reinforces continuity of care and promotes active self-management.
In summary, the results describe clinical stability and social adaptation, with manageable late toxicities. Developing integrative nurse-led models is essential to optimise long-term outcomes and enhance QoL beyond survival.

Disclosure: Not conflict interest.

NP18

THE EXPERIENCE OF PATIENTS UNDERGOING CAR T CELL THERAPY: A PHENOMENOLOGICAL-INTERPRETATIVE STUDY

Alfonso Parisi[1], *Giorgia Gobbi*[1], *Angela Tolotti*[2]
[1]*Istituto Nazionale dei Tumori, Milano, Italy,* [2]*Ente Ospedaliero Cantonale, Bellinzona, Switzerland*

Background: In recent years, immune therapy, particularly that based on chimeric antigen receptor T cells (CAR-T), has represented one of the most promising treatments in the oncology and haematological field(1-3). Despite clinical efficacy, CAR T-cell therapy is associated with adverse events, including cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS)(4–6). CAR-T cell therapy and its associated toxicities can have a significant impact on patients' quality of life(7). A qualitative study found that a significant portion of patients undergoing CAR T therapy experienced difficulties in maintaining social relationships, during and after therapy; while 72% experienced fears regarding the efficacy of the treatment(8) The scientific literature still shows a lack of qualitative studies that explore the experience lived by patients during this therapeutic path. The aim of this study was to investigate the experiences of people undergoing CAR T therapy, exploring their fears, difficulties encountered, and the strategies adopted to address them.

Methods: A qualitative phenomenological-interpretative approach inspired by Patricia Benner's theoretical framework was adopted(9). This perspective allowed us to grasp the participants' experience in their embodied dimension, valorising the meaning attributed to illness and treatment(10)
Five semi-structured interviews were conducted with patients treated with CAR T cells at the National Cancer Institute in Milan, between 1° February 2025 – 1° October 2025. The interviews were analyzed through a circular hermeneutic process that allowed the emergence of profound meanings and recurring themes.

Results: The sample has a homogeneous distribution by gender, composed of 3 women and 2 men, with a mean age of 54.6 years (range between 35 and 63 years, median 58 years). The analysis revealed four main themes that describe the participants' experiential trajectory: "A leap into the dark"," Relation as an act of care", "From fear to rebirth," and "The Return to Non-Normal". The first theme recounts the entry into the CAR T path, experienced as "A leap into the dark" in which the fear of unknowns and the awareness of refractory disease intertwine. The second theme concerns the relationship with the healthcare team, experienced as an" Act of care." Transparent communication, along with autentic listening generates trust. The third theme, "From fear to rebirth", concerns strategies that help patients nurture hope. The final theme is "The return to new normality", which highlights the need to redefine everyday life, listening to one's own fragilities after therapy**.**

Conclusions: Participants describe a transformative process in which illness, therapy, and convalescence redefine body, relationships, and time, producing a new, more fragile, and consecrated-vole "non-normality".

The findings offer a deeper understanding of the experience of patients undergoing CAR T therapy, orienting nursing practice toward a care model that is more attentive to the needs of patients and their caregivers, placing greater importance on communication and education.

Disclosure: I have no conflicts of interest.

NP40

FINANCIAL TOXICITY AND ITS INFLUENCING FACTORS IN PATIENTS WITH ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHINA: A CROSS-SECTIONAL STUDY

Liyuan Qin[1], *Yang He*[1], *Qinyun Liu*[1], *Linyan Liu*[1], *Jie Li*[1], *Ahui Yuan*[1]
[1]*Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a potentially curative treatment for various hematologic malignancies. However, the substantial and prolonged costs associated with the procedure, lifelong immunosuppression, and management of complications such as graft-versus-host disease impose a severe economic strain on patients and their families, a phenomenon termed financial toxicity (FT). While FT is increasingly recognized globally, data specific to Chinese allo-HSCT patients remain scarce. Given China's unique healthcare system and socio-cultural context, understanding the prevalence and determinants of FT in this population is crucial for developing tailored supportive interventions.

Methods: A cross-sectional study was conducted at a major tertiary hospital in Shanghai between March 2024 and June 2025. A sample of 114 adult patients who had undergone allo-HSCT was recruited via convenience sampling. FT was measured using the validated Chinese version of the Comprehensive Score for Financial Toxicity (COST), where lower scores indicate higher toxicity. Perceived social support was assessed with the Perceived Social Support Scale (PSSS), and psychological resilience was evaluated using the Connor-Davidson Resilience Scale (CD-RISC). Demographic, clinical, and socioeconomic data were collected via a structured questionnaire. Statistical analyses included descriptive statistics, univariate tests (t-tests, ANOVA), Pearson/Spearman correlations, and hierarchical multiple linear regression to identify independent predictors of FT.

Results: The mean COST score was 18.73 ± 7.25, indicating severe financial toxicity (established threshold: COST<22). Univariate analyses identified several significant correlates of FT ($p<0.05$), including lower educational attainment, rural residence, lower monthly household income per capita (<3000 RMB), unemployment or sick leave due to illness, and type of health insurance. Correlation analyses revealed that both higher perceived social support ($r=0.303$, $p=0.001$) and greater psychological resilience ($r=0.365$, $p<0.001$) were significantly associated with lower FT (higher COST scores). Hierarchical regression, controlling for significant demographic and clinical variables, demonstrated that social support independently explained 8.7% of the variance in FT ($\Delta R^2=0.087$, $p<0.001$), and resilience contributed an additional 2.1% ($\Delta R^2=0.021$, $p=0.023$). A monthly household

income >5000 RMB was a strong protective factor. A notable and counterintuitive finding was that patients with a junior high school education reported significantly higher FT than those with only an elementary school education.

Table Hierarchical regression analysis of FT in patients with allogeneic hematopoietic sten

Resiliency					
adjustR2		0.439		0.531	
ΔR2		0.033		0.087	
ΔF		2.198		20.996	

Conclusions: This study reveals a high burden of financial toxicity among Chinese allo-HSCT survivors, driven by intersecting socioeconomic vulnerabilities such as low income and

unemployment. Importantly, it identifies modifiable psychosocial factors—specifically, robust social support and psychological resilience—as significant independent buffers against FT. The paradoxical finding regarding education level suggests a non-linear relationship and highlights a potentially vulnerable "awareness-penalty" subgroup that may be overlooked. These results underscore the necessity of integrating systematic FT screening into post-transplant care. They also support the development of multi-faceted, evidence-based interventions that combine financial navigation services with strategies to strengthen patients' psychosocial resources, ultimately aiming to improve treatment adherence, quality of life, and long-term outcomes for this high-risk population globally.

AN APPLIED STUDY OF STEPWISE EXERCISE NURSING PROGRAM FOR HEMATOPOIETIC STEM CELL TRANSPLANTATION PATIENTS

Mengjing Li[1], *Fengwei Du*[1]
[1]*The First Affiliated Hospital, Zhejiang University School of Medical, Hangzhou, China*

Background: In recent years, various rehabilitation nursing interventions for HSCT patients have been reported.However, studies focusing on exercise interventions for HSCT patients have mostly been small-sample feasibility studies, lacking high-quality randomized controlled trials, and there is still no unified standard for intervention formats and safety criteria.Moreover, during HSCT, patients often experience significant fluctuations in hematological parameters and are prone to infection or bleeding risks. Therefore, how to conduct effective exercise interventions while ensuring safety remains unclear and lacks evidence-based support.

Methods: A single-center, parallel-group, single-blind randomized controlled trial was conducted. A total of 66 adult HSCT patients were enrolled and randomly assigned to the experimental group (n=33) or the control group (n=33). Based on literature review and data analysis, a stepwise exercise program was developed for patients during HSCT. The experimental group received the stepwise exercise intervention, while the control group received routine exercise education. After the intervention, cardiopulmonary function, joint muscle strength, and self-care ability were compared between the two groups.

Results: After the intervention, patients in the experimental group showed significantly better lower limb muscle strength and longer six-minute walking distances than those in the control group ($P<0.001$), with marked improvement in daily living ability ($P<0.001$). The experimental group also demonstrated better nutritional status and a lower incidence of grade II or higher oral mucositis ($P=0.006$). In terms of psychological status, anxiety and depression were significantly alleviated ($P<0.05$). Regarding transplantation outcomes, the experimental group exhibited faster hematopoietic recovery, reduced transfusion

requirements, shorter febrile duration, and shorter hospital stays (P<0.05). No serious exercise-related adverse events occurred during the intervention.

Conclusions: Stepwise exercise intervention during HSCT in adults is safe and feasible, and it can improve cardiopulmonary function, exercise endurance, psychological status, and nutritional condition. This provides a new model and evidence-based approach for exercise rehabilitation management during HSCT.

INVESTIGATION OF THE ACCEPTANCE AND APPLICABILITY OF ACCELEROMETRIC MEASUREMENT OF PHYSICAL ACTIVITY BEFORE, DURING, AND AFTER ALLOGENEIC STEM CELL TRANSPLANTATION

Aleksandra Trojan[1]
[1]*University Hospital of Cologne, Köln, Germany*

Background: Allogeneic stem cell transplantation (allo SCT) is a complex and demanding form of therapy that can lead to long-term limitations in muscle strength, function and activity levels in affected individuals. Continuous and objective recording of physical activity makes it possible to detect these changes at an early stage and initiate targeted therapeutic measures during treatment and after care.
The aim of the study was to investigate the applicability and acceptance of accelerometric measurement of physical activity before, during and after allo SCT, as well as to analyze subjective and objective activity patterns and changes in strength and body composition.

Methods: The pilot study used a mixed method design with three measurement points. Physical activity was measured using accelerometry and using the Movement and Sports Activity Questionnaire. In addition, handgrip strength, body composition and acceptance were recorded. Qualitative data was evaluated according to Mayring, while quantitative data were analyzed descriptively and by using ANOVA or the Friedman test.

Results: Twelve of the fifteen recruited individuals completed all surveys and measurements. A high level of acceptance and good applicability of the accelerometric measurement were determined. Objectively recorded activity data showed a distinct decline during hospitalization and only partially recovered after discharge. In contrast the duration of bed rest increased continuously over all three measurement points. The subjective assessment reflected this downward trend, but underestimated the level of activity. In addition, handgrip strength, muscle mass and phase angle decreased. At the same time, extracellular mass and its ratio to body cell mass increased, indicating a reduced nutritional and hydration status. Due to the small and heterogeneous sample size the results should be interpreted with caution and confirmed in larger studies with longer observation periods.

Conclusions: The pilot study highlights the relevance of objective activity assessment and shows clinically relevant deterioration in activity, strength, and body composition. At the same time, the high acceptance and applicability of accelerometric measurement prove that this method can be used in the context of allo SZT. The results underline the need for further studies, early identification of at-risk patients, and intensified after care programs. Overall, the study makes a valuable contribution to a field that has otherwise been hardly researched in Germany and contributes to sustainably improve the care structures for this vulnerable patient group.

Disclosure: Nothing to declare.

NP46

LIVED EXPERIENCES AND PERCEIVED QUALITY OF CARE IN ALLO-HSCT: A QUALITATIVE SUBSTUDY OF THE PHARALLO PROGRAMME

Paula Guijarro Martínez[1], *Raquel Luengo González*[2], *Begoña Hinojo Marín*[1], *Gema Nova Ruíz*[1], *Beatriz Maza Muela*[1], *Marina Sánchez Cuervo*[1], *Maria de los Angeles Parro Martín*[1], *Alejandro Luna de Abia*[1], *Anabelle Chinea Puente*[1], *Pilar Herrera Puente*[1], *Javier López Jimenez*[1], *Ana María Álvarez Díaz*[1]
[1]*Ramón y Cajal University Hospital, IRYCIS, Madrid, Spain,* [2]*University of Alcalá. Alcalá de Henares (Madrid, Spain), Madrid, Spain*

Background: Allogeneic haematopoietic stem cell transplantation (allo-HSCT) profoundly influences patients' emotional, physical and social experiences. The PHARALLO study (PHARmaceutical care program in patients undergoing ALLOgeneic hematopoietic stem cell transplantation), a historically controlled intervention programme conducted at our hospital between 2023 and 2024, evaluated whether a comprehensive pharmaceutical care model improves health and patient-reported outcomes. The programme included structured follow-up through day +100 post-transplant, covering the critical early recovery period. Within this framework, this qualitative substudy explored participants' lived experiences and examined how patients and families perceive care, information and support throughout the transplant process.

Methods: A descriptive qualitative design was used. Patients included in PHARALLO were invited to participate voluntarily in an in-person semi-structured group interview. All participants had already completed the PHARALLO follow-up period (Day +100), ensuring that interviews captured their full early post-transplant recovery experience. Purposeful sampling yielded three patients and one accompanying family member, limited by feasibility constraints related to distance, recent complications or admissions. The interview, facilitated by an expert in qualitative research, was audio-recorded, transcribed verbatim and analysed through thematic analysis. The analytic process included: (1) literal transcription; (2) open coding to identify units of meaning; and (3) axial coding to integrate codes into broader conceptual categories. This inductive–deductive approach enabled a reconstruction of the experiential trajectory of allo-HSCT. All participants provided written informed consent. The

study was conducted in accordance with the Declaration of Helsinki and approved by the local ethics committee (Code: 245/23).

Results: Multiple descriptive codes were grouped into families representing emotional responses, physical symptoms, coping strategies, social challenges and interactions with healthcare teams. Through axial coding, three overarching categories were identified:

1. **Diagnosis of the disease: biographical rupture and fear**
   Patients described the diagnosis as a "vital blow", characterised by fear of death, shock, perceived injustice and sudden disruption of daily life. Immediate hospitalisation intensified anxiety and loss of control. Emotional containment by relatives and clear explanations from professionals mitigated early distress.
2. **Hospital admission: vulnerability and multidimensional support**
   Patients experienced profound physical fragility—weakness, mucositis, pain, fatigue, dysphagia and functional decline. Nurses, haematologists and pharmacists were perceived as a stabilising anchor, providing safety, trustworthy information and therapeutic education. Family caregivers served as key emotional and practical support.
3. **Post-discharge uncertainty: living on a tightrope**
   The post-discharge period was dominated by persistent fear of relapse, hypervigilance towards bodily changes and heightened anxiety around follow-up analyses. Patients used active coping strategies (e.g. walking, yoga, guided exercises), promoting a sense of agency. Recovery was described as a fluctuating "roller coaster", with ongoing physical limitations and emotional instability. Social and financial vulnerability emerged as major stressors. Despite this, participants reported personal growth, redefined priorities and renewed hope.

Conclusions: This qualitative substudy highlights allo-HSCT as a transformative experience marked by emotional rupture, bodily fragility, caregiver dependence and persistent uncertainty after discharge. The multidisciplinary support offered in PHARALLO was perceived as essential for safety, education and emotional containment. Qualitative research provides valuable insights that deepen understanding of patient needs and inform refinement of person-centred care strategies in allo-HSCT.

EVALUATION OF THE EFFICACY OF ULTRASOUND-GUIDED MEDIUM-LENGTH CATHETERS IN THE COLLECTION OF PERIPHERAL BLOOD HEMATOPOIETIC STEM CELLS FROM HEALTHY DONORS

Fengwei Du[1]
[1]*The First Affiliated Hospital, Zhejiang University School of Medical, Hangzhou, China*

Background: The efficacy of peripheral blood hematopoietic stem cell collection is influenced by catheter placement. Clinically, 16G cannula needles are commonly used for the puncture of the median cubital vein at the elbow. However, approximately 5% of healthy

donors have inadequate peripheral venous access. When peripheral venous puncture fails or insufficient blood flow for collection is obtained, central venous catheterization or arterial catheterization is often selected. How to efficiently and safely collect peripheral blood hematopoietic stem cells while minimizing donor discomfort remains a key focus in current hematopoietic stem cell transplantation research.

Methods: A retrospective study was conducted on 95 healthy donors who underwent peripheral blood hematopoietic stem cell collection at our center between January and June 2025. The control group (n=47) from January to March utilized 16G arteriovenous fistula puncture needles. The observation group (48 cases) used ultrasound-guided placement of medium-to-long-length catheters as the collection access route from April to June. The study compared the following parameters between groups: first-puncture success rate, puncture pain intensity, anxiety level, collection comfort, incidence of catheter-related complications, attainment rate of blood flow rate, and number of low-pressure alarms during collection.

Results: Compared with the control group, the observation group demonstrated significantly higher first-attempt puncture success rates ([100% vs 87.23%], P<0.05). Puncture pain scores (NRS) among donors in the observation group were significantly lower than those in the control group (P<0.05). Donors in the observation group reported significantly higher comfort scores during the collection process than those in the control group (P<0.01). Regarding complications, the overall complication rate was significantly lower in the observation group than in the control group ([6.25% vs 23.40%], P<0.05). No significant differences were observed between the two groups in anxiety scores (GAD-7), blood flow rate attainment rates, or the number of low-pressure alarms in the collection pathway (P>0.05).

Conclusions: In the collection of peripheral blood hematopoietic stem cells from healthy donors, the use of ultrasound-guided placement of medium-to-long-length catheters offers advantages such as high puncture success rates, ease of operation, stable blood flow velocity, high donor comfort, and fewer complications. This technique represents a safe, effective, and ideal method for establishing vascular access and warrants widespread adoption in clinical practice.

Disclosure: Nothing to declare.

NP118

APPLICATION OF FAMILY CONSTRUCTION MODEL IN HEMATOPOIETIC STEM CELL TRANSPLANTATION COMBINED WITH CAR-T CELL THERAPY IN PATIENTS WITH LYMPHOMA

Shasha Li[1], *xiaoli chen*[1], *jun rao*[1], *xi zhang*[1]
[1]*Blood Disease Medicine Center, Second Affiliated Hospital of Army Medical University, Chongqing, China*

Background: Objective To evaluate the Family-Centered Care Model (FCCM) in improving psychosocial support and treatment outcomes for relapsed/refractory lymphoma patients undergoing hematopoietic stem cell transplantation (HSCT) combined with chimeric antigen receptor T-cell (CAR-T) therapy.

Methods: A prospective cohort study was conducted from 2023 to 2024, enrolling 30 leukemia patients receiving HSCT followed by CAR-T therapy. Participants were divided into an FCCM intervention group and a conventional care group. The intervention group received the following FCCM interventions: 1. Family collaboration plan: Multidisciplinary teams worked with families to establish treatment goals, nursing responsibilities, and emergency protocols. 2. Family empowerment education: Online/offline training to enhance families' ability to recognize and manage complications (e.g., chronic fatigue syndrome [CRS], infections). 3. Psychological support: Weekly family group counseling and emotional management sessions. Outcome measures included HADS anxiety/depression scores, treatment adherence, complication rates, and Family Assessment of Disease (FAD) scores.

Results: The intervention group showed significantly lower anxiety (HADS-A: 6.2±1.8 vs. 10.5±2.3) and depression (HADS-D: 5.8±1.6 vs. 9.1±2.1) scores compared to the control group (*P*<0.01). Treatment adherence improved to 94.3% (control group: 74.3%, *P*=0.021). The Family Activity Domain (FAD) score showed significant improvement (1.9±0.4 vs. 2.7±0.5, *P*<0.001), with a marked reduction in severe chronic fatigue syndrome (CRS, grade 3 or higher) incidence (14.3% vs. 34.3%, *P*=0.047).

Conclusions: By enhancing family involvement and collaborative management, the family support model effectively alleviates psychological stress in lymphoma patients and reduces treatment-related complications, providing a robust nursing support strategy for the complex treatment regimen of hematopoietic stem cell transplantation (HSCT) combined with chimeric antigen receptor T-cell therapy (CAR-T).

NP53

SECONDARY CANCERS AFTER STEM CELL/BONE MARROW TRANSPLANT: INCIDENCE, SCREENING, AND EDUCATION IN A SINGLE-CENTRE REVIEW

Paul Hickey[1], *Fiona Dignan*[1], *Marie Jones*[1]
[1]*Manchester Royal Infirmary, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Stem cell/bone marrow transplant (BMT) is a curative treatment for haematological malignancies but carries long-term risks, including secondary cancers reported to be seen in 5-10% of patients (Martelin et al, 2019) . In our centre once patients are medically stable and in remission, they transition to the late effects of transplant clinic for lifelong monitoring. This clinic is led by a haematology consultant and supported by

Advanced Nurse Practitioners (ANPs) who together play a pivotal role in delivering education, health promotion, and implementing health screening strategies. Early detection of secondary cancers is essential so treatment can be initiated to improve outcomes and reduce morbidity and mortality (EBMT, 2024).
Objective: Review the incidence of secondary cancers among BMT patients attending a late effects clinic over 12 month and evaluate the impact of screening and education strategies.

Methods: A prospective and retrospective review was conducted of all BMT patients attending the late effects clinic during a 12-month period. Data collection included:

- Original haematology diagnosis
- Transplant type, conditioning regimen, and donor type
- Type of cancer developed and time post-transplant
- Method of cancer detection
- Prior cancer history

Screening strategies included annual prostate-specific antigen (PSA) testing and adherence to national cancer screening programs. Patients were educated on lifestyle risk reduction (e.g., weight loss, exercise, smoking cessation, sun protection and skin monitoring).

Results: The results indicate that 10% of patients seen over the 12-month period developed a secondary cancer post-transplant. In addition, the data highlighted that 14% of our total patient group had been diagnosed with a cancer before or after BMT. Of these:

- 70% developed cancer post-transplant
- 30% had a different cancer prior to transplant
- 6 patients had cancers both pre- and post-transplant
- 5 patients had more than two cancers

The most common pre-transplant cancers were:

- Breast (18%)
- Bladder (18%)
- Prostate cancer (12%)
- Haematology cancers (15%) (Hodgins disease, myeloma, lymphoma- not the transplant indication)

Other cancers included lung, rectal, cervical, bowel, liver and oesophageal
The most common post-transplant cancers were:

- Skin (49%)
- Prostate (25%)
- Breast (6%)
- Lung (6%)
- Brain (3%)

Other cancers included oral, ovarian, genitourinary, gastric, and additional haematological malignancies.

Additionally, MGUS was detected in 6 patients.
Notably, 18 prostate cancers were diagnosed through early PSA screening (non-symptomatic patients), enabling timely intervention and treatment.

Conclusions: Secondary cancers remain a significant late effect following BMT, with an incidence of approximately **10%** in our patient group, similar to the reported incidence (Martelin et al, 2019), risk factors in our patient population will be further analysed. Along with medical colleagues ANPs are integral to implementing education, surveillance, and screening strategies. Early detection, such as targeted PSA testing can demonstrate benefit in reducing delays to diagnosis and improving patient outcomes. Continued emphasis on patient education, lifestyle modification, and proactive screening is essential to reduce cancer-related morbidity and mortality in this patient group.

SETTING UP A PRE AND POST ALLOGENIC BONE MARROW TRANSPLANT (BMT) OUTPATIENT PHYSIOTHERAPY SERVICE IN A UK TERTIARY HOSPITAL SETTING - INITIAL RESULTS AND REFLECTIONS

Emma Nicholls[1]
[1]*Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom of Great Britain and Northern Ireland (the)*

Background: A Physiotherapist was recruited for the first time in to our BMT service to develop and provide a new, highly specialist, evidence-based Physiotherapy service to patients treated within the BMT Team within the Haematology Department at the Churchill Hospital, Oxford University Hospitals NHS Trust (OUHFT). A new pathway was implemented for Stem Cell Transplant patients offering Physiotherapy input both pre and post transplant to optimise quality of life and functioning and to monitor standards of practice and the impact on patient care and outcomes.

Methods: A Physiotherapist was embedded in to our Bone Marrow Transplant clinics and services to see people pre and post Allograft.
All pre Allogeneic Transplant patients receive either an in person consultation or telephone call with Prehabilitation (Prehab) guidance and advice prior to transplant, including targeted exercise prescription.
Post Allograft patients are referred on a need by need basis via the nursing and medical team. Referral criteria include join and skin Graft versus Host Disease, mobility issues,

fatigue and deconditioning/sarcopenia. Onward referrals are completed for those needing to access local exercise interventions or Community Physiotherapy/OT/Dietetics support. Outcome measures collated include the FACIT fatigue scale, 1 minute sit to stand, OUH GVHD range of movement score and SARC-F sarcopenia score.

Results: To date 66 patients have received prehab. 76 patients have been treated post Allograft.
Incomplete data sets exist currently for the outcome measures outlined above and collation of these are ongoing. Despite this, sarcopenia has been identified in our patients pre transplant across age groups, with some scoring higher than expected, indicating the potential for complications during and after transplant.
14/19 patients showed signs of sarcopenia on discharge post transplant, with 6/19 of these with sarcopenia at levels indicative for poor outcomes.12/19 patients were still showing signs of sarcopenia 100 days post transplant but only 4 at a level considered indicative for poor outcome.

Conclusions: The Physiotherapy service has been well received by staff and patients with positive feedback received.
The levels of sarcopenia identified in patients pre and post transplant demonstrates a need for timely access to clinicians trained in prehab, rehab and exercise prescription for this patient cohort.
Challenges have been recognised with regards to delivering an equitable Physiotherapy service within a tertiary centre setting. During the first year of service, Prehab was an opt in for patients, with most receiving a telephone call rather than in person prehab consultations due to the distance required to travel to hospital. As of January 2026, we plan to integrate the Physiotherapy Prehab service as an opt out component to patient's work up investigations pre transplant and include MUST score screening to identify those at risk of malnutrition. We plan to complete additional outcome measures during this appointment, including hand grip dynamometry, timed up and go and EORTC QLQ 30, to further demonstrate the impact of prehab screening and intervention for our patients.

Disclosure: Physiotherapy role has been funded on a trial basis for 3 years by Anthony Nolan.

NP90

NUTRITION IMPACT SYMPTOMS AND NUTRITIONAL STATUS IN ADULT ALLO-HSCT RECIPIENTS DURING 1-YEAR FOLLOW-UP

Sebastian Sundsbarm[1,2], *Asta Bye*[2,1], *Geir Erland Tjønnfjord*[1,3], *Per Ole Iversen*[1,3], *Kristin Joan Skaarud*[1,4]
[1]*Oslo University Hospital, Oslo, Norway,* [2]*Oslo Metropolitan University, Oslo, Norway,* [3]*University of Oslo, Oslo, Norway,* [4]*Lovisenberg Diaconal University College, Oslo, Norway*

Background: Nutrition impact symptoms (NIS) are contributors to impaired nutritional status in allo-HSCT patients. However, the impact of patients' reported NIS on nutritional

status are poorly described. This study investigated changes in NIS and nutritional status, and associations between NIS and nutritional status during a 1-year follow-up of allo-HSCT patients.

Methods: We used data from 117 patients (57 intervention, 60 control) who participated in a randomized controlled nutritional intervention trial. Linear mixed models were used to analyse changes in NIS over time. Ordinal logistic regressions were used to analyse associations between NIS and nutritional status.

Results: Nausea and vomiting and constipation were significantly lower in the intervention group than the control group during 1-year follow-up ($p = 0.015$ and $p < 0.001$, respectively). Initially, nutritional status declined in both study groups post-allo-HSCT but improved over time. Significantly fewer patients in the intervention group were malnourished at 3 weeks ($p = 0.020$) and 6 weeks post-transplantation ($p = 0.028$). Associations between NIS and nutritional status varied over time and differed between the study groups at 6 weeks post-transplantation (OR 3.702, 95% CI: (1.355, 10.100), $p = 0.011$).

Conclusions: In conclusion, our findings emphasize the need for long term monitoring of symptoms and nutritional status in allo-HSCT patients, supporting individualized nutritional assessments as part of long-term care strategies.

Disclosure: Geir Erland Tjønnfjord has received research grants from Mundipharma and Alexion Pharmaceuticals, advisory board honoraria from Alexion Pharmaceuticals and Johnson & Johnson, and lecture honoraria from Novartis, Johnson & Johnson, Alexion Pharmaceuticals, and Mundipharma. The other authors declare no competing interest.

Symptom Management and Supportive Care

NG10-01

PAIN MANAGEMENT PRACTICES DURING PAEDIATRIC ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE COHORT STUDY

Karin Plummer[1,2], *Maria McCarthy*[2,3,4], *Heather Weerdenburg*[2], *Michelle Tennant*[2,3], *Diane Hanna*[2,3,4], *Hyatt Assafiri*[2], *Theresa Cole*[2], *Molly Williams*[2], *Dyan Cana*[2], *Olivia Haynes*[2], *Maddie Gilsenan*[2], *Hannah Walker*[2,3,4]
[1]*Griffith University, Gold Coast, Australia,* [2]*The Royal Children's Hospital, Melbourne, Australia,* [3]*Murdoch Children's Research Institute, Melbourne, Australia,* [4]*University of Melbourne, Melbourne, Australia*

Background: Pain during paediatric haematopoietic stem cell transplantation (HSCT) is severe, prolonged, and frequently refractory to multimodal treatment. Existing literature focuses largely on acute mucositis, providing limited insight into pain and pain-related

distress across the broader early post-transplant period. Understanding real-world analgesic practices and supportive care use is essential to optimising care for this vulnerable population.
The objective of this study was to characterise pharmacological and supportive care practices used to manage pain and pain-related distress in children undergoing allogeneic HSCT from conditioning to day +100 post-transplant.

Methods: We conducted a single-centre retrospective cohort study of paediatric patients (0–18 years) undergoing first allogeneic HSCT at a tertiary paediatric cancer centre in Australia between 2016 and 2022. Data were extracted from the electronic medical record using automated retrieval. Descriptive analyses summarised patient characteristics and pain management practices across the HSCT trajectory. Continuous variables were reported as medians with interquartile ranges (IQR), and categorical variables as frequencies and percentages. Analyses were conducted using R software in accordance with a pre-specified analysis plan.

Results: Of 203 children undergoing first allogeneic HSCT, 190 (93.6%) had complete pain management data and were included. Among these, 110 (57.9%) had malignant indications, most commonly acute myeloid leukaemia (35/110, 31.8%). Median age at transplant was 6.8 years (IQR 3.0–13.1), and matched unrelated donors were most frequent (77/190, 40.5%).
All children (190/190) received analgesic medication post-HSCT. Morphine and oxycodone were used in >90% of patients, and fentanyl in 87 (45.8%). During days 1–30, median duration of opioid use was 18 days (IQR 9–25) for morphine, 11 days (IQR 4–19) for fentanyl, and 2 days (IQR 1–4) for oxycodone. Paracetamol was used universally (median 11 days, IQR 7–17). Common adjuvant agents included ketamine (112/190, 59.0%; median 10 days, IQR 4–15.5) and gabapentin (35/190, 18.4%; median 12 days, IQR 0–22).
Although most pain assessments indicated no or mild pain (88%), 137 children (72%) experienced at least one episode of severe pain. Severe pain episodes occurred predominantly during days 1–30 (104, 55%), with persistence through days 31–60 (44, 23%) and days 61–100 (29, 15%). Acute pain services were accessed via inpatient referral orders in 72 children (35%, median day +12), whereas palliative care consultation occurred in 51 children (27%) and was initiated later (median day +59).

Conclusions: Children undergoing HSCT experience a substantial and enduring pain burden requiring complex multimodal analgesia, with severe pain episodes remaining common despite widespread pharmacological and supportive care use. Specialist pain and palliative care services were accessed in a subset of patients and were often initiated later in the transplant course. These findings provide important real-world evidence of current pain management practices during paediatric HSCT and identify opportunities to optimise the timing, coordination, and standardisation of multimodal pain care.

Disclosure: No conflicts of interest to disclose.

ASSESSMENT AND MONITORING OF NUTRITIONAL STATUS IN ONCO-HEMATOLOGICAL PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT): TOOLS, SCALES AND MULTIDISCIPLINARY APPROACH

*Silvia Gnecchi[1,2], **Alice Passoni**[1], Giacomo Amietta[2], Chiara Gandossi[1], Andrea Pontara[1], Lorenzo Lazzari[1], Fabio Ciceri[1,2], Anna Carmagnola[1,2]*
[1]IRCCS San Raffaele Scientific Institute, Milan, Italy, [2]Vita-Salute San Raffaele University, Milan, Italy

Background: Allogeneic Hematopoietic Stem Cell Transplantation (Allo-HSCT) is a therapeutic approach for numerous onco-hematological diseases. Conditioning chemotherapy and the transplant itself expose patients to a high risk of malnutrition due to multiple adverse effects. Despite the importance of nutritional monitoring, the current assessment tools adopted for patients undergoing allo-HSCT are poorly specific and obsolete in the Italian setting. The primary aim of this review is to identify specific methods and tools for the assessment and monitoring of the nutritional status of patients undergoing allo-HSCT. Considering the Lombardy Regional Resolution No. 1812 of January 3, 2024, which mandates the use of the *Malnutrition Universal Screening Tool* (MUST) or the *Nutritional Risk Screening 2002* (NRS-2002), the secondary aim is to determine which of the two tools is more effective to evaluate the target population.

Methods: A scoping review was conducted searching in the following databases: MEDLINE (PubMed), CINAHL (EBSCO), and Scopus (Elsevier). Articles published between 2000 and 2025 in English or Italian language were included. Other inclusion criteria were: population of onco-hematological patients aged >18 years undergoing Allo-HSCT; nutritional assessment and screening tools in patients undergoing allo-HSCT; and bio-psycho-physical outcomes resulting from the systematic use of targeted nutritional scales and multidisciplinary approaches.

Results: From the 23 articles included in the review, five nutritional scales used in patients undergoing HSCT emerged. The tools identified in the literature as particularly relevant and effective in the onco-hematological and transplant setting were the *Patient-Generated Subjective Global Assessment* (PG-SGA) and the NRS-2002, both validated in Italian. The former allows the early identification of malnutrition and detailed information collection. The latter, NRS-2002, allows a quick stratification of the nutritional risk distinguishing the onco-hematological and the transplanted patients. The MUST appeared to be poorly sensitive and specific for the screening and monitoring of malnutrition risk in the target population.

Conclusions: The identified scales are effective in detecting the risk of malnutrition and improving clinical outcomes in the population of interest. Among the tools evaluated, only the *Malnutrition Screening Tool* (MST) has not yet been validated in Italian. Between MUST and NRS-2002, the NRS-2002 proved to be more sensitive and specific. The integration of PG-SGA or NRS-2002 appears to be the most appropriate approach for nutritional screening and monitoring in oncohematological and transplant in the Italian settings.

The findings of this work represent a solid starting point for the progressive implementation of NRS-2002 in the Bone Marrow Transplant Unit in IRCCS San Raffaele Scientific Institute in Milan. It is advisable to develop a specific pathway combining assessment tools with biochemical and anthropometric parameters. In a preliminary phase, NRS-2002 could be integrated to the MUST which is currently mandatory according to the Standard Operating Procedures in all the Units. Its systematic introduction could promote the adherence to the most recent clinical-nutritional recommendations.

NP25

EARLY NURSING ASSESSMENT AND MANAGEMENT OF OCULAR GRAFT-VERSUS-HOST DISEASE IN TAIWANESE LONG-TERM ALLO-HSCT SURVIVORS: A TWO-YEAR RETROSPECTIVE STUDY

Chiao-Fang Chang[1], *Jui-Yi Chen*[1], *Hui-Ju Tsai*[1], *Chien-Chin Lin*[1]
[1]*National Taiwan University Hospital, Taipei, Taiwan (Province of China)*

Background: Ocular graft-versus-host disease (oGVHD) is a frequent complication among long-term survivors after allogeneic hematopoietic stem cell transplantation (Allo-HSCT) and significantly impairs quality of life. Data on its timing, severity, and the role of nursing interventions in Taiwanese populations are limited. This study aimed to characterize the clinical features of oGVHD and to evaluate the impact of early nursing assessment and intervention.

Methods: A total of 30 adult Allo-HSCT recipients at National Taiwan University Hospital who were continuously followed by a designated case manager were retrospectively enrolled in 2023. Patients who died post-transplant, underwent a second transplant, or had pre-existing ocular disease were excluded. Eighteen long-term survivors (>2 years post-HSCT) were analyzed. Standard assessments were conducted at 3, 6, 12, 18, and 24 months post-transplant. oGVHD was graded using the NIH Chronic GVHD Eye Scoring System. Patients with eye score ≥1 received standardized nursing education (humidification, warm compresses, artificial tear use), counseling for ocular red-flag symptoms, and referral to ophthalmology. Demographics, GVHD organ involvement, and oGVHD onset, severity, and course were collected.

Results: The cohort included 12 males and 6 females with a mean age of 45 years (range 22–69). Related donors accounted for 77.8% of transplants; 44.4% were fully HLA-matched, 44.4% haploidentical, and 11.1% partially mismatched. The most common GVHD manifestations were skin (66.7%) and oral involvement (61.1%), with oGVHD as the third most frequent (44.4%). Other affected organs included liver (16.7%), lung (11.1%), and gastrointestinal tract (11.1%).
Most oGVHD cases developed within 3–6 months post-transplant (75%), with one case each at 12 months and 25 months. All patients initially presented with eye score 1 and received nursing intervention and ophthalmology referral. Two patients progressed to score 2: one

due to poor adherence to artificial tears while working overseas, which improved back to score 1 after treatment; the other following three donor lymphocyte infusions for early relapse associated with worsening skin GVHD, remaining stable at score 2 without functional impairment. Of the remaining six patients, five maintained stable score 1 disease, and one achieved complete resolution (score 0) by 22 months post-transplant.

Conclusions: Despite the limited sample size, oGVHD was the third most common manifestation of chronic GVHD in this cohort and most frequently developed within 3–6 months after transplantation. Persistent ocular symptoms were associated with functional limitations, including difficulty with work and driving. Our findings suggest that early nursing assessment, prompt self-care education, and timely ophthalmologic referral may effectively prevent disease progression from eye score 1 to score 2.
Larger prospective studies with longer follow-up are warranted to further evaluate nursing intervention outcomes and to explore associations between oGVHD severity and quality of life. Early identification and early intervention remain essential strategies for optimizing long-term survivorship outcomes following Allo-HSCT.

Disclosure: Nothing to declare.

NP33

ASSESSING THE TOLERANCE OF FIBRE BASED FEEDS FOR PAEDIATRIC PATIENTS DURING AN ALLOGENEIC STEM CELL TRANSPLANT

Chloe Elliott[1]
[1]*Great Ormond Street Hospital for Children, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Enteral nutrition is an inevitable part of treatment for a Haematopoietic Stem Cell Transplant (HSCT), due to the side effects of chemotherapy. The prescription of fibre-devoid hydrolysed (HF) and amino acid formulas (AAF) is standard practice for the management of gastrointestinal mucositis. However, within this complex cohort, there is limited evidence to support these formulas over whole protein fibre-based formulas. Conversely, there is growing evidence to support the beneficial role of fibre in promoting a healthy gut microbiome, which may mitigate the gastrointestinal side effects of HSCT as well as improve transplant-related outcomes. Therefore, from June 2024, whole protein fibre-based formulas were prescribed for patients undergoing an HSCT,
Aim: To compare the gastrointestinal tolerance and incidence of parenteral nutrition (PN) between whole protein fibre-based formulas with fibre-devoid HF and AAF during HSCT.

Methods: Data were collected retrospectively from EPIC on demographics, diagnoses, conditioning regimens, enteral formula type, and PN from June 2023 to June 2025.

Results: 99 patients were included in the data collection. 33 (33%) children received a fibre formula, 44 (44%) received a HF, 21 (21%) received an AAF and 4 (4%) received a whole

protein non fibre feed (4%). PN was required by 52 patients (53%). Fibre and AAF **reduced** the likelihood of PN in children who had **Myeloablative Conditioning Reduced-Toxicity (MAC RT): p=0.01.**
The type of feed formula (fibre vs non fibre) did not impact the likelihood of PN in children who had Minimal/Reduced Intensity Conditioning (MIC/RIC) conditioning: p=0.73
Fibre
Of the 33 patients; 16 patients (48%) required PN. 10 patients (63%) received MAC, 5 (31%) patients received MAC RT and 1 patient (6%) received MIC/RIC.
HF
Of the 41 patients; 28 patients (68%) required PN. 12 patients (42%) received MAC, 13 (46%) patients received MAC RT and 3 patient (12%) received MIC/RIC
AAF
Of the 21 patients; 7 patients (33%) required PN. 1 patient (14%) received MAC, 5 (72%) patients received MAC RT and 1 patient (14%) received MIC/RIC
Whole protein
Of the 4 patients; 1 patient (25%) required PN. This patient received MAC,

Conclusions: Fibre- based feeds are well tolerated during conditioning as well as during mucositis and does not increase the use of PN. Children receiving MAC may tolerate fibre feeds during transplant and not require escalation to PN. Longer term data is needed to assess the clinical outcomes between fibre and non-fibre-based enteral formula including graft vs host disease.

Disclosure: nil

NP105

NURSING MANAGEMENT OF A COMPLEX PEDIATRIC ALLO-HSCT CASE FOR BETA-THALASSEMIA MAJOR WITH MULTIPLE SEVERE POST-TRANSPLANT COMPLICATIONS

Dung Tran Thi[1]
[1]*Vinmec International Hospital, Hanoi, Viet Nam*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is one of the curative treatment options for beta-thalassemia major. However, pediatric patients undergoing allo-HSCT—especially from partially matched donors—are vulnerable to early life-threatening complications that require vigilant, highly skilled nursing care. This report describes a complex case in a 4-year-old girl who developed multiple severe post-transplant complications. The case highlights the essential role of transplant nursing in early recognition, timely intervention, and coordinated management during critical phases of clinical deterioration.

Methods: Case Presentation: A 4-year-old girl with transfusion-dependent beta-thalassemia major underwent allo-HSCT from an HLA 9/10 sibling donor. On Day +4, she developed persistent high-grade fevers occurring every 4 hours, ranging from 38°C to 42°C,

accompanied by marked fatigue, poor oral intake, irritability, and limited cooperation due to her young age. Blood culture on Day +4 grew Enterobacter cloacae. Despite antimicrobial adjustment, she continued to spike high fevers, and by Day +6, blood cultures were positive for multidrug-resistant Klebsiella pneumoniae. On Day +11, the patient developed severe veno-occlusive disease with hepatomegaly, painful abdominal distension, respiratory distress, and hemodynamic instability requiring ICU transfer. Additional complications included acute kidney injury from Cyclosporin A inhibitors, BK virus–related hemorrhagic cystitis presenting as painful red urine, severe mucositis, diarrhea, and prolonged febrile episodes.
Nursing Management:
(1) Early detection of sepsis through continuous monitoring of recurrent high fevers, rapid clinical changes, and escalation for antimicrobial adjustment.
(2) Central-line management, including strict aseptic technique, wound assessment, removal of the infected catheter, and preparation for the placement of a new line.
(3) VOD monitoring, assessing weight gain, abdominal girth, hepatomegaly, worsening dyspnea, and coordinating timely initiation of Defibrotide.
(4) Respiratory and hemodynamic support, including monitoring work of breathing, oxygen saturation, fluid overload, and assisting with ICU-level interventions.
(5) Renal care, optimizing hydration and adjusting immunosuppressive therapy.
(6) Management of BK cystitis, documenting hematuria, ensuring bladder comfort, hydration, and pain relief.
(7) Symptom relief for mucositis, anorexia, fatigue, and distress, while providing age-appropriate emotional support for a poorly cooperative young child.
(8) Family education, helping parents understand evolving complications and treatment expectations.

Results: Result: Neutrophil and platelet engraftment occurred on Days +22 and +40. Donor chimerism reached 90% by Day +30. All major complications—including VOD, MDR sepsis, respiratory distress, renal toxicity, and BK virus cystitis—gradually resolved with intensive supportive care. At long-term follow-up on Day +552, the patient remains clinically stable, transfusion-independent, and demonstrates 93% donor chimerism with normal organ function and appropriate growth for age.

Conclusions: Conclusion: This complex case illustrates how comprehensive nursing surveillance and rapid multidisciplinary coordination are critical to managing multiple life-threatening complications after pediatric allo-HSCT. Early detection of sepsis, meticulous catheter care, close monitoring of VOD and organ dysfunction, and age-appropriate supportive strategies contributed significantly to the successful recovery of this high-risk patient.

"LIGHTING THE WAY" -ENABLERS OF IMPLEMENTING PHOTOBIOMODULATION THERAPY FOR MUCOSITIS IN PAEDIATRIC HSCT

Elaine Smyth[1]
[1]*University College Dublin / Children's Health Ireland, Dublin, Ireland*

Background: Oral mucositis (OM) is a common, painful, and debilitating complication of haematopoietic stem cell transplant (HSCT). Guidelines recommend photobiomodulation (PBM) therapy to prevent and treat OM in children and adolescents undergoing HSCT. However, healthcare professionals caring for this cohort have resisted adopting this intervention. This review aims to synthesise knowledge supporting the implementation of guidelines to inform clinical practice, improve patient care, enhance quality of life, and reduce healthcare costs.

Methods: A comprehensive search strategy was developed to identify pre-existing evidence addressing the implementation research question: What factors facilitate the implementation of photobiomodulation therapy for managing mucositis in children and adolescents undergoing haematopoietic stem cell transplants? Yielding relevant studies across the evidence hierarchy advanced the understanding of the implementation challenges. The iPARIHS (Promoting Action on Research Implementation in Health Services) framework was employed to frame the synthesis (Huang et al., 2024)

Results: Results after synthesising and analysing 17 studies that met the inclusion criteria, four themes emerged as significant components in translating PBM into clinical practice:
• Standardisation and protocol development
• Stakeholder support - education and training
• Organisational leadership and collaboration
• Innovation integration - resource allocation
Although translating evidence into practice is considered complex and challenging, the author proposes a series of strategic actions guided by implementation science and systems thinking to facilitate a coordinated, multidimensional approach that engages interdisciplinary stakeholders in implementing PBM therapy to prevent and treat OM in children and adolescents undergoing HSCT.

Conclusions: This study identifies barriers and facilitators that influence the implementation of PBM therapy to prevent and treat OM in children and adolescents undergoing HSCT. Successful implementation has the potential to improve patient care practices in the management of mucositis. Future studies exploring patients' and clinicians' preferences and values would gain a more holistic understanding of their diverse insights and perspectives. As the evidence for PBM therapy evolves, the role of ANP as a facilitator is crucial in championing and leading change, bridging the gap between current evidence and clinical practice, harnessing the potential to alleviate suffering and improve the quality of life for paediatric HSCT patients

Disclosure: No Conflict of interest

NP113

PHOTOBIOMODULATION IN THE TREATMENT OF ORAL MUCOSITIS IN THE TRANSPLANT SETTING FOR CHILDREN AND YOUNG PEOPLE

Sarah Davies[1], *Darren Lamport*[1], *Helen Pearson*[1], *Caroline Furness*[1]
[1]*The Royal Marsden Hospital, Sutton, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Oral mucositis is a frequent complication affecting children and young people (CYP) receiving high dose treatment for cancer and undergoing bone marrow transplantation. Mucositis causes loss of mucosal lining leading to pain, ulceration and consequently poses an increased risk of systemic infection. Current treatment modalities include both preventative and symptomatic control which include difficulties with administration, cooperation and unwanted side effects/toxicities.
Effective treatment and prevention are paramount to patients, families and oncology services to reduce the impact on CYP with cancer, to reduce the disruption to their cancer treatment and to prevent the subsequent rise in the expense and burden of cancer care.
Photobiomodulation is a national and international supported treatment option of mucositis for CYP with research shown to improved quality of life, reduced pain levels leading to a reduction in treatment pain modalities, improved nutrition, reduced prolonged hospitalisation and reduced risk of infection.

Methods: **Intervention:** Photobiomodulation is a form of light therapy involving LED in the visible and infrared spectrum. It is a simple, quick, non-invasive and non-thermal treatment which alters cellular metabolism through absorbing light energy by photoreceptors situated in the mitochondrial membrane. This encourages mucosal repair, promotes tissue damage and prevents cellular breakdown.
The aim is to commence the first photobiomodulation treatment within 24-hours of chemotherapy and continue daily for the duration of treatment. For treatment of established oral mucositis, treatment should be delivered a minimum of three times per week until completion of treatment or resolution of symptoms. Treatment is delivered across five areas with one minute per treatment area – extra oral over right cheek, extra oral over left cheek, extra oral over lips and closed mouth, intra oral above tongue/below tongue. Where intra-oral treatment is not possible extra oral treatment can be delivered alone.
Photobiomodulation cannot be used over known malignant or infected lesions.

Results: **Improvement:** The photobiomodulation service was introduced in November 2025 administered to CYP within the inpatient setting.
Seven patients have been/are being treated with photobiomodulation - five allografts and two autografts. So far, four patients did not require a PCA/NCA with no/minimal oral mucositis suggestive of a potential reduction in mucositis/improvement in pain management.
* Retrospective data collection and analysis will commence at six months since implementation to explore the impact on patient and family experience, pain levels including use of analgesic medications and impact on nutrition.

Conclusions: **Applicability:** Improving pain from mucositis and improving CYP quality of life is a primary objective in implementation. Improvements seen thus far and discussions with other NHS Trusts offering this service suggests this is a valuable service. However, research is required to evidence this effectively and is the next phase in this new service. Currently, photobiomodulation is only available for inpatients. Research findings will inform a business case to expand this service offering it in the outpatient setting.
*Data on numbers of patients will be updated at the time of poster presentation .

NP114

COMPREHENSIVE SYMPTOM MANAGEMENT AND SUPPORTIVE NURSING CARE IN A PRETERM TODDLER UNDERGOING HSCT FOR PYRUVATE KINASE DEFICIENCY

Dung Tran Thi[1]
[1]*Vinmec International Hospital, Hanoi, Viet Nam*

Background: Preterm toddlers undergoing hematopoietic stem cell transplantation (HSCT) are highly susceptible to treatment-related toxicities, infections, and poor medication tolerance. Pyruvate kinase deficiency (PKD) further increases transfusion dependence and infection risk. Nursing-led interventions are essential for early detection of complications, prevention of adverse events, and facilitation of safe home care, yet detailed reports of pediatric nursing strategies in this context are limited.

Methods: A descriptive case study was conducted on a 2.5-year-old preterm boy (36 weeks, 1.9 kg) with transfusion-dependent PKD undergoing allogeneic HSCT from a fully HLA-matched sibling after Busulfan-Cyclophosphamide-Thiotepa-Fludarabine conditioning. Nursing interventions were central to care delivery:
(1) **Proactive symptom monitoring and rapid intervention**: hourly temperature checks, immediate blood cultures, and nursing-initiated IV antibiotic escalation for neutropenic fever.
(2) **Nursing-led mucositis and pain management**: frequent oral hygiene, multimodal analgesia, and hydration optimization.
(3) **Medication and nutritional support**: tailored administration strategies to overcome poor oral tolerance and maintain adherence.
(4) **Central line management**: strict nursing protocols to prevent catheter-related bloodstream infections during prolonged Hickman use.
(5) **Family-centered education**: caregiver training in line care, infection monitoring, medication administration, oral hygiene, and safe home follow-up.

Results: Despite severe mucositis, difficulty swallowing medications, and neutropenic fever, no major infections or organ toxicities occurred. Platelet and neutrophil engraftment were achieved on Days +14 and +15; full donor chimerism (100%) was established by Day +28 and remained stable at one year. Nursing-led interventions directly prevented complications, optimized treatment adherence, and enabled safe transition to home care.

Conclusions: This case highlights the pivotal role of specialized nursing in high-risk pediatric HSCT. Proactive symptom surveillance, rigorous infection prevention, medication and nutritional management, and structured caregiver education are key nursing contributions to safe and successful transplant outcomes.

Disclosure: Nothing to declare

NP132

NURSING CARE OF A PATIENT WITH REFRACTORY HEMOPHAGOCYTIC SYNDROME UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION

Liwei Xu[1]
[1]*Bone Marrow Transplantation Center, the First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China*

Background: This report summarizes the nursing experience of a patient with refractory hemophagocytic syndrome who underwent salvage haploidentical hematopoietic stem cell transplantation.Prior to transplantation, the patient's hemophagocytic syndrome was uncontrolled, presenting with recurrent fever, persistently elevated serum ferritin, cytokines, and liver function, accompanied by EBV infection and pulmonary infection. During the early treatment phase, complications included atrial fibrillation, internal environment disturbances, bloodstream infection, hypoalbuminemia, and limb mobility impairment. The transplantation process carried a high risk of life-threatening complications such as arrhythmia and multiple organ failure, posing significant challenges for both medical treatment and nursing care.

Methods: Key nursing interventions included:
Pre-transplant Multidisciplinary Assessment: A multidisciplinary team evaluated the patient’s organ functions to formulate a chemotherapy regimen and implement anticipatory nursing measures.Close Monitoring During Transplantation: Vital signs, laboratory parameters, and clinical changes were strictly monitored. Medications were administered as prescribed to control body temperature and prevent complications like arrhythmia.
Enhanced Caregiver Management: Strict protocols were enforced to minimize the risk of cross-infection.
Focus on Psychological Support: Psychological nursing was emphasized to alleviate negative emotions.
Comprehensive Rehabilitation Support: A tailored nutritional plan was developed by the dietetics department, and functional exercises were guided by the rehabilitation team to promote recovery.
Personalized Education and Follow-up: Individualized health education and follow-up management were conducted to ensure continuity of care and condition monitoring.

Results: No severe complications occurred during the transplantation period. By day 30 post-transplant, the patient achieved hematopoietic engraftment (WBC 6.66×10^9/L, Hb

69g/L, PLT 72×10⁹/L), with infections controlled and liver function normalized. The patient was discharged as ordered and remains in good condition during outpatient follow-up.

Conclusions: Hematopoietic stem cell transplantation (HSCT) is a lifesaving treatment for patients with refractory hemophagocytic lymphohistiocytosis (HLH), whose nursing care is highly specialized and challenging. Effective nursing centers on comprehensive management with infection prevention and control as the cornerstone and proactive complication management as the priority. Alongside disease treatment, equal emphasis must be placed on providing psychological, nutritional, and social support. The entire process requires close multidisciplinary collaboration among the medical team, pharmacists, and nutritionists to implement evidence-based, individualized nursing care plans.

ASSESSMENT OF EXERCISE TOLERANCE IN PATIENTS UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION DURING HOSPITALIZATION: AN OBSERVATIONAL STUDY

Rossella Raffo[1], *Menada Gardalini*[1], *Annalisa Priano*[1], *Lorella Gambarini*[1], *Francesca Palmisano*[1], *Michela Lazzarini*[1], *Roberta Di Matteo*[1], *Tatiana Bolgeo*[1]
[1]*Azienda Ospedaliero-Universitaria SS. Antonio e Biagio e C. Arrigo, Alessandria, Italy*

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is associated with physical and psychological side effects, and the related period of protective isolation is known to contribute to functional decline and decreased exercise tolerance. Physical performance is commonly assessed using the Six-Minute Walking Test; however, this test is often not feasible within isolation settings. Conversely, the 1-Minute Sit-to-Stand Test (1MSTS) may represent a valid alternative, as it is reliable, reproducible, and easy to administer even in environments with limitations.
The aim of this study was to assess and quantify exercise tolerance impairment in adult patients undergoing allogeneic HSCT during hospitalization using the 1MSTS.

Methods: This ongoing monocentric observational study enrolls patients aged 18-70 years with hematologic malignancies admitted to the Transplant Unit. Exclusion criteria include inability to maintain an upright position, clinical instability at the time of assessment, or severe psychiatric disorders. Functional evaluations are performed on the first day of hospitalization (T0) and on day 28 (T1). The 1MSTS is administered to assess functional exercise tolerance, while perceived exertion is measured using the Borg Scale. Descriptive statistics are reported as means and standard deviations or as absolute and relative frequencies. Paired Student's t-tests are used for inferential analysis.

Results: To date, 18 patients have been enrolled (partial data), including 9 females. The mean age was 58.8 years (SD = 7.58). The 1MSTS showed a significant decrease from T0 (mean repetitions: 23.1) to T1 (mean repetitions: 18.7; $p < 0.00025$), indicating a 19.05%

reduction. Beyond statistical significance, these findings also exceed the minimally clinically important difference reported in the literature (3 repetitions). Linear regression analysis indicated that sex and baseline (T0) performance influence performance at T1. The Borg Scale also showed significant differences between T0 and T1 ($p < 0.021$).

Conclusions: Preliminary results indicate a significant and clinically relevant decline in functional performance on the 1MSTS, accompanied by increased perceived exertion assessed with the Borg Scale. The 1MSTS also appears feasible in other clinical settings requiring functional assessment of immunocompromised or hospitalized patients.

NP69

BEYOND THE PCR: CMV PNEUMONIA DESPITE NEGATIVE SERUM AND BRONCHIAL LAVAGE CMV VIRAL LOAD – CHALLENGE FOR ADVANCED NURSE PRACTITIONER

Hsin-Ju Yeh[1], *Jia-Hau Liu*[1], *Bor-Sheng Ko*[1], *Wan-Yu Chen*[1], *Min-Hsuan Hsu*[1], *Yu-Chen Fan*[1]
[1]*National Taiwan University Cancer Center, Taipei, Taiwan (Province of China)*

Background: Cytomegalovirus (CMV) pneumonia is a life-threatening complication in hematopoietic stem cell transplantation (HSCT) recipients. Standard preemptive therapy relies on monitoring CMV PCR viral load in serum or bronchoalveolar lavage (BAL). However, due to intracellular localization of CMV, tissue-invasive disease may exist despite low or negative viral loads from extracellular specimen, e.g. blood or bronchial lavage. This diagnostic discordance poses a significant challenge for Advanced Nurse Practitioners in decision-making or interpretation of clinical situation with physicians, leading to delayed treatment.

Methods: We shared a series of 7 adult hematological patients (post-HSCT or chemotherapy) presenting CMV pneumonia with diagnostic discordance in CMV pneumonia and serum or bronchial lavage. We compared clinical severity against CMV PCR levels in serum and BAL. We evaluated the outcomes based on the timing of interventions, specifically the combination of CMV treatment of Ganciclovir and CMV hyperimmune globulin (Cytotect).

Results: **Case 1 (DLBCL)** and **Case 2 (NHL)** presented with severe interstitial pneumonia and respiratory failure but had low serum and **undetectable** BAL viral loads while pneumonia was severe. Due to the lack of virological evidence, CMV directed treatment was delayed, and both patients died of the pneumonia. CMV pneumonia were diagnosed via postmortem autopsy/biopsy.
Case 3 (T-LBL) and **Case 4 (AML)** presented with interstitial pneumonia and respiratory failure after chemotherapy but without transplantation,
BAL viral load was undetectable and antibiotics were ineffective in intensive unit for more than one month. But therapeutic trial of Cytotect and Ganciclovir resulted in full resolution of pneumonia and discharge of the patients. Case 5 had pneumonia but undectable BAL viral

load, but survived due to early initiation of CMV treatment because of detectable serum CMV viral load. Case 6 survived the CMV pneumonia due to early administration of CMV medication despite undetectable CMV viral load from serum and BAL specimen, but died of lung GVHD related infection. Case 7 had CMV pneumonia proven by lung biopsy but had undetectable CMV viral load from BAL specimen. He died of CMV pneumonia despite initiation of CMV medications. Retrospectively, all patients had predisposing factors contributing to the CMV pneumonia (listed in table).

Case	Age / Sex	Diagnosis	Transplant / Status	CMV PCR (Serum)	CMV viral load (Bronchial wash)	Risk factor	Clinical Severity (Organ Involvement)	Key Treatment	Duration of Therapy	Outcome
1	58 /M	DLBCL	10/10 Sibling PBSCT	Undetectable	Undetectable	Post CAR-T, immediate after Bendamustine	Severe Pneumonia	GCV + foscarnet + Cytotect (delayed)	4 weeks	Expired (Autopsy confirmed CMV inclusions)
2	74 /F	AML	MUD PBSCT	Low (<1000 IU/ml)	Undetectable	Extensive chronic GVHD prolonged steroid use	Pneumonitis	Valcyte+ GCV + Cytotect + DLI Foscarnet	9 months	ARDS, Expired
3	70 /F	T-LBL	Pre-HSCT (Post-Chemo)	Low (296 IU/ml)	Undetectable	Lymphoid malignancy, after steroid	Pneumonia, Severe GGO	GCV + Cytotect	~14 weeks	Recovered (GGO disappeared) connect to HSCT
4	56 /M	AML	Post-Chemo (Relapsed)	High (15.5k IU/ml)	Undetectable	Steroid use for lung inflammation	Pneumonia	GCV + Cytotect	~6 weeks	Success / Recovered

5	31/F	Ph ALL	MUD PBSCT	Undetectable	Undetectable	Delayed immune reconstitution after HSCT	CNS/Retinitis/ Pneumonitis	GCV + Cytotect	N/A	Survived (Chronic complications)
6	64/F	AML	Haplo-PBSCT	Low (<1000 IU/ml)	Undetectable	Prolonged steroid use and immediate after pulse steroid for lung GVHD	Pneumonia	Valcyte+ GCV + Foscarnet Cytotect	Intermittent (~1 month)	Died of GVHD related infection
7	48/M	ATLL	MUD PBSCT	Undetectable	Undetectable VATS biopsy: CMV pneumonitis	Prolonged steroid use for grade III acute GVHD	Fatal Pneumonitis	Late GCV +Cytotect	N/A	Expired (CMV pneumonitis)

Conclusions: This case series illustrates that relying solely on viral loads extracellular specimen could be misleading. A negative CMV PCR in serum—or even in bronchial lavage—does not definitively preclude tissue-invasive CMV pneumonia. For Advanced Nurse Practitioners, interpretation of these data with physicians and explanations to the patients and their families should be cautious. Experienced Advanced Nurse Practitioners could identify risk factor of CMV disease, e.g. after chemotherapy, especially bendamustine, prolonged or high dose corticosteroid for intractable GVHD, after allogeneic transplantation, or lymphoid malignancy using steroid in the treatment. Early reminding the physician about the possibility of CMV pneumonia in patients with interstitial pneumonia refractory to all the current medication based on the risk factor and clinical judgment could be important. Multidisciplinary team work may also be pivotal for these difficult hematological patients.

Clinical Trial Registry: **N/A**

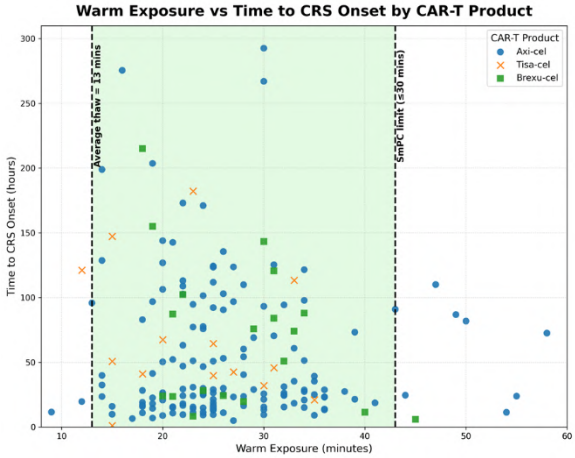
EVERY MINUTE COUNTS: DO THAW-TO-INFUSION INTERVALS AND INFUSION TIME OF DAY INFLUENCE CRS ONSET AND HOSPITAL STAY IN CAR-T THERAPY? A NURSE-LED RETROSPECTIVE REAL-WORLD ANALYSIS

Donna Walsh[1], *Brooke Evans*[1], *Jessica Moore*[1], *Aristides Madriaga*[1], *Caitlin Barton*[1], *Tajinder Kaur*[1]
[1]*University Hospitals Birmingham, Birmingham, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Safe delivery of CAR-T therapy depends on precise, nurse-controlled procedures during product thawing and infusion, time-critical steps rarely reported in clinical trials but essential in real-world care. Nurses are the final custodians of this process, ensuring that thawed CAR-T cells are handled within manufacturer limits to preserve viability and safety. While manufacturing and transport are tightly regulated, the bedside phase introduces subtle, human-controlled variability. Strict procedural adherence is vital to preserve cell integrity and consistency. Once thawed, CAR-T cells lose viability rapidly, and manufacturer guidance specifies infusion within 30 minutes. Prolonged warm exposure may impair cell viability and cytokine kinetics. This nurse-led study examined whether thaw-to-infusion interval and infusion time of day influence cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity (ICANS), or hospital length of stay (LOS), using timing precision as a marker of nursing quality.

Methods: A retrospective, single-centre review included 243 CAR-T infusions (2019–2025). Products with alternative thawing workflows were excluded. After timestamp validation, 198 infusions were analysed (axi-cel n=154; brexu-cel n=24; tisa-cel n=20). Data included thaw start and end times, infusion start and end times, and time of first fever >38°C as a proxy for CRS onset. CRS and ICANS were graded per ASTCT criteria. Analyses used Spearman correlation, Kruskal–Wallis tests, and partial correlations controlling for product type ($p<0.05$).

Results: Median age was 63 years with 62% male. Diagnoses included large B-cell lymphoma (84%), mantle cell lymphoma (9%), B-cell acute lymphoblastic leukaemia (6%), and follicular lymphoma (2%) under clinical-trial indication. Median warm exposure was 25 minutes (range 9–58) and infusion duration 11 minutes (range 1–37). Most infusions (77%) occurred between 12:00–15:59, and 85% met the 30-minute specification. Median time to CRS onset was 29.6 hours, varying by product: axi-cel 29.8 h, brexu-cel 74 h, tisa-cel 50.7 h ($p<0.01$). No correlation was seen between warm exposure and CRS onset ($\rho=-0.03$, $p=0.68$). CRS grade ≥2 occurred in 50% and ICANS grade ≥2 in 34%. A weak, non-significant trend suggested higher ICANS grades with longer exposure ($\rho=0.14$, $p=0.054$).



Conclusions:

Nurse-controlled thaw-to-infusion timing was measurable, auditable, and aligned with manufacturer standards, underscoring nursing precision in advanced cell therapy. Over 85% of infusions met the manufacturer-specified ≤30-minute interval, confirming this standard is achievable and safe in practice. Thaw-to-infusion warm exposure and infusion time of day showed no association with CRS, ICANS, or LOS, reflecting high procedural fidelity. Product-specific biology, rather than procedural timing, remains the principal determinant of outcomes. The absence of timing effects on toxicity or hospitalisation indicates consistent, safe nursing delivery. Findings informed updates to nursing education and competency frameworks and support inclusion of thaw-to-infusion monitoring as a nursing quality indicator. A UK multicentre, nurse-led CAR-T registry is in development to benchmark these variables and strengthen national auditing and JACIE alignment. Emerging fresh, non-cryopreserved CAR-T products may remove freeze–thaw timing variability, making this cryopreserved cohort an important benchmark for comparison. By quantifying the impact of bedside precision on safety and efficacy, this study reaffirms that in CAR-T therapy, every minute — and every nurse — counts.

NP03

OPTIMISATION OF CAR-T LEUKAPHERESIS USING A MONONUCLEAR CELL–BASED PREDICTIVE COLLECTION TOOL: A SINGLE-CENTRE EXPERIENCE

Clair Scott[1], *Paul Chiappini*[1], *James Dungate*[1], *Safia Belbachir*[1], *Duncan Purtill*[1], *Shane Gangatharan*[1], *Hasib Sidiqi*[1], *Gareth Gregory*[1], *Allison Barraclough*[1]
[1]*Fiona Stanley Hospital, Murdoch, Australia*

Background: Chimeric Antigen Receptor T-cell (CAR-T) therapy has transformed the management of hematologic malignancies. Treatment depends on the efficient collection of mononuclear cells (MNCs) through leukapheresis. Accurate prediction of MNC yield is critical for optimising collection efficiency (CE), minimising patient toxicities by reducing leukapheresis time and ensuring adequate starting material for CAR-T cell manufacturing. This study aimed to validate a predictive calculation tool for MNC yield to optimise the leukapheresis procedure for CAR-T therapy recipients.

Methods: We retrospectively analysed all consecutive leukapheresis procedures for axicabtagene ciloleucel (axi-cel, n=43) and ciltacabtagene autoleucel (cilta-cel, n=6) at our centre (Oct 2022-May 2025). Apheresis was performed on the Spectra Optia, using the Continuous Mononuclear Cell Collection (CMNC) protocol. Peripheral collection was utilised if patients had adequate venous access, otherwise central venous access was used. Peripheral blood flow cytometry was performed prior to apheresis. The MNC calculation tool, adapted from our locally validated stem cell collection model, used the pre-apheresis peripheral blood monocyte plus lymphocyte counts multiplied by a collection efficiency of 60% to determine the total blood volume to process to achieve the MNC Target.
Figure 1.0 FSH MNC Calculation

$$\frac{\text{Target MNC (absolute count)} ____ \times 10^9}{0.6 \times (\text{Lymphocytes} ____ 10^9/\text{L} + \text{Monocytes} ____ 10^9/\text{L})} = _____ \text{L} + \text{IEV*} _____ \text{L} = \textbf{Volume to process in Litres} _____ \text{L}$$

*IEV - Interface Establishment Volume – Volume of blood processed to establish interface
*CE- Collection Efficiency – Previously validated collection efficiency

Results: Forty-nine CAR-T leukapheresis procedures were analysed, (axi-cel n=43; cilta-cel n=6), All collections (100%) achieved or exceeded the prescribed MNC target, resulting in a 100% manufacturing success rate. 67% (n=36) of axi-cel collections and 100% (n=6) of cilta-cel Leukapheresis collections processed <12L whole blood to achieve the MNC target. The median collection efficiency was 71% for axi-cel and 74% for cilta-cel. For axi-cel, the median whole blood volume processed was 11 L, with a median reduction in collection time of 30 minutes compared with historical practice. For cilta-cel, 100% of collections processed ≤10.5 L of whole blood, with a median reduction in collection duration of 77 minutes compared with the historic cohort (median 270 vs 192.5 minutes).

Conclusions: The validated MNC calculation tool reliably ensured 100% collection success for CAR-T manufacturing while reducing leukapheresis time and processed blood volume at our centre. These findings support the incorporation of the MNC calculation tool into routine clinical practice for local CAR-T leukapheresis. Prospective multicentre studies are needed to validate our results.

OPTIMIZING CRS AND ICANS MANAGEMENT IN CAR-T CELL THERAPY: IMPACT OF A NURSE-LED STRUCTURED WORKFLOW ON EARLY RECOGNITION AND MANAGEMENT OF CRS AND ICANS

Kwee Cheng Chia[1], *Sally Ang*[1], *Esther Chan*[1], *Edwin Thong*[1], *Harstdale Edwin Dean*[1], *Hurul'Ain Md Idrus*[1], *Jenny Lee*[1], *Yahui Wei*[1], *Nan Thinzar*[1], *Yoke Lai Tang*[1], *Ana Latip*[1], *Michelle Limei Poon*[1], *Yu Ting Ngo*[1]
[1]*National University Cancer Institute Singapore, National University Health System (NUHS), Singapore, Singapore*

Background: Despite the therapeutic success of chimeric antigen receptor T-cell (CAR-T) therapy for the treatment of hematologic malignancies, this therapy is commonly complicated by cytokine release syndrome (CRS) and Immune Effector Cell-Associated Neurotoxicity Syndrome (ICANS), both of which may progress rapidly and result in significant morbidity. Early detection, accurate grading, and timely intervention are therefore essential. Given their continuous patient contact and central coordination role, nurses are uniquely positioned to identify early clinical deterioration. However, standardized nurse-driven processes for CRS and ICANS assessment and escalation remain limited. This study aimed to evaluate the effectiveness of a novel, nurse-centric workflow designed to enhance early recognition and management of CAR-T-related toxicities.

Methods: A prospective, single-centre study was conducted over 12 months following the development and implementation of an interdisciplinary workflow focused on structured nursing assessment and escalation. The intervention comprised three key components: (1) development of a standardized assessment tool aligned with the American Society for Transplantation and Cellular Therapy (ASTCT) consensus grading criteria for CRS and ICANS; (2) establishment of a nurse-led escalation protocol enabling direct activation of physicians upon identification of early toxicities; and (3) an intensive training program delivered to 39 nursing staff, covering symptom recognition, grading, and initiation of early supportive interventions. The primary outcomes reviewed included review of the confidence level of nurses as well as assessment of time to symptom escalation and time to treatment initiation. Secondary outcomes included duration of CRS/ICANS episodes and incidence of grade 3 and above toxicities. Pre-implementation data served as the historic control.

Results: Primary outcomes: Post implementation, nurses' confidence increased substantially, rising from 58.5% to 96.8%. The median time to symptom escalation decreased from 60 minutes to 15 minutes, while the median time to treatment initiation reduced from 60 minutes to 15 minutes.
Secondary outcomes: Consequently, CRS and ICANS resolution time decreased by 1-2 days. In the post-implementation cohort, the incidence of grade 3 CRS or ICANS was 0%. Notably, the incidence of cerebral oedema, a severe manifestation of ICANS, was reduced from two cases in the pre-implementation group to zero cases post-implementation. All patients in the post-implementation group achieved complete resolution of symptoms without progression to severe CRS or ICANS, and no case of long-term neurotoxicity was reported.

Conclusions: The structured workflow significantly enhanced nurse-physician collaboration and supported timely, coordinated management of CAR-T therapy complications. Nursing vigilance and proactive collaboration proved vital in early recognition and management of CRS and ICANS. This study demonstrates the crucial impact of early recognition and escalation of symptoms in reducing complication severity and resolution time, underscoring the indispensable role of specialized nursing care in CAR-T therapy.

Disclosure: Nothing to declare

NP10

MONITORING TOXICITY-RELATED COMPLICATIONS IN PATIENTS UNDERGOING CAR-T: OBSERVATIONAL, PROSPECTIVE STUDY

Francesca Palmisano[1], *Sara Butera*[1], *Giulia Zacchi*[1], *Martina Rosa Riccomagno*[1], *Rosanna Gaino*[1], *Ignazio Favata*[1], *Roberta Di Matteo*[1], *Tatiana Bolgeo*[1], *Chiara Cannici*[1]
[1]*AOU Santi Antonio e Biagio e Cesare Arrigo, Alessandria, Italy*

Background: CAR-T cell therapy represents an advanced treatment option for refractory hematologic malignancies but is associated with relevant toxicities, including Cytokine Release Syndrome (CRS), Immune effector Cell–Associated Neurotoxicity Syndrome (ICANS), cytopenias, and infectious complications. These events may affect patients' functional status and Quality of Life (QoL), emphasizing the critical role of nursing care in early detection, symptom management, and implementation of supportive interventions. Regular follow-up with validated scales should be used to facilitate early detection and suitable management.

Methods: This observational, prospective, monocentric, non-interventional study aimed to monitor toxicities in patients undergoing CAR-T therapy in our Italian center. Consecutive patients were enrolled from April 2022 to April 2025. Secondary objectives included the evaluation of Patient-Reported Outcomes (PROs), grading of toxicity severity, and duration of hospitalization. Data collection was performed at predefined time points using validated instruments: the Immune Effector Cell-associated Encephalopathy (ICE) Score for neurotoxicity, EuroQol-5D (EQ-5D) for QoL, Hospital Anxiety and Depression Scale (HAD) for psychological status, Patient-Generated Subjective Global Assessment (PG-SGA) for nutritional condition, and Cancer Linear Analogue Scale (CLAS) for symptom burden and daily functioning.

Results: Fifty-seven patients were included, 59.6% were men, with a median age of 59.4 years (range 24-75). Diagnoses mainly included Diffuse Large B-Cell Lymphoma (75.4%) and Multiple Myeloma (15.8%). The median hospital stay was 20.65 days (range 12-41), and 7% needed Intensive Care Unit (ICU) admission. ICANS did not occur in 77% of patients, while grades 3 to 4 were reported in 3.6%. CRS onset happened at a median of 2.69 days (range 0-11), with 5.3% experiencing grades 3 to 4. Anxiety scores, measured by HAD, significantly decreased over time (global p=0.038; T0 to T2 p=0.020), while depression scores remained stable. CLAS scores for movement, energy, and daily activities did not show

significant changes. However, overall QoL improved significantly between T1 and T2 (p=0.025). PG-SGA indicated a significant worsening from T0 to T1 (p<0.001), followed by improvement from T1 to T2 (p<0.001), with no difference between T0 and T2 (p=0.94). At baseline, 66.7% of patients were PG-SGA A (well nourished) and 33.3% PG-SGA B (moderate or suspected malnutrition). At T2, 67.6% were PG-SGA A, and only one patient (2.9%) was PG-SGA C (severe malnutrition). EQ-5D Index values showed good perceived health at baseline (0.830), a slight drop at T1 (0.795), and recovery at T2 (0.850), with a statistically significant improvement from T1 to T2 (p=0.0419). CAR-HEMATOTOX stratification classified 33.3% of patients as high-risk and 66.7% as low-risk.

Conclusions: CAR-T–related toxicities were generally manageable, with low rates of severe ICANS and rapid CRS resolution. QoL was mostly stable, with a notable improvement observed during the second week after CAR-T infusion. Hematotoxicity risk stratification was feasible. These findings emphasize the vital role of nursing care in monitoring, early recognition of complications, and integration of PROs during the acute post-CAR-T hospitalization phase.

Disclosure: The authors have no conflicts of interest to disclose

NP104

NURSING PRACTICE AND SAFETY IN ANTI-CD19 CAR-T CELL THERAPY FOR PEDIATRIC REFRACTORY SLE: A CASE SERIES OF 10 PATIENTS

Xiaoyuan Wu[1], *Lanzhu Su*[1], *Guanyi Li*[1], *Shengnnan Zhou*[1], *Jing Pan*[1], *Fengying Chen*[1]
[1]*Beijing Gobroad Hospital, Beijing, China*

Background: Anti-CD19 chimeric antigen receptor (CAR) T-cell therapy provides a novel treatment option for refractory systemic lupus erythematosus (SLE). However, specific practical experience data, particularly regarding the clinical application of nursing-led toxicity monitoring and management, remain limited. This study aimed to investigate the nursing implementation points and safety management measures for this therapy in pediatric patients with refractory SLE, to provide an evidence-based reference for improving clinical nursing quality and reducing adverse events.

Methods: We conducted a retrospective analysis of the first 10 pediatric patients with refractory active SLE who received anti-CD19 CAR-T cell therapy at our center. The nursing team implemented a structured and standardized whole-process monitoring protocol. The nursing protocol comprised the following core measures: First, a reinforced post-infusion monitoring plan was implemented, which included systematic vital signs and oxygen saturation checks every 4 hours, alongside dynamic neurological assessments using the Immune Effector Cell-Associated Encephalopathy (ICE) score sheet. Second, cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were strictly graded according to the American Society for Transplantation and Cellular Therapy (ASTCT) consensus criteria, with corresponding alert and management protocols activated upon identification. Third, for patients with grade 1–2 CRS, standardized non-

pharmacological interventions—such as physical cooling and ensuring adequate fluid intake—were prioritized. Finally, medication orders (e.g., for tocilizumab or corticosteroids) for patients requiring pharmacological treatment were executed accurately and promptly.The entire nursing process emphasized systematic monitoring, standardized grading, stepwise intervention, and team collaboration to ensure treatment safety.

Results: Among the ten treated patients, four (40%) developed cytokine release syndrome (CRS), with all cases categorized as grade 1 (according to ASTCT criteria). The median time to CRS onset was four days post-infusion. No instances of immune effector cell-associated neurotoxicity syndrome (ICANS), macrophage activation syndrome, or treatment-related mortality were observed. Neurological monitoring was performed systematically, with an average of 20 assessments completed per patient. Fever associated with CRS was effectively managed in all cases through initial nursing-led non-pharmacological interventions. At the last follow-up (median 3 months), all patients exhibited B-cell clearance and showed a reduction in SLEDAI scores.

Conclusions: This preliminary experience indicates that during anti-CD19 CAR-T therapy for SLE, CRS is common but mostly mild and manageable. A systematic and proactive nursing monitoring and management pathway is crucial for early toxicity identification, ensuring timely intervention and patient safety. These early findings provide a foundation for optimizing nursing protocols in larger-scale studies.

Disclosure: Nothing to declare.

NP124

COMMON ORGAN DYSFUNCTIONS AMONGST POST CHIMERIC ANTIGEN RECEPTOR T-CELL THERAPY PATIENTS: A SINGLE CENTRE SURVEY

Kevin Aguilar[1], *Joy Pe Benito*[1], *Karen Bradley*[1]
[1]*Imperial College Healthcare NHS Trust, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Chimeric antigen receptor (CAR) T-cell therapy, a novel immune effector cell therapy that uses genetically engineered T-cells to target cancer cells has revealed significant efficacy in the management of haematological malignancies, autoimmune diseases and solid tumours. While capable of producing protracted durable remissions in several malignancies, there are associated treatment toxicities with the two most common being Cytokine release syndrome (CRS) and Immune effector cell-associated neurotoxicity syndrome (ICANS). However, as CAR T-cell procedures increase and the therapeutic applications expand, the increased risk of off-target effects is emerging, where healthy cells expressing tumour-associated antigens (TAA) or similar markers are inadvertently targeted. This can lead to a range of other unpredicted treatment-related toxicities and significant tissue/organ damage. Expanding clinical knowledge and expertise to enable early detection and rapid intervention is essential for which nursing assessment plays a critical role in strategies to reduce adverse outcomes.

Methods: A retrospective analysis of the case notes from the electronic health records (EHR) of all 33 post CAR-T cell patients of Hammersmith Hospital was done for this abstract. This review focused on identifying the common organs affected by the off-target toxicity ability of CAR T-cells observed in the clinical area.

Results: The review revealed that the most common organ affected by CAR-T cell therapy is the liver, with 48.5% of the 33 patients had mild to moderate transaminitis few days post CAR-T infusion. The lungs ranked second as 13 out of 33 patients developed tachypnoea and hypoxemia requiring oxygen support using nasal cannulas ranging from 1 to 5 litres/min and some up to the use of non-invasive ventilation. Tachycardia and hypotension requiring inotropic support were also seen in 27% of this cohort of patients, leading to admission to intensive care unit. While most patients come back to the ward about 3 to 5 days after ITU transfer, 2 patients remained longer averaging up to 1 week due to overlapping conditions such as prolonged inotropic support and difficult oxygen weaning. Gastric affectation manifested by non-infectious diarrhoea were also noted in one fifth of these patients or 21%. While only three patients developed rashes of more than 10% of their body surface area, and two patients had significant rise in ferritin levels after infusion of CAR-T cells, signalling significant inflammation.

Conclusions: The use of CAR T-cell therapy is becoming more widespread globally and as the efficacy of this immunotherapy treatment is proven in certain types of haematological malignancies and research continues the therapeutic application of this treatment modality is rapidly expanding. Side by side with this is the rise in complex and rare side-effects. Hence, a systematic and comprehensive approach to tracking the occurrence of these adverse events is crucial for aiding better understanding of the aetiology and underlying mechanisms that trigger these treatment-related toxicities, to improve prevention and management strategies, or at least to mitigate severity, to improve patient safety and outcomes.

Disclosure: Nothing to declare.

NP55

EMERGENCY: IEC-COLITIS POST CAR-T CELL THERAPY IN MULTIPLE MYELOMA

Daniel Verina[1], *Catherine Williams*[1], *Christine Russo*[1]
[1]*Mount Sinai Medical Center, New York, United States of America (the)*

Background: A 69-year-old man with IgM kappa multiple myeloma presented in 2021 with pancytopenia, hypercalcemia, extensive lytic lesions and bone marrow biopsy with 90% kappa-restricted plasma cells. Received five lines of therapy including cilta-cel (Carvykti) CAR-T in February 2023. In October 2025 was diagnosed with immune effector cell–associated colitis (EIC-colitis), raising concern for a late, T cell–mediated gastrointestinal toxicity in the context of prior CAR-T exposure.
This case is unusual for the very late onset of severe colitis more than two years post–CAR-T, its overlap with recurrent enteric infections (C. difficile, Salmonella and norovirus), and the

prolonged, relapsing course required combined anti-infective, immunosuppressive and supportive nursing strategies.

Methods: admitted for endorsing up to 20 watery and later bloody bowel movements per day, associated with abdominal pain, lightheadedness and impaired oral intake. Evaluation showed positive C. difficile and Salmonella PCR positivity; he received sequential oral vancomycin, fidaxomicin, and intravenous ceftriaxone with only transient improvement, and was repeatedly discharged still symptomatic. On readmission in September 2025, stool PCR again confirmed Salmonella without C. difficile toxin- GI, ID and cellular therapy teams differential of persistent infectious colitis, CAR-T–associated enteritis and immunodeficiency-associated colitis. Management included repeat stool cultures, serial fecal calprotectin, escalation to rifaximin plus high-dose oral prednisone with a taper. Ongoing elevation in fecal calprotectin and relapsing diarrhea prompted introduction of vedolizumab (Entyvio) every four weeks, careful monitoring for hepatotoxicity and infection, adjustment of antimicrobial therapy (oral vancomycin then Vantin) and initiation of IVIG every two weeks to address probable post–CAR-T hypogammaglobulinemia.

Results: With combined antimicrobial therapy, corticosteroids and gut-selective biologic therapy - stool frequency gradually decreased and abdominal pain improved, allowing maintenance of oral intake and functional status in the outpatient setting. The patient continued to experience intermittent loose stools, and fluctuating fecal calprotectin.
Close nursing surveillance of fluid balance, weight, infection signs and treatment toxicity supported safe steroid tapering, timely vedolizumab dosing and coordination of frequent laboratory and stool testing. The patient reported feeling more secure and engaged in self-management through nurse-led education on infection prevention, symptom monitoring and when to seek urgent care

Conclusions: This case underscores that severe colitis in CAR-T recipients may emerge long after infusion, with overlapping infectious and immune-mediated mechanisms that can be easily misattributed to isolated infection or irritable bowel disease. For HCT and cellular therapy nurses, key lessons include maintaining a high index of suspicion for serious late gastrointestinal toxicity, advocating for repeated microbiologic testing and biomarker assessment when diarrhea persists despite standard therapy, and coordinating early GI and ID involvement.
Nursing practice should prioritize meticulous assessment of stool pattern, hydration, nutrition and functional status; patient and caregiver education about promptly reporting diarrhea; and vigilant monitoring for complications of combined antibiotics, steroids, biologics and IVIG. Application of these principles may facilitate earlier recognition, multidisciplinary management and improved outcomes for other CAR-T and HCT survivors presenting with complex, recurrent colitis.

Transplant and CAR-T Coordination, and Early Follow-up

NP27

THE IMPACT OF DOSE REDUCTION OF POST-TRANSPLANT CYCLOPHOSPHAMIDE TO 70 MG/KG ON EARLY TOXICITY: A SINGLE-CENTRE EXPERIENCE

Vanessa Magerová[1], *Adéla Čermáková*[1], *Václav Heřman*[1], *Veronika Válková*[1], *Jan Vydra*[1]
[1]*Institute of Hematology and Blood Transfusion, Prague, Czechia*

Background: Post-transplant cyclophosphamide (PtCy) is associated with significant adverse effects that negatively impact quality of life during hematopoietic cell transplantation. Based on previous reports and preliminary data, we reduced the PtCy dose from 2×50 mg/kg to 2×35 mg/kg with the aim of decreasing toxicity while maintaining efficacy. Here, we report a retrospective single center analysis of the incidence of the most common early complications, including mucositis, hemorrhagic cystitis, and cardiotoxicity.

Methods: All patients who underwent allogeneic HCT at the Institute of Hematology and Blood Transfusion in Prague using PtCy based GvHD prophylaxis between 2018 and 6/2025 were included in the analysis. The data were retreived from our institute‘s transplant database and by chart review.

Results: A total of 367 patients were analyzed and divided into two cohorts: the pre–dose-reduction PtCy cohort (n = 307) and the post–dose-reduction PtCy cohort (n = 60). Patient and transplant characteristics are summarized in Table 1. The cohorts receiving PtCy 70 mg/kg and 100 mg/kg differed in age, comorbidities (HCT-CI), and distribution of donor types (MRD/MUD/MMUD/haplo).
In the pre-reduction cohort, hemorrhagic cystitis occurred in 46 patients (15 %), predominantly Grade 1 (11,4 %, n = 35) and Grade 2 (2,6 %, n = 8), with a single case of Grade 3 (1 %). In the post-reduction cohort, the incidence was 10 patients (16,7 %), again with predominance of Grade 1 (15 %, n = 9). No Grade 2 cases were observed, and one patient experienced Grade 3 (1,7 %).
The incidence of mucositis was high in both cohorts. Before dose reduction, most patients experienced Grade 2 (36,2 %, n = 111) or Grade 3 (28 %, n = 86) mucositis; Grade 4 occurred in six patients (2 %). Following the dose adjustment, severity shifted toward lower grades: Grade 2 (30 %, n = 18) and Grade 3 (30 %, n = 18) predominated, and Grade 4 occurred in only one patient (1,7 %).
Early cardiac events were reported in 24 patients (7.8%) before dose reduction and in five patients (8.3%) after dose reduction.
Mechanical ventilation was needed in 13 patients (4,25 %) in the pre-reduction group and 3 (5 %) in the post-reduction group, dialysis incidence was similar at 10 patients (3,3 %) before dose reduction and 2 (3,3 %) after.

		PtCy 70 mg/kg N = 60
Age	years (median, range)	53 (22, 68)
Donor type	Haplo	11 (18%)
	MMUD	13 (22%)
	MRD	7 (12%)
	MUD	29 (48%)
HCT-CI	>2	23 (38%)
	0	21 (35%)
	1-2	16 (27%)
Karnofsky	<90	15 (25%)
	>=90	45 (75%)
Diagnosis Group	ALL a LBL	4 (6.7%)
	AML	37 (62%)
	MDS	11 (18%)
	MPN	4 (6.7%)

	NHL	2 (3.3%)
	other	2 (3.3%)
Conditioning	myeloablative	39 (65%)
CMV D/R = neg/neg	neg/neg = TRUE	4 (6.8%)
F donor / M recipient	F > M = TRUE	7 (12%)

Conclusions: Overall, the comparison of early toxicity between 70 mg/kg and 100 mg/kg PtCy did not show significant differences. The incidence and severity of mucositis, hemorrhagic cystitis, cardiac events, and the need for organ support (mechanical ventilation or dialysis) were similar between groups.

NP108

EVALUATION OF NURSE CASE MANAGER FOLLOW-UP IN PEDIATRIC POST-HSCT PATIENTS

Laura Jiménez Prat[1], *Sonia Alonso Peral*[1], *Rosa Maria Carmona Jiménez*[1], *Laura Fernández Camarero*[1]
[1]*Hospital Sant Joan de Déu, Esplugues de Llobregat, Spain*

Background: Hematopoietic stem cell transplantation (HSCT) is the treatment of choice for several hematologic, oncologic, and congenital disorders in children. The specialized HSCT nurse case manager is associated with improved quality of life, treatment adherence, and reduced readmissions. This study evaluates the follow-up activities performed by the nurse case manager in the outpatient setting after HSCT.

Methods: A descriptive observational study was conducted in the HSCT Outpatient Clinic (2023–2025). Activities were categorized into clinical, educational, and administrative domains. Variables analyzed included: follow-up visits (SEGIN), scheduled telephone consultations (ATELEF), and urgent telematic consultations (ATTEL). Data were obtained from internal clinical records. Frequencies, percentages, measures of central tendency, and Pearson correlations were calculated using Microsoft Excel 365. Retrospective analysis with anonymized data; ethics and data protection principles were observed.

Results: A total of 3,894 follow-up visits, 764 urgent telematic consultations, and 493 scheduled telephone consultations were recorded. SEGIN was the predominant activity

(80.94% in 2023; 73.74% in 2024; 71.45% in 2025), showing a slight relative decrease. ATTEL increased steadily (12.32% to 17.11%), while ATELEF rose from 6.74% to 11.44%. Correlation analysis revealed a strong positive relationship between SEGIN and ATTEL (up to r=1.00), suggesting that higher in-person follow-up is associated with increased urgent telematic demand. ATELEF showed low correlations, indicating independence from other activities.

Conclusions: The nurse case manager plays a key role in post-HSCT care, providing clinical monitoring, pharmacological management, education (self-care, school reintegration), psycho-emotional support, and multidisciplinary coordination. In-person follow-up remains predominant, but the rise in urgent telematic care highlights the need for flexible resources tailored to the complexity of pediatric transplant patients. Joint planning of in-person and remote follow-up, continuous training, and updated protocols are recommended to ensure quality and safety.

NP68

IMPLEMENTING A NURSE-LED CAR-T PATIENT CARE PATHWAY IN A DISTRICT GENERAL HOSPITAL: ENHANCING PRE- AND POST-TREATMENT SUPPORT THROUGH ADVANCED CLINICAL PRACTICE

Nicola Knightly[1]
[1]*England, Swindon, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has emerged as one of the most significant advances in the treatment of haematological malignancies in recent decades. Its demonstrated clinical effectiveness has led to rapidly expanding eligibility, enabling increasing numbers of patients to access this innovative treatment (Porter et al., 2011). While CAR-T infusion and acute management must take place within specialised centres, referring district general hospitals (DGHs) are responsible for preparing patients prior to treatment and providing safe and effective follow-up after discharge. These responsibilities demand streamlined collaboration, clear communication and a skilled workforce capable of recognising and managing CAR-T complications. Without effective structure and continuity, patient outcomes may be compromised through delayed referral, unmanaged toxicities or inadequate holistic care. In response to this challenge, a nurse-led CAR-T pre- and post-treatment pathway was developed and implemented in a DGH setting.

Methods: The pathway was designed and led by an Advanced Clinical Practitioner (ACP) specialising in transplantation and cellular therapies. The objective was to create a structured, nurse-led service that ensured timely pre-assessment, coordination of bridging therapy, delivery of comprehensive patient education, and consistent post-CAR-T follow-up. To ensure clinical governance and alignment with best practice, a standard operating procedure (SOP) was developed in accordance with the specialised centre recommendations and reviewed by relevant stakeholders through the DGH governance framework. A formal

nurse-led initial assessment was introduced to accompany referral documentation, capturing holistic needs and clinical stability indicators to streamline communication with the treating centre's multidisciplinary team (MDT).
Targeted nurse education covering treatment principles and complication recognition, including cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS), was incorporated into annual competency programmes. Education resources were recorded and made available across the MDT. A nurse-led review clinic was also established to provide consistent follow-up during bridging therapy and after patient discharge.

Results: Early referral to specialist centres continued, supporting timely eligibility assessment and optimal treatment planning. The initial assessment tool enabled proactive identification of supportive needs, such as psychological support, dietetic input and physiotherapy, facilitating early interventions that supported patients' wellbeing and preparedness for treatment. Clear communication strengthened patient trust and improved collaboration with specialist centres.
The ACP-led clinic provided a single point of continuity, allowing regular monitoring and early complication management. Pre-treatment complications, including pleural effusion and PICC-line infections, were identified promptly, preventing delays to CAR-T admission.
Post-treatment complications—such as neutropenia, infection and early relapse—were managed swiftly due to consistent monitoring and patient access to the ACP outside of scheduled appointments. Patients received follow-up appointments before discharge from specialist care, demonstrating improved coordination between centres.

Conclusions: Implementation of a nurse-led CAR-T care pathway within a DGH demonstrates that advanced nursing leadership can improve treatment coordination, safety and patient experience. The ACP role delivers expert knowledge, clinical decision-making and collaboration that strengthens the wider MDT and improves continuity of care. Structured local pathways support timely referrals, early intervention and effective complication management, ultimately contributing to optimised outcomes for patients undergoing CAR-T therapy.

Clinical Trial Registry: NA

NP91

COLLABORATION BETWEEN TRUSTS TO MAINTAIN CONTINUITY OF AUTOLOGOUS STEM CELL TRANSPLANTATION DURING SERVICE DISRUPTION

Sheila Fox[1], *Jo Mayo*[1]
[1]*Bristol Haematology and Oncology Centre, Bristol, United Kingdom of Great Britain and Northern Ireland (the)*

Background: In early 2025, a regional hospital experienced an unexpected interruption in chemotherapy compounding services, following the closure of part of its sterile preparation unit after a regulatory inspection. This disruption rendered the site unable to supply chemotherapy essential for autologous stem cell transplantation (ASCT). This created an immediate risk of treatment delays for patients.
Our centre, which already has an established collaborative working relationship with the regional hospital for allogeneic transplant patients were approached to provide urgent support. Given the clinical urgency and potential impact on patient outcomes, we rapidly integrated their patients into our service, using are protocols and guidelines.
Aim: To describe how inter-trust collaboration enabled uninterrupted delivery of ASCT, during an unplanned service disruption, and to outline the operational and pathway adaptations implemented.

Methods:

- **Rapid Integration:** Immediate incorporation of patients from the regional hospital into our ASCT programme, following our standard operating procedures and existing clinical governance structures.
- **Initial Informal Coordination:** Leveraging pre-existing allogeneic transplant pathways and resources to facilitate urgent communication and scheduling.
- **Enhanced Communication:** Establishment of dedicated communication channels between teams, to ensure seamless care.
- **Formalisation:** Transition from informal collaboration to a formal service-level agreement, when it became evident that the disruption would persist beyond initial expectations.
- **Operational Adaptations:** Adjustments to resource allocation and documentation processes to accommodate increased patient volume without compromising safety or quality.

Results:

- All patients requiring ASCT were treated equally, maintaining compliance with national standards and institutional protocols.
- Adaptations included flexible scheduling, intensified multidisciplinary communication to support continuity of care.
- No adverse events reported, and patient safety was preserved throughout the process.
- Minimal disruption to patient care was achieved, despite the sudden increase in workload.

Conclusions: This case highlights the critical role of established inter-trust relationships, rapid operational response, structured communication in safeguarding and essential transplant services during unforeseen disruptions.
Future work should incorporate patient-reported outcomes to evaluate experience and satisfaction. This should provide a more comprehensive assessment of the impact of such collaborative interventions.
The poster will illustrate the adapted ASCT pathway, operational modifications and communication strategies that facilitated seamless patient transition and continuity of care.

Jo Mayo - Nothing to declare

NP93

ASSESSMENT OF NUTRITIONAL STATUS IN PATIENTS UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Sara Marcos Asensio[1], *Katia Benito-Sendin Plaar*[2], *Heather Stacey Villanueva Alvarado*[2], *Carmen Muñoz Muñiz*[2], *Marta Sanchez Fernandez*[2], *Elena Delgado Pascual*[2], *Lourdes López Vazquez*[1], *Estefanía Perez López*[1], *Ana África Martín López*[1], *Lucía López Corral*[1]
[1]*Complejo Asistencial Universitario de Salamanca, Instituto de Investigacion Biomédica de Salamanca, Salamanca, Spain,* [2]*Complejo Asistencial Universitario de Salamanca, Salamanca, Spain*

Background: The nutritional status of patients undergoing allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a factor that must be taken into account because of its involvement in the impact of early and late complications, particularly mucositis, graft-versus-host disease (GVHD), and infectious complications.

Methods: Analysis of data from pre-transplant nutritional assessments conducted by the Nutrition Department of our center during the period from April 2025 to November 2025. Descriptive statistics were performed using SPSS v25.

Results: During the study period, 41 patients scheduled to undergo allogeneic hematopoietic stem cell transplantation (allo-HSCT) within the following 4–6 weeks were evaluated. Of these 41 patients, one was excluded from the subsequent analysis because allo-HSCT was ultimately not performed, although previous evaluation had been assessed. Demographic data are presented in Table 1. All patients were advised to perform physical exercise prior to allo-HSCT, as well as to follow dietary recommendations. The 10 patients who presented disease-related malnutrition (DRM) had received chemotherapy prior the nutritional assessment was performed.

Sex	Men: 23 (56.1%) Women: 18 (43.9%)
Age (mean)	51.79 years (range: 20–72)
Hematological diagnosis	Acute Myeloid Leukemia: 11 (26.8%) Myelofibrosis: 7 (17.1%) Non-Hodgkin Lymphoma: 6 (14.6%) Acute Lymphoblastic Leukemia: 5 (12.2%) Myelodysplastic Syndrome: 7 (17.1%) Plasma Cell Leukemia: 2 (4.9%) Hodgkin Lymphoma: 1 (2.4%) Others: 1 (2.4%) Chronic Myelomonocytic Leukemia: 1 (2.4%)

Chemotherapy prior to the nutritional assessment	No: 14 (34.1%) Yes: 27 (65.9%)
Previous HSCT prior the nutritional assessment	No: 33 (80.5%) Yes: 8 (19.5%)
Type of allo-HSCT planned	Related donor allo-HSCT: 12 (29.3%) Unrelated donor allo-HSCT: 25 (61.0%) Haploidentical allo-HSCT: 4 (9.8%)
Disease-related malnutrition (DRM) prior to allo-HSCT	No: 31 (75.6%) Yes: 10 (24.4%) - Moderate: 5 (50%) - Severe: 5 (50%)
Nutritional supplementation prior to allo-HSCT	No: 29 (70.7%) Yes: 12 (29.3%)

Table 1. Demographic characteristics

Conclusions:

Pre-transplant nutritional status is important for assessing potential post-transplant complications. The prevalence of malnutrition prior to allo-HSCT is higher among patients who have received standard chemotherapy before allo-HSCT. Receiving novel agents prior to allo-HSCT, instead of standard chemotherapy, does not appear to affect nutritional status. Further follow-up of this study is important to evaluate post-transplant complications in relation to nutritional status.

Disclosure: No disclosure.

NG27-01

DEFINING NATIONAL RESEARCH PRIORITIES IN HSCT NURSING USING THE DONABEDIAN MODEL, DELPHI METHODOLOGY, AND CONSENSUS RATIFICATION

Ozgun Gokmen Kaya[1], *Remziye Semerci Şahin*[2], *Sevinc Ince*[3], *Seckin Erdal*[3]
[1]*Koç University, Graduate School of Health Sciences, Istanbul, Turkey,* [2]*Koç University, School of Nursing, Istanbul, Turkey,* [3]*Acıbadem Altunizade Hospital, Istanbul, Turkey*

Background:

The rapid progression of Haematopoietic Stem Cell Transplantation and Cell Therapies necessitates the identification of standardized, evidence-based nursing research areas. National research priorities in Haematopoietic Stem Cell Transplantation (HSCT) nursing are crucial due to variations in local infrastructure, resource constraints, and clinical practice across countries. To establish a national, evidence-based roadmap, this study aimed to define and prioritize HSCT nursing research areas in Turkey, guided by the Donabedian Quality Model (Structure, Process, Outcome).

Methods: A rigorous three-round modified Delphi study was conducted nationwide. Our expert panel was highly selected, consisting of academic and clinical HSCT nurses with a minimum of 10 years of intensive clinical experience (n=17).
Round 1 (Qualitative Data): 456 raw research suggestions were initially gathered from practicing nurses (n=51) across the country. These suggestions were subjected to thematic analysis and refined into 23 distinct research categories, mapped to Donabedian's Structure, Process, Outcome, and Special Themes dimensions.
Rounds 2 & 3 (Quantitative Rating): The expert panel rated the 23 categories using a 5-point Likert scale. In Round 3, individual scores and the group's statistical feedback (Median and Interquartile Range - IQR) were provided to promote convergence.
Consensus Criteria: Consensus for a priority item was strictly defined by a Median ≥4.0 and an IQR ≤1.0.To enhance methodological robustness and promote national implementation, all consensus items will be ratified at a National Consensus Meeting scheduled for January 2026. Representatives from all Turkish national HSCT centers will be invited to this session to facilitate immediate integration of the findings into clinical practice.

Results: 14 HSCT nursing experts participated in all rounds of this study. Following the third round, consensus was achieved for 19 out of 23 categories (82.6%), demonstrating a high degree of agreement among national experts.
The highest-ranking thematic areas (Median=5.00) were predominantly concentrated in the Process and Outcome dimensions. Specific high-priority areas identified in the Structure dimension included Y1: Nursing Workload and Personnel Optimization. High-priority Outcome areas included O4: Nurse Burnout and Mental Health (although it did not reach the IQR consensus threshold, the Median score of 5.00 indicated very high perceived importance).

The three highest-ranked research priorities that achieved full consensus based on Round 3 Median scores are:

1. S-5 (Process): Medication Management and Toxicity Monitoring (Median: 5.00, IQR: 1.00)
2. S-2 (Process): Central Venous Catheter (CVC) Care (Median: 5.00, IQR: 1.00)
3. O-6 (Outcome): Patient Safety and Satisfaction (Median: 5.00, IQR: 1.00)

The four research categories that did not reach consensus (IQR > 1.0) were S3 (Mucositis Management), S4 (GVHD Nursing Management), O4 (Nurse Burnout), and ÖZ3 (Biological/Genetic Factors).

Conclusions: This study defines HSCT and CT nursing research priorities specific to the national healthcare system realities, providing a rigorous, evidence-based foundation for future research. The high consensus on items related to Process and Patient/Staff Outcomes underscores the need to focus resources on clinical practice standardization and personnel well-being. The prioritized findings, following ratification by the National Consensus Meeting, will provide a concrete, nationally relevant roadmap for advancing evidence-based practice across all Turkish HSCT centers.

Clinical Trial Registry: Not applicable.

Disclosure: None.

NG27-05

ECP 2.0: TECHNICAL, ORGANIZATIONAL AND PATIENT-CENTERED EVALUATION OF HIGH-FLOW VENOUS PORTS AS SYSTEMATIC ACCESS FOR POST-TRANSPLANT EXTRACORPOREAL PHOTOPHERESIS

Barbara Loconte[1], *Mauro Baglioni*[1], *Davide Sari*[2], *Roberta Bordone*[3], *Georg Stüssi*[3], *Laura Orlando*[1]
[1]*Cellular Therapy Program, Department of Nursing, Oncology Institute of Southern Switzerland, Ente Ospedaliero Cantonale (EOC), Bellinzona, Switzerland,* [2]*Department of Nursing Oncology, Institute of Southern Switzerland, Ente Ospedaliero Cantonale (EOC), Bellinzona, Switzerland,* [3]*Cellular Therapy Program, Clinic of Hematology, Oncology Institute of Southern Switzerland, Ente Ospedaliero Cantonale (EOC), Bellinzona, Switzerland*

Background: Extracorporeal photopheresis (ECP) is a well-established therapy for acute and chronic graft-versus-host disease (GVHD). At the Cellular Therapies Program (CTP) of the Oncology Institute of Southern Switzerland, high-flow venous ports were systematically introduced to improve continuity, safety, and patient comfort in post-transplant ECP pathways. Despite the increasing use of this device, evidence supporting its routine adoption remains limited. The primary aim of this study was to assess technical safety and procedural efficiency of ECP performed through high-flow ports compared with peripheral or central venous access. Secondary aims included evaluating organizational impact, access stability,

acceptability, emphasizing the importance of patient experience in ECP, and preliminary biological results within a multicenter European analysis.

Methods: A retrospective observational descriptive-analytic study was conducted on ECP procedures performed between May 2022 and November 2023. 13 patients (9 chronic GVHD, 4 acute GVHD) underwent more than 200 ECP procedures. Machine-recorded data (alarms, duration, treated volumes) were integrated with anonymized clinical variables (age, sex, GVHD type and site, venous access) and organizational indicators from 2022–2024. Statistical analysis included descriptive measures, ANOVA comparisons across access types, Pearson correlations, and selected graphical representations. Cell viability and apoptosis profiles from the associated European multicenter study were also analyzed.

Results: **Use of access devices:** The high-flow port was the most frequently used access (9 patients, 69%), demonstrating sustained stability over time.
Technical safety:

- Mean alarm frequency showed no significant differences between access types (ANOVA $p > 0.05$).
- Alarms related to Vascular Access Devices were rare and not specifically associated with port use.
- Technical issues did not lead to procedures interruption.

Operational efficiency:

- Procedure duration was longer with ports (mean 140 min) compared with peripheral (103 min) and CICC access (88 min) ($p < 0.001$), consistent with single-needle modality, without compromising procedural quality.
- Maximum treated volumes were comparable across access types, with no clinically meaningful differences.

Correlations:

- No significant correlation between alarm frequency and procedure duration (Figure 1).
- No association between access type and alarms related to Vascular Access Devices.

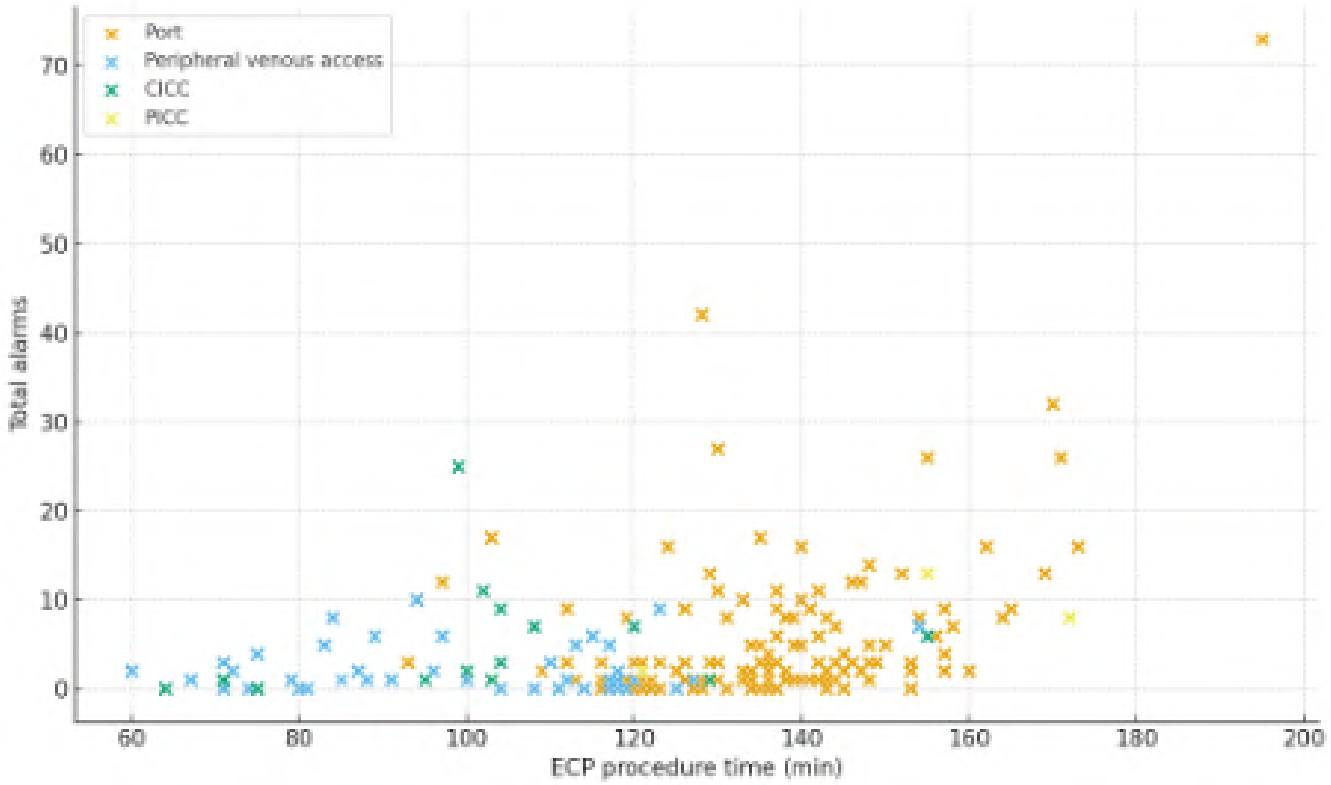

Figure 1 Correlation between procedure time and total alarms by vascular access

Organizational impact: ECP activity increased markedly, from 71 procedures in 2022 to 221 in 2023 and 317 in 2024, confirming sustainability of the model and absence of port-related operational limitations.
Preliminary biological findings: Cell viability and apoptosis profiles before and after photoactivation were comparable across access types, supporting biological equivalence.

Conclusions: Systematic use of the high-flow venous port for ECP procedures is safe, technically stable, and comparable to other venous access options. The longer duration associated with single-needle modality does not compromise overall efficiency. Beyond technical performance, adopting the port represents an ethical, patient-centered choice: it prevents repeated peripheral punctures and enables patients to rely on a single, well-tolerated access throughout their therapeutic journey, including outpatient visits and supportive treatments. Its reproducibility across organizational models and the equivalence of biological outcomes further support its use. A validation phase assessing patient-reported quality is planned to integrate the patient perspective into the global evaluation of the procedure.

Disclosure: Nothing to declare.

Advancing the Art of Patient Care

NP20

PATIENT SATISFACTION OF A NURSE-LED BONE MARROW ASPIRATION (BMA) SERVICE

Sophie Bertorelli[1], *Charis Hillberg*[1], *Emille Sy*[1], *Kriselaine Del Rosario*[1], *Leanne Howells*[1]
[1]*University Hospital of Wales, Cardiff, United Kingdom of Great Britain and Northern Ireland (the)*

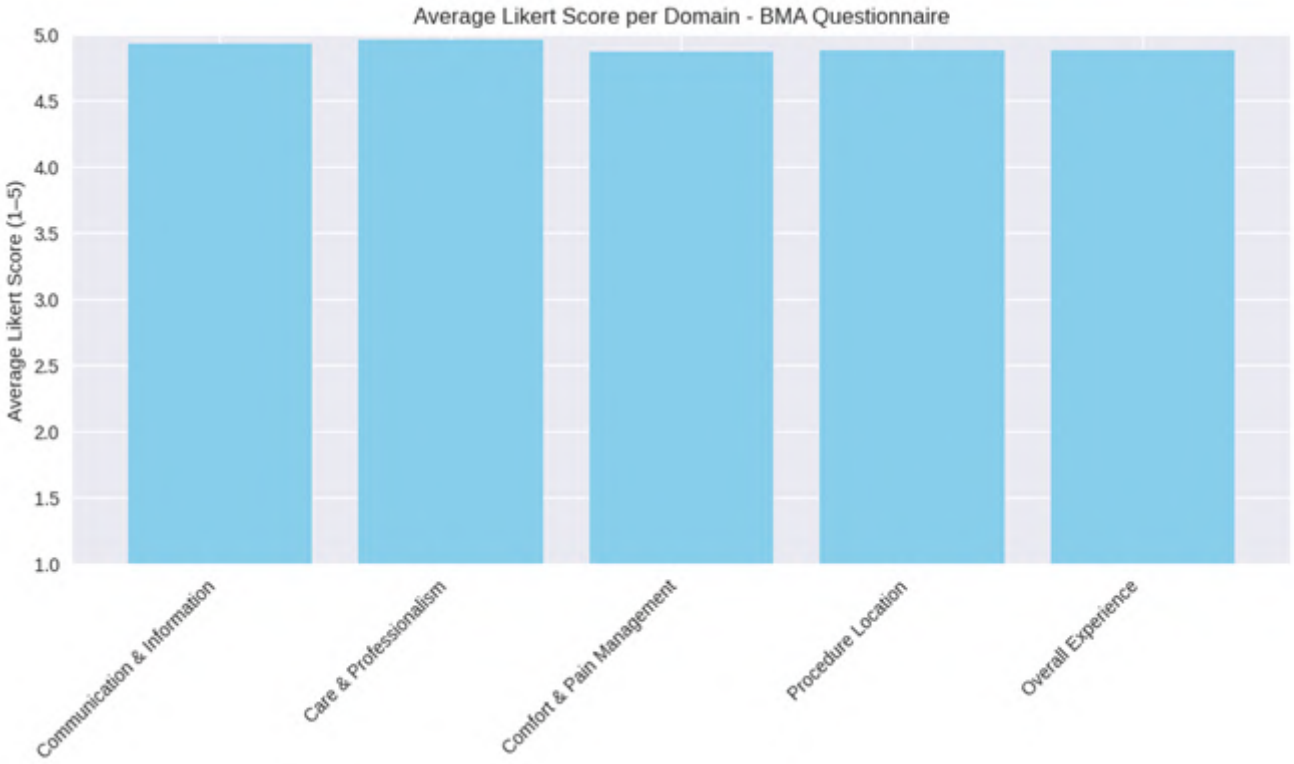
Background: Bone marrow aspirations (BMAs) are essential after haematopoietic stem cell transplant (HSCT) to assess disease status and donor chimerism (Qin et al., 2014). With the rising number of allogeneic transplants, the burden of BMAs on medical staff became overwhelming, resulting in delays, procedures performed at incorrect time points, and long patient waits. To address this, the SWBMT Programme introduced nurse-led BMA lists in 2017 to improve patient experience, ensure timely procedures, and provide holistic care. Patient feedback is vital for service improvement and recognition of clinical excellence (Kumah et al., 2017). A satisfaction questionnaire was therefore developed to evaluate the nurse-led BMA service.

Methods: Between July and November 2025, satisfaction questionnaires were prospectively collected from 80 patients using a 5-point Likert scale (Batterton and Hale, 2017). The cohort included 49 males and 31 females, median age 61 years (range 20–77). Feedback was obtained immediately post-procedure by the nurse performing the aspiration.

Results: The questionnaire covered five domains: communication, care and professionalism, comfort and pain management, procedure location, and overall experience, with space for comments.

- **Communication and information**: 93% strongly agreed they received clear explanations before, during, and after the procedure, with opportunities to ask questions.
- **Care and professionalism**: 97% strongly agreed nurses were professional, respectful, and competent.
- **Comfort and pain management**: 89% strongly agreed pain was managed effectively and appropriate aftercare advice was given; 10% agreed, while 1% were neutral or dissatisfied.
- **Procedure location**: 90% strongly agreed the environment was clean, safe, private, and well-equipped; 8% agreed, 2% were neutral or dissatisfied.
- **Overall experience**: 93% strongly agreed they were satisfied, would undergo nurse-led BMAs again, and would recommend the service.

Overall, ratings across domains were overwhelmingly positive, with most responses at "strongly agree." Notably, 86% had prior experience of nurse-led BMAs.
Qualitative feedback Comments frequently described the service as "professional," "pain-free," "compassionate," "gentle," and praised "excellent communication." A small number highlighted areas for improvement, including waiting times, bed size, and space constraints.



Conclusions: This evaluation demonstrates that nurse-led BMAs are safe, effective, and highly valued by patients. Across all domains—communication, professionalism, comfort, environment, and overall experience—feedback was overwhelmingly positive, with most participants rating their care as excellent. Qualitative comments reinforced these findings, particularly nurses' compassion and skill in pain management. Minor concerns regarding space and waiting times were noted but did not detract from overall satisfaction.
Implications The results support continued development and expansion of nurse-led services in haematology. This model offers patient-centred, professional, and efficient care, enhancing both patient experience and clinical outcomes.

Disclosure: Nothing to declare.

NURSE LEADERSHIP IN MANAGING ATG REACTIONS IN PEDIATRIC ONCOLOGY: "KOV IN THE LEAD"

Kirsten Madeleine van der Peijl[1], *Manon van Slooten*[1]
[1]*Prinses Maxima Centre, Utrecht, Netherlands (the)*

Background: Antithymocyte globulin (ATG) administration in pediatric hematology and oncology is frequently associated with infusion-related reactions, ranging from mild fever and rash to severe anaphylaxis. Traditionally, physicians were primarily responsible for intervention during such reactions. To enhance nurse autonomy and ensure timely, high-quality care, a nurse-led protocol, *"Kinderoncologieverpleegkundige (Pediatric Oncology Nurse) in the lead" (KOV in the lead)*, was developed at the Princess Máxima Center for Pediatric Oncology *.

At the Princess Máxima Center, nurses work every day with dedication and passion to push boundaries in pediatric oncology care. The center's vision emphasizes professional leadership, collaboration, and continuous improvement, ensuring that every child receives the best possible care.

Methods: A structured protocol was implemented on the pediatric oncology ward, defining clear actions for mild (Pediatric Early Warning Score [PEWS] 0–4), moderate (PEWS 5–8), and severe (PEWS ≥8) ATG reactions **. Nurses were educated to recognize symptoms such as fever, urticaria, dyspnea, and hypotension, and to administer appropriate medication (paracetamol, clemastine, and prednisolone) as part of their pediatric oncology education. The protocol specifies when to act autonomously and when to consult a physician. Team education, simulation sessions, and debriefings were used to enhance clinical confidence and decision making.

Results: Following implementation, nurses demonstrated greater leadership and confidence in managing ATG reactions. The initial responses from the pediatric oncology nurses are positive. This emerged during the daily team time-out in the day shift. They feel more confident and believe that this leads to faster collaboration with the physicians on the ward. The initiative reinforced a culture of shared responsibility, where nurses take an active, leading role in patient safety and acute care. Evaluation and team feedback supported continuous learning and refinement of the protocol.

Conclusions: The "KOV in the lead" initiative shows how passionate and forward thinking nurse leadership can drive improvements in safety, autonomy, and quality of care. By giving nurses the confidence and clear guidelines to make important decisions, this approach helps different healthcare professionals work better together and improves pediatric cancer care, leading to the best possible outcomes for children now and in the future. This aligns with our mission: to cure every child with cancer, while ensuring the best possible quality of life.

Disclosure: Nothing to declare

NP54

ESTABLISHING A NURSE-LED BONE MARROW ASPIRATION (BMA) SERVICE POST-HAEMATOPOIETIC STEM CELL TRANSPLANT (HSCT): SHARING EXPERTISE TO IMPROVE PATIENT EXPERIENCE AND SERVICE DELIVERY

Sophie Bertorelli[1], *Kriselaine Del Rosario*[1], *Leanne Howells*[1], *Emille Sy*[1], *Charis Hillberg*[1]
[1]*University Hospital of Wales, Cardiff, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Bone marrow aspirations (BMAs) are a critical element of post-haematopoietic stem cell transplant (HSCT) care, providing essential information on disease status and donor chimerism. However, the rising number of allogeneic transplants has placed considerable pressure on clinical teams, leading to delays, procedures being undertaken at inappropriate timepoints, and negative patient experiences due to prolonged waiting times and inadequate facilities. To address these challenges, the South Wales Bone Marrow Transplant (SWBMT) Programme introduced a nurse-led BMA service in 2017. This initiative was designed to improve patient care and experience, ensure procedures are performed in a timely manner, and streamline processes to enhance service sustainability. At present, only a limited number of health boards in Wales offer such a service, highlighting an important opportunity to share learning and extend provision across the region.

Methods: A robust governance and competency framework was established to support the development of the nurse-led BMA service. Training was delivered through a structured pathway in which an Advanced Nurse Practitioner (ANP), initially trained by a Specialist Registrar (SpR), subsequently trained Clinical Nurse Specialists (CNSs). This pathway progressed from observation to supervised practice and finally independent sign-off, typically completed within three to four months. Competence was maintained through re-assessment every two years, with a requirement to perform a minimum of twelve BMAs annually. Clinical governance measures included the introduction of a lidocaine Patient Group Direction (PGD), standard operating procedures (SOPs), a competency booklet, and a clear escalation plan for medical support. Service delivery was organised through dedicated nurse-led BMA lists held twice weekly, supported by a referral system, administrative infrastructure, and routine audit to ensure quality and sustainability.

Results: The introduction of the nurse-led BMA service has delivered clear benefits for both patients and staff. Patient outcomes have improved through reduced waiting times, procedures being carried out at the correct timepoints, and enhanced continuity of care, all contributing to a more positive overall experience. For staff and service delivery, the initiative has released medical time for other priorities, expanded the nursing scope to include advanced practice, and generated high levels of staff satisfaction alongside improved efficiency. In the past twelve months alone, 384 BMAs were performed by the nurse-led team, and since the service was established, medical staff have rarely needed to undertake BMAs. Feedback from patients and staff has been overwhelmingly positive. The work has been shared more widely through a presentation to the Wales Haematology Cancer Site

Group, and a survey has been distributed to other health boards to gauge interest in adopting similar models.

Conclusions: The nurse-led BMA service has delivered substantial benefits, including improved patient experience, timely and efficient service delivery, enhanced nursing competencies, and optimal use of resources. This model demonstrates scalability across Wales, the wider UK, and internationally, offering significant potential for shared learning and broader adoption. By promoting best practice in post-transplant care, it provides a framework for sustainable service development and improved outcomes for patients and healthcare systems alike.

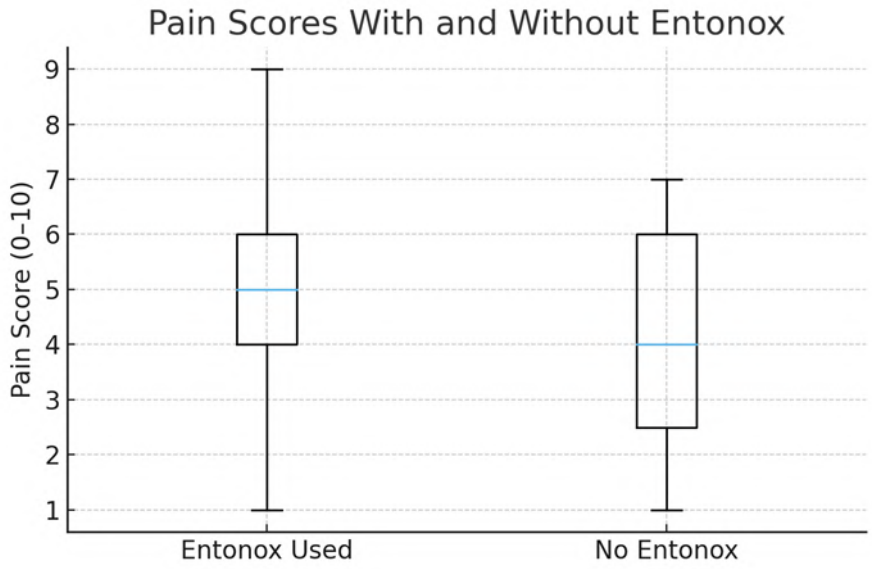
PATIENT REPORTED EXPERIENCE OF BONE MARROW ASPIRATE AND TREPHINE BIOPSY. A NURSE LED SERVICE ESTABLISHMENT AND IMPROVEMENT PROJECT

Sara Main[1], *Mariam Amer*[1], *Annie Major*[1], *Kelly Lanaghan*[1], *Deborah Richardson*[1], *Christopher Dalley*[1], *Jing Hiew*[1], *Amy Creighton*[1], *Alice Jenkins*[1], *Kim Orchard*[1], *Madeleine Norbury*[1]
[1]*University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Bone marrow aspirate and trephine (BMAT) biopsy is an essential diagnostic procedure but is often associated with anxiety and procedural pain. As part of a programme to strengthen nurse-led practice within a regional transplant programme, a new Standard Operating Procedure (SOP) and competency framework were developed to support consistent, safe delivery of BMAT by advanced and specialist nurses. Understanding patient-reported experience was essential both to evaluate the newly formalised nurse-led service and to identify opportunities for improvement, including enhanced analgesic options. This baseline audit aimed to describe current patient experience of BMAT and use these findings to inform a prospective evaluation of inhaled methoxyflurane (Penthrox) as an alternative to Entonox.

Methods: A prospective baseline audit was undertaken between September and December 2025. Adults undergoing BMAT on the haematology day unit were invited to complete an anonymous questionnaire assessing: pre-procedure anxiety (0–10), procedural pain (0–10), satisfaction with pain management (1–5), use and perceived benefit of Entonox, recall of consent and aftercare advice, and free-text feedback. Findings were analysed descriptively and used to refine the SOP, education materials, and local guidance. Concurrent preparatory work included submission of an updated SOP incorporating Penthrox, approval through the Drugs and Therapeutics Committee, creation of an ARIA protocol for methoxyflurane prescribing, and development of staff education and a revised audit tool for prospective evaluation beginning January 2026.

Results: A MS Forms link to the questionnaire was sent out to 72 sequential patients via email. Forty patients participated (20 male, 20 female). Median pre-procedure anxiety was 5/10 (IQR 3–7), with 30% reporting anxiety ≥7. Median procedural pain was 5/10 (IQR 3–6); 55% reported pain ≥5 and 40% reported pain ≥6. Entonox was used by 21/40 (52.5%); of these, two-thirds found it helpful, though several reported dislike of the device or a preference to avoid it. Satisfaction with pain management was high (82.5% rated 4–5 stars; 60% rated 5 stars). Consent was recalled in 93% of cases, and aftercare advice in 100%. Free-text feedback emphasised the value of skilled, confident operators; clear explanations; reassurance; and continuity—strengths consistently associated with the nurse-led model. A minority expressed desire for improved analgesia or anxiolysis.



Conclusions: This audit demonstrates that while overall satisfaction with BMAT is high, many patients continue to experience moderate–severe pain or significant anxiety. The findings support targeted refinements to nurse-led BMAT practice, including enhanced pre-procedure information, improved psychological support, and access to alternative analgesia for suitable patients. The SOP, competency framework, and preparatory governance work have established the foundations for a prospective evaluation of methoxyflurane for procedural pain management commencing January 2026. Penthrox is reported to be both quicker and superior as a short acting, reversible inhaled analgesic. It is also more sustainable that using bottled Entonox. Based on our baseline audit, around 50% of BMAT patients use Entonox. Substituting Penthrox (0.84 kg CO_2e) for Entonox (98.89 kg CO_2e) in this group would save ~4.9 tonnes CO_2e for every 100 BMAT procedures, supporting a low-carbon analgesia strategy.

GRAFT VS. HOST DISEASE - ADVANCED PRACTICE NURSE. A POTENTIAL KEY ROLE IN THE INTERPROFESSIONAL CARE OF PATIENTS WITH GVHD

Talea Jacobsen[1]
[1]*Uniklinik Köln/ University Hospital Cologne, Cologne, Germany*

Background: Graft-versus-host disease (GVHD) is a serious complication associated with allogeneic stem cell transplantation that severely affects patients physically, psychologically, and psychosocially. The complex care required necessitates cross-sector, interprofessional support. An advanced practice nurse (APN) can play a central role in this. A systematic literature review (March 2025) reveals a research gap regarding the specific care needs of this patient group and therefore also the relevance of an APN in this field in Germany.

Methods: The aim is to highlight the specific care needs of patients with GvHD and how these can be addressed by the care provided by an APN within an interprofessional team. The qualitative research will be conducted in two phases using guided expert interviews evaluated according to Kuckartz. In phase 1 (April 2025), APNs who already work with GvHD patients will be interviewed. In phase 2 (June 2025), an interprofessional team without APN structures will be interviewed. This will be followed by a comparison of the perspectives.

Results: In phase 1, a total of four APNs from three German clinics will be interviewed online. The requirements for the structural implementation of an APN and the psychosocial and long-term care needs of patients will be recorded. In phase 2, a total of five professional groups from a multidisciplinary team at a German clinic will be interviewed in six focus group interviews. A diverse range of care needs is identified, with a focus on a standardized care system and the resulting areas of activity for an APN. The need for a continuous, cross-sectoral contact person with bundled expertise is emphasized.
The results highlight a specific need for care. Depending on the perspective, the focus varies: the multi-professional team reflects a standardized and acute need to restore functionality. The APNs surveyed focus on the long-term consequences and psychosocial aspects. The study situation reinforces both perspectives. The results are embedded in the needs pyramid according to the needs hierarchy. The APNs surveyed focus on the long-term consequences and psychosocial aspects. The study situation reinforces both perspectives. The embedding of the results in Maslow's hierarchy of needs serves as an organizational model and is intended to support the prioritization of care needs. The dynamic progression of needs must be taken into account here. With the help of the trajectory model according to Corbin and Strauss, chronic care management can be carried out in a structured manner.

Conclusions: A generally transferable care requirement for patients with GvHD exists in the areas of safety and information transfer, physical, psychological, and psychosocial stability, as well as comprehensive GvHD expertise with adequate networking. Providing optimal care for GvHD patients is a balancing act between standardization and individualization, from acute to long-term care with internal and supraregional networks. An APN can address these needs as a continuous care coordinator within an interprofessional collaboration.

Maria della Misericordia" Udine University Hospital, Azienda Sanitaria Universitaria Friuli Centrale, Udine, Italy*

Background: Haematopoietic stem cell transplantation (HSCT) and chimeric antigen receptor T-cell (CAR-T) therapy are gold-standard treatments for refractory haematologic malignancies but remain burdened by significant toxicity affecting prognosis and quality of life. Complications include treatment-specific syndromes—such as GvHD, CRS, and ICANS—and shared side effects like fatigue, mucositis, and fever. Nursing care is crucial in preventing, recognizing, and managing these complications, directly influencing patient outcomes. Nursing-sensitive outcomes (NSOs) reflect conditions or perceptions directly affected by nursing interventions and allow objective evaluation of care quality. However, NSOs may differ between HSCT and CAR-T contexts, and no standardized framework currently defines them in adult populations. This study aimed to identify relevant NSOs for adult HSCT and CAR-T therapy.

Methods: A two-round Delphi consensus was conducted to identify nursing-sensitive outcomes (NSOs) relevant to HSCT and CAR-T-cell therapy. The process, carried out anonymously via Microsoft Forms, involved two groups: a Research Team (RT, Table 1), responsible for developing and validating the preliminary list of NSOs, and an Expert Panel (EP) of nurses and physicians from Italian GITMO-accredited centres. The initial NSO pool, derived from Oncology Nursing Society outcomes (Given, 2005) BAand literature review, was refined through RT input and evaluated by the EP for clarity and relevance on a 4-point Likert scale. Consensus was defined as the minimum agreement required for inclusion in the final set. Descriptive and inferential statistics were applied to compare responses by round, profession, and clinical activity, with significance set at $p<0.05$.

Results:

Definition of Consensus: Consensus was defined as the level of agreement required for an NSO to be considered validated and retained in the final set. Specifically, an item was considered to have reached consensus if the following occurred: *At least 75% of all respondents rated it as 3 or 4 on the 4-point Likert scale (where 1 = not relevant and 4 = highly relevant) and at least 75% agreement was observed within each professional subgroup, namely, nurses and haematology physicians.* This dual-level threshold was applied to ensure that the consensus reflected a balanced and shared perception across different professional perspectives, enhancing the validity and acceptability of the selected NSOs in interdisciplinary transplant and CAR-T-cell care settings. ***The Expert Panel (EP)**: Comprised nurses and physicians from centres accredited by the Italian Group for Bone Marrow Transplantation (GITMO). In these centres, haematology physicians serve as program directors for transplant activities, while nurses are designated by the directors as official representatives. Participation in the panel was voluntary and based on professional experience in HSCT or CAR-T-cell therapy. **NSO**: Nursing Sensitive Outcome; **Med**: Median; **M**: Mean; **IQR**: Interquartile Range; **SD**: Standard Deviation; **%3-4**: % of responses rated 3 or 4; **CAUTIs**: Catheter-Associated Urinary Tract Infections; **CLABSIs**: Central Line-Associated Bloodstream Infections; **Bold**: NSOs with ≥75% responses of 3 or 4 on the Likert scale.

Eighty-two professionals participated in Round 1 (79% nurses, 21% physicians), and 37 completed Round 2 (70% nurses). Most respondents were female, aged 51–55 years, with over 11 years' experience in HSCT or CAR-T settings (Table 1).In Round 1, 25 NSOs were assessed, and 17 (68%) reached the consensus threshold. Highest agreement concerned pain, fatigue, ADLs, nutritional status, anxiety, depression, emotional distress, and major safety indicators (falls, CLABSIs, CAUTIs, drug extravasation).
In Round 2, 14 NSOs (56%) achieved consensus, showing partial consolidation of opinions. ADLs, anxiety, drug extravasation, and patient satisfaction reached 100% agreement; recognition of clinical instability, self-efficacy, and therapy-related knowledge remained ≥95%. Conversely, pain, fatigue, and nutritional status fell below the threshold, while sleep disturbances, nausea, and vomiting reached consensus only in Round 2.
Full results are available in Figure 1.

Conclusions: This study identified 14 nursing-sensitive outcomes (NSOs) relevant to adult HSCT and CAR-T therapy, covering symptom management, functional ability, psychological well-being, and patient safety. Differences between nurses and physicians were limited and progressively narrowed through the Delphi process, highlighting its value in fostering interdisciplinary alignment. Nurses consistently attributed greater importance to patient-centred domains such as comfort, empowerment, and emotional health.The main limitation

was the modest Round 2 response rate, which may have favoured participants more aware of NSO concepts; moreover, results reflect expert perceptions rather than objective measurements.
This study provides a validated 14-item NSO framework for adult HSCT and CAR-T care and supports integrating nursing perspectives to promote holistic, patient-centred, and truly multidisciplinary practice, fostering the development of more consistent and shared models of care.

COMMUNICATION COMPETENCE, SELF-EFFICACY, AND SPIRITUAL INTELLIGENCE: EVIDENCE FROM NURSES WORKING IN BMT UNIT

Komal Mundhe[1]
[1]*ACTREC, TMC, Navi Mumbai, India*

Background: Nurses working in Bone Marrow Transplant (BMT) units manage complex clinical care alongside significant emotional and psychosocial demands. Effective communication, strong self-efficacy, and spiritual intelligence are essential for ensuring patient safety, supporting patients and families, facilitating teamwork, and maintaining professional resilience. Despite their importance, limited evidence is available regarding these psychosocial competencies among BMT nurses in the Indian healthcare context.

Methods: A descriptive cross-sectional study was conducted among 50 nurses working in the BMT unit of a tertiary cancer center. Data were collected using a structured, anonymous, self-administered questionnaire comprising three validated instruments: the Nurses' Communication Competence Scale (NCCS-18) developed by Hur, Kwak, and Jang (2011), the Communication Self-Efficacy Scale developed by McCroskey and McCroskey (1988), and the Spiritual Intelligence Scale (22 items) developed by King (2008). Demographic and professional variables included age, gender, educational qualification, total clinical experience, BMT experience, and prior training exposure.

Data were entered in Microsoft Excel and analyzed using SPSS version 26. Categorical variables were summarized using frequencies and percentages, while continuous variables were summarized using mean ± standard deviation. Associations between demographic

variables and categorized competency levels were analyzed using the Chi-square test or Fisher's exact test. Differences in mean scores between two groups (e.g., prior training: yes vs no) were assessed using the independent t-test, while comparisons across more than two groups (e.g., qualification and experience categories) were performed using one-way ANOVA with post-hoc Tukey analysis. A p-value <0.05 was considered statistically significant.

Results: All 50 nurses (100%) completed the survey. Most participants were female (36, 72%), with the highest representation in the 20–25 years (15, 30%) and 31–35 years (15, 30%) age groups. The majority held a BSc Nursing qualification (35, 70%), followed by GNM (11, 22%). Prior training related to communication skills, confidence-building, or spiritual well-being was reported by 28 nurses (56%), while 22 (44%) had not received such training.

Overall communication competence and self-efficacy scores were moderate to high, reflecting satisfactory interpersonal effectiveness and professional confidence among BMT nurses. Spiritual intelligence scores were consistently high across all domains, with the strongest performance observed in compassion and moral values, highlighting a strong ethical and empathetic foundation. Nurses who had received prior training demonstrated significantly higher communication competence and self-efficacy scores compared with those without training ($p < 0.05$). Additionally, increasing total clinical experience and longer BMT exposure were associated with progressively higher scores across communication competence, self-efficacy, and spiritual intelligence.

Conclusions: BMT nurses demonstrated satisfactory communication competence, self-efficacy, and strong spiritual intelligence. Higher competency levels were associated with greater experience and prior training exposure. These findings support the need for structured educational interventions focusing on communication skills, confidence-building, and spiritual well-being to further enhance nursing performance and quality of care in high-intensity BMT settings.

Clinical Trial Registry: Not applicable. This observational questionnaire-based study did not require clinical trial registration. The study received approval from the Institutional Ethics Committee of ACTREC, Tata Memorial Centre, Kharghar, India.

Disclosure: All authors declare no conflicts of interest and no external funding.

EXPLORING DETERMINANTS OF STAFF RETENTION IN PAEDIATRIC BONE MARROW TRANSPLANT NURSING

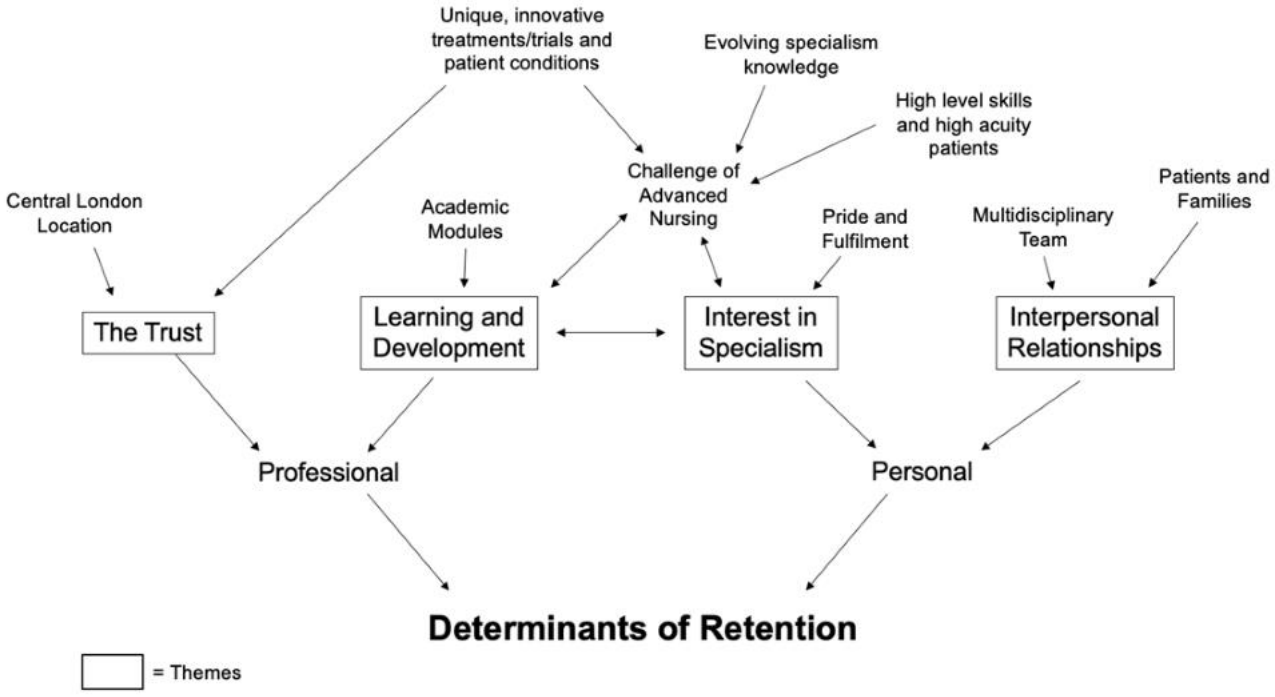
Charlotte Rigby[1], *Tamzin Dawson*[2], *Milli Lipshaw*[2]
[1]*Great Ormond Street Hospital, London, United Kingdom of Great Britain and Northern Ireland (the),* [2]*London South Bank University, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Retention of nursing staff is a constant battle across the NHS, and directly impacts patient safety. With a growing number of paediatric Bone Marrow Transplants (BMTs) being undertaken in the UK and the expansion of the service – coupled with the niche,

specialist skills required to care for these patients and families, the retention of Paediatric BMT nurses is critical. A review of the literature has found there is little UK based research in this area.

Methods: Nurses (n=68) working in inpatient BMT care at a single London Tertiary Centre were recruited via purposive sampling. Participants completed an open-ended questionnaire, created for this study based on existing literature and Appreciative Inquiry perspective. Thematic and documentary analysis was conducted by the study lead using the Ritchie and Spencer Framework and READ approach, respectively.

Results:



Themes identified as professional and personal motivating factors for paediatric nurses to remain working in this area included 'The Trust', 'Learning and Development', 'Interest in Specialism' and 'Interpersonal Relationships'. Through in-depth critical analysis, it became apparent that these factors could not be solely categorised as either professional or personal motivators. Rather, the workplace environment and the individual's personal beliefs intersected, thus contributing to multiple overlapping themes.

Conclusions: **Discussion:** While these findings align with existing literature on advanced nursing practice, and peer and family relationships in the long-term haemato-oncology patient group, it highlights a gap in personal interest in BMT as a retentive factor, and the impact of specific diagnoses and treatment regimes, suggesting a need for further research. Research should focus on the wider specialist paediatric nursing population at this Trust, as well as BMT inpatient nursing across the UK.

Disclosure: **Ethical Considerations:** Ethical approval was granted by the School of Health and Social Care Ethics Committee at London South Bank University, London (Reference - 24/A/16) on 20th January 2025. NHS Trust Approval was granted by [Local Trust Name] Hospital NHS Foundation Trust Research and Development Team (Reference - 4011) on 24th November 2024.
Author Contributions:
Charlotte Rigby (CR) is the lead researcher in this study and has been working in Paediatric Haematology/Oncology and BMT Nursing at two world-leading centres. She was responsible for all aspects of this study – background research, methodology, data collection, data analysis, discussion, manuscript write up and dissemination.
Dr Tamzin Dawson (TD) is a Senior Lecturer and the Deputy Head of School for Children's and Community Nursing, and Mental Health and Learning Disability Nursing at London South Bank University. She is an accomplished academic, and has published many qualitative studies, with a keen interest in PICU and Nursing Education. She acted as Academic Supervisor for this Dissertation service evaluation study.
Milli Lipshaw (ML) is a Lecturer of Children's Nursing at London South Bank University with clinical experience working in Paediatric Oncology and Orthopaedics in the NHS. She is a member of the Children & Young People's Cancer Association (CCLG) and acted as co-supervisor for this Dissertation service evaluation study.
Declaration of Conflicting Interest: CR declared potential conflict of interest, as they were employed by [Local Trust Name] Hospital NHS Foundation Trust throughout the research process and at time of publication.
TD and ML declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.
Funding Statement: The research was conducted as part of CR's MSc Dissertation module at London South Bank University, London. This academic module was funded by [Local Trust Name] Hospital Learning Academy (GLA) Scholarship.

NP133

A DESCRIPTIVE NURSING STUDY ON GUT MICROBIOTA AND GRAFT-VERSUS-HOST DISEASE IN PATIENTS UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Rosalba Daniela Minniti[1], *Roberto Latella*[1], *Maria Caterina Micò*[1], *Jessica Germanò*[1], *Martina Pitea*[1], *Massimo Martino*[1]
[1]*Centro Trapianti di Midollo Osseo, Grande Ospedale Metropolitano "Bianchi-Melacrino-Morelli", Reggio Calabria, Italy*

Background: The gut microbiota maintains immune homeostasis, intestinal barrier integrity, and inflammation control, profoundly influencing outcomes after allogeneic hematopoietic stem cell transplantation (allo-HSCT). Dysbiosis strongly correlates with acute gastrointestinal graft-versus-host disease (GVHD), infections, delayed immune reconstitution, graft failure, and elevated transplant-related mortality. Different factors like conditioning regimens, prolonged neutropenia, immunosuppressants, and broad-spectrum

antibiotics devastate microbial diversity. Nurses drive impact through vigilant surveillance, targeted nutrition, patient education, and early intervention, aligning with EBMT Handbook recommendations for infection prevention and supportive care in HSCT.

Methods: Narrative review of peer-reviewed literature (2015-2025) on microbiota, allo-HSCT outcomes, and nursing, per EBMT evidence standards. Structured via NANDA diagnoses, NIC interventions, and NOC outcomes. Key protocols: systematic nutrition assessments (EBMT nutritional guidelines), neutropenic/protective diet education, gastrointestinal monitoring (stool frequency/consistency/pain scales), infection control (hand hygiene, isolation), and adherence promotion across transplant phases.
The aim is primarily to describe gut microbiota profiles in adult allo-HSCT patients and their link to intestinal GVHD onset/severity, leveraging nursing outcomes (NOC) to gauge care efficacy. Secondarily, delineate nurses' roles in sample collection, monitoring, and education; propose recognized recommendations for microbiota-preserving strategies, emphasizing high-impact nursing interventions like diet optimization and adherence support.

Results: NOC outcomes track nutrition (stable weight/BMI, normal albumin), gut function (reduced stool frequency, firmer consistency, less pain), fluid balance (adequate diuresis, stable electrolytes), and tolerance (no nausea/vomiting/distension)—directly impacting GVHD prophylaxis. Additional metrics: infection rates <5%, >90% adherence, improved quality-of-life scores (gut symptoms/psychosocial distress). Early dysbiosis detection via nursing surveillance enables 20-30% faster interventions, per cohort studies. EBMT-supported strategies like pre/probiotic use, fecal microbiota transplantation (FMT), and high-fiber/low-residue diets restore diversity, slashing GVHD risk by up to 40% and boosting survival. Nurses enforce tolerance monitoring, reinforce prescriptions, and educate on risks/benefits, curbing pathogenic dominance linked to grade 3-4 GVHD.

Conclusions: Microbiota modulation elevates nursing to a high-impact frontier in EBMT programs, slashing GVHD incidence, accelerating recovery, and enhancing graft survival—potentially improving 1-year OS by 15-25%. Integrate standardized protocols: daily microbiota risk screens, personalized diets (e.g., Mediterranean-style pre-HSCT), FMT coordination post-engraftment, and multidisciplinary audits. EBMT should champion nurse-led trials on these interventions for scalable, cost-effective GVHD mitigation, transforming transplant care. Further research is needed to define standardized nursing interventions aimed at microbiota preservation in transplant settings.

Disclosure: "Niente da dichiarare"

KNOWLEDGE AND SKILLS OF NURSES IN RECOGNIZING EARLY SIGNS OF VENO-OCCLUSIVE DISEASE (VOD) AMONG HSCT PATIENTS: A CROSS-SECTIONAL STUDY AT ACTREC

Suman Kubal[1]
[1]*ACTREC,TMC, Navi Mumbai, India*

Background: Hepatic Veno-Occlusive Disease (VOD), also known as Sinusoidal Obstruction Syndrome, is a potentially life-threatening early complication following hematopoietic stem cell transplantation (HSCT). Early recognition is essential to prevent rapid progression to severe VOD, which carries high morbidity and mortality. Nurses play a critical role in detecting early indicators such as sudden weight gain, hepatomegaly, rising bilirubin, fluid retention, and abdominal girth changes. Limited Indian data exist regarding nurses' preparedness in identifying early VOD signs in HSCT settings.

Methods: A descriptive cross-sectional study was conducted among **60 nurses** working in HSCT/BMT units at ACTREC. A validated 29-item questionnaire assessed demographics, VOD knowledge, skills, case-scenario interpretation, and training needs. Knowledge items (Q7–12) and scenario items (Q22–25) were scored, generating:

- Knowledge score (0–6)
- Scenario score (0–4)
- Total competency score (0–10) categorized as:
  Adequate (8–10), *Average* (5–7), *Inadequate* (0–4).

Descriptive and inferential statistics (chi-square, t-test, ANOVA) were applied; significance set at **$p < 0.05$**.

Results: A total of 60 nurses participated. Most were **female (71.7%)**, aged 31–35 years (31.7%) and >35 years (28.3%). The majority held **BSc Nursing qualifications (70%)**, and more than half had ≥1 year HSCT experience. Only **19 nurses (31.7%)** reported prior VOD-related training.
Knowledge performance was moderate, with a mean score of **4.63 ± 1.50** (range: 0–6). Knowledge gaps were notable in diagnostic criteria understanding, although early signs such as unexplained weight gain and bilirubin elevation were recognized by most.
Scenario-based interpretation skills were comparatively strong, with a mean score of **3.50 ± 1.03** (range: 0–4). Nurses demonstrated high accuracy in identifying early red-flag patterns such as rapid weight gain, increases in abdominal girth/ascites, and bilirubin-associated abdominal pain.
The overall **total competency score** was **8.13 ± 2.32**. Categorization demonstrated:

- **Adequate:** 46 nurses (76.7%)
- **Average:** 8 nurses (13.3%)
- **Inadequate:** 6 nurses (10%)

Inferential analysis found no significant association between prior training and competency level ($\chi^2 = 3.54$, $p = 0.17$). Although trained nurses had higher mean scores (8.79 vs 7.85), the difference was not statistically significant ($t = 1.89$, $p = 0.063$). Educational qualification also showed no significant association with knowledge scores (ANOVA $F = 0.30$, $p = 0.82$). Overall, findings highlight a workforce with **strong clinical judgment** but **uneven foundational VOD knowledge**, particularly among nurses without formal training.

Conclusions: HSCT nurses at ACTREC demonstrated strong ability to recognize early VOD indicators in clinical scenarios, but theoretical understanding remains variable. Strengthening structured education, simulation-based learning, and VOD-specific competency training may

bridge existing knowledge gaps and further enhance early detection. Improved nurse preparedness has the potential to optimize patient monitoring, reduce delays in escalation, and improve outcomes in HSCT patients at risk for VOD.

Clinical Trial Registry: Not applicable.
This observational questionnaire-based study did not require clinical trial registration. The study received approval from the Institutional Ethics Committee of ACTREC, Tata Memorial Centre, Kharghar, India.

NP78

A STUDY TO ASSESS NURSES' KNOWLEDGE ON CYTOKINE RELEASE SYNDROME IN HAPLOIDENTICAL HSCT: A CROSS-SECTIONAL STUDY AT TERITARY CARE CENTRE, INDIA

Ramineni Anjaneyulu[1]
[1]*Tata Memorial Centre (ACTREC), Navi Mumbai, India*

Background: Cytokine release syndrome (CRS) is a potentially life-threatening toxicity after haploidentical hematopoietic stem cell transplantation (HSCT). Bedside nurses play a critical role in early recognition and escalation of care. Evidence on CRS-related nursing knowledge in transplant settings, especially in India, is limited.

Methods: A descriptive cross-sectional study was conducted among registered nurses working in the bone marrow transplant (BMT) services at Tertiary care Centre, India. A validated 40-item multiple-choice questionnaire assessed knowledge of CRS definition, symptoms, grading, monitoring, laboratory investigations, and management. Each correct response scored 1 point (maximum 40). Knowledge levels were categorized as good (≥30), moderate (20–29), and poor (<20). Descriptive statistical methods were used.

Results: Forty-seven nurses completed the survey. The majority were female (74.5%), aged 31–35 years (34%), and held BSc Nursing qualifications (70.2%). Nearly half (48.9%) had more than five years of clinical experience, and 87.2% reported previous HSCT exposure. The mean knowledge score was **36.2 ± 3.4** (range 20–40). Most participants demonstrated **good knowledge** of CRS (46/47; 97.9%), while 1 (2.1%) had moderate knowledge and none had poor knowledge. Knowledge gaps were identified in accurately recognizing **non-primary CRS treatments** (44.7% correct) and understanding the **time of CRS onset** (51.1% correct). Because almost all participants scored within the "good" category, analysis of associations with demographic variables was not statistically meaningful.

Conclusions: Nurses working in the BMT units of this tertiary cancer Centre demonstrated strong overall knowledge of Cytokine Release Syndrome (CRS), reflecting good preparedness

for early recognition and prompt escalation in haploidentical HSCT care. Although most participants achieved high scores, specific knowledge gaps were observed in recognising the timing of CRS onset and differentiating non-primary treatment options. Addressing these gaps through focused educational sessions and structured CRS competency modules may further enhance nursing readiness, ensure timely interventions, and strengthen patient safety within transplant services.

Clinical Trial Registry: NO

Disclosure: The author declares no conflicts of interest and has received no financial support, sponsorship, or institutional funding for this study. The work was conducted independently as part of nursing research and quality improvement at ACTREC. Nothing to declare.

NP81

NURSING ASPECTS AND OUTCOMES OF PATIENTS WITH MYELODYSPLASTIC SYNDROMES UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A FIVE-YEAR RETROSPECTIVE STUDY (2020-2024)

Lucija Kralj[1]
[1]*University Hospital Centre Zagreb, Zagrbe, Croatia*

Background: Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal hematopoietic disorders characterized by ineffective hematopoiesis, peripheral cytopenias, and a variable risk of progression to acute myeloid leukemia. Allogeneic hematopoietic stem cell transplantation (HSCT) remains the only curative treatment option for eligible patients. The role of nurses is crucial throughout the transplant process, particularly in patient preparation, complication management, and post-transplant care. This study presents a retrospective overview of MDS patients who underwent HSCT over a five-year period at the University Hospital Centre Zagreb, Department of Hematology.

Methods: This retrospective study included all patients diagnosed with MDS who underwent allogeneic HSCT between 2018 and 2023 at the University Hospital Centre Zagreb. Data were collected from the hospital information system (BIS), physicians' records, and nursing documentation (nursing decursus). The analyzed variables included demographic data (age, sex), disease characteristics, type of donor, conditioning regimen, complications, and patient outcomes. The data were analyzed descriptively and presented in numerical and percentage form.

Results: During the five-year study period, a total of 52 patients with MDS underwent allogeneic HSCT. The median age at transplantation was 59.3 years (48,1% male, 51,9% female). Most transplants were performed using unrelated donors 71%, with reduced intensity conditioning regiments (46%).The average length of hospital stay was 39.8 days, while the mean time to neutrophil recovery was 17.6 days. .The most common early post-

transplant complications included ferbrile neutropenia (94,2%) mucositis (63.5%). During hospitalization, participants most frequently reported hypertension (57.7%), diarrhea (57.7%), headache (53.8%), and skin rash and redness (50%). Nursing documentation emphasized key nursing interventions related to infection prevention, nutritional support, pain control, and psychological support. A total of 86.5% of patients developed sepsis. Overall, 42.3% of patients had or currently have GVHD. Among the affected organ systems, cutaneous GVHD was the most common (29.7%), followed by gastrointestinal involvement (27%), hepatic GVHD (16.2%), ocular and oral involvement (10.8%), and pulmonary GVHD (5.8%). A survival rate analysis showed that 48.1% of patients were alive, while 51.9% had died. The cause of death was relapse or transformation into leukemia in 52.4% of cases, whereas sepsis accounted for 28.6% of deaths.

Conclusions:

Patients with myelodysplastic syndromes undergoing allogeneic hematopoietic stem cell transplantation face significant clinical challenges, including high rates of sepsis, graft-versus-host disease, and transplant-related complications. Nursing care plays a critical role in monitoring, early detection, and management of these complications to improve patient outcomes. Our five-year retrospective analysis highlights the importance of comprehensive nursing interventions in supporting survival, reducing morbidity, and enhancing quality of care in this high-risk population.

IMPROVING CHRONIC GVHD CARE: DEVELOPMENT OF A CHRONIC GVHD-MODULE WITHIN AN EHEALTH FACILITATED INTEGRATED CARE MODEL: *SMILE*

Tabea Sommer[1,2], *Julia Moreno*[1], *Anja Schmid*[1], *Sabine Valenta*[2,3], *Sabina De Geest*[3,4], *Miriam Mozaffari Jovein*[1], *Kristina Maas-Bauer*[1], *Daiana Stolz*[1], *Alexandra Teynor*[5], *Claudia Wehr*[1], *Robert Zeiser*[1], *Lynn Leppla*[1,3]
[1]*Medical Center – University of Freiburg, Freiburg, Germany,* [2]*Medical Center – University of Tübingen, Tübingen, Germany,* [3]*University of Basel, Basel, Switzerland,* [4]*Katholieke Universiteit Leuven, Leuven, Belgium,* [5]*Technical University of Applied Sciences Augsburg, Augsburg, Germany*

Background: Re-engineering follow-up care after allogeneic stem cell transplantation (alloSCT) is essential given the increasing numbers of long-term survivors with complex needs related to complications such as chronic Graft-versus-Host Disease (cGvHD). cGVHD affects up to 50-70% of alloSCT recipients and significantly reduces quality of life and physical functioning while imposing severe psychological, emotional, and socio-economic burdens. Early detection and timely treatment are crucial to prevent severe and irreversible organ damage, especially in lung-cGvHD, where treatment options are limited. However, current health care structures insufficiently address the complex, long-term needs of cGvHD-patients.
An *Integrated Care Model (ICM) for allogeneic SteM cell transplantatIon faciLitated by eHealth* (SMILe-ICM) has been developed, evaluated and established as a routine follow-up post-alloSCT at the University Hospital Freiburg (Germany). The SMILe-ICM comprises two main components: (1) An advanced practice nurse (APN) team to support patient self-management and to enable early detection of acute health deteriorations by structured nursing interventions, (2) the SMILeApp connecting patients with the APN team by remotely monitoring medical, symptom, and behavioral parameters during the first post-transplant year. To address the specific and long-term needs of cGvHD-patients, we aimed to extend the SMILe-ICM based on patients' needs, provider insights and existing evidence.

Methods: Following the SMILe-ICM development methodology, we performed a contextual analysis steering the development process, running from 9/2024-10/2025. We applied the following steps:
1. Conducting 7 semi-structured interviews with cGvHD-patients and one focus group with clinicians (n=8), analyzed by deductive-inductive qualitative content analysis based on the Chronic-Care-Model;
2. Performing an unsystematic literature review;
3. Developing intervention content, timing, dosing and frequency using the Behavior Change Wheel (BCW);
4. Applying iterative user-tests (n=5 patients) of the eHealth components;
5. Starting a feasibility study with 15 patients.

Results: Interviews and literature revealed that cGvHD affects all aspects of patients' lives and presents substantial physical, psychological, and emotional challenges. Patients require self-management support addressing cGvHD prevention, symptom recognition, cGvHD management and resources enhancing their coping strategies. Clinicians highlighted the potential of remote monitoring of cGvHD-specific symptoms for early detection and monitoring to improve therapeutic and supportive measures. Both patients and healthcare professionals emphasized the importance of a multidisciplinary team including cGvHD-specialists and consistent, trusted care providers as first points of contact and identified APNs as suitable primary contacts and care-coordinators.
Consequently, we developed a cGvHD-specific SMILe-module comprising:
1. At least five APN-led, face-to-face interventions ensuring continuity of care and promoting prevention, early detection and self-management after alloSCT by using up to 28 BCW behaviour-change-techniques.;
2. cGvHD-specific symptom detection and monitoring via the cGvHD-module, including an adaption of the Lee Symptom Scale and home spirometry (3x/week) for early detection of lung-cGvHD;

3.Implementation of a well-connected multidisciplinary care team including cGvHD-experts and APNs as first points of contact.

Conclusions: cGvHD-patients often face unmet and specific care needs. The cGvHD-SMILe-module aims to address these needs, strengthen patient self-management, improve patient care quality and enhance treatment monitoring. The ongoing feasibility testing will evaluate the module's acceptance, appropriateness, and patient adherence, providing insights for refinement and scalable integration into routine patient care.

THE POTENTIAL OF AI CHATBOTS AS CLINICAL DECISION-SUPPORT TOOLS IN NURSING: AN EVALUATION OF SYMPTOM MANAGEMENT RECOMMENDATIONS DURING ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

Aysenur Cetin Uceriz[1], *Busra Kocas*[2], *Zeynep Sude Yigit*[2], *Merve Karabıyık*[2], *Cagla Yuksel*[2]
[1]*Koç University, Istanbul, Turkey,* [2]*Haliç University, Istanbul, Turkey*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a complex and high-risk procedure frequently associated with severe complications such as acute graft-versus-host disease (aGVHD), infections, and multi-organ toxicities. Effective symptom management and accurate nursing decision-making are essential to improving patient outcomes during this demanding treatment process. In recent years, large language models (LLMs) have emerged as potential tools to support clinical reasoning, interpret patient data, and assist in the development of nursing care plans. However, their reliability, guideline adherence, and clinical applicability within allo-HSCT settings remain insufficiently explored, highlighting the need for further investigation in this area.

Methods: This study aimed to evaluate the effectiveness of three large language models (ChatGPT-4o, DeepSeek-V3, Gemini 2.5 Flash) in generating nursing care recommendations for symptom management during the allogeneic hematopoietic stem cell transplantation (allo-HSCT) process using a hypothetical case study.To this end, five researchers with expertise in hematology and nursing evaluated the models' performance based on the European Society for Blood and Marrow Transplantation (EBMT) guidelines, focusing on the accuracy and relevance of nursing care recommendations, appropriateness of symptom management strategies, clarity and organization of responses, use of professional terminology, and overall effectiveness.

Results: The results indicated that while all language models were able to generate relevant nursing care recommendations for major symptoms during the allo-HSCT process, their overall performance varied across evaluation criteria. In the present study, the three major language models were examined. While these models were able to accurately diagnose aGVHD in the study's cases, it is noteworthy that they employed different sets of criteria for diagnosis. ChatGPT and Gemini EBMT satisfied only two of the three criteria, while DeepSeek satisfied one. This further highlights the discrepancy between the models in terms of guidance. In terms of overall performance, ChatGPT has been found to demonstrate a more reliable approach to clinical decision-making through its use of evidence-based methods. However, it has been observed that the system has been prone to certain inaccuracies in certain data details. In comparison, DeepSeek has been found to produce more comprehensive and detailed nursing care plans, while Gemini has been identified as the most effective system in terms of risk analysis. However, Gemini has been found to demonstrate the least success in accurately identifying nursing diagnoses.

Conclusions: The findings indicate that the AI model has considerable potential in the domains of allo-HSCT process diagnosis, symptom management and nursing decision support. However, further advanced model development is necessary for critical aspects such as compatibility, data accuracy, standardisation of nursing diagnoses and generation of evidence-based recommendations. Further research is warranted to advance model optimization through the integration of domain-specific datasets, adherence to clinical guidelines, and expert-informed algorithmic refinement. The reliability, safety, and translational applicability of these technologies in evidence-based nursing practice must be established through controlled evaluations within real-world clinical environments.

NURSES' AWARENESS AND READINESS TOWARD FUTURE USE OF ARTIFICIAL INTELLIGENCE (AI) TOOLS IN PREDICTING GVHD AND INFECTION IN HSCT PATIENTS: A CROSS-SECTIONAL STUDY AT ACTREC

Amish Kale[1], *Suman Kubal*[1], *Bharti Veer*[1]
[1]*ACTREC,TMC, Navi Mumbai, India*

Background: Artificial intelligence (AI)-enabled prediction tools for graft-versus-host disease (GVHD) and infections are increasingly explored in hematopoietic stem cell transplantation (HSCT). As frontline caregivers, nurses play a pivotal role in early recognition, monitoring, and integration of emerging digital technologies. Their awareness and readiness to adopt AI tools will be critical for future implementation in HSCT settings. However, evidence describing AI preparedness among HSCT nurses in India remains scarce.

Methods: A descriptive cross-sectional survey was conducted among **91 consenting nurses** in HSCT/BMT units at ACTREC using a structured, validated questionnaire incorporating Technology Acceptance Model (TAM) and Unified Theory of Acceptance and Use of Technology (UTAUT) constructs (Likert scale 1–5). Descriptive statistics summarized demographic and domain data. Associations were examined using chi-square, t-tests, and one-way ANOVA. A multivariable linear regression model identified predictors of readiness. Significance was set at $p < 0.05$.

Results: A total of 91 nurses participated. More than half (59.3%) had heard of AI in healthcare, while only 9.9% reported receiving formal AI training. Mean readiness to use AI tools was high (4.03 ± 0.57). Perceived usefulness (4.05 ± 0.49) and performance expectancy (4.09 ± 0.55) were the highest scoring domains, whereas trust/anxiety was moderate (3.10 ± 0.77). Internal consistency across domains was acceptable to excellent (Cronbach's α = 0.69–0.88).

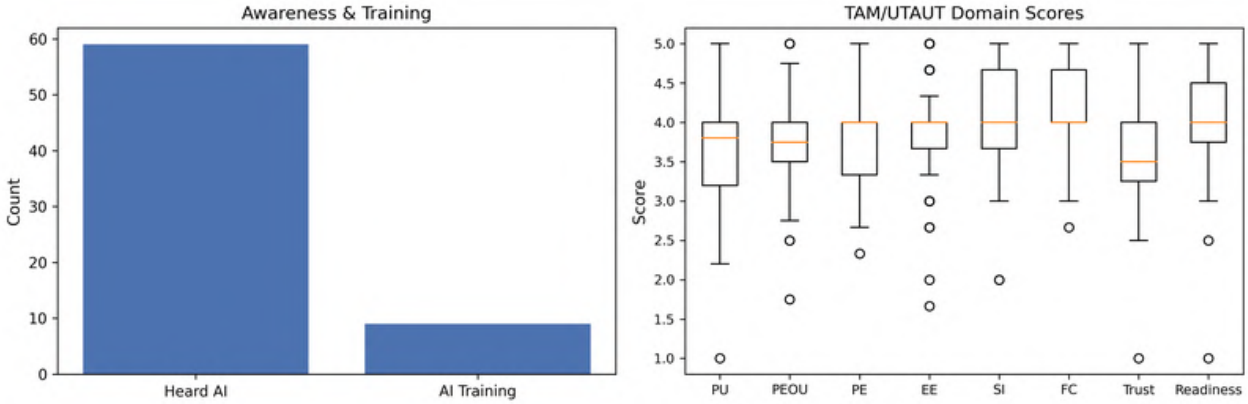

Figure 1 summarizes AI awareness, training status, and the distribution of TAM/UTAUT domain scores.

Awareness of AI was associated with higher readiness ($\chi^2 = 3.84$, $p = 0.050$). Nurses with prior AI training demonstrated higher readiness, although this was not statistically significant ($p = 0.096$). Readiness did not differ significantly by qualification ($p = 0.566$).

In multivariable regression ($R^2 = 0.164$), **having heard about AI was the only independent predictor** of readiness ($\beta = 0.31$, $p = 0.034$). Trust demonstrated a positive, non-significant trend ($p = 0.092$). Age, total nursing experience, BMT experience, and AI training were not significant predictors.

Conclusions: Nurses demonstrated high readiness to use AI tools despite limited formal exposure. AI awareness emerged as the strongest independent determinant of readiness, underscoring the importance of early digital literacy and foundational AI education. These findings highlight the need for structured AI training programs and capacity-building

initiatives within HSCT nursing to support safe, effective integration of predictive technologies in future clinical practice.

Clinical Trial Registry: Not applicable.
This study is an observational, non-interventional survey and does not require clinical trial registration.
The study received approval from the **Institutional Ethics Committee** of ACTREC, Tata Memorial Centre, Kharghar, India.

DIGITAL HEALTH STRATEGIES FOR PATIENT EDUCATION IN HAEMATOPOIETIC STEM CELL TRANSPLANTATION: A SCOPING REVIEW

Ozgun Gokmen Kaya[1], *Remziye Semerci Şahin*[2]
[1]*Koç University, Graduate School of Health Sciences, Istanbul, Turkey,* [2]*Koç University, School of Nursing, Istanbul, Turkey*

Background: Haematopoietic Stem Cell Transplantation (HSCT) is a life-saving but highly intensive treatment associated with a heavy symptom burden, complex self-care requirements, and significant psychosocial distress. Effective patient education is paramount for promoting adherence, early symptom recognition, and improved quality of life (QoL).Where traditional education methods often fall short, technology-based Interventions (TTMs)—such as mobile applications, e-learning platforms, and virtual reality—are rapidly emerging as critical tools to deliver education, monitor symptoms, and offer psychosocial support remotely. A synthesis of the current evidence is needed to guide the development and implementation of high-quality digital health strategies within HSCT nursing practice.

Methods: This comprehensive scoping review was carried out in line with the PRISMA-ScR guidelines. A broad and systematic search was conducted across six major databases (PubMed, Cochrane Library, Scopus, Web of Science, CINAHL, and Medline) using a combination of keywords related to: "stem cell transplantation," "patient education," "digital health," "mobile application," "e-learning," and "telehealth." Two independent reviewers screened the titles, abstracts, and full texts of the retrieved articles. Eighteen studies met the inclusion criteria, focusing on TTMs designed for HSCT patient education across the pre-transplant, peri-transplant, and post-transplant phases. Information regarding the study design (e.g., RCT, Qualitative), intervention type, specific technology functionalities, target outcomes (clinical and patient-reported), and evidence level was collected using a standardized extraction tool and analyzed thematically.

Results: The analysis of the 18 studies revealed a high concentration of research originating from North America and Europe, with study designs increasingly including high-quality randomized controlled trials. The most prevalent TTMs identified were Mobile Applications and Web-based Patient Portals. These technologies were leveraged primarily to support three core nursing roles: information delivery and adherence, remote symptom monitoring and management, and psychosocial support. The first theme includes providing accessible, tailored, and interactive educational content on infection control, medication schedules, and self-care tips. The second primarily focuses on enabling patients to digitally track symptoms (e.g., fatigue, mucositis, graft-versus-host diseas signs) and receive instant, algorithm-driven feedback or alerts for nurse review. The last one is about incorporating virtual reality for distraction during procedures, providing guided mindfulness exercises, and facilitating peer support access. As a result, TTMs consistently demonstrated effectiveness in improving outcomes. The findings highlighted significant increases in patient knowledge and self-efficacy, alongside reductions in anxiety, depression, and symptom distress. While the evidence for direct clinical outcomes, like readmissions, is still developing, the strong impact on preparatory, psychological, and self-management capabilities underscores their value.

Conclusions:

Technology-based interventions represent a powerful paradigm shift in HSCT patient education, moving care towards personalized, continuous, and accessible models. Nurses are uniquely positioned to lead the integration of these tools to optimize patient self-management, symptom burden, and ensure continuity of care. Nursing practice must evolve to incorporate the use of digital data for timely intervention, focus on training patients in digital literacy, and advocate for the development of TTMs specifically targeting critical post-transplant issues like chronic-GVHD management and long-term survivorship. The review strongly supports the continued adoption and rigorous evaluation of digital solutions to elevate the quality of care for patients.

SAFETY PROFILES OF TWO ANTI-THYMOCYTE GLOBULIN FORMULATIONS IN PEDIATRIC HEMATOPOIETIC CELL TRANSPLANTATION: IMPLICATIONS FOR NURSING CARE

Beatriz Del Amo Mateos[1], Isabel Salcedo De Diego[2], Lucía Becerro Méndez[1], Sofía Estébanez Barrena[1], Aida Nieto Moyano[1], Claudia Pina Pino[1], María Jose Mesa Ibar[3], Juana Membrado Gil[3], María Sol Albert Velert[4], Eugenia Trigoso Arjona[4], Laia Seguer Cabré[5], ***Julia Ruiz Pato***[1]
[1]Niño Jesus Children's Hospital, Madrid, Spain, [2]IIS Puerta de Hierro-Segovia Arana,*

Majadahonda, Spain, [3]Santa Creu i Sant Pau Hospital, Barcelona, Spain, [4]La Fe Hospital Universitario y Politécnico, Valencia, Spain, [5]Vall d´Hebron Hospital, Barcelona, Spain

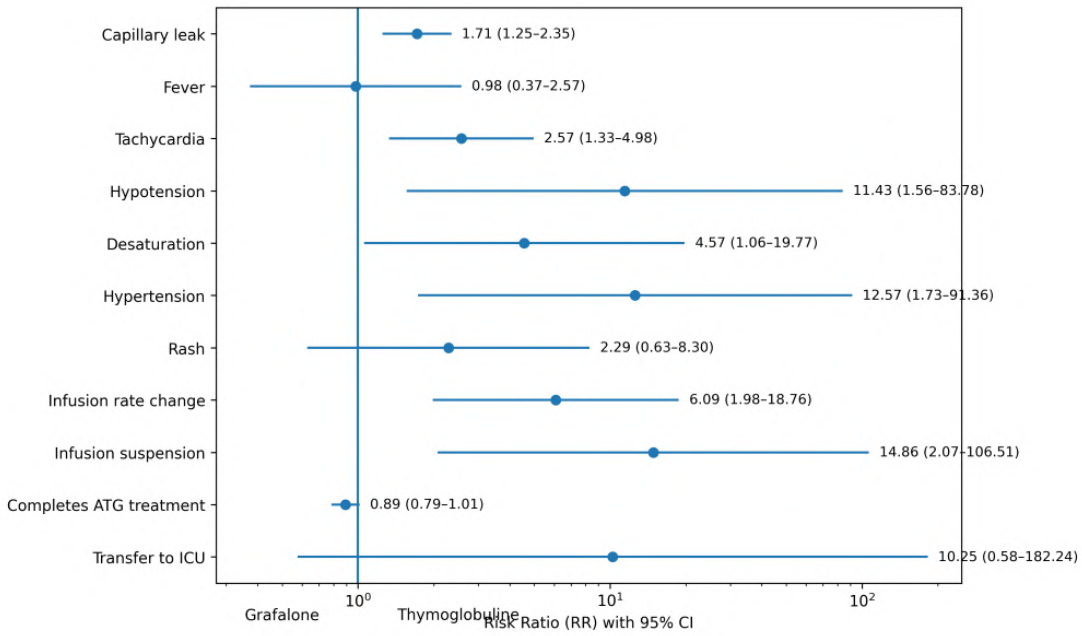
Background: **Introduction:** The use of immunosuppressive agents such as anti-thymocyte globulin (ATG) for hematopoietic cell transplantation (HCT) has become essential due to the increasing use of alternative donors. Currently, two main ATG formulations are used in clinical practice: Thymoglobulin® (rabbit-derived anti-human thymocyte immunoglobulin) and Grafalon® (anti-human T lymphocyte immunoglobulin). While some studies have compared their efficacy, evidence regarding threir safety profiles, particularly in the pediatric population, remains limited.
The occurrence of ATG-related AE has a direct impact on nursing workload, nurse-to-patient ratios, and the need for highly trained nursing staff capable of early detection and management of infusion-related events and potentially serious complications, such as capillary leak syndrome. Although the reported AE of both formulations are generally similar, clinical nursing observations have identified a reduction in immediate infusion-related AE following Grafalon over Thymoglobuline, which requires further investigation.
The aim of the study is to evaluate the incidence of AE associated with the administration of Grafalon® and Thymoglobulin® in pediatric patients undergoing HCT.

Methods: We conducted a multicenter, retrospective cohort study based on electronic health records. Inclusion criteria: pediatric patients (0–18 years) undergoing HCT between 2018 and July 2025 who received either Thymoglobuline® or Grafalon® as part of conditioning. Exclusion criteria: use of both drugs in the same regimen or ATG for GVHD treatment.
The units of analysis were HCT procedures. Baseline variables included sociodemographic and HCT-related characteristics. Outcomes included adverse events (capillary leak syndrome, fever, rash, hypotension, hypertension, tachycardia, desaturation), infusion modifications/suspension and ICU transfer, all within 72 hours of ATG initiation. Relative risks (RR) with 95% confidence intervals and Fisher's exact test were used for comparisons. The study was approved by the Research Ethics Committee.

Results: Preliminary data from a single centre are shown. More data will be available for the annual meeting.A total of 60 HCT procedures performed in 56 patients between February-2020 and July-2025 were analyzed (4 excluded for receiving ATG as treatment); 58.3% were male; the median age was 6 years (range 0–19). Among HCTs using ATG (n=60), 46.7% (n=28) used Thymoglobuline and 53.3% (n=32) Grafalon. Statistically significant differences were observed before ATG in stem cell source (81.2% peripheral blood in Grafalon vs 53.6% in Thymoglobuline; p=0.0354) and graft manipulation (62.5% in Grafalon vs 33.3% in Thymoglobuline; p=0.0384) (Table 1). HCTs performed with Thymoglobuline showed significantly higher risk of AE (hypotension, hypertension, tachycardia, desaturation), infusion rate changes/suspension, capillary leak syndrome (RR: 1.714; IC 1.253-2.346), and ICU transfer. None of Grafalon patients required ICU transfer within 72 hours, whereas 14.3% (n=4) of Thymoglobuline patients did (p=0,042) (Figure 1).

Table 1. Pre-transplant characteristics of study population according to ATG Type

	Baseline	Thymoglobuline (n=28)	Grafalon (n=32)	p-value
Age at HCT	Years: Median (IQR)	4.5 (8.5)	6.5 (9.5)	0.372
Sex	Male Female	18 (64.3%) 10 (35.7%)	17 (53.1%) 15 (46.9%)	0.278
Disease	Malignant Non malignant	8 (28.6%) 20 (71.4%)	11 (34.4%) 21 (65.6%)	0.5057
HCT source	Peripheral blood Bone marrow Umbilical cord blood	15 (53.6%) 7 (25%) 6 (21.4%)	26 (81.2%) 5 (15.6%) 1 (3.1%)	0.0354
Graft manipulation	Yes No	9 (33.3%) 18 (66.7%)	20 (62.5%) 12 (37.5%)	0.0384
Type of donor	Haploidentical Identical related Identical non related Non identical-non related	8 (32%) 5 (20%) 10 (40%) 2 (8%)	18 (58.1%) 7 (22.6%) 4 (12.9%) 2 (6.4%)	0.1027
Conditioning regimen	Myeloablative Non myeloablative	21 (75%) 7 (25%)	20 (62.5%) 12 (37.5%)	0.379
Functional status (Lansky)	100 90 80 70	19 (70.4%) 6 (22.2%) 2 (7.4%) 0	12 (37.5%) 15 (46.9%) 4 (12.5%) 1 (3.1%)	0.128
*HCT: Hematopoietic Cell Transplantation				



Conclusions: Grafalone demonstrated a more favorable safety profile during the first 72 hours of ATG infusion compared to Thymoglobuline. Its higher incidence of capillary leak and ICU transfer underscores the need for adequate nursing staffing and training to ensure patient safety. These findings should be interpreted with caution as they are based on preliminary data from a single center; results will be complemented by data from additional centers and multivariate analyses to control for confounding factors.

Clinical Trial Registry: N/A

LISTENING TO THE YOUNG: EMPOWERING CHILDREN AND ADOLESCENTS IN SHAPING HEALTHCARE PLANNING

Julia Ruiz Pato[1], *Beatriz del Amo Mateos*[1], *Montserrat Barrilero López*[1], *Ana Guerrero Pizarro*[1], *Miriam Isabel Mateos Terradillos*[1], *Gabriela Pina Pino*[1], *Claudia Pina Pino*[1], *Beatriz Segura Díaz*[1], *Azahara Gutierrez Gabriel*[1]
[1]*Niño Jesus Children´s Hospital, Madrid, Spain*

Background: Humanization strategies within the healthcare system aim to incorporate the patient's experience to enhance the quality of care. Traditionally, in pediatric and adolescent care, the voices of children have often been represented by adults: parents, guardians, or healthcare professionals. However, listening to the voices of children and adolescents in the

hospital setting is their right.
At the Niño Jesús University Children's Hospital, as part of its humanization program, strategies have been developed to capture the perspectives of children and adolescents (the patient's voice). This approach ensures that their views inform the design of care planning that is truly centered around their physical, psychological, and social needs.

Methods: We launched the first oncology and hematopoietic stem cell transplantation course, taught by patients themselves, for healthcare professionals.
The course covered key topics affecting pediatric oncohematology and transplanted patients. A total of 6 topics were delivered by 3 children and 3 adolescents: What is cancer and an hematopoietic stem cell transplant?; What is a porth-a-cath and how to take care of it?; What is chemotherapy and its side effects?; What is neutropenia and how to manage it?; Daily life in hospitalization and day hospital care; Long-term effects, focused on fertility. The final session, about how information is delivered to patients and families and decision-making, was held as a roundtable discussion.
Each session was co-prepared by the child or adolescent alongside a healthcare professional (nurse, physician, or healthcare assistant), blending scientific evidence with real-life experiences to offer actionable insights, concluding with suggestions for improvement.

Results: Children and adolescents who participated completed a satisfaction survey using a Likert scale (1 to 5, from very dissatisfied to very satisfied). 100% (6 participants) expressed being very satisfied with the experience. They were asked to write down the improvements that they had proposed during the course. The primary feedback, especially from adolescents, was focused on the need for clearer, more transparent information about their treatment process and having a private space for consultations with healthcare professionals. Other suggestions included making the porth-a-cath less visible by using different type of dressings and providing more detailed information about the side effects of certain medications, such as corticosteroids.

Conclusions: These strategies have allowed us to capture the perspectives of children and adolescents going through an onco-hematological disease journey. As a result, the hospital is implementing continuous improvements in care planning that is child and adolescent centered. Collaborative educational materials were developed, and a focus group is being established to further refine and implement the proposed improvements.

LEXI'S LEGACY - A LETTER TO HEALTHCARE PROFESSIONALS

Karen Nicholson[1,2], *Rachel Miller*[1]
[1]*Anthony Nolan, London, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Great North Children's Hospital, Newcastle upon Tyne, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Teenagers undergoing a haematopoietic stem cell transplant (HSCT) for an inborn error of immunity (IEI) have often undergone multiple hospital admissions, referrals to different specialities and multiple investigations and treatments prior to their referral to the specialist HSCT team. Their journey through HSCT can be a long and difficult road, with prolonged admissions, involvement of specialists' teams and complex medical language. While most teenagers are enjoying spending time with their peers, developing their independence, testing boundaries and learning who they are as a person. Those undergoing HSCT are often isolated for long periods, with only their parent or caregiver for company. This can be especially difficult for those with IEI, who may have already spend much of their childhood in hospital away from their peers.

Methods: Lexi was 12 years old when she was referred to her specialist HSCT centre and the decision was made to proceed with a HSCT for her IEI. She admitted to the HSCT unit just after her 13th Birthday. Lexi's transplant course wasn't smooth, and she endured a prolonged stay in hospital, requiring TPN and then ECP treatment for GVHD. Lexi met many different specialist teams and healthcare professionals having spent time long periods in both her local hospital and her transplant centre. Lexi experienced varied levels of care during her treatment, often feeling left out of conversations, unsure of what was being discussed and a lack of understanding by some professionals. With a desire to address these issues Lexi wrote a letter to healthcare professionals after her transplant in the hope of highlighting her observations and improving care for other young people.

Results: Lexi together with her family and Touch Design Ltd. developed Lexi's letter to HCP's, producing an animation of the original letter. Sadly, Lexi was unable to complete the project herself, so her sister Ella completed the narration of the animation, on her behalf. Lexi's wish was for the letter and animation to be used as a learning tool for HCP's to improve patient care for young people spending long periods in hospital. She hoped it would be shared on her behalf and her words used to improve patient care.
Lexi's Letter

Conclusions: Teenagers often report experiences of being 'treated like a child' not being included in decisions or involved in their care by health professionals and being misunderstood during hospital admissions, impacting on their wellbeing and development. This can be compounded during complex admissions for treatments such as HSCT, where they are faced with complicated procedures and conversations. Lexi wrote her letter and developed her animation with the hope of sharing her experiences of this with HCP's to help them understand how it feels for teenagers and young people. Lexi's wish was to improve the experiences in the future for other teenagers and young people. We hope by sharing Lexi's story, letter and animation we can help make Lexi's wish a reality and improve the patient experience for other teenagers and young people.

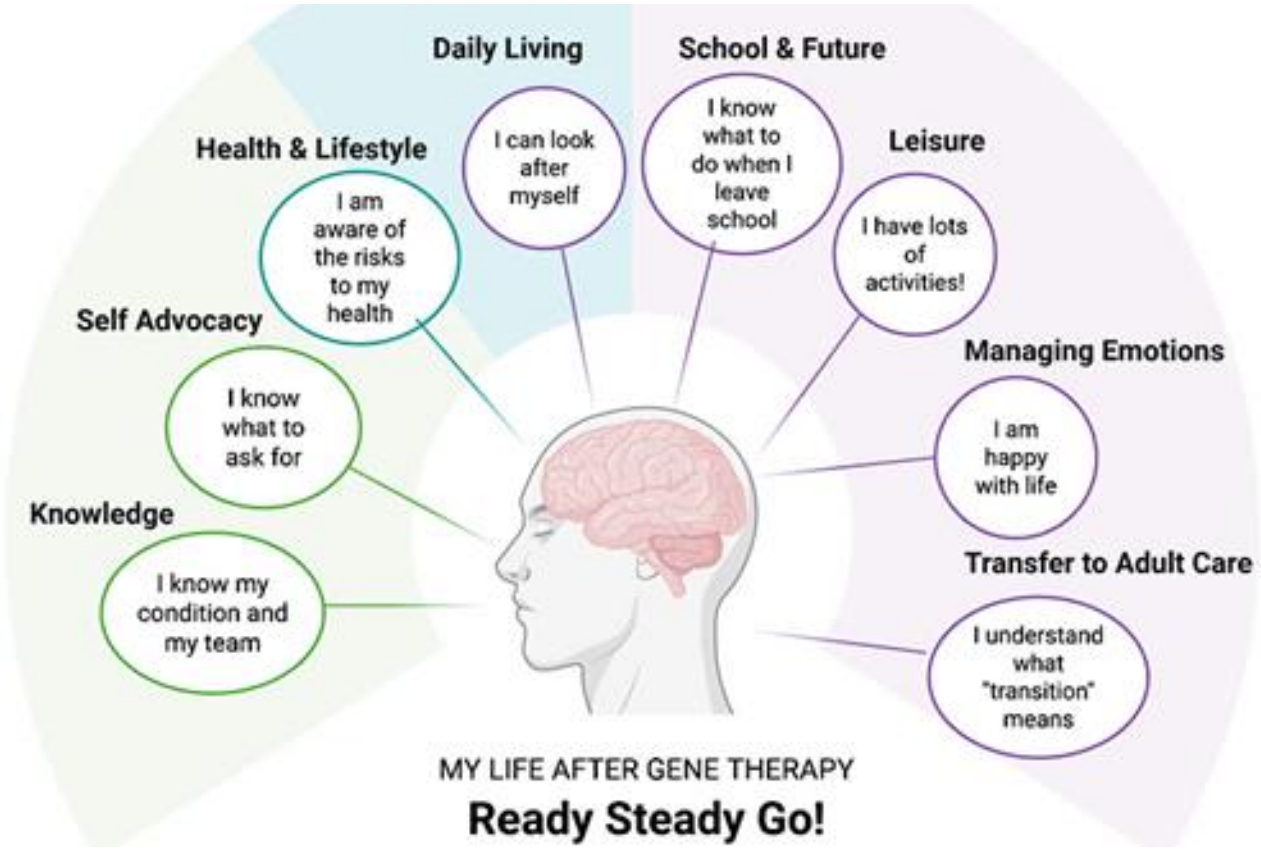
SERVICE EVALUATION OF 'READY STEADY GO' TRANSITION QUESTIONNAIRE IN POST-CD34⁺ EX-VIVO GENE THERAPY PAEDIATRIC PATIENTS

Rima Ahmed[1], *Gráinne O'Toole*[1], *Camilla Duran-Persson*[1], *Claire Booth*[1], *Konstantinos Vazouras*[1], *Jinhua Xu-Bayford*[1]
[1]*Great Ormond Street Hospital, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: CD34⁺ ex-vivo gene therapy has transformed outcomes for children with genetic primary immune deficiencies through using their own modified stem cells. The U.S. Food and Drug Administration recommend 15 years of follow-up, often extending into adulthood, making transition planning essential. These therapies are mainly delivered in paediatric centres, with few adult services having established gene therapy pathways. Transition readiness research in this population is limited and may not capture their unique long-term implications. The 'Ready, Steady Go' (RSG) questionnaire is a validated tool assessing healthcare independence, but gene therapy patients face extra challenges like complex regimens and psychosocial issues.

Methods: This cross-sectional evaluation included nine post-CD34⁺ gene therapy patients (aged 12–18) with chronic granulomatous disease, severe combined immunodeficiency, and adrenoleukodystrophy, attending routine follow-up. They completed the RSG questionnaire covering eight areas: Knowledge, Self, Health & Life, Daily Living, School, Leisure, Emotions, and Transition, answering "Yes," "No," or "Comment." Correlations between readiness, age, and time since therapy were analysed.



Results: Nine patients (aged 12–18), 1–12 years post-ex vivo CD34⁺ gene therapy, completed the RSG questionnaire. The overall readiness rate was 86.1%, with 33.3% "Ready," 55.6% "Mostly Ready," and 11.1% needing additional support. Readiness was highest in Daily living, School, and Leisure domains (100%), while Self-advocacy was lowest at 56%, indicating a key area for intervention. Older age correlated positively with readiness ($r = +0.583$), whereas longer time since gene therapy correlated negatively ($r = 0.552$), suggesting that readiness may decline over time without structured, ongoing support.

Conclusions: The Ready Steady Go questionnaire effectively assessed transition readiness in post-CD34⁺ gene therapy patients. Despite good overall readiness (86.1%), variation across domains highlighted the need for improved self-advocacy, age-appropriate transition planning, and sustained long-term follow-up. Embedding structured transition support may enhance continuity of care and long-term independence for this growing patient population.

NP34

PREVENTION AND MANAGEMENT OF ORAL MUCOSITIS IN PEDIATRIC ONCO-IMMUNO-HEMATOLOGICAL PATIENTS: A SCOPING REVIEW

Silvia Gnecchi[1,2], *Davide Bonomi*[1,2], *Alessia Bennici*[2], *Maria Ester Bernardo*[1,2], *Alessandro Aiuti*[1,2], *Anna Carmagnola*[1,2]
[1]*IRCCS San Raffaele Scientific Institute, Milan, Italy,* [2]*Vita-Salute San Raffaele University, Milan, Italy*

Background: Oral mucositis is one of the most common and debilitating complications in patients undergoing myeloablative chemotherapy, hematopoietic stem cell transplantation, and gene therapies, with a significant impact on quality of life and the therapeutic pathway. Despite the existence of consolidated guidelines for the management of mucositis in the adult population, evidence in the pediatric setting remains heterogeneous. Prevention and management of mucositis in pediatric onco-immuno-hematological patients therefore represent a clinical and care priority. The aim of this scoping review is to identify multidisciplinary therapeutic and preventive strategies for mucositis in pediatric onco-immuno-hematological patients.

Methods: A scoping review was conducted in accordance with the Joanna Briggs Institute Manual criteria. The following databases were searched: MEDLINE via PubMed, EBSCO Cumulative Index of Nursing and Allied Health Literature (CINAHL), and Elsevier Scopus. Inclusion criteria encompassed articles addressing the management and/or prevention of mucositis in pediatric oncologic and immuno-hematological patients, with particular attention to non-pharmacological interventions promoted by nurses and other healthcare professionals. Articles regarding combined pharmacological and non-pharmacological interventions managed by a multidisciplinary team were also included.

Results: A total of 46 articles were included in the review. Promising results emerged regarding photobiomodulation. Favorable evidence was also found for the use of honey, olive oil, and Aloe vera, owing to their anti-inflammatory and wound-healing properties. Education on oral hygiene promotes prevention and early recognition of signs and symptoms. Other emerging treatments, including glutamine and palifermin, have demonstrated efficacy in reducing the incidence of mucositis. Among treatments of questionable effectiveness in prevention, mouthwashes containing chlorhexidine at concentrations equal to or below 0.2% were identified; although widely used, they appear excessively irritating and not statistically significant in terms of outcomes for the management of pediatric mucositis.

Conclusions: In conclusion, for the prevention and management of pediatric mucositis in the onco-immuno-hematological setting, there is a need to combine pharmacological and non-pharmacological treatments within a multidisciplinary care approach. Prevention consists of promoting oral hygiene educational interventions for young patients and caregivers through demonstrations and simulations. Education should be accompanied by targeted clinical oral examinations and the use of tailored products selected by dental hygienists, nurses, and physicians. Several authors suggest the introduction of natural substitutes, such as honey, olive oil, and Aloe vera, combined with photobiomodulation in the management of pediatric oral mucositis, which may be proposed as alternatives to chlorhexidine, whose

effectiveness remains uncertain. In daily practice, a multidisciplinary approach is recommended, with early involvement of the dental hygienist and primary nurse for the prevention and early identification of the first signs of mucositis. Recommended non-pharmacological and pharmacological interventions include daily observation of oral cavity assessment forms, oral hygiene education, and the routine introduction of products based on alcohol-free formulations combined with photobiomodulation. Interventions should be adapted to the characteristics of the individual patient.

Disclosure: Nothing to declare

NP37

PERCEIVED BARRIERS AND FACILITATORS OF FAMILY-CENTERED ROUNDS IN PEDIATRIC HEMATOPOIETIC STEM CELL TRANSPLANTATION, A HEALTH CARE PROFESSIONALS SURVEY

Madelief Sterre Hübner[1], *Romy Esmee van Eck*[1], *Dagmar Berghuis*[1], *Mariska Möhlmann*[1], *Hilda Mekelenkamp*[1]
[1]*Willem-Alexander Children's Hospital, Department of Pediatrics, Leiden University Medical Center, Leiden, Netherlands (the)*

Background: Family-centered care is an important core principle in pediatric care. Family-centered rounds are an important approach to engage patients and their family caregivers in daily care and treatment decision-making. Research shows that family-centered rounds lead to improved care, reduced stress and pain in children, and increased satisfaction among both family caregivers and children. Besides, it can also save time for healthcare professionals, improve communication, satisfaction, understanding and relationship. Our aim is to investigate which barriers and facilitators healthcare professionals perceive and what is needed for successful implementation of family-centered rounds in the pediatric HSCT and CT unit.

Methods: A survey based on a literature search, consisting of 13 questions, including eight closed-ended multiple-choice and five open-ended questions. Closed questions were analyzed using descriptive statistics, and open responses were categorized. The online survey was distributed by email to the medical team in October 2025.

Results: A total of 30 healthcare professionals completed the survey. Of these, 50% were specialized pediatric nurses, 23% medical residents, 10% pediatric immunologists/hematologists, 3% team lead, and 13% nursing trainees. The current rounds received an average satisfaction score of 7 (0=not satisfied and 10=totally satisfied), with a range of five to nine.
The most frequently reported facilitating factor for family-centered rounds was that family caregivers and children are better informed about current care (22/30), and receive care more aligned with their needs, which increases the satisfaction score (22/30). For additional facilitating factors see Table 1.
The most frequently mentioned barrier was the presence of language barriers and/or cultural

differences (23/30), and that nurses and physicians may feel less free to speak openly (23/30). Frequently repeated open responses included concerns that family-centered rounds may take more time and that family caregivers might misinterpret physicians' explanations. Respondents also mentioned that having rounds inside the patient's room could involve too many people to maintain isolation guidelines. For additional barriers see Table 1.
Respondents were also asked how often they would prefer family-centered rounds to take place; most preferred once per week (53%), followed by 3 times a week (23%), and on a daily basis (21%). They also indicated a preference for as few staff members as possible in the room to avoid overwhelming the child and family caregivers.
The majority of the respondents indicated that information about family-centered rounds should be provided by the nurse (21/30). The nurse would introduce the topic and provide information to family caregivers and children. Many respondents also indicated it would be a good idea to create an informational leaflet about family-centered rounds, which could be distributed during the admission interview. (20/30). And 7/13 of the respondents answered 'other'.

Conclusions: Most healthcare professionals in our survey believe that family-centered care is highly important during stem cell transplantation. Our findings support the literature that family-centered rounds can improve recovery and satisfaction among both family caregivers and children. Based on the barriers and facilitators, we currently are working with a multi-disciplinary team on a strategy to implement and evaluate family-centered rounds within our unit.

Perceived barriers	Total
1. The presence of language barriers and/or cultural differences	23 (77%)
2. Nurses and physicians may feel less free to speak openly	23 (77%)
3. There is less time for education of residents	6 (20%)
4. Other	21 (70%)
Perceived facilitators	
1. Family caregivers participation in ward rounds ensures that they are more thoroughly informed about prescribed medications and discharge-related matters	22 (73%)
2. Clarity for family caregivers when to ask their questions and to whom	12 (40%)
3. Child and family caregivers participation leads to care that better meets the needs of both the child and the parent, resulting in higher satisfaction with the care for both parties.	22 (73%)
4. Children understand why they need to take a certain medication or why they are not yet allowed to get out of bed. As a result, children and family	5 (17%)

caregivers adhere more closely to the treatment recommendations, because they support them themselves. All of this has a positive effect on recovery	
5. It leads to less pain and distress (negative emotions such as fear, sadness, and panic) in children	1 (3%)
6. It saves time for nurses and physicians. By conducting an immediate clinical assessment of the patient, a comprehensive overview is obtained, enabling the formulation of an appropriate treatment strategy	18 (60%)
7. Other	3 (10%)
Disciplines needed	
1. Pediatric Nurse	29 (97%)
2. Medical resident	25 (83%)
3. Pediatric immunologist/hematologist	28 (93%)
4. Physiscian assistant	14 (47%)
5. Other	5 (17%)
Tabel 1: Outcome online survey

ROLE OF TANZANIAN NURSES IN OPENING A PEDIATRIC BONE MARROW TRANSPLANT UNIT AND NURSING CARE IN SICKLE CELL PATIENTS AT BENJAMIN MKAPA HOSPITAL IN DODOMA

*Alen Patrick Magoha[1], Gerald Xavier Mwombeki[1], Emily Morton Mwakilele[1], Sawia Arab Salum[1], Stella Wmalangahe[1], Shakilu Jumanne[1], Peter Mushi[1], **Silvia Gnecchi**[2,3], Anna Carmagnola[2,3], Marta Gavezzotti[2], Chantal Moser[2], Giulia Colombo[2], Valeria Tarizzo[4], Musa Dubali[5], Pietro Pioltelli[4], Fabio Giglio[2], Antonella Capasso[2], Cornelio Uderzo[6]*
[1]Benjamin Mkapa Hospital, Dodoma, Tanzania, United Republic of, [2]IRCCS San Raffaele Scientific Institute, Milan, Italy, [3]Vita-Salute San Raffaele University, Milan, Italy,

[4]Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy, [5]Tor Vergata Hospital, Rome, Italy, [6]HELP3 ODV, Monza, Italy

Background: Sickle cell disease (SCD) is a hereditary blood disorder that causes severe anemia, pain, and organ damage. In Tanzania, an estimated 11,000 children are born with SCD annually, with 15–20% of the population carrying the sickle cell trait. Newborn screening shows 0.8–1.2% of infants are affected by SCD. The disease accounts for 7% of childhood deaths under five years old. Pediatric Bone Marrow Transplantation (BMT) is a life-saving therapy for children with malignant and non-malignant hematological disorders. However, delivering safe and effective pediatric BMT care in low- and middle-income countries (LMICs) is challenged by limited infrastructure, shortage of trained personnel, constrained finances, and high patients' burden. Nurses play a central role in bridging these gaps, as they are continuously involved in direct patient care, family education, infection prevention, and psychosocial support. This abstract describes the nursing experience in establishing a pediatric BMT program within a limited-resource setting, highlighting challenges, adaptive strategies, and lessons learned with the support of an Italian no-profit association HELP3-ODV.

Methods: This narrative experience is based on nursing practice in a newly established pediatric BMT unit in a resource-constrained hospital: Benjamin Mkapa Hospital in Dodoma, Tanzania. The project was promoted in different phases starting in 2018 with the first Italian mission. The first step consisted in setting and resources assessment to manage BMT in pediatric sickle cell patients. The main nursing competences were identified and promoted through the support of voluntary HELP3-ODV nurses through in presence teaching, simulation and remote training. Observations were gathered from daily clinical practice, multidisciplinary meetings, and interactions with patients and caregivers. Evaluations of nurses' competences and educational needs are collected through personalized questionnaires.

Results: Nurses faced multiple challenges, including limited availability of isolation rooms, shortages of personal protective equipment, restricted access to essential medications, and inadequate laboratory and diagnostic support. High nurse-to-patient ratios increased workload and risk of error. Despite these constraints, nurses adopted innovative and cost-effective strategies to maintain quality care. These included strict hygiene enforcement, rational use of available resources, development of simplified nursing protocols, task sharing, and close collaboration with physicians, pharmacists, and laboratory staff. Continuous bedside education for caregivers improved adherence to infection prevention measures and early reporting of complications. Nurses also played a critical role in monitoring graft-versus-host disease, managing chemotherapy side effects, and providing emotional support to children and families facing prolonged hospitalization. Standard Operating Procedures were elaborated. All the implementation phases were supported by the Nurses Italian team of HELP3-ODV.

Conclusions: The Benjamin Mkapa Hospital experience demonstrates that pediatric BMT nursing care is feasible in limited-resource settings when nurses are empowered with appropriate training, strong teamwork, and context-adapted protocols. Nurses serve as advocates, educators, and frontline defenders against complications, significantly influencing transplant outcomes. Investment in nursing education, supportive supervision, and basic

infrastructure is essential to strengthen pediatric BMT services in LMICs. Sharing nursing experiences from resource-limited units is crucial to inform best practices, promote capacity building, and improve survival and quality of life for children undergoing BMT.

NURSING TRAINING IN A PEDIATRIC HSCT UNIT: IMPLEMENTATION, SATISFACTION OUTCOMES AND EVALUATION FRAMEWORK IN RABAT (MOROCCO)

*Fatima Batnaoui[1], Oumaima Gamgam[1], Nada Belarbi[1], Houda Oukessou[1], Oumaima Labyed[1], Asmae Chtioui[1], Rabie El Othmani[1], Mohammed Bahmou[1], Mohammed Bettah[1], Meriam Lakhrissi[1], **Eugenia Trigoso**[2], Julia Challinor[3], Laila Hessissen[1], Maria El Kababri.[1]*
[1]Service d'Hématologie et d'Oncologie Pédiatrique- Hôpital d'Enfant - University Hospital Ibn Sina, Rabat, Morocco, [2]Hospital Universitario y Politécnico La Fe, Valencia, Spain, [3]Consultan, Los Angeles, United States of America (the)

Background: Morocco, a lower-middle-income country, has a population of 38 million, with 31% <15 years, and <9% of the population lives in poverty. The Pediatric Haematology and Oncology Service (SHOP) in Rabat, part of the Francophone Africa Pediatric Oncology Group (GFAOP) network, operates a 6-bed transplant unit and has performed 144 hematopoietic stem cell transplants (HSCT) since 2014, including 36 allogeneic transplants. A national and hospital nursing shortage means only 2 nurses are assigned each shift. Initial BMT nursing training has been done. However, the increasing complexity of pediatric HSCT and rising activity highlighted the need for structured and standardised nursing training to ensure safe, high-quality care.

Methods: A visiting (JACIE-inspector) pediatric bone marrow transplant (BMT) nurse expert from Spain attended the unit for two weeks in September 2025. An initial introduction to the team included a presentation of transplantation of a child with Fanconi anaemia, a discussion of nursing training in general, and planning with 4 local nurse experts for a full-day structured pediatric BMT training. For the training, 40 participants (27 nurses) attended. The curriculum covered: 1) an overview of HSCT activity in Rabat, 2) HSCT fundamentals, 3) patient preparation, 4) stem cell collection, 5) nursing management on transplant day (Day 0), 6) early complications, 7) acute and chronic GVHD care, 8) long-term follow-up organisation, and 9) JACIE accreditation requirements.
Evaluation included:

- a satisfaction questionnaire using a 5-point Likert scale,
- a pre- and post-test to objectively measure knowledge acquisition; results will be reported once analysis is completed.

Results: Feedback from the training satisfaction questionnaire showed consistently high ratings across all domains, with ratings of 4–5/5 indicating that participants found the item

satisfactory to very satisfactory. Twenty-one participants rated the clarity of objectives and relevance of the material 5/5, while 17–21 participants rated the applicability and knowledge enrichment between 4 and 5/5. Trainers were also highly rated: 20 participants gave a score of 5 for communication clarity, 22 for adherence to objectives, and 20 for enthusiasm. Practical examples were rated 4–5/5 by 22 participants. Logistic aspects, including organisation and audiovisual conditions, mostly received scores of 4–5/5, with 16–18 participants rating them 5. Overall satisfaction was similarly high, with 17 participants giving 5/5 and 6 participants 4/5. Qualitative feedback highlighted the richness and relevance of the content, the quality of discussions, and strong team engagement. The pre- and post-test was administered and are currently under analysis.

Conclusions: This structured training day was highly valued by participants and effectively addressed core competencies required in pediatric HSCT nursing. While satisfaction indicators were strong across all domains, the forthcoming pre- and post-test analysis will provide an objective measure of knowledge acquisition. Implementing recurring, standardised training sessions with continuous evaluation will strengthen nursing capacity and support high-quality HSCT care within the GFAOP network.
