Preliminary Abstract Book

#EBMT26

Preliminary Abstract Book Statement

This abstract book represents a preliminary compilation of accepted abstracts as of 16 March 2026. It is intended for informational purposes only and does not replace or supersede the official journal publication.

Please note that only abstracts from authors who were registered by this date are included in this version. The absence of an abstract in this preliminary book does not preclude its inclusion in the final official journal publication.

Abstract Presentation Codes

Abstracts included in this book are categorized by topics according to their presentation format and session allocation, as indicated by the following codes:

- **OS (number)** – Oral presentations scheduled within the Oral Sessions
- **A (number)** – Poster presentations scheduled for Poster Session A (Monday, 23rd of March)
- **B (number)** – Poster presentations scheduled for Poster Session B (Tuesday, 24th of March)
- **P (number)** – Electronic poster presentations (ePosters), displayed on screens in the designated ePoster area

Abstracts can be searched within the online programme by entering the abstract code or title at the following link: https://ebmt2026.abstractserver.com/programme/#/programme/1/horizontal

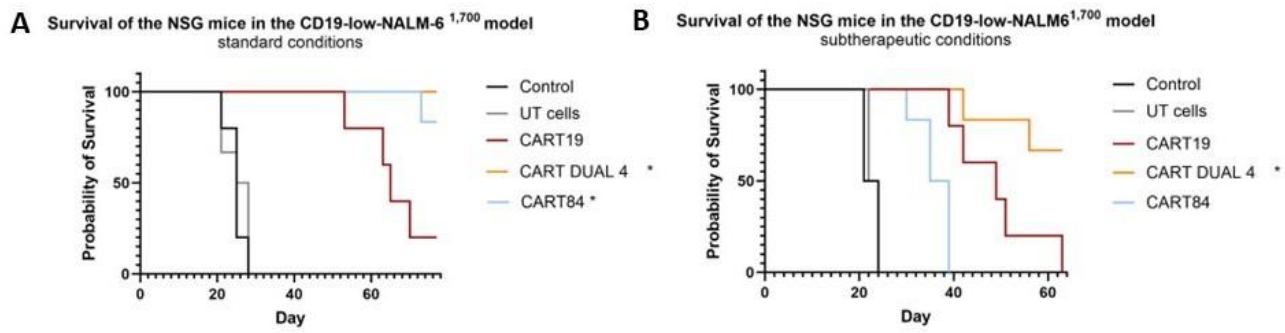
Background: Relapse driven by reduced or absent CD19 expression could limit the long-term efficacy of CD19-directed CAR T-cell therapy in B-ALL, underscoring the need for approaches that maintain function when antigen density falls below the activation threshold.

Methods: To model antigen-low relapse, CD19-low NALM6 variants were generated using CRISPR/Cas9 disruption followed by controlled CD19 re-expression under a truncated promoter. A series of CD19/CD84 dual-targeting CAR T cells were engineered, including an AND-gated construct (DUAL 1m; anti-CD19 scFv–CD3ζ–P2A–anti-CD84 scFv–4-1BB) and IF-BETTER designs, DUAL 4 (anti-CD19 scFv–4-1BB–CD3ζ–P2A–anti-CD84 scFv–4-1BB) and DUAL 5 (anti-CD19 scFv–4-1BB–CD3ζ–P2A–anti-CD84 scFv–CD28). All dual constructs incorporated a mutated CD8α hinge (C164S/C181S) to prevent unintended dimerization. Immune phenotype was characterized through analysis of T-cell subsets and activation/exhaustion markers. CAR T-cell function was evaluated through cytotoxicity and in vitro tumor rechallenge assays, as well as avidity analysis; in vivo efficacy was assessed in two NSG xenografts with WT or CD19-low NALM6 cells. In the CD19-low NALM6 in vivo model, two CAR T-cell doses were evaluated: 5×10^6 and 2×10^6 CAR T cells. Hematologic toxicity was tested by co-culture with $CD34^+$ progenitor cells, and activity was additionally tested on primary B-ALL samples.

Results:



Both IF-BETTER constructs expanded efficiently and preserved a memory-like T-cell distribution comparable to conventional CART19, without premature exhaustion. In cytotoxicity assays, DUAL 4 and DUAL 5 killed $CD19^+$ NALM6-WT, with activation strictly dependent on CD19 engagement despite measurable CD84 expression on target cells, and no cytotoxicity was observed against $CD19^-$ $CD84^+$ MOLM-13 acute myeloid leukemia cells. In long-term in vitro rechallenge assays, IF-BETTER CAR T cells exhibited greater functional persistence, with DUAL 4 maintaining sequential tumor clearance for substantially more rounds than single CART19. In vivo, both DUAL 4 and DUAL 5 achieved tumor control and survival outcomes indistinguishable from single CART19 in the NALM6 WT xenograft.In CD19-low disease models, IF-BETTER DUAL 4 outperformed single CART19. In vitro, DUAL 4 achieved higher cytotoxicity than single CART19. In vivo, DUAL 4 improved tumor control and survival in CD19-low xenografts at both CAR T-cell doses, achieving statistically significant survival benefit in both settings. Importantly, despite CD84 being present on hematopoietic progenitors, DUAL 4 did not eliminate $CD19^-CD34^+$ cells, indicating that CD19 engagement is required for its activation and supporting the safety of this design. Finally, across primary B-ALL samples, IF-BETTER DUAL 4 achieved high cytotoxicity comparable to or exceeding single CART19, supporting its translational relevance.

Conclusions: CD84 emerges as a compelling co-target for CD19-directed CAR T-cell therapy, providing a biologically meaningful co-stimulation without compromising antigen specificity. The IF-BETTER architecture yields dual CD19/CD84 CAR T cells with functional persistence and strict dependence on CD19 for full activation. The DUAL 4 construct matches CART19 performance in CD19-high settings while delivering markedly improved efficacy against CD19-low B-ALL. Overall, these findings support CD19/CD84 IF-BETTER CAR T cells as a promising strategy to prevent or overcome CD19-low relapse in B-ALL.

OS03-04

DECITABINE PREVENTS POST-TRANSPLANT RELAPSE IN ACUTE MYELOID LEUKEMIA BY IMMUNOMETABOLIC REPROGRAMMING OF MACROPHAGES VIA THE H3K4ME3–ACOD1–ITACONATE AXIS

Yutong Xie[1], *Zhigang Chen*[1], *Chenmo Li*[1], *Junhong Wu*[1], *Chao Yang*[1], *Lei Gao*[1,2]
[1]*Medical Center of Hematology, Xinqiao Hospital, State Key Laboratory of Trauma, Burn and Combined Injury, Army Medical University, Chongqing, China,* [2]*Jinfeng Laboratory, Chongqing, China*

Background: Decitabine (DAC) maintenance therapy has been shown to markedly lower the risk of relapse in acute myeloid leukemia (AML) following hematopoietic stem cell transplantation (HSCT). However, the immunomodulatory mechanisms underlying this benefit remain incompletely defined. This study investigates how DAC reshapes the post-transplant immune microenvironment, identifying the H3K4me3–ACOD1–itaconate axis as a pivotal mediator of macrophage metabolic reprogramming.

Methods:

- Clinical Cohorts: Prospective (n=30) and Retrospective (n=40) analysis of bone marrow samples pre- and post-HSCT (1, 3, 6, 12 months).
- Multi-Omics: RNA-seq, CUT&Tag, ChIP-qPCR, Untargeted Metabolomics, LC-MS/MS, Isotope Tracing.
- Functional Assays: Seahorse XF analysis, Flow Cytometry, In vitro gain/loss-of-function.
- In Vivo: Humanized AML mouse model with bioluminescence imaging.

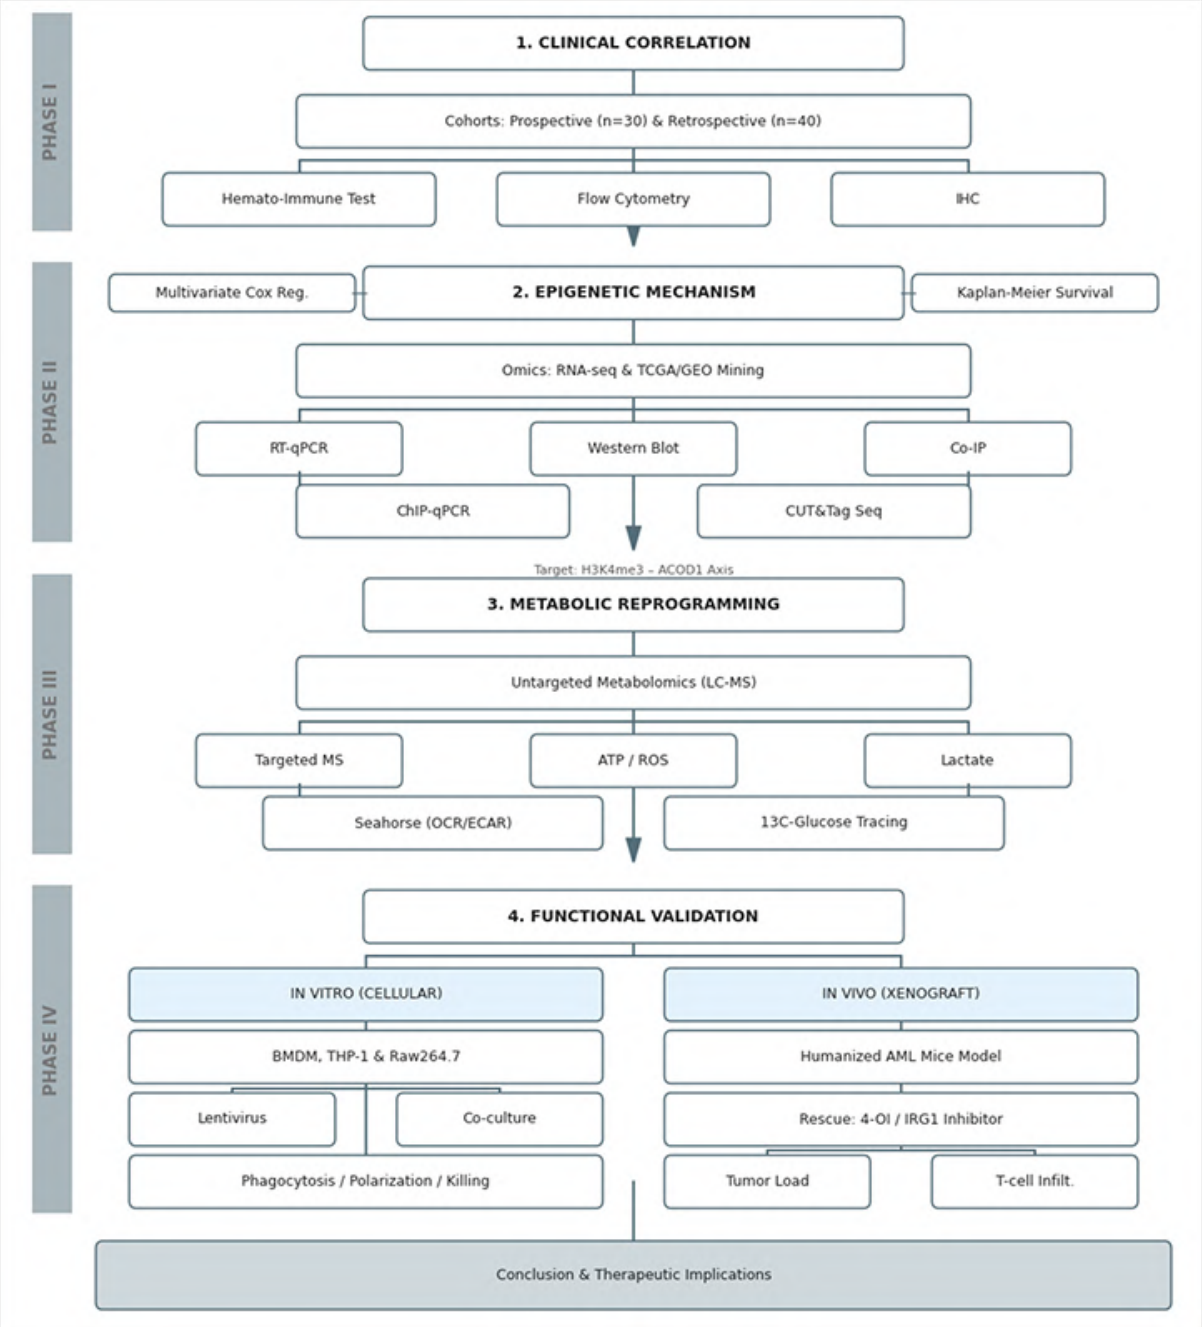

Figure 1 | *Schematic Overview of the Experimental Design. The study is divided into four phases: clinical correlation, epigenetic mechanism, metabolic reprogramming, and functional validation.*

Results: In a prospective cohort (n=30), longitudinal flow cytometric profiling of bone marrow macrophages at pre-transplant and 1, 3, 6, and 12 months post-HSCT revealed

divergent polarization trajectories. Non-relapsed patients maintained elevated CD80 expression throughout follow-up, whereas relapsed cases exhibited progressive accumulation of $CD163^+$ and $CD206^+$ macrophages, with CD206 MFI reaching ~9,000 at 12 months. Kaplan-Meier analysis demonstrated superior median overall survival in patients with M1-predominant profiles (495 vs 385 days, $p<0.05$). Multivariate Cox regression identified M1 polarization as an independent protective factor against relapse (HR 0.42, 95% CI 0.21–0.84).
Retrospective validation (n=40) confirmed significant upregulation of M1 markers (CD80, iNOS) in non-relapsed patients ($p=0.0001$, $p=0.0003$), while CD163 and CD206 were elevated in relapsed cases ($p=0.0193$, $p=0.0075$ for relapse×time interaction). IRG1 showed dynamic regulation with significant time-dependent changes correlating with relapse risk ($p=0.0001$ for interaction term).
Integrated RNA-seq and CUT&Tag analysis revealed decitabine-mediated suppression of ACOD1 transcription via reduced H3K4me3 enrichment at its promoter (fold-change -2.8, $q<0.001$). Untargeted metabolomics and ^{13}C-isotope tracing confirmed decreased itaconate production and restored TCA cycle flux. Seahorse metabolic profiling demonstrated enhanced glycolytic capacity (ECAR/OCR ratio increased 2.1-fold) and M2a-to-M1 repolarization upon ACOD1 silencing.
In a humanized NSG-AML xenograft model, decitabine treatment increased the M1/M2 ratio 3.2-fold by week 6, suppressed bone marrow IRG1 expression (-65%, $p<0.01$), and reduced tumor burden by bioluminescence imaging (mean radiance decreased 78% vs vehicle, $p<0.001$). Pharmacological IRG1 inhibition partially abrogated these effects. Median survival was significantly prolonged in the decitabine arm (58 vs 42 days, log-rank $p=0.012$), with M1 predominance conferring independent survival benefit on multivariate analysis.

Conclusions: Decitabine modulates the H3K4me3–ACOD1–itaconate axis, reprogramming macrophage metabolism and polarization to improve the immune microenvironment and prolong survival after HSCT in AML patients. These findings reveal a novel immunometabolic mechanism and highlight ACOD1 as a promising therapeutic target for post-transplant relapse prevention.

REAL-WORLD EVIDENCE FOR THE SAFETY AND EFFICACY OF GLOFITAMAB COMBINED WITH CAR-T THERAPY IN RELAPSED/REFRACTORY B-CELL LYMPHOMA

*Xingcheng Yang[1], Yi Wang[2,3], Xiaoxi Zhou[1], Dehui Zou[2,3], **Jia Wei**[1,4]*
[1]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China, [2]State Key Laboratory of Experimental Hematology National Clinical Research Center for Blood Diseases, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjing, China, [3]Tianjin Institutes of Health Science, Tianjing, China, [4]Immunotherapy Research Center for Hematologic Diseases of Hubei Province, Wuhan, China

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has substantially improved prognosis for patients with relapsed/refractory B-cell non-Hodgkin lymphoma (r/r B-NHL), yet relapse remains a significant challenge. Glofitamab, a CD20/CD3 bispecific antibody, represents a potent strategy to enhance durable responses. This study aimed to investigate the clinical benefit of combining Glofitamab with CAR-T in a multinational real-world setting, and to define the molecular mechanism for sustaining T-cell function and persistence.

Methods: From January 24, 2024, to July 3, 2025, this multicenter retrospective study included 27 r/r B-NHL patients who received single or dual-targeted CAR-T therapy (CD19/CD19-20/CD19-22) coupled with Glofitamab (bridging and/or maintenance), compared to a control cohort of 34 patients treated with CAR-T alone (Table 1). Among the 27 patients, 17 received Glofitamab bridging therapy (median cycles: 3, range: 2-10), and 18 received maintenance therapy (median cycles: 3, range: 1-12). Primary endpoints included ORR, CR rate, PFS, and OS. Mechanistic dissection utilized scRNA-seq on post-CAR-T PBMC from 3 Glofitamab-maintained PR patients versus 3 public controls. In vitro assays quantified T cell cytotoxicity, T effector memory phenotype (Tem), and immunological synapse formation.

Results: As of November 25, 2025, at a median follow-up of 11.97 months (range, 1.6-21.2 months), the Glofitamab combination group demonstrated an ORR of 88.9% and a CR rate of 59.3%, both superior to the control group's ORR of 67.6% and CR rate of 44.1%. The combination group achieved significantly superior PFS and OS (Figure 1); median PFS and OS were not reached in the combination group vs. median PFS 12.19 months in the control group ($p < 0.05$). Univariate Cox regression analysis suggested that Glofitamab bridging and maintenance were protective factors for PFS. Advanced stage (Ann Arbor stage 3-4) was identified as a risk factor for disease PFS. Safety analysis showed no increased risk of high-grade CRS or ICANS in the combination group. Mechanistically, scRNA-seq analysis revealed concurrent upregulation of multiple activation pathways (Cytotoxicity, TCR, NF-kappa B) alongside a critical synchronous activation of the anti-apoptotic pathway. This T-cell viability was strongly correlated with activation of the JAK/STAT signaling pathway. Furthermore, the key JAK/STAT ligand, IL-15, was specifically upregulated in the monocyte and granulocyte

populations. In vitro data validated that Glofitamab significantly enhanced CAR-T cell cytotoxicity and CD107a degranulation, promoted differentiation toward Tem. Confocal microscopy further confirmed Glofitamab role in significantly increased the size of T-cell-tumor cell clusters and the ratio of T-cells engaged in clustering (Figure 1).

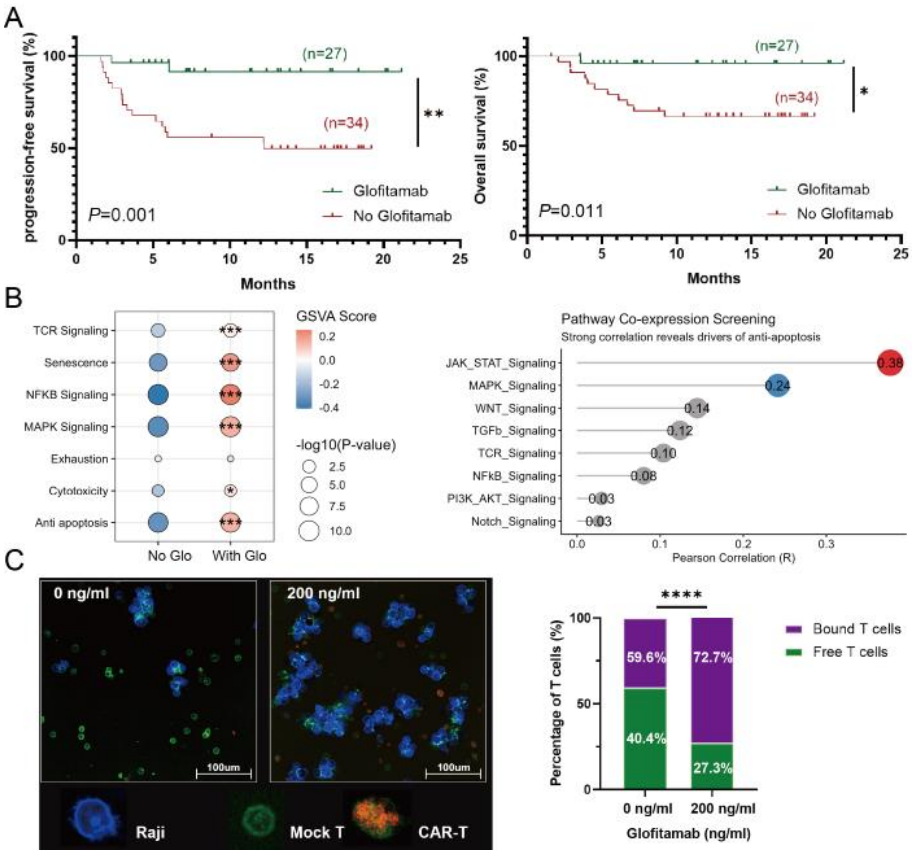
Figure 1. Glofitamab combination therapy achieves superior PFS and OS, correlating with the activation of a T-cell JAK/STAT and enhanced immunological synapse formation in vitro



Conclusions: This real-world study demonstrates that Glofitamab combined with CAR-T therapy achieves superior PFS and OS in r/r B-NHL. Single-cell data reveal that the clinical benefit correlates with a sustained JAK/STAT survival circuit in T cells, specifically driven by IL-15 from monocytes/granulocytes. Supported by functional data showing enhanced T cell cytotoxicity, Tem differentiation, and immunological synapse formation, these findings highlight Glofitamab combination therapy as a key strategy for enhancing long-term T-cell persistence and immune surveillance post-CAR-T therapy.

Background: High tumor mutational burden (TMB) expands the neoantigen repertoire but may simultaneously impose selective pressure for disruption of antigen presentation and immune signaling pathways. While elevated TMB is a favorable biomarker in immunotherapies dependent on endogenous T-cell recognition, its biologic consequences in CD19-directed CAR-T therapy have not been systematically examined in large B-cell lymphoma (LBCL).

Methods: Tumor genomic profiling was performed using whole-exome sequencing (WES) and/or clinically validated targeted next-generation sequencing to quantify TMB. Associations between TMB and post–CAR-T outcomes were evaluated using competing-risk regression for relapse/progression and multivariable Cox models for progression-free survival (PFS) and overall survival (OS), adjusting for key clinical covariates. Transcriptomic profiling was used to interrogate immune and inflammatory pathway activity. Comparative analyses were conducted in a large front-line LBCL cohort treated with chemoimmunotherapy, with study-level TMB normalization to account for inter-assay variability.

Results: The study included 114 patients with relapsed/refractory LBCL treated with commercial CD19 CAR-T therapy (48% axicabtagene ciloleucel, 17% lisocabtagene maraleucel, 35% tisagenlecleucel), predominantly in the ≥3rd line. Pre-infusion tumor sequencing was available by WES (n=89), targeted sequencing (n=25), or both (n=65). Median WES-derived TMB was 2.82 mutations/Mb (interquartile range [IQR] 1.86–3.98). Higher WES-derived TMB correlated with genomic instability metrics, de novo LBCL histology, and higher baseline metabolic tumor volume (MTV) (all $p<0.01$), but not with cell of origin, double-hit status, TP53 mutation, MYC rearrangement, or age. Higher TMB was independently associated with inferior outcomes following CAR-T therapy. Patients in the highest TMB quartile (>4.0 mut/Mb) experienced increased risk of relapse or progression (subdistribution HR 2.68, $p<0.001$), inferior PFS (HR 2.32, $p<0.01$), and inferior OS (HR 3.04, $p<0.001$) after multivariable adjustment (Fig. 1A, B).

While high-TMB tumors were enriched for increased numbers of clonal neoantigens with strong predicted patient-specific HLA binding, they concurrently exhibited selective loss of HLA genes predicted to present these neoantigens, alongside mutations affecting antigen-processing and presentation machinery (Fig. 1C). Paired transcriptomic profiling (n=40) demonstrated coordinated downregulation of inflammatory and cytotoxic signaling pathways, including TNF–NFκB, IL2–STAT5, and apoptosis (FDR-adjusted p<0.05; Fig. 1D).
Because WES is not routinely available in clinical practice, TMB was also derived from a clinically deployed targeted sequencing assay (MSK-IMPACT). In patients with panel-based sequencing available (n=90), higher targeted TMB reproduced the adverse associations observed with WES-derived TMB, supporting feasibility of clinical implementation .
To compare the effect of TMB across treatment settings, we evaluated its impact in a front-line multi-study cohort of 2,126 LBCL patients treated with chemoimmunotherapy. In contrast to the CAR-T setting, higher TMB demonstrated a reverse association, with improved PFS among patients in the highest scaled-TMB quartile (HR 0.88, p<0.01; Fig. 1E) .

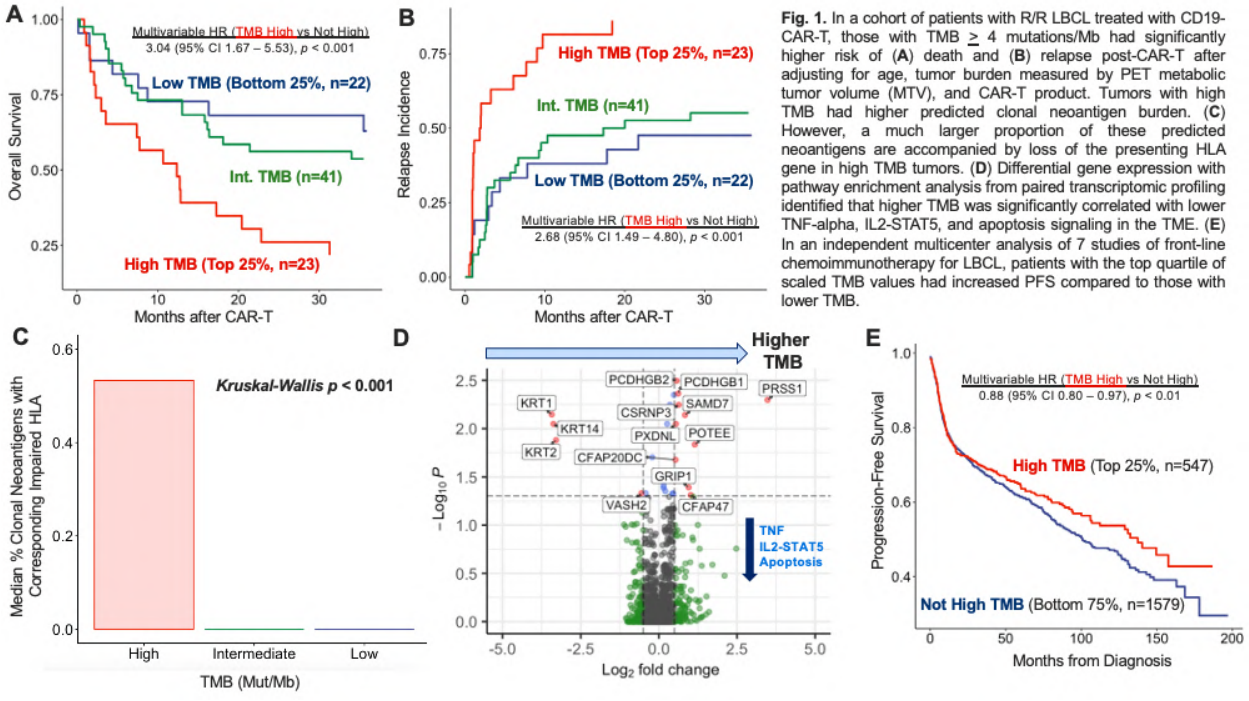

Fig. 1. In a cohort of patients with R/R LBCL treated with CD19-CAR-T, those with TMB ≥ 4 mutations/Mb had significantly higher risk of (**A**) death and (**B**) relapse post-CAR-T after adjusting for age, tumor burden measured by PET metabolic tumor volume (MTV), and CAR-T product. Tumors with high TMB had higher predicted clonal neoantigen burden. (**C**) However, a much larger proportion of these predicted neoantigens are accompanied by loss of the presenting HLA gene in high TMB tumors. (**D**) Differential gene expression with pathway enrichment analysis from paired transcriptomic profiling identified that higher TMB was significantly correlated with lower TNF-alpha, IL2-STAT5, and apoptosis signaling in the TME. (**E**) In an independent multicenter analysis of 7 studies of front-line chemoimmunotherapy for LBCL, patients with the top quartile of scaled TMB values had increased PFS compared to those with lower TMB.

Conclusions: High tumor mutational burden defines an immune-evasive tumor state associated with inferior outcomes after CD19 CAR-T therapy in relapsed/refractory LBCL, characterized by impaired antigen presentation and attenuated immune signaling despite expanded neoantigen repertoires. In contrast, TMB demonstrates a reverse association in front-line chemoimmunotherapy, underscoring its context-dependent impact across immune treatment modalities and supporting its translational utility as a clinically actionable biomarker for CAR-T risk stratification.

MYELOID DERIVED SUPPRESSOR CELLS (MDSC) AFFECT IMMEDIATE EFFICACY AND ACUTE TOXICITIES OF ANTI-CD19 CAR-T IN PATIENTS WITH LARGE B-CELL LYMPHOMA

Eugenio Galli[1], *Federica Sorà*[1,2], *Alessandra Battaglia*[3], *Marco Fossati*[4], *Ilaria Pansini*[1,2], *Silvia Bellesi*[1], *Giacomo Di Cesare*[1], *Marcello Viscovo*[1,2], *Andrea Guarneri*[5], *Lucia Leccisotti*[5,6], *Alexia Buzzonetti*[4], *Chiara Anna Cimmino*[4], *Patrizia Chiusolo*[1,2], *Stefan Hohaus*[1,2], *Andrea Fattorossi*[4], *Simona Sica*[1,2]

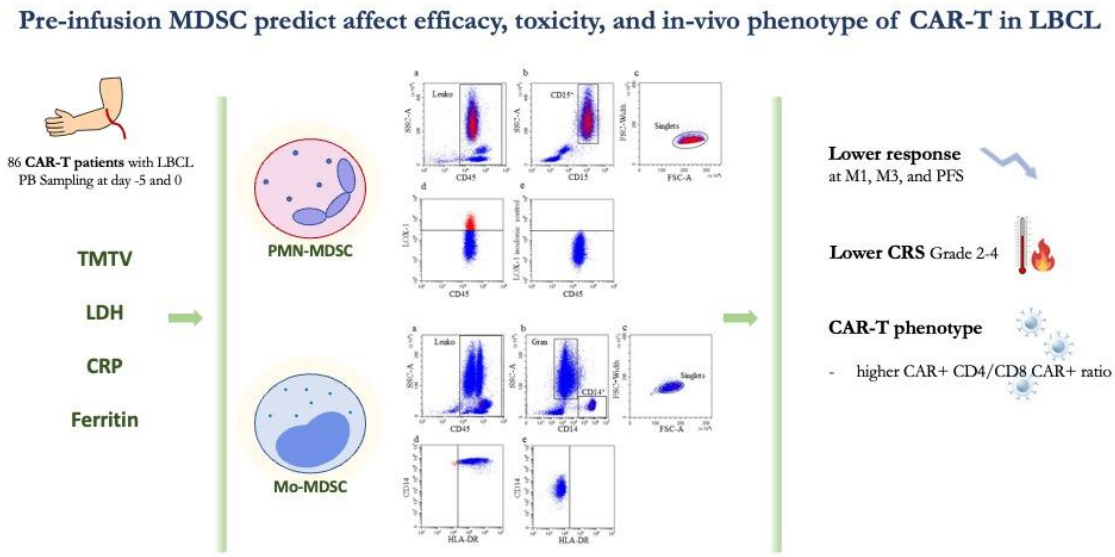
Gemelli IRCCS, Rome, Italy, [5]UOC di Medicina Nucleare, Dipartimento di Diagnostica per Immagini e Radioterapia Oncologica, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy, [6]Sezione di Medicina Nucleare, Università Cattolica del Sacro Cuore, Rome, Italy

Background: Despite the success of CD19-directed CAR-T-cells in relapsed/refractory (R/R) large B-cell lymphoma (LBCL), a substantial proportion of patients experience treatment failure. **Myeloid-derived suppressor cells** of monocyte (Mo-MDSC) and polymorphonuclear (PMN-MDSC) origin **are key regulators of immune suppression in cancer** and may affect immunotherapy efficacy. Their role in modulating CAR-T-cell efficacy and toxicity is still under investigation. Here, we compared circulating MDSC subsets across CAR-T-cell treated R/R LBCL patients with different outcomes using a common staining panel for the identification of these cells directly in fresh whole blood by multiparameter flow cytometry.

Methods: This prospective observational study included adult patients receiving commercial CAR-T-cell therapy for R/R LBCL. Peripheral blood (PB) was collected before lymphodepletion (LD) and at CAR-T infusion. Mo-MDSC were quantified as $CD45^{+}CD14^{+}HLA\text{-}DR^{neg}$ cells and PMN-MDSC as $CD45^{dim/+}CD15^{+}LOX\text{-}1^{+}$ cells. Data were expressed as cells/μL Additionally, PMN-MDSC maturation status was assessed by differential CD10, CD11b, and CD16 expression. CAR-T-cell expansion was evaluated at days 7, 14, and 30 by $CD3^{+}CAR^{+}$ flow cytometry.
We evaluated the correlation of PMN-MDSC and Mo-MDSC with overall response rate (ORR), progression-free survival (PFS), CAR-T-cell expansion, and toxicities.

Results: Eighty-six patients were included. At 1 and 3 months post-infusion, ORR was 72.9% and 59.1%, respectively. Median PFS was 371 days.
Before LD, immature and mature PMN-**MDSC** significantly **correlated with TMTV and systemic inflammation** (CRP, ferritin and LDH) and Mo-MDSC significantly correlated with CRP. These observations are in line with the complex interrelations between tumor burden and the immune system status.

LD selectively affected PMN-MDSC populations as it decreased immature PMN-MDSC (p<0,01) and increased mature PMN-MDSC although not significantly. There was a trend towards a LD-induced Mo-MDSC decrease.
Despite these changes, immature and mature PMN-MDSC strongly predicted **lack of response at month 1** both when measured before LD (OR 3.76, p<0,001; OR 3.63, p<0.001; respectively) and at CAR-T-cell infusion (OR 1.97, p<0,001; OR 2.34, p<0.001, respectively). Conversely, Mo-MDSC were informative only before LD (OR 6.93, P=0.01). Only immature PMN-MDSC at CAR-T-cell infusion predicted lack of response at month 3 (OR 1.77, p<0.006). The stratification of early response by MDSC was not maintained over time, as neither PMN-MDSC nor Mo-MDSC predicted long-term PFS.
We hypothesized that MDSC had affected CAR-T-cell expansion. Neither PMN-MDSC nor Mo-MDSC associated with quantitative peak (day+7) of CAR-T-cell. However, high mature PMN-MDSC before LD predicted **increased CAR-T CD4/CD8 ratio** (R^2=0.12, p=0.018) in peripheral blood: the concomitance of an unbalanced ratio towards CD4+ associated with a lower response, may enforce the role of CD8+CAR-T-cells in leading the anti-lymphoma effect.



Toxicity was influenced by MDSC. Higher mature PMN-MDSC and Mo-MDSC at CAR-T-cell infusion were associated with a **reduced incidence of grade ≥2 CRS** (OR 0.61, p=0.048 and OR 0.40, p=0.020, respectively) and a lower need for tocilizumab. No association with ICANS was observed.

		CAR+ CD4/CD8 at peak	CRS 2-4	Tocilizumab	Response M1	Response M3	PFS

Conclusions: Present findings suggest that immune environment influences CAR-T-cell therapy and call for the importance of integrating the MDSC profiling into the clinical management of R/R LBCL. MDSCs might represent a potential therapeutic target in CAR-T-cell bridging or lymphodepleting strategies.

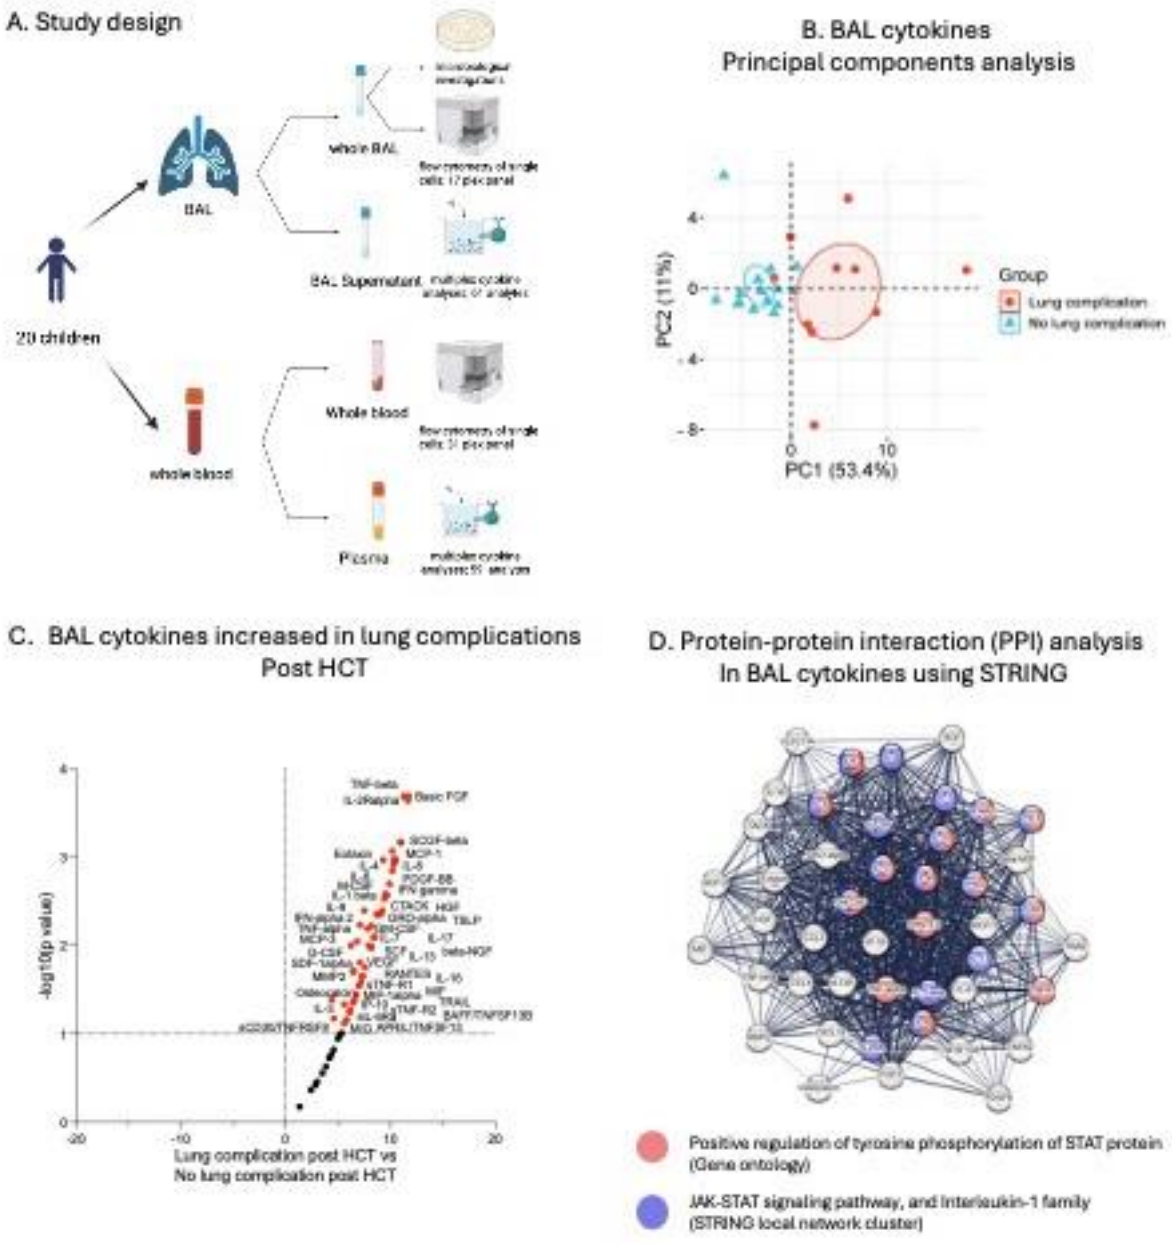
PULMONARY AND SYSTEMIC IMMUNE PROFILING REVEALS JAK-STAT SIGNALLING AS A MEDIATOR OF POST-HCT LUNG COMPLICATIONS IN CHILDREN

Hannah Walker[1,2,3], *Theresa Cole*[3,2,1], *Liam Gubbels*[2], *Diane Hanna*[3,1], *Gabrielle Haeusler*[2,3,1], *Shivanthan Shanthikumar*[2,3,1], *Melanie Neeland*[2,1]
[1]*University of Melbourne, Melbourne, Australia,* [2]*Murdoch Children's Research Institute, Melbourne, Australia,* [3]*The Royal Children's Hospital, Melbourne, Australia*

Background: Allogeneic haematopoietic stem cell transplantation is a curative therapy for a range of serious conditions affecting children. Unfortunately, approximately 50% of children undergoing allogeneic HCT develop pulmonary toxicities, which can be life-threatening. There is little known about the biological drivers of these pulmonary diseases and as a result there are few options for risk prediction, early detection and targeted therapies. To further evaluate immune correlates of pulmonary disease pre- and post-HCT, we designed the prospective study 'BREATH', recruiting children undergoing allogenic HCT at a single centre.

Methods: This research aims to identify pathogenic drivers of lung complications and signatures of normal lung immune reconstitution post allogeneic HCT. We aimed to describe, through extensive immunological profiling (utilising flow cytometry and cytokine analyses), patients who maintained 'lung health' as well as those who developed lung disease post-HCT. This prospective longitudinal observational study, 'BREATH', enrolled 20 paediatric patients undergoing HCT at The Royal Children's Hospital in Melbourne and involved the collection of serial paired bronchoalveolar fluid and peripheral blood, combined with detailed clinical data. Patients were eligible to have biospecimen samples collected up to 12 months post the day of stem cell infusion. Patients were only eligible for one biospecimen collection timepoint pre-HCT but eligible for multiple repeated timepoints in the first year post-HCT. Mann-Whitney U tests were used to compare the concentration of analytes (pg./mL) and proportions of cell populations (% of live CD45+ cells) between groups (HCT lung health, HCT lung complication and controls). For lung complication timepoints where paired lung assays were available (n = 8, 6 patients)—that is, cell proportion data obtained by flow cytometry analysis of BAL and soluble analyte data obtained by cytokine profiling of BAL (20 analytes as part of JAK-STAT pathway)—we performed correlation analyses using two-tailed Spearman correlation. For all statistical analyses, a p value < 0.05 was considered significant.

Results: Overall, 40% of children developed a lung complication post-HCT and required a clinically indicated BAL. In total, 49 sample timepoints were collected with a median of 2.6 timepoints per patient (range 1–6). Our primary aim was to identify if children post HCT who developed a lung complication had a unique inflammatory signal compared to children who do not develop lung complications. We found enrichment of the JAK-STAT and IL-1 signalling and profibrotic pathways in both the lung and whole blood, at the time of post-HCT lung complication. Changes in granulocyte and alveolar macrophages populations in BAL were correlated with soluble mediators of the JAK-STAT pathway in these patients with lung disease.



Pulmonary and Systemic Immune Profiling Reveals JAK-STAT Signalling as a Mediator of Post-HCT Lung Complications in Children

Conclusions: This research represents a potential pathogenic pathway for why these patients may develop lung complications as well as a potential therapeutic target (e.g. the JAK-STAT inhibitor ruxolitinib) which requires investigation in larger studies. Improved

understanding of the mechanisms driving this lung disease will enable improved diagnostics and pave the way for the introduction of novel therapeutic approaches.

Clinical Trial Registry: N/A

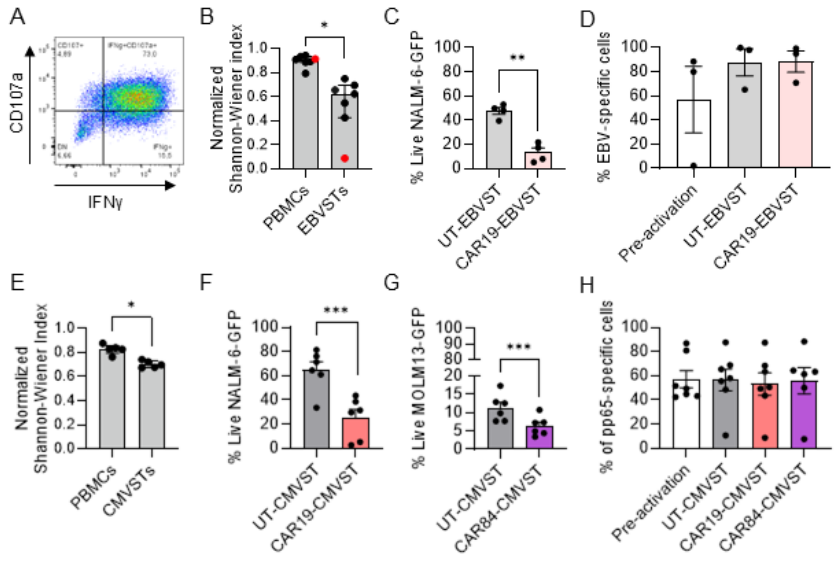
Background: Chimeric antigen receptor (CAR) T-cell therapy has reshaped treatment paradigms for hematologic malignancies, yet truly off-the-shelf products remain hindered by alloreactivity, limited persistence, and the need for gene editing. Virus-specific T cells (VSTs) targeting Epstein–Barr virus (EBV) or cytomegalovirus (CMV) exhibit long-term persistence, viral-restricted TCR repertoires, and a low risk of graft-versus-host disease (GVHD), making them an attractive platform for allogeneic CAR T-cell development. This study evaluates the engineering of EBV- and CMV-reactive T cells with CARs targeting CD19 and CD84 to generate dual-functional products for the treatment of B-cell acute lymphoblastic leukemia (B-ALL) and acute myeloid leukemia (AML).

Methods: VSTs were generated from seropositive donor PBMCs using peptide stimulation followed by cytokine-supported expansion. Phenotype, antiviral functionality, and cytotoxic activity were assessed by flow cytometry, intracellular cytokine staining, and killing assays. TRB CDR3 sequencing was used to characterize repertoire narrowing in VST products. Cryopreserved VSTs were reactivated using anti-CD3/CD28 beads or anti-CD3 antibody prior to lentiviral transduction with second-generation CAR19 or CAR84 vectors. CAR expression, viral responsiveness, and CAR-mediated cytotoxicity were analyzed following expansion. Additional experiments evaluated early lentiviral transduction during antigen-driven stimulation.

Results: EBVSTs and CMVSTs expanded efficiently, maintaining high viability and a consistent predominance of CD3+ T cells throughout expansion. Both EBVSTs and CMVSTs exhibited robust antiviral functionality, characterized by degranulation responses and polyfunctional cytokine secretion upon stimulation with the corresponding viral peptides. TRB CDR3 sequencing revealed marked repertoire focusing relative to unmanipulated PBMCs, with enrichment of clonotypes previously associated with CMV and EBV-epitopes. Functionally, VSTs selectively eliminated autologous or partially HLA-matched allogeneic targets only when pulsed with the appropriate viral peptides, confirming preserved antiviral specificity and absence of detectable alloreactivity.
We next optimized CAR-VST manufacturing from cryopreserved VSTs, mimicking the use of donor-derived VST banks. Anti-CD3/CD28 bead stimulation consistently yielded high CAR19 and CAR84 expression. However, this approach substantially reduced antiviral responsiveness across donors, indicating loss of virus specificity upon strong polyclonal activation. In contrast, anti-CD3 antibody-mediated activation supported efficient CAR transduction while maintaining EBV- or CMV-directed responses. CAR19-EBVST and CAR19-CMVSTs generated under these conditions expressed CAR19, eliminated CD19+ B-ALL targets, and responded to viral peptides. Likewise, CAR84-CMVSTs expressed CAR84, preserved CMV specificity, and displayed cytotoxicity against CD84+ AML cells.



Functional activity, repertoire diversity, and cytotoxicity of EBV- and CMV-specific T cells (VST) before and after CAR transduction. **(A)** Representative dot plots of CD107a and IFN-γ expression in $CD3^+CD8^+$ EBVSTs following overnight stimulation with EBV peptide pools in the presence of monensin and brefeldin. **(B)** TRB CDR3aa diversity (normalized Shannon–Wiener index) in PBMCs and expanded EBVSTs (paired t-test; N=7). **(C)** Cytotoxicity of untransduced (UT) or CAR19-transduced EBVSTs against NALM-6 cells at a 2:1 E:T ratio for 24h (paired t-test vs. UT; N=3–4). **(D)** Frequency of EBV-reactive $CD3^+CD8^+$ T cells ($CD107a^+$, IFN-γ^+, or double-positive) in thawed EBVSTs stimulated as in A before or after expansion with OKT-3 and UT or CAR19-transduced (one-way ANOVA; N=3). **(E)** TRB CDR3aa diversity in PBMCs and expanded CMVSTs (paired t-test; N=5). **(F)** Cytotoxicity of UT or CAR19-CMVSTs against NALM-6 at a 2:1 E:T ratio for 24h (paired t-test vs. UT; N=6). **(G)** Cytotoxicity of UT or CAR84-CMVSTs against MOLM-13 at a 2:1 E:T ratio for 24 h (paired t-test vs. UT; N=6). **(H)** Frequency of virus-reactive $CD3^+CD8^+$ cells in thawed CMVSTs stimulated as in A before or after expansion with OKT-3 and UT, CAR19- or CAR84-transduced (one-way ANOVA; N=7). All data are shown as mean ± S.E.M. *p < 0.05; **p < 0.01; ***p < 0.005.

Finally, lentiviral transduction during the antigen-driven VST expansion phase was evaluated to enable generation of a fully allogeneic CAR-VST product. Early transduction preserved proliferative capacity and leveraged physiological TCR stimulation rather than non-specific activation. Early-transduced CAR19-CMVSTs achieved stable CAR expression, maintained potent cytotoxicity against CD19+ target cells, and retained CMV specificity. Early-transduced CAR84-CMVSTs exhibited a more variable CAR expression, yet maintained cytotoxicity against CD84+ target cells.

Conclusions: VSTs constitute a selective T-cell population with virus-focused repertoires and minimal alloreactivity that can be engineered to express CARs while preserving antiviral function. Anti-CD3 antibody-based activation and early transduction strategies support scalable production of dual-functional CAR-VSTs. This framework advances the development of donor-derived, off-the-shelf CAR T-cell platforms.

IMMUNE MODULATION BY CAR-T CELLS: EXTRACELLULAR VESICLES AND SECRETOME AS DRIVERS OF MONOCYTE ACTIVATION

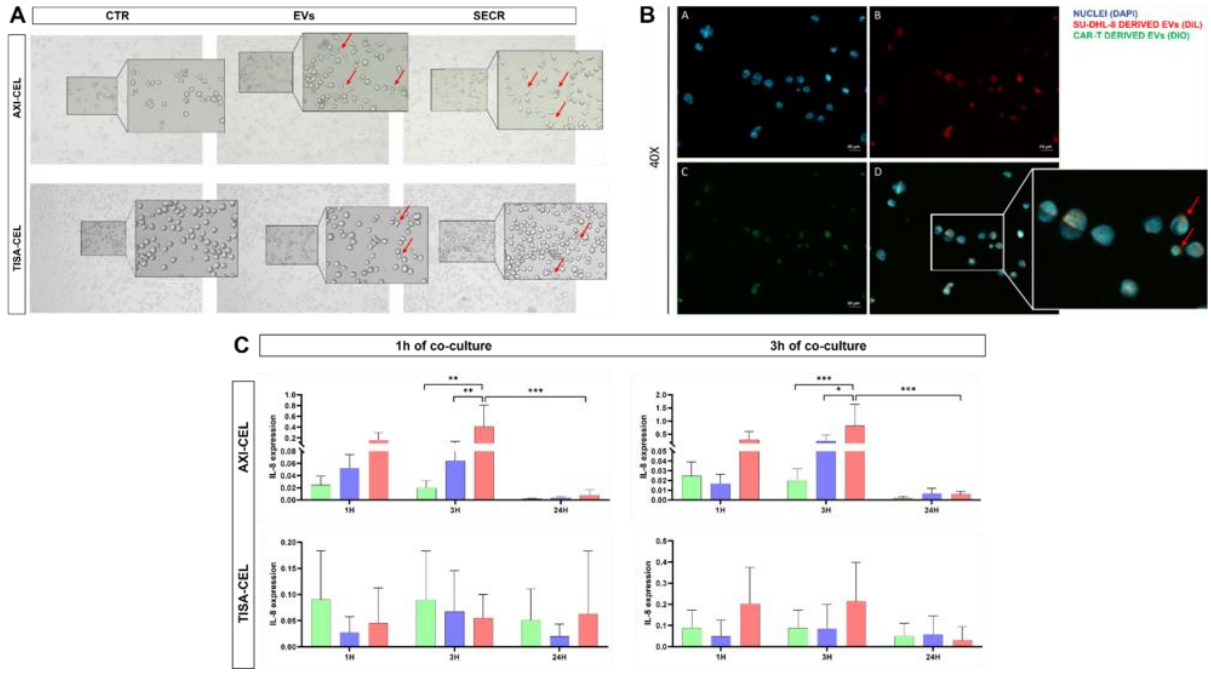
Besjana Xhahysa[1], *Mirko Farina*[2], *Luca Garuffo*[1], *Ilaria Grossi*[1], *Rosalba Monica Ferraro*[1], *Alessandro Leoni*[2], *Alessia Cavalleri*[1], *Silvia Mutti*[1], *Federica Trenta*[1], *Federica Re*[1], *Enrico Morello*[2], *Daniele Avenoso*[1,2], *Piera Balzarini*[1], *Alessandro Salvi*[1], *Michele Malagola*[1,2], *Domenico Russo*[1,2], *Simona Bernardi*[1]
[1]*University of Brescia, Brescia, Italy,* [2]*ASST Spedali Civili of Brescia, Brescia, Italy*

Background: Chimeric Antigen Receptor-T (CAR-T) cell therapy has transformed the treatment of $CD19^+$ B cell malignancies. However, its clinical success is tempered by acute and late toxicities with unclear mechanisms. Increasing evidence points to inflammation and innate immune activation as key drivers, with the monocyte–macrophage compartment playing a central role. Yet CAR-T effects on monocytes remain poorly characterized. We investigated how CAR-T cells interact with monocytes and trigger immune activation.

Methods: CAR-T cells (axicabtagene ciloleucel, axi-cel, and tisagenlecleucel, tisa-cel) were isolated from infusion bag washes of eight Non-Hodgkin Lymphoma patients (with Diffuse Large B-Cell Lymphoma or Follicular Lymphoma) with low-grade CRS and ICANS. To investigate the role of CAR-T-released particles in monocyte activation, cells were co-cultured for 1-3 h with $CD19^+$ SU-DHL-8 lymphoma cells. Extracellular Vesicles (EVs) and the complete secretome (SECR) were collected and used to treat THP-1 monocytes for 1, 3, and 24h. Monocyte-to-macrophage transition was analysed morphologically and molecularly. EV uptake was assessed by fluorescence microscopy, and cytokine expression quantified by digital PCR.

Results: Neither EVs nor SEC significantly affected THP-1 proliferation in either axi-cel or tisa-cel products. When treated for 1-3h with both EVs and SEC, monocytes adopted an irregular shape, with pseudopods formation. This aspect was more evident in cells treated with axi-cel-derived EVs and SEC (Fig.1A) and weren't appreciable after 24h. To assess if these changes were actually related to the monocyte's differentiation, the quantification of *PPM1A* transcript was performed via dPCR. EVs and SEC obtained after 1h of co-culture of

axi-cel products induced *PPM1A* overexpression after 24h of treatment, while EVs and SEC obtained after 3h of co-culture induced the overexpression also after 1-3h post-treatment. Surprisingly, cells treated with tisa-cel-derived EVs and SEC showed an opposite trend, with an increased expression after 1h of treatment with EVs and SEC, not observed after 24h. Collectively, these findings suggest that CAR-T-derived factors promote monocyte differentiation toward a macrophage-like phenotype rather than proliferation. Fluorescence microscopy confirmed EVs uptake by monocytes, indicating their key role in cells activation (Fig.1B). Cytokine analysis revealed significant over-expression of *IL-8*, after 1-3h with axi-cel-derived EVs and SEC, but not after 24h. In tisa-cel context just the treatment with EVs and SEC obtained after 3h of co-culture induce cytokines overexpression after 1-3h, but not after 24h (Fig.1C). *TNF-α*, *ICAM1*, and *IL-1β* transcripts shows the same trend. No effects were observed using EVs or SEC from naive SU-DHL-8.



Conclusions: For the first time, we demonstrate that CAR-T cells release factors capable of inducing monocyte-to-macrophage transition and transient pro-inflammatory activation. These findings highlight a key role for CAR-T-derived EVs and SECR in modulating innate immune responses, with potential implications for clinical outcomes and toxicities in CAR-T-treated patients.

LARGE SCALE MANUFACTURING OF GMP GRADE CORD BLOOD DERIVED MEGAKARYOCYTES FOR CHEMOTHERAPY INDUCED THROMBOCYTOPENIA

*Mayela Mendt[1], Hila Shaim[1], Hani Lee[1], Bijender Kumar[1], Alejandro Ramirez[1], Indreshpal Kaur[1], Torey Mallory[1], Arthur Aquino[1], Patrick Olivarez[1], Cody Hensley[1], Mecit Kaplan[1], Pinaki Banerjee[1], Rafet Basar[1], **Yosra Aljawai**[1], Jeffrey Wilson[1], Jeremy Ramdial[1], Uday Popat[1], Vahid Afshar-Kharghan[1], Nichola Cooper[2], Katy Rezvani[1], Elizabeth Shpall[1]*
[1]MD Anderson Cancer Center, Houston, United States of America (the), [2]Hammersmith Hospital, Imperial College, London, United Kingdom of Great Britain and Northern Ireland (the)

Background: The global shortage of donor platelets underscores the urgent need for reliable and sustainable alternatives. Close to 3 million platelet units are transfused annually in Europe, mostly in patients receiving chemotherapy or bone marrow transplantation. These patients often require multiple transfusions due to the short lifespan of transfused platelets (3–5 days), high consumption rate, and the development of immune refractoriness to platelet transfusions. Currently, platelet supply depends exclusively on adult donor apheresis. This supply is limited by both the short storage lifespan of platelets and reliance on donor availability. We thus developed a large-scale, multi-phase, good manufacturing practice (GMP) compliant method to generate platelets and megakaryocytes (MKs) *ex vivo,* using $CD34^+$ cord blood (CB) cells co-cultured with CB-derived mesenchymal stem cells (MSCs) in bioreactors. Our strategy utilizes the large global cord blood bank inventories as a renewable platelets source.

Methods: CB-derived $CD34^+$ cells were cultured on CB-MSCs monolayers with dynamically titrated cytokines to mimic the bone marrow microenvironment across distinct developmental stages. Supplements included a caspase-3 inhibitor, a histone deacetylase inhibitor, and a ROCK inhibitor to enhance MK viability and platelet production. Cells were expanded and differentiated through sequential co-culture phases: (1) CD34+ cells expansion with GMP media with early differentiation cytokines (TPO, SCF, FLT3L, IL-3, IL-6), (2) expansion of progenitors and differentiation to immature megakaryocytes using MK differentiation media (TPO, SCF, IL-11, IL-6 supplemented with histone deacetylase inhibitor), (3) maturation and large-scale expansion of megakaryocytes in a static bioreactor supplemented with a caspase 3 inhibitor, (4) final maturation of enriched CD61+ cells and platelet production (induced via shear force in a closed, hollow-fiber bioreactor), in the presence of a ROCK inhibitor. On Day 24, cultures were harvested, yielding a combined MK/platelets product.

Results: After 24 days, cultures yielded ~50 × 10^6 pure (>95%), mature MKs and ~0.5 × 10^{10} platelets. The MK were polyploid, and platelet functionality was confirmed by thrombin-induced aggregation, demonstrating robust aggregation *in vitro*. The product was tested for endotoxin, mycoplasma and sterility. Following infusion of the final product (containing 4.2 × 10^6 MKs and 0.15 × 10^8 platelets) into sublethally irradiated thrombocytopenic NSG mice, human $CD41^+$/$CD61^+$ platelets were detected in peripheral circulation within 1 hour. Moreover, platelets produced *in vivo* by the infused MKs, emerged by day 4, reaching their

highest levels by day 11. Notably, human platelets persisted in some mice at day 21, confirming both the rapid and durable thrombopoietic activity of the combined MK/platelet product. The product was well-tolerated with no observed toxicity. Our results highlight the clinical potential of this approach. The novelty of this approach includes the transfusion of a product containing both megakaryocytes and platelets, offering a promising strategy for addressing platelet shortages and improving patient outcomes.

Conclusions: We have developed a scalable platform for clinical use, generating MKs and platelets from CB. The combined infusion of MKs and platelets enables both immediate and sustained platelet reconstitution. Additionally, we have designed a phase I clinical trial to evaluate the safety and efficacy of this approach.

GENETIC MECHANISMS UNDERLYING CLONAL EVOLUTION DURING RELAPSE FOLLOWING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PHILADELPHIA CHROMOSOME–POSITIVE ACUTE LYMPHOBLASTIC LEUKEMIA

Jing Zheng[1,2], *Yanmin Zhao*[1], *Yi Luo*[1], *Jian Yu*[1], *Xiaoyu Lai*[1], *Jinuo Wang*[1], *Yishan Ye*[1], *Lizhen Liu*[1], *Huarui Fu*[1], *Luxin Yang*[1], *Yibo Wu*[1], *Jie Sun*[1], *Weiyan Zheng*[1], *Jingsong He*[1], *Yi Zhao*[1], *Wenjun Wu*[1], *Zhen Cai*[1], *Guoqing Wei*[1], *He Huang*[1], *Jimin Shi*[1]
[1]*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China,* [2]*The First College of Clinical Medical Science, China Three Gorges University, Yichang, China*

Background: (1) Philadelphia chromosome-positive acute lymphoblastic leukemia (Ph^+ALL) is a high-risk subtype due to the BCR::ABL1 fusion gene. While tyrosine kinase inhibitors (TKIs) and allogeneic hematopoietic stem cell transplantation (allo-HSCT) have improved outcomes, relapse after transplantation remains a major issue, driven by genetic clonal evolution. This study aims to uncover the genetic mechanisms behind post-allo-HSCT relapse in Ph^+ALL, identify key driver genes and pathways using a multi-omics approach, and provide a foundation for early detection and prevention of relapse.

Methods: We retrospectively analyzed clinical data and collected bone marrow samples at various stages (diagnosis, post-transplant, and/or relapse) from 112 Ph^+ ALL patients who underwent allo-HSCT, including 44 relapsed and 68 non-relapsed cases. We used integrated cytogenetic and genomic analyses, including G-banding karyotyping and high-throughput sequencing with a 74-gene panel, to study clonal evolution. Bioinformatics tools, such as GO and KEGG pathway analyses, PPI network construction via STRING, core gene identification with Cytoscape, and miRNA–gene and transcription factor–gene network analyses, were

employed to understand clonal evolution patterns. Statistical analyses were conducted using SPSS version 25.0, with significance set at P<0.05.

Results: (1) 1. **Clonal Evolution Dynamics**: After allo-HSCT in Ph⁺ ALL, clonal architecture changed significantly. The relapse group had a higher ABL1 mutation rate than the non-relapse group (31.8% vs. 4.4%, P<0.001), with 93% being the T315I drug-resistance mutation. IKZF1 deletions were common at diagnosis (29.5%) but reduced at relapse (2.3%, P=0.001), indicating clonal replacement. 2. **Cytogenetic Subgroup Evolution**: 2.1. +der(22) Subgroup: JAK2 mutations were more frequent (14.3% vs. 1.2%, P=0.017), suggesting a link between chromosome 22 gain and JAK–STAT pathway activation. 2.2. +8 Subgroup: CDKN2B mutations were more common (16.7% vs. 1.0%, P=0.026), implicating trisomy 8 in cell-cycle control issues. 2.3. −7 Subgroup: Increased mutations in ABL1, CREBBP, and TP53 (P<0.05) suggest that chromosome 7 loss may lead to genome instability and mutational accumulation. 2.4. Complex Karyotype Subgroup: TET2 and JAK2 mutations (P<0.05) are linked to chromosomal instability and epigenetic issues. 3. **Multi-Omics Regulatory Network**: A PPI network identified 14 core genes, including TP53 and ABL1. GO and KEGG analyses showed enrichment in pathways like histone modification and p53 signaling. The T315I mutation alters interactions among ABL1, microRNAs (e.g., hsa-miR-203a-3p), and transcription factors (e.g., CREBBP), leading to abnormal pathway activation. 4. **Clinical Prognostic Associations**: ABL1 mutations are an independent risk factor for relapse post-transplant, with mutation carriers having lower complete remission (57.1% vs. 86.7%, P=0.030) and overall survival rates (26.5% vs. 73.3%, P=0.005). Patients with T315I mutations had significantly shorter survival after relapse than those without (7.6 vs. 29.2 months, P=0.001). A positive measurable residual disease (MRD) status before transplantation predicted the development of ABL1 (P=0.035) and CDKN2B (P=0.021) mutations, suggesting its role in predicting clonal evolution.

Conclusions: (1) This study identifies cytogenetically background-specific clonal evolution in post-transplant Ph⁺ ALL and elucidates ABL1 (especially T315I), TP53, JAK2 and their interaction networks as central drivers. These findings support individualized risk stratification and mutation-guided combination targeted therapy to prevent relapse.

A006

GRAFT PLATFORM AND VIRAL REACTIVATION IMPRINT LONG-TERM ALPHABETA AND GAMMADELTA T-CELL CLONAL AND TRANSCRIPTIONAL REMODELING AFTER ALLO-HSCT

Anniek Stuut[1], *Anke Janssen*[1], *Peter Brazda*[1], *Farid Keramati*[1], *Tim Hutten*[1], *Trudy Straetemans*[1], *Dennis Beringer*[1], *Zsolt Sebestyen*[1], *Julia Drylewicz*[1], *Moniek de Witte*[1], *Jurgen Kuball*[1]
[1]*University Medical Center Utrecht, Utrecht, Netherlands (the)*

Background: Immune reconstitution after allogeneic hematopoietic stem cell transplantation (allo-HSCT) is shaped by many factors, including graft composition and viral reactivations. However, how graft engineering strategies and CMV/EBV reactivation jointly govern long-term αβ and γδ T cell numerical recovery, clonal architecture, and functional polarization remains poorly understood. We investigated how graft platform (abT-cell-depleted vs T-cell-replete) and CMV/EBV reactivation shape long-term abT cell and gdT cell numerical recovery, clonal architecture, and functional programs.

Methods: We analyzed 213 adult patients, transplanted for hematologic malignancies with matched related or unrelated donors, who received either αβT cell-depleted (n=146) or T-cell-replete (n=67) grafts. Longitudinal immune phenotyping was performed for up to three years and integrated with bulk- and single-cell-T cell receptor (TCR) repertoire and transcriptomic profiling. Clonotypes were defined by CDR3 sequence identity.

Results: CMV-reactivation was associated with pronounced CD8+ abT cell expansion across both platforms. Furthermore, CMV-reactivation was associated with sustained numerical dominance of $Vd2^{neg}$ gdT cells in recipients of ab-T-cell-depleted grafts. In this cohort, $Vd2^{neg}$ gdT cells underwent early polyclonal expansion, followed by repertoire focusing, which was largely independent of CMV reactivation. In contrast, abT cells remained clonally restricted. Reduced early $Vδ2^{pos}$ γδTCR diversity was associated with subsequent EBV reactivation. Single-cell TCR profiling one year post-transplant showed marked hyperexpansion of abTCR clonotypes and a low frequency of TCR singlets in recipients of abT-cell-depleted allo-HSCT. In contrast, gdTCR repertoires showed more inter-patient than inter-platform variability. Limited donor-recipient overlap for abTCRs and $Vd2^{neg}$ gdTCRs indicated that these repertoires are largely newly generated post-transplant.
Transcriptomic analyses demonstrated predominantly effector programmes across T cell subsets one year after allo-HSCT, which were markedly different transcriptomically compared to their donors. Platform-dependent polarization was observed, with enrichment of AREG-associated tissue-repair signatures in T-cell-replete recipients and KLRC2/KLRC3-linked cytotoxic programs in αβT cell-depleted recipients.

Conclusions: Long-term T-cell reconstitution after allo-HSCT is durably imprinted by the graft platform, with viral reactivation amplifying cytotoxic lineages without fully dictating repertoire architecture, and distinct rebuilding rules for αβ and γδ lineages. Defining these platform- and virus-associated trajectories may inform immune monitoring strategies and the rational timing of post-transplant immunomodulatory therapeutic interventions.

ACCELERATING PATIENT CRITICAL TIME METRICS VIA RAPID POINT-OF-CARE MANUFACTURING OF LEUKAPHERESIS-FREE THIRD-GENERATION CD19 CAR-T CELLS

Maria Giannaki[1], *Fani Stavridou*[1], *Ioanna Vallianou*[1], *Ioulia Mavrikou*[1], *Kiriaki Paschoudi*[1,2], *Ioannis Kyriakou*[1], *Giorgos Karavalakis*[1], *Ioanna Sakellari*[1], *Evangelia Yannaki*[1], *Anastasia Papadopoulou*[1,2]
[1]*"George Papanikolaou" Hospital, Thessaloniki, Greece,* [2]*Aristotle University of Thessaloniki, Thessaloniki, Greece*

Background: CAR-T therapy has transformed the treatment of B-cell malignancies. However, the manufacturing of commercially available CAR-Ts requiring leukapheresis and centralized production is time-consuming and costly. The complex supply chain of the commercial products leads to prolongation of critical time metrics ("brain-to-vein" or "vein-to-vein" time) that limits timely patient access to treatment. Here, we aimed to develop and validate a rapid, simplified and GMP-compliant manufacturing platform of third-generation CD19-CAR-Ts from small peripheral blood volumes using G-Rex technology.

Methods: Two manufacturing protocols using a CAR-19 γ-retroviral vector(BCM, Houston) were evaluated: (a)"Expansion-in-G-Rex", involving anti-CD3/CD28 peripheral blood mononuclear cell (PBMCs) activation, transduction in plates on day 2, and transfer to G-Rex-bioreactors for expansion(day 6-9); (b)"Transduction-in-G-Rex", where activated PBMCs were transferred directly to G-Rex (day 2) for transduction and expansion. Three seeding densities (0.25, 0.5, 0.8 $\times 10^6$ cells/cm²) and two viral vector volumes (0.4, 0.75ml/cm²) were tested. Metabolic parameters guided harvest timing. Expansion, phenotype, transduction efficiency, proliferation and cytotoxicity were assessed by FCM, while specificity was evaluated by ELISPOT.

Results: The "Expansion-in-G-Rex" protocol yielded high transduction efficiency (58-81%) and expansion (26-32 fold). However, it required 2-3weeks to complete and involved multiple handlings. To overcome these limitations, we developed the "Transduction-in-G-Rex" protocol, in which both transduction and expansion were performed in G-Rex. The optimal condition (0.25×10^6 cells/cm², 0.4ml/cm² vector) enabled up to 120-fold CAR-T expansion within only 7 days, demonstrating that transduction directly in G-Rex markedly accelerates cell kinetics. GMP validation using PBMCs from one healthy donor and two DLBCL patients confirmed the method's robustness, resulting in 164±53-fold expansion within 8-9 days, producing $1.2\pm0.7\times10^9$ cells with high CAR expression (67±3%), low vector copy number (1.4±0.2), and a polyclonal CD8+/CD4+ composition (48±14%/50±14%, respectively). Phenotypically, CAR-T cells were enriched in naïve (26±7%) and memory subsets (central memory:32±5%, effector memory:33±10%), expressed high activation markers (CD69+:59±14%, CD25+:52±5%), and exhibited a favorable functional profile with increased CD27 and CD62L (68±3%, 58±10%, respectively) and low expression of exhaustion/senescence markers (PD-1^+:11±2%, CTLA-4^+:2.9±0.2%, $CD27^-/CD45RA^+/CD57^+$:6±2%). Functionally, the CAR-T-products showed robust proliferative responses upon CD3 re-stimulation compared to baseline (divided:84% vs 0%, $p<0.0001$; proliferation index:2.9 vs 0, $p=0.0004$) and strong, antigen-specific IFN-γ secretion and cytotoxicity against $CD19^+$ Raji cells compared to untransduced T cells (SFC/25,000 cells:795±51 vs 89±38, p=0,0004; % lysis Raji cells:82±2% vs 31±6%, $p<0.0001$). Activity was specific, as reactivity against $CD19^-$/K562 targets was minimal and comparable to untransduced T-cells (SFC/25,000 cells:38±12 vs 21±16, p=0.0001; %lysis: 43±7% vs 46±2%, p=0.7).

Conclusions: The "Transduction-in-G-Rex" protocol enables rapid, scalable, GMP-compliant and highly efficient CAR-T cell manufacturing from small blood volumes, requiring minimal handling, reduced viral vector input and no leukapheresis, thus addressing major cost and complexity drivers of CAR-T production. Collectively, its robustness, scalability, and ability to generate clinical-scale doses support its suitability for decentralized, point-of-care manufacturing, with the potential to considerably shorten patient time-to-treatment and improve patient access to CAR-T therapy.

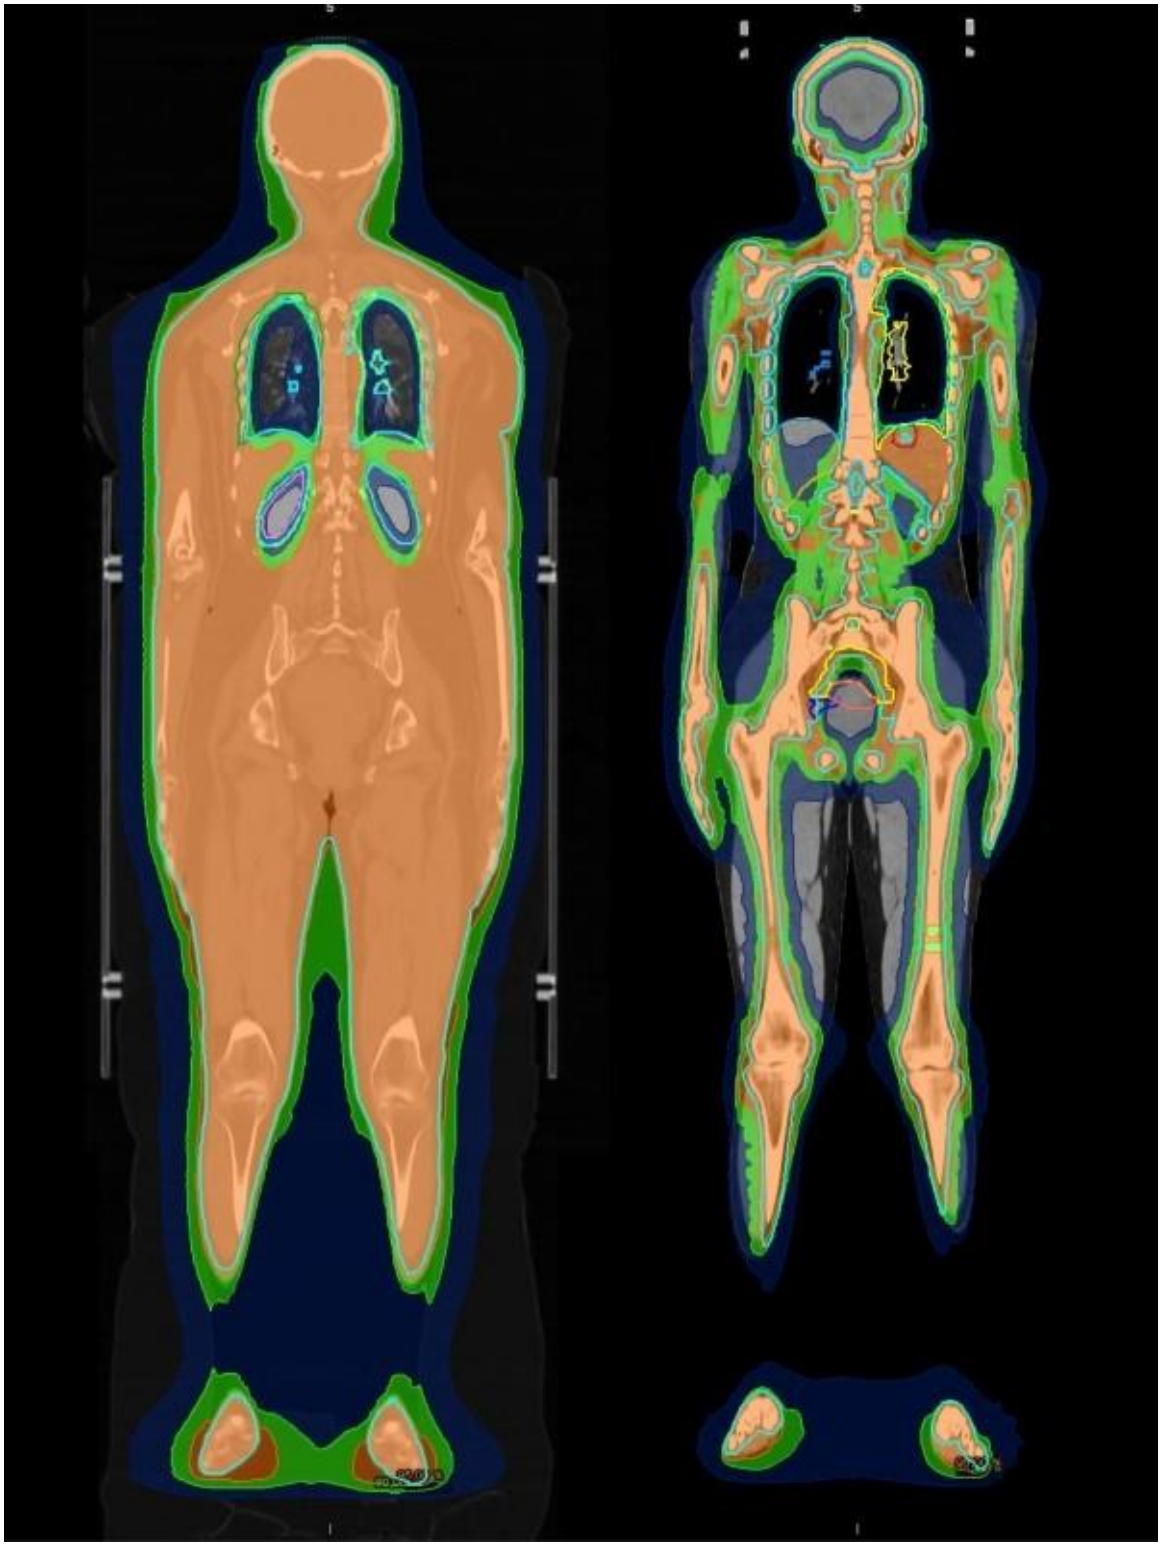
OPTIMIZING CONDITIONING REGIMENS FOR HSCT: TMLI AS AN ORGAN-SPARING ALTERNATIVE TO TBI

Alena Zverava[1], *Nadezhda Timofeenko*[1], *Denis Yastremskii*[1], *Maksim Pronin*[1], *Anatoly Uss*[1]
[1]*State Institution "Minsk Scientific and Practical Center for Surgery, Transplantology and Hematology", Minsk, Belarus*

Background: Total Body Irradiation (TBI) remains a cornerstone of myeloablative conditioning for hematopoietic stem cell transplantation (HSCT), enabling immunosuppression, eradication of residual malignancy, and creation of marrow "space." However, its broader use is limited by toxicity, damage to organs at risk (OARs), the risk of secondary malignancies, and reduced suitability for patients with comorbidities. Targeted Total Marrow and Lymphoid Irradiation (TMLI), delivered with the Radixact X9 helical tomotherapy system, offers an organ-sparing alternative by enabling precise high-dose delivery to hematopoietic and lymphoid tissues while minimizing exposure to surrounding organs. Based on a review of the current clinical landscape, we conducted this study to present our center's initial experience. The primary objective was a dosimetric comparison of TMLI and intensity modulated IM-TBI for myeloablative conditioning prior to HSCT, with the specific aim of quantitatively assessing the organ-sparing benefits of TMLI.

Methods: A dosimetric comparison was performed for 65 patients (IM-TBI: n=32; TMLI: n=33) treated between January 2024 and October 2025 using the Radixact X9 system, all planned to a total dose of 12 Gy. Dose-volume histograms (DVHs) for 16 OARs were analyzed, and mean doses and relative differences were calculated.

Results: Planning target volume (PTV) coverage was comparable between techniques (IM-TBI: 96.6% vs TMLI: 95.2%). TMLI resulted in substantial reductions in mean dose to most OARs. The most pronounced reductions (>40%) were observed in gastrointestinal structures: oral cavity (67.2%), stomach (43.9%), and rectum (45.6%). Significant sparing (25–40%) was achieved for the liver (38.2%), heart (37.0%), breasts (36.6%), larynx (36.6%), intestines (35.5%), salivary glands (31.7%), central nervous system structures (brain 26.4%, brainstem 28.9%), and urinary bladder (29.2%). Kidney dose was reduced by 22.1%. Lung doses were comparable between techniques (2.7% reduction). A modest dose increase was observed for the eyes (13.5%) and lenses (4.2%), although absolute lens doses remained within clinically acceptable limits (<3 Gy). Overall, the mean dose to critical structures was reduced by 33.7% with TMLI (6.74 Gy vs 10.17 Gy for IM-TBI).



Conclusions: This analysis confirms the superior organ-sparing capability of TMLI compared with IM-TBI, consistent with international experience. The most clinically relevant dose reductions were observed in OARs highly susceptible to acute and late toxicities (e.g., CNS, gastrointestinal tract, heart, liver), which may translate into improved conditioning safety, reduced long-term complications, and enhanced post-HSCT quality of life. Although TMLI produced a small dose increase to the eyes, the absolute values are unlikely to result in clinically significant ophthalmologic toxicity. Kidney sparing is particularly important given the potential for combined nephrotoxicity with chemotherapy. Overall, TMLI provides a more selective conditioning modality that effectively targets marrow and lymphoid tissues while optimizing protection of vital organs, potentially expanding HSCT eligibility in comorbid patients and enabling safe dose escalation in selected clinical scenarios.

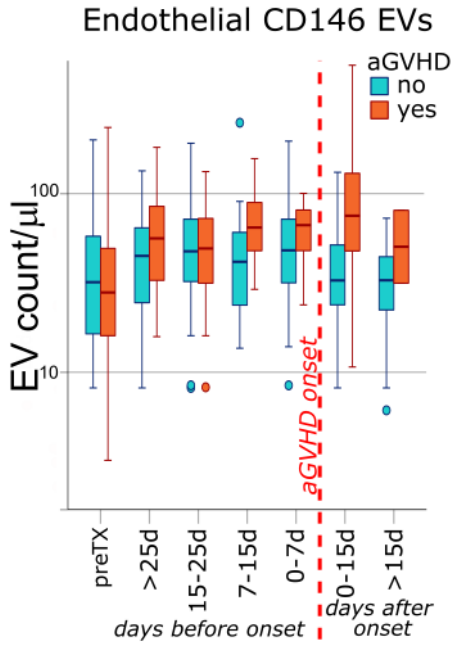
SEQUENTIAL MONITORING OF EXTRACELLULAR VESICLES UNCOVERS EARLY ENDOTHELIAL PERTURBATIONS ASSOCIATED WITH ACUTE GVHD

Giuseppe Lia[1,2], Alessia Melis[1,2], Federica Ferrando[1,2], Michele Dicataldo[1,2], Aurora Martin[1,2], Andrea Evangelista[2], Irene Dogliotti[1,2], Chiara Maria DellaCasa[2], Alessandro Busca[2], Benedetto Bruno[1,2], ***Luisa Giaccone***[1,2]
[1]Università di Torino, Torino, Italy, [2]A.O.U. Città della Salute e della Scienza di Torino, Torino, Italy*

Background: Acute Graft-versus-Host Disease (aGVHD) remains a major complication after allogeneic hematopoietic stem cell transplantation (HSCT), and the absence of reliable early biomarkers continues to hinder timely diagnosis and intervention. We investigated extracellular vesicle (EV) membrane proteins as potential biomarkers and identified a possible association between aGVHD risk and CD146 expression. CD146, a cell adhesion molecule expressed on activated endothelial cells as well as selected lymphocyte subsets and macrophages, may reflect early endothelial dysfunction. This study employed a patented polychromatic flow cytometry (PFC) protocol to characterize post-transplant EV kinetics and determine the cellular origin of $CD146^+$ EVs associated with aGVHD.

Methods: Eighty HSCT recipients were monitored longitudinally; 19 developed aGVHD (grade II: n=10; grade III–IV: n=9). Serial blood samples were obtained from pre-transplant baseline through day +180, with EV profiling performed at 0, 3, 7, 10, 14, 18, 24, 28, 35, 45, 60, 70, 80, and 90 days post-HSCT. A patented BD® PFC assay quantified and phenotyped EV populations using phalloidin-FITC, a lipophilic cationic dye, and markers CD31, CD45, CD41a, and CD146. This multiparametric approach enabled precise enumeration (via BD Trucount Absolute Counting Tubes) of leukocyte-derived (LK), platelet-derived, and endothelial cell–derived (EC) EVs, including activated $CD146^+$ subsets. Associations between EV phenotypes, evaluated as absolute counts and proportional changes from baseline, and subsequent aGVHD were analyzed using logistic regression.

Results: Platelet-derived EVs showed dynamics strongly correlated with platelet count recovery (rho = 0.75; p < 0.001), supporting the biological robustness of the analytical workflow. Total LK EVs and CD146⁺ LK EVs, although elevated relative to healthy donors, did not demonstrate significant temporal changes nor predictive value for aGVHD. In contrast, EC-derived EVs exhibited pronounced early post-transplant kinetics. A distinct rise in EC EVs, particularly the CD146⁺ subpopulation, emerged within the first two weeks after HSCT, consistent with early endothelial activation or injury. Importantly, CD146⁺ EC EV levels were significantly associated with subsequent aGVHD, both as absolute concentrations (Figure1: OR 1.11 p = 0.038) and as proportional increases over time (OR 1.094 p = 0.043). Furthermore, the ratio of CD146⁺ EC EVs to total EC EVs proved highly informative: this ratio increased well before clinical onset of aGVHD, indicating early endothelial stress. Its predictive relevance held for both absolute values (OR 1.248 p = 0.043) and dynamic changes (OR 1.183 p = 0.033). These temporal patterns support a model in which endothelial perturbation precedes the immune dysregulation that culminates in aGVHD, aligning with current mechanistic concepts of transplant-associated vascular injury.



Conclusions: This study demonstrates that endothelial-derived CD146⁺ EVs undergo early post-HSCT alterations reflective of endothelial dysfunction and correlate with later development of aGVHD. CD146⁺ EC EVs represent promising, non-invasive biomarkers capable of identifying high-risk patients before clinical symptoms emerge. A prospective validation study is ongoing, integrating expanded immunophenotyping with the MACSPlex EV platform to establish robust, clinically applicable biomarkers.

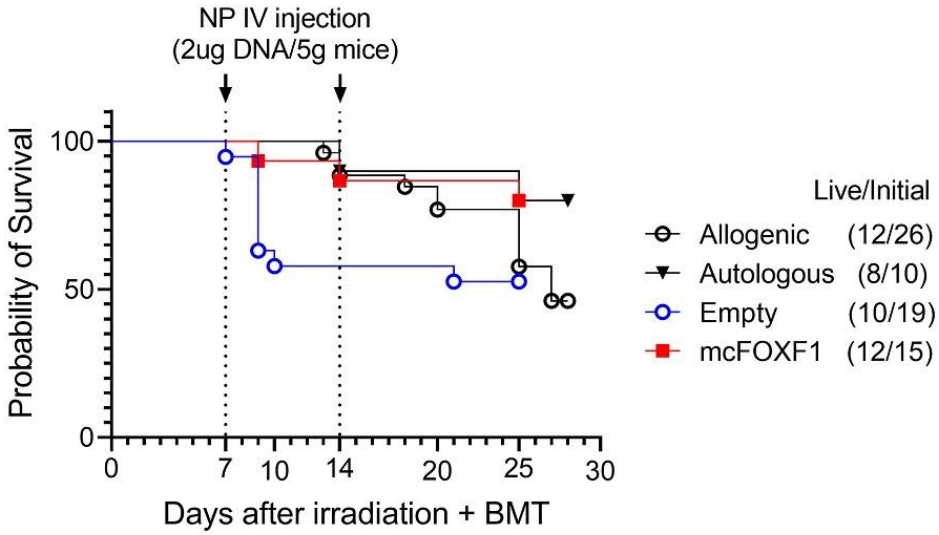
RESTORATION OF PULMONARY ENDOTHELIAL HEALTH AND OVERALL SURVIVAL *FOLLOWING ALLOGENEIC HSCT THROUGH MINICIRCLE FOXF1 MRNA NANOPARTICLE THERAPY IN JUVENILE MICE*

Clayton Long[1,2], *Ying-Wei Lan*[2], *Jonathan Do*[2], *Hana Roushdy*[2], *Xia Mai*[2], *Roberta Adams*[1,2,3], *Tanya Kalin*[1,2], *Mostafa H. Elberry*[2]
[1]*Phoenix Children's, Phoenix, United States of America (the),* [2]*University of Arizona College of Medicine, Phoenix, United States of America (the),* [3]*Mayo Clinic, Phoenix, United States of America (the)*

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is a curative therapy for many malignant and non-malignant pediatric diseases but is frequently complicated by endothelial injury. Pulmonary endothelial cells (ECs) are particularly vulnerable, contributing to severe post-transplant complications such as idiopathic pneumonia syndrome, diffuse alveolar hemorrhage, and pulmonary thrombotic microangiopathy. FOXF1 is a lung-enriched transcription factor essential for pulmonary vascular development, endothelial maintenance, and repair. Congenital FOXF1 loss leads to pulmonary hemorrhage and death in infancy. Acquired FOXF1 downregulation has been linked to acute lung injury and fibrosis. Its role in transplant-associated pulmonary endothelial injury and its therapeutic potential remains incompletely defined. We hypothesized that allogeneic HSCT induces sustained pulmonary EC loss through FOXF1 downregulation and that targeted FOXF1 restoration could rescue endothelial injury and improve survival.

Methods: Juvenile mice (postnatal day 8–10) underwent total body irradiation (13 Gy, split dose) followed by intravenous injection of 3 × 10^6 bone marrow cells. Experimental groups included syngeneic (autologous) HSCT, allogeneic HSCT (BALB/c → C57BL/6), and non-irradiated controls. Pulmonary tissue and blood were collected at days 7, 14, and 28 post-transplant. Pulmonary ECs were quantified by flow cytometry and FOXF1 expression was assessed in sorted ECs by qPCR. To evaluate therapeutic rescue, a subset of allogeneic HSCT mice received intravenous nanoparticle-mediated minicircle FOXF1 (mcFOXF1) mRNA delivery on days 7 and 14 post-transplant. The negative control included allogeneic HSCT mice injected at the same timepoints with empty minicircle (Empty) infusions not containing FOXF1mRNA. Survival, endothelial recovery, FOXF1 expression, and lung histopathology were assessed.

Results:



Allogeneic HSCT resulted in reduced survival and weight loss but full donor engraftment, consistent with systemic graft-versus-host disease. Compared with autologous and control mice, allogeneic HSCT mice demonstrated a marked and persistent reduction in pulmonary ECs at all time points, accompanied by sustained FOXF1 downregulation. In contrast, autologous HSCT mice showed transient FOXF1 suppression and EC loss with pulmonary EC recovery by day 28 and improved survival. Lung tissue from allogenic HSCT mice showed significant inflammation and alveolar destruction compared to autologous HSCT. Therapeutic delivery of mcFOXF1 significantly improved survival in allogeneic HSCT with similar survival curves as autologous models. Given comparable outcomes and shared biological interpretation, Empty and Allogeneic groups were combined into a single control group, increasing statistical power. Compared to the pooled allogenic group, mcFOXF1 nanoparticle treatment significantly reduced mortality (20% vs 51%; RR 0.39, 95% CI 0.14–1.12; $p = 0.04$). Further analysis showed that mcFOXF1 was able to restore the pulmonary EC population in conjunction with increased endogenous FOXF1 expression. Histologic evaluation showed reduced inflammatory lung remodeling with improved alveolar architecture.

Conclusions: Allogeneic HSCT induces sustained pulmonary endothelial loss associated with FOXF1 downregulation in juvenile mice compared to autologous HSCT. Transient restoration of FOXF1 using nanoparticle-delivered mRNA to pulmonary endothelial cells is sufficient to rescue the endothelial population and alveolar integrity with improvement in survival. These findings identify FOXF1 as a central regulator of transplant-associated pulmonary injury and support FOXF1 targeted therapy as a novel, endothelial-specific strategy to mitigate lung complications following HSCT.

PHARMACOLOGICAL MODULATION OF CAR30 AND CAR19 T CELL STEMNESS AND *EX VIVO* EXPANSION WITH PI3K AND CBP/P300 INHIBITION

Irene Pascual-Latorre[1,2], *Ana Carolina Caballero*[1,2], *Paula Pujol-Fernández*[1,2], *Paula Poyatos*[1,2], *Maria Guardiola-Perelló*[1,2], *Paola Jara-Bustamente*[1,2], *Alicia Sánchez-Mata*[1,2], *Alejandra Estefanía Moreira-Ramos*[1,2], *Maria de Rosa-Torres*[1,2], *Melisa Morcillo-Sánchez*[1,2], *Àngels Alcina-Milà*[1,2], *Mario Vázquez-Portero*[1,2], *Laura Escribà-Garcia*[1,2], *Javier Briones*[1,2]
[1]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain,* [2]*Institut de Recerca Sant Pau (IR SANT PAU), Barcelona, Spain*

Background: Increasing the proportion of stem memory T-cells (T_{SCM}) in CART infusion products (IP) is associated with improved clinical outcomes. The goal is to analyze the impact of Idelalisib [PI3K inhibitor (PI3Ki), that blocks differentiation] and SGC-CBP30 [inhibitor of CBP/p300 (CBP/p300i), epigenetic expansion promotor] in *ex vivo* CART anti-CD30 (CAR30T) and CART anti-CD19 (CAR19T) cultures.

Methods: T-cells from relapsed and refractory (R/R) Hodgkin Lymphoma (HL) patients were transduced with 4-1BBz-CAR30 and subjected to PI3Ki (0.5μM, 1μM), CBP/p300i (0.5μM, 1μM, 2μM) or a dual-treatment [DT, a combination of PI3Ki (0.5μM) and CBP/p300i (0.5μM)] and untreated (UT) as control. T-cells from R/R B cell non-Hodgkin Lymphoma (BNHL) were transduced with 4-1BBz-CAR19 and PI3Ki (0.5μM), CBP/p300i (0.5μM), DT and UT cultures were performed. CART cultures were performed during 10 days. CART cells composition was determined by flow cytometry. CAR30T cytotoxicity assays were performed against L540 (HL) and CAR19T against Raji (BNHL) at different effector-target ratios.

Results: PI3Ki CAR30T preserved viability and fold-expansion (UT, 15.1±4.4 vs 0.5μM,13.9±4.2; p=0.89) and augmented T_{SCM} proportion (UT vs 0.5μM: $CD4^+$ 4.0%±1.2 vs 14.3%±4.3, p<0.05; $CD8^+$ 9.2%±1.3 vs 30.7%±4.5, p<0.05); however, displayed lower antitumor effect (0.5μM and 1μM vs UT, p<0.05).
CBP30/p300i CAR30T enhanced viability (UT 64.4%±7.0; 0.5μM, 71.7%±6.4 p<0.01; 1μM, 74.3%±6.6, p<0.05) and fold-expansion (UT, 12.7±4.4 vs 0.5μM, 26.3±9.4; p<0.05). CBP/p300i preserved T_{SCM} (UT vs 0.5μM: $CD4^+$ 2.4%±1.1 vs 8.5%±3.9, p=0.072; $CD8^+$ 4.1% ±2.0 vs 14.3% ±6.8, p=0.09) and antitumor efficacy (0.5μM p=0.54; 1μM p=0.30). To enhance expansion and T_{SCM}, DT CAR30T were performed. No differences in fold-expansion was observed in DT (14.0±6.7) compared to PI3Ki (8.7±2.8 p=0.32) or UT (10.8±4.4, p=0.30); CBP/p300i remained higher (22.4±6.9 p<0.05). T_{SCM} in DT ($CD4^+$ 14.7%±3.5; $CD8^+$ 23.7%±4.5) increased similarly to PI3Ki ($CD4^+$ 14.8%±4.6, p=0.94; $CD8^+$ 25.1%±8.6, p=0.71) and exceeded UT ($CD4^+$, 4.2%±1.4, p<0.05; $CD8^+$, 7.2%±2.5, p<0.05) and CBP/p300i ($CD4^+$, 6.8%±2.3, p<0.01; $CD8^+$, 9.9%±4.5, p<0.05). DT cytotoxic capacity was similar to CBP/p300i (p=0.9) and UT (p=0.31), but higher than PI3Ki (p<0.05). CBP/p300i and DT CAR19T enhanced viability at day 6 (UT, 65.7%±3.1 vs CBP/p300i, 75.3%±4.5, p<0.05; UT vs DT 75.4%±4.6, p<0.05), but no PI3Ki (67.4%±4.5 p=0.42). On day 10, only CBP/p300i maintained viability (UT 66.0%±5.2 vs CBP/p300i 58.5%±5.5 p=0.06; UT vs PI3Ki 46.4%±6.9, p<0.05; UT vs DT 47.6%±2.04, p<0.05). CBP/p300i

increased capacity expansion (p<0.01), particularly on day 6 when cell count doubled (UT, $4.1\pm1.9x10^5$ vs CBP/p300i, $8.0\pm1.3x10^5$ p<0.05). CBP/p300i preserved T_{SCM} (UT vs CBP/p300i; $CD4^+$, 6.5%±3.1 vs 7.2%±3.0 p=0.14; $CD8^+$, 5.4%±1.8 vs 6.7%±1.8 p=0.17). Antitumor activity was maintained in CBP/p300i (p=0.15) but decreased in PI3Ki (p<0.01) and DT(p<0.05).

Conclusions: Combination of CBP/p300i and PI3Ki resulted in a CAR30T-IP with increased expansion, T_{SCM} and *in vitro* antitumor effect over single agent use. CBP/p300i resulted in a CAR19T-IP with enhanced expansion without T-cell differentiation maintaining antitumor effect. Targeted pharmacological inhibition may contribute to generate enhanced antitumor efficacy CART products.

INFLAMMATORY AND STROMAL ALTERATIONS OF THE HEMATOPOIETIC NICHE ASSOCIATED WITH POST–CAR-T CYTOPENIAS

*Martín Gómez Redondo[1,2], Sandra Muntión Olave[1,2], Silvia Preciado Pérez[1,2], Almudena Navarro Bailón[2,1], **Carmen Santos Marcos**[2,1], Ana África Martín López[2,1], Juan Flores Montero[1,2], Estefanía Pérez López[2,1], Magdalena Sierra Pacho[2,1], Marta Rodríguez González[2,1], Diego Bueno Sacristán[2,1], María Belén Vidriales Vicente[2,1], Miriam López Parra[2,1], Lucía López Corral[2,1], Almudena Cabero Martínez[2,1], Fermín Sánchez-Guijo Martín[2,1]*
[1]Instituto de Investigación Biomédica de Salamanca, Salamanca, Spain, [2]Complejo Asistencial Universitario de Salamanca, Salamanca, Spain

Background: Persistent cytopenias following CAR-T therapy are one of the most clinically relevant toxicities of this treatment. Their pathophysiology is not fully understood, but studies seem to point to a multifactorial origin involving inflammatory damage that affect HSCs and the hematopoietic niche. The aim of this study was to identify the mechanisms of inflammation and hematopoietic dysregulation and the bone marrow microenvironment associated with the development of long-term cytopenias after therapy.

Methods: This single-center study included 35 consecutive Diffuse Large B Cell Lymphoma patients treated with axicabtagene ciloleucel whom peripheral blood and bone marrow (BM) samples were taken prior to lymphodepletion and on day +28 after infusion. Plasma from both compartments was analyzed using Luminex to assess inflammatory and hematopoietic regulatory cytokines. In BM, hematopoietic capacity was evaluated using clonogenic assays (CFU-GM, BFU-E, and CFU-F), and the phenotype of the monocyte/macrophage population was characterized by flow cytometry. In addition, mesenchymal stem cells (MSCs) were isolated and expanded for studies of gene expression, DNA damage, and ROS production. Results were compared between patients with and without grade 2–4 cytopenias at day 100 after CAR-T infusion.

Results: Patients with neutropenia had a baseline inflammatory state prior to treatment, with elevated concentrations of OPN, IL18, and CXCL10 in BM plasma, and dysregulation of

the hematopoietic compartment and niche with lower levels of IL7 and ANG1. At 28 days, they have reduced concentrations of CXCL12. Treatment significantly decreased CFU-GM and BFU-E production in both groups. In BM macrophages, we observed a significant increase in CD64, associated with a proinflammatory phenotype. In MSCs, an increase in phosphorylated ATM was detected after therapy, and elevated ROS production was observed in BM mononuclear cells prior to treatment. Finally, gene expression analysis in MSCs from neutropenic patients showed increased levels of S100A9, along with higher basal expression of PPARG and lower expression of ALPL on day +28, suggesting the presence of a disbalanced pro-inflammatory stroma with an adipogenic differentiation predisposition and reduced osteogenic capacity, and therefore less favorable for hematopoietic recovery.

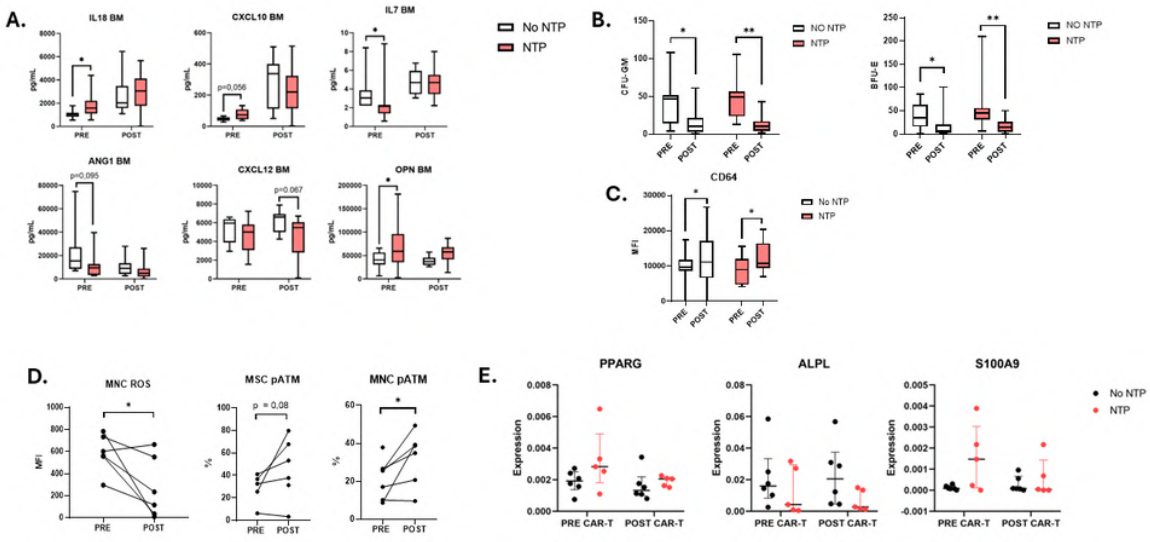

Figure 1. Multiparametric analysis of bone marrow and MSCs in patients treated with CAR-T. A. Quantification of cytokines in bone marrow plasma. B. Hematopoietic clonogenic assays (CFU-GM and BFU-E). C. Phenotyping of bone marrow macrophages by flow cytometry. D. Evaluation of oxidative stress and ATM activation in bone marrow mononuclear cells and MSCs. E. Gene expression of MSCs associated with differentiation and inflammatory response. NTP: grade 2–4 neutropenia; No NTP: absence of neutropenia.

Conclusions: Our findings suggest that post-CAR-T cytopenias develop in a microenvironment that is already altered prior to treatment, characterized by inflammation and niche dysregulation.

EVALUATION OF THE STATUS OF THE HEMATOPOIETIC NICHE PRE-LYMPHODEPLETION IN THE DEVELOPMENT OF POST–CAR-T HEMATOTOXICITY

Carmen Santos Marcos[1], *Almudena Navarro Bailón*[1], *Magdalena Sierra Pacho*[1], *Juan Alejandro Flores Montero*[1], *Diego Bueno Sacristán*[1], *Marta Rodríguez González*[1], *Ana África Martín López*[1], *Estefanía Pérez López*[1], *Almudena Cabero Martínez*[1], *Martín Gómez Redondo*[1], *Sandra Muntión Olave*[1], *Silvia Preciado Pérez*[1], *María Belén Vidriales Vicente*[1], *Miriam López Parra*[1], *Lucía López Corral*[1], *Fermín Sánchez-Guijo*[1]
[1]*IBSAL-University Hospital of Salamanca, University of Salamanca, Salamanca, Spain*

Background: Post-treatment cytopenias are among the most frequent long-term complications of chimeric antigen receptor T-cell (CAR-T) therapy. Their pathophysiology has not been fully elucidated, with inflammatory response and bone marrow hematopoietic reserve proposed as relevant factors in their development.

Methods: This study aimed to analyze the pre-CAR-T characteristics of the hematopoietic bone marrow (BM) niche, and to evaluate their correlation with the degree of cytopenias during the first 28 days after infusion.
A prospective study was conducted including 17 patients with diffuse large B-cell lymphoma treated consecutively with *axicabtagene ciloleucel* at our institution. Bone marrow aspirates and biopsies were obtained before lymphodepletion and subjected to cytomorphological, histopathological, and flow cytometric analyses to evaluate cellularity, mesenchymal stromal cells (MSC), and hematopoietic precursors. The resulting data were correlated with the presence of persistent cytopenias. Patients were stratified according to the median duration of each cytopenia during the first 28 days post-infusion (4 days for anemia, 9 days for neutropenia and 1 day for thrombocytopenia).

Results: Baseline clinical characteristics and hematological variables are summarized in Table 1. Most patients (82%) presented a low CAR-HEMATOTOX score. Cytokine release syndrome occurred in 94% (predominantly grade 1), and nearly half developed neurotoxicity. Anemia was the most common post-CAR-T cytopenia (94%), followed by thrombocytopenia (88%) and neutropenia (70%). The presence of pre-lymphodepletion anemia and thrombocytopenia was associated with persistent cytopenias during early follow-up ($p = 0.029$ and $p = 0.002$, respectively). Poorer bone marrow cellularity was observed in patients with persistent cytopenias, although the difference was not statistically significant (Figure 1A). Flow cytometry revealed significantly lower CD34+ progenitor counts ($p = 0.04$) in patients with persistent cytopenias (Figure 1B).

Table 1. Descriptive analysis of baseline characteristics and clinical variables (n=17 patients).

Variable	Results n (%)
Gender:	10 (59%) 7 (41%)

• Female • Male	
Age: • Less than or equal to 60 • Greater than 60	13 (76%) 4 (24%)
Medium number of prior lines of therapy	1 (range: 1-5)
Pre-lymphodepletion disease status: • Progression • Partial response • Complete response	9 (53%) 7 (41%) 1 (6%)
CAR-HEMATOTOX Score: • Low (0-1) • High (2 or greater)	14 (82%) 3 (18%)
Cytokine release syndrome (CRS): • Grade 1 • Grade 2 • Early (24h)	12 (75%) 4 (25%) 10 (62%)
Neurotoxicity (ICANS): • Grade 1 • Grade 3	3 (43%) 4 (57%)
Treatment of complications: • Tocilizumab • Dexamethasone • Anakinra • Siltuximab	16 (94%) 14 (88%) 2 (12%) 1 (6%)
Response on day +30: • Complete response • Partial response	13 (76%) 3 (18%) 1 (6%)

• Stable disease	

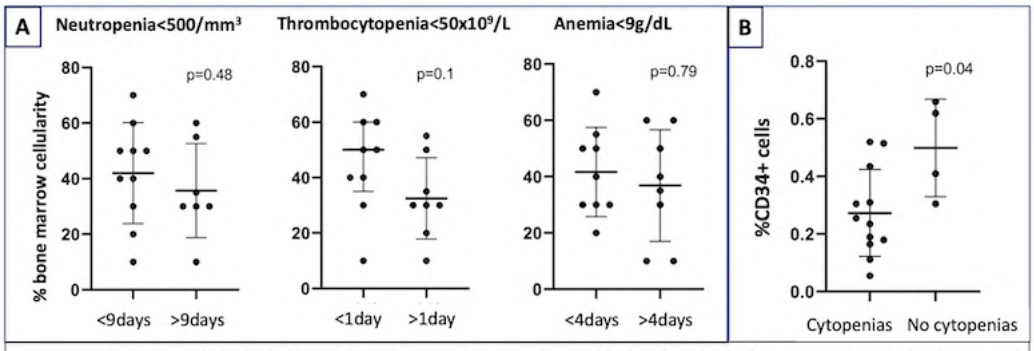

Figure 1. A. Percentage (%) of cellularity in bone marrow biopsies obtained before lymphodepletion according to the duration of cytopenias in the first 28 days after CAR-T infusion. **B.** Percentage (%) of CD34+ cells by flow cytometry in bone marrow pre-lymphodepletion according to the presence or absence of persistent cytopenias in the first 28 days.
Visually assessed by the same pathologist.

Conclusions: A decreased hematopoietic reserve pre-lymphodepletion, with the presence of peripheral blood cytopenias, lower bone marrow cellularity, and a lower number of hematopoietic progenitors, is associated with the development of persistent cytopenias after CAR-T cell therapy during the early follow-up period. The sample size of the study is being expanded and BM samples obtained on day +28 are being evaluated to further investigate the pathophysiology of these cytopenias.

CLINICAL RELEVANCE OF NON-HLA REGIONS DIFFERENCES IN ADDITION TO HLA MOLECULAR MISMATHCES BETWEEN DONOR AND RECIPIENT IN HAPLO-HSCT USING PTCY

Jairo Niño[1], Marta Fonseca[1], Pilar Terradillos-Sánchez[1], Ariadna Vicente Parra[1], Isabel Jimenez Hernaz[1], Nuria Calzada[1], Juan López-Pérez[1], Estefania Pérez[1], Almudena Navarro-Bailón[1], Fermin Sánchez-Guijo[1], Ramón García-Sanz[2], Lucía López-Corral[1], Amalia Tejeda Velarde[1], ***Francisco Javier Gil-Etayo***[1]
[1]*Hospital Universitario de Salamanca, Salamanca, Spain,* [2]*Hospital Universitario Gregorio Marañon, Madrid, Spain*

Background: Despite improvements in haploidentical hematopoietic stem cell transplantation (haplo-HSCT) using post-transplant cyclophosphamide (PTCy), outcomes remain suboptimal. Exploring genetic regions beyond HLA may enhance donor selection and transplant success.
The aim of this study was to evaluate the clinical impact of short tandem repeat (STR) disparities between donor and recipient in haplo-HSCT, and their biological relevance alongside HLA molecular mismatches and NK cell alloreactivity.

Methods: This study included 145 patients undergoing related-donor haplo-HSCT. Fifteen STR loci were analyzed using PowerPlex® 16HS (Promega). STR disparity was defined as the presence of an allele in one individual absent in the other, assessed bidirectionally and in GvH/HvG directions. HLA typing was performed via NGS and PCR-SSO, with peptide mismatch load quantified by the PIRCHE algorithm. KIR genotyping and NK alloreactivity were evaluated using missing-ligand and licensing models.

Results: Univariate analysis showed that patients with ≥10 bidirectional STR mismatches had lower relapse rates at 3 years (40% vs. 60%, HR: 0.37). >2 GvH-direction mismatches were associated with improved GRFS (HR: 0.55). Multivariate analysis confirmed ≥10 STR mismatches (HR: 0.29) and low HvG PIRCHE scores (<28) as independent predictors of reduced relapse. High DRI (HR: 2.52) and major ABO incompatibility (HR: 4.88) correlated with worse outcomes. GRFS was improved with >2 GvH STR mismatches and low HvG PIRCHE scores, but worsened with HCT-CI >3 and >2 iKIR mismatches.

Conclusions: STR and KIR mismatches contribute significantly to post-transplant outcomes in haplo-HSCT with PTCy, complementing HLA-based risk stratification. STR disparity may reflect graft-versus-leukemia (GvL) effects, suggesting its utility in donor selection alongside PIRCHE and NK models.

CD33-CAR INKT CELLS MITIGATE THE IMPACT OF ANTIGENIC HETEROGENEITY IN ACUTE MYELOID LEUKEMIA THROUGH DIRECT CYTOTOXICITY AND ACTIVATION OF CONVENTIONAL T CELLS

Sisi Wang[1], *Guangyu Zhou*[1], *Rebecca Richards*[2], *Hao Yan*[3], *Astrid Beerlage*[4], *Alejandra Gomez-Cadena*[1], *Thomas Longval*[1], *Chiara Bernardi*[1], *Amandine Pradier*[3], *Benedetta Fiordi*[1], *Chaiyaporn Boonchalermvichian*[3], *Astrid Melotti*[1], *Yara Hajj Younes*[1], *Pragallabh Purwar*[1], *Elena Sotillo*[3], *Yves Chalandon*[1], *Lukas Jeker*[5], *Camilla Jandus*[1], *Crystal Mackall*[3], *Robert Negrin*[3], *Federico Simonetta*[1]
[1]*University of Geneva, Geneva, Switzerland,* [2]*University of Wisconsin, Madison, United States of America (the),* [3]*Stanford University, Stanford, United States of America (the),* [4]*University of Pennsylvania, Philadelphia, United States of America (the),* [5]*University of Basel, Basel, Switzerland*

Background: Acute myeloid leukemia (AML) displays extensive inter- and intra-patient antigenic heterogeneity, a major limitation for CAR-based therapies. Cellular platforms capable of coupling potent direct cytotoxicity with the capacity to engage endogenous immune responses may mitigate the impact of antigenic heterogeneity. Invariant natural killer T (iNKT) cells are uniquely suited for allogeneic immunotherapy due to their lack of alloreactivity. Moreover, iNKT cells can promote cross-priming of conventional T cells (PMID: 34376537), offering a strategy to extend tumor control beyond the targeted antigen. To exploit this potential against AML, we generated CD33-directed CAR iNKT cells, we assessed their antitumor activity against CD33-expressing AML cell lines *in vitro* and *in vivo*, we tested their immunomodulatory effects in primary bone marrow samples, and their ability to address antigenic heterogeneity in a mixed tumor *in vitro* system.

Methods: Human iNKT cells were isolated from peripheral blood using the 6B11 monoclonal antibody and magnetic bead enrichment. Purified iNKT cells were activated with anti-CD3 and anti-CD28 antibodies, transduced with a second-generation CD33-CAR containing a CD28 co-stimulatory and a CD3ζ signaling domains, and subsequently restimulated and expanded with α-galactosylceramide (α-GalCer) in the presence of IL-15. Transduction efficacy was assessed by flow cytometry using protein L staining. Cytotoxicity against CD33+ AML cell lines was evaluated in vitro and in vivo in xenograft models. Primary AML bone marrow samples, obtained from AML patients at initial diagnosis, were used to assess blast killing, modulation of HLA class I/II expression on residual blasts, and activation of endogenous T cells after 48 hours of co-culture with CD33-CAR iNKT cells. Antigen heterogeneity was modelled by co-culturing CD33-expressing GFP+ and CD33-knockout (KO) mCherry+ MOLM-14 cells with CD33-CAR iNKT cells alone or in combination with conventional T cells.

Results: CD33-CAR iNKT cells were efficiently generated at high purity and with robust transduction efficacy and expansion across multiple donors. They mediated potent CD33-dependent cytotoxicity against the OCI-AML-3 and the MOLM-14 AML cell lines *in vitro* and significantly extended animal survival *in vivo* in a MOLM-14 xenograft model. In primary AML bone marrow samples, CD33-CAR iNKT cells eliminated primary AML blasts and induced upregulation of HLA class I/II molecules on residual leukemic cells. This was accompanied by activation of endogenous bone-marrow T cells, reflected by increased CD38 and HLA-DR expression, consistent with the previously reported iNKT-mediated immunomodulatory and cross-activating functions. In antigen-heterogeneous co-cultures, CD33-CAR iNKT cells alone selectively eliminated CD33-expressing MOLM-14 cells but did not control CD33-KO cells. However, when both CD33-CAR iNKT cells and conventional T cells were added to the co-culture, we observed a tumor growth inhibition of both CD33-expressing and CD33-KO MOLM-14 cells, resulting in almost 50% reduction in CD33-KO MOLM-14 expansion.

Conclusions: Our findings indicate that CD33-CAR iNKT cells not only exert potent antigen-specific cytotoxicity against AML but can also initiate conventional T cell responses, leading to an antitumor effect that goes beyond the target antigen expressing cells. Altogether, these data support the development of CAR iNKT cells as a robust allogeneic, off-the-shelf immunotherapy for AML.

HLA–KIR INTERACTIONS AS PREDICTIVE BIOMARKERS OF NK ALLOREACTIVITY IN HAPLOIDENTICAL TRANSPLANTATION WITH PTCY

Francisco Javier Gil-Etayo[1], *Jairo Niño*[1], *Rodrigo Gil-Manso*[1], *Marta Fonseca*[1], *Pilar Terradillos-Sánchez*[1], *Isabel Jiménez Hernaz*[1], *Ariadna Vicente-Parra*[1], *Nuria Calzada*[1], *Juan López-Pérez*[1], *Estefania Pérez*[1], *Sara Marcos Asensio*[1], *Monica Cabrero*[1], *Almudena Navarro-Bailón*[1], *Fermin Sánchez-Guijo*[1], *Ramón García-Sanz*[2], *Lucía López-Corral*[1], *Amalia Tejeda Velarde*[1]
[1]*Hospital Universitario de Salamanca, Salamanca, Spain,* [2]*Hospital Universitario de Gregorio Marañón, Madrid, Spain*

Background: Natural killer (NK) cell reconstitution and KIR receptor–mediated alloreactivity after allogeneic hematopoietic stem cell transplantation (HSCT) from an HLA-haploidentical donor (haplo-HSCT) have gained increasing attention due to their potential contribution to the graft-versus-leukemia (GvL) effect. However, the clinical relevance of NK alloreactivity remains controversial, particularly in unmanipulated graft strategies employing post-transplant cyclophosphamide (PTCy), where T-cell depletion is not performed.
This study aimed to evaluate the clinical impact of predicted KIR alloreactivity in haplo-HSCT with PTCy, using graft-versus-host disease and relapse-free survival (GRFS) as a composite endpoint to reflect global transplant success.

Methods: A total of 145 patients with hematological malignancies who underwent haplo-HSCT with PTCy were retrospectively analyzed. HLA typing of recipients was performed by next-generation sequencing (NGS), while donor HLA typing was performed by PCR-SSO whenever haplotype segregation within the family was available. The second-field resolution of the non-shared donor haplotype was inferred using the most frequent allele from the HaploStats database.
Donor–recipient pairs were genotyped for KIR genes using the KIR-SSO assay. NK alloreactivity was assessed according to several predictive interaction models, including the inhibitory KIR mismatch (iKIRmm), missing-ligand, and missing-licensing models. Clinical follow-up extended to 36 months post-transplant.

Results: The most common indications for transplantation were acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS), representing 52% of the cohort. Forty-eight patients (33%) had previously undergone HSCT. Reduced-intensity conditioning (RIC) was used in 72% of cases. The hematopoietic cell transplantation–comorbidity index (HCT-CI) was ≥3 in 30% of patients, and the disease risk index (DRI) was high or very high in 17%. Prediction of NK-KIR alloreactivity based on HLA–KIR interaction models revealed that the presence of multiple inhibitory KIR mismatches (iKIRmm) was significantly associated with inferior GRFS. Using the missing-ligand model, patients with multiple iKIR mismatches showed a median GRFS of 5 months compared with 25 months in the overall cohort (HR: 2.46, p = 0.001). A similar association was observed when applying the missing-licensing model (HR: 2.41, p = 0.015).
In multivariate analysis, both the missing-ligand (HR: 2.16, p = 0.008) and missing-licensing (HR: 2.27, p = 0.022) models remained independent predictors of reduced GRFS. Additionally, an HCT-CI ≥3 independently predicted inferior GRFS (HR: 1.79, p = 0.019 and HR: 1.91, p = 0.008, respectively).
These results were exponentially more pronounced in patients who received RIC and whose underlying pathology was myeloid.

Conclusions: Assessment of HLA–KIR interaction models to predict NK-KIR alloreactivity may represent a valuable approach to optimizing donor selection in haploidentical HSCT. Identifying donor–recipient combinations with unfavorable KIR interaction profiles could improve patient stratification and clinical outcomes, contributing to more personalized and immunogenetically informed transplant strategies.

EXTRACELLULAR VESICLES AS NONINVASIVE BIOMARKERS OF IMMUNE AND ENDOTHELIAL ACTIVATION IN CAR T-CELL THERAPY RECIPIENTS

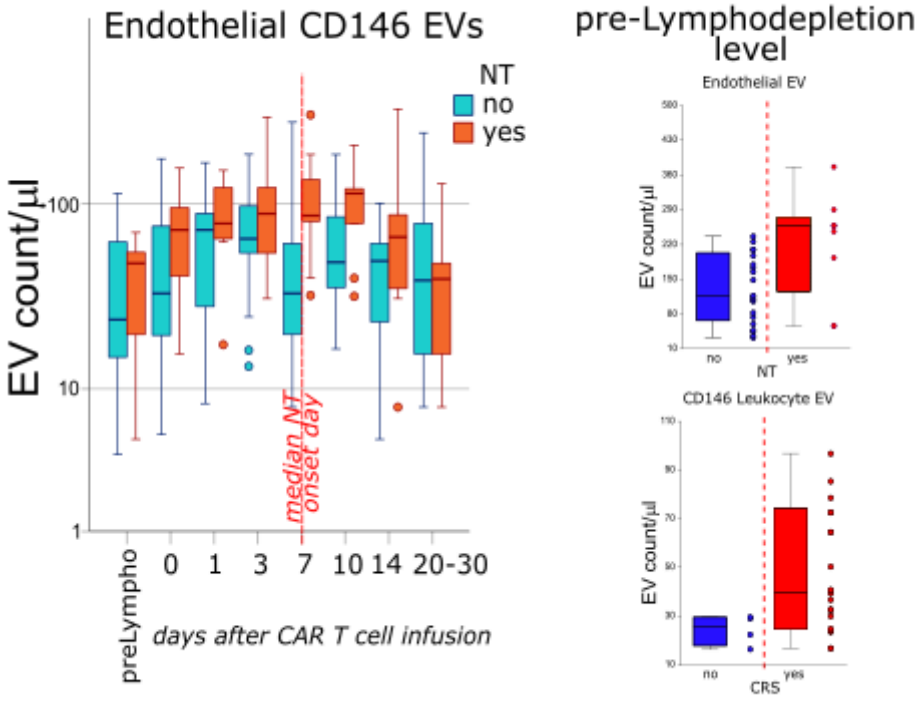
*Giuseppe Lia[1,2], Michele Dicataldo[1,2], Alessia Melis[1,2], Federica Ferrando[1,2], Irene Dogliotti[2], Alessandro Busca[2], Simone Ragaini[1], Valentino Granero[2], Barbara Botto[2], Michele Clerico[2], Mattia Novo[2], Federica Cavallo[1], **Luisa Giaccone**[1,2], Benedetto Bruno[1,2]*
[1]Università di Torino, Torino, Italy, [2]A.O.U. Città della Salute e della Scienza di Torino, Torino, Italy

Background: CAR T-cell therapy has transformed the management of hematologic malignancies, yet the development of cytokine release syndrome (CRS), neurotoxicity (NT), and prolonged cytopenias highlights the need for early and reliable biomarkers. Existing predictive tools rely on parameters that typically emerge only after toxicity becomes clinically apparent. Extracellular vesicles (EVs) have shown promise as biomarkers, but their early kinetic behavior remains insufficiently characterized. To address this gap, we employed a patented polychromatic flow cytometry (PFC) assay to evaluate whether specific EV signatures could serve as early indicators of toxicity.

Methods: Thirty patients treated with commercial CAR T-cell products [axicabtagene ciloleucel (n=21), tisagenlecleucel (n=6), or brexucabtagene autoleucel (n=3)] were enrolled. Blood samples were collected pre-lymphodepletion (pre-Lym) and at days 0, 1, 3, 7, 10, 14, and 20-30 post-infusion. Most patients (n=20) had diffuse large B-cell lymphoma; the remaining had follicular lymphoma (n=6), mantle cell lymphoma (n=3), or high-grade B-cell lymphoma (n=1). PFC enabled absolute quantification of EVs derived from leukocytes (LK), endothelial cells (EC), platelets, and activated subsets using phalloidin, LCD, and antibodies targeting CD31, CD45, CD41a, and CD146 in BD Trucount™ tubes (acquired on a BD FACSLyric). Associations between EV kinetics and toxicity were analyzed using Mann-Whitney tests (M-W), logistic regression models (LRM), and receiver operating characteristic (ROC) curve analysis, performed with STATA 15 and SPSS 25.

Results: CRS developed in 26 patients (grades 1–2), and NT occurred in 9. A key finding was the strong association between elevated pre-Lym $CD146^+$ LK EV levels and subsequent CRS onset. Their strong predictive performance (ROC 0.911) suggests these EVs may serve as sensitive pre-infusion biomarkers. Patients who developed prolonged cytopenias (n=11) also exhibited significantly higher baseline levels of total EVs, $CD146^+$ EVs, and LK EVs. Mann-Whitney testing showed that both absolute $CD146^+$ LK EV counts and their proportional increase within total LK EVs were associated with CRS ($p=0.010$ and $p=0.033$, respectively), a trend further supported by LRM (OR 1.104 $p=0.064$). Regarding NT, pre-Lym EC EVs and $CD146^+$ LK EVs were significantly higher in patients who developed NT (M-W $p=0.049$ and $p=0.040$, respectively). Notably, an increase in $CD146^+$ EC EVs preceded NT onset (median day 7), with strong statistical significance (M-W $p=0.003$; LRM OR 1.012 $p=0.044$), highlighting a dynamic endothelial activation process that temporally aligns with emerging

neurological symptoms.



Conclusions: EV profiling identified distinct immunologic and vascular signatures associated with CRS and NT, supporting their utility as real-time indicators of CAR T-mediated inflammation. This prospective analysis demonstrates that CD146⁺ EVs, particularly those derived from LK and EC compartments, are powerful, noninvasive biomarkers capable of anticipating CAR T-related toxicities before clinical onset. Elevated pre-Lym CD146⁺ LK EVs strongly predicted CRS, whereas rising CD146⁺ EC EVs distinguished patients progressing toward NT. These findings underscore the translational potential of PFC-based EV monitoring as a tool for early risk stratification and personalized management in CAR T recipients. Future analyses will expand EV profiling to include immunologic, inflammatory, and endothelial damage markers.

SHORT-TERM POST-TRANSPLANT PROTEOMICS REVEAL TEMPORAL AND DISEASE-SPECIFIC TRAJECTORIES IN MYELOID MALIGNANCIES

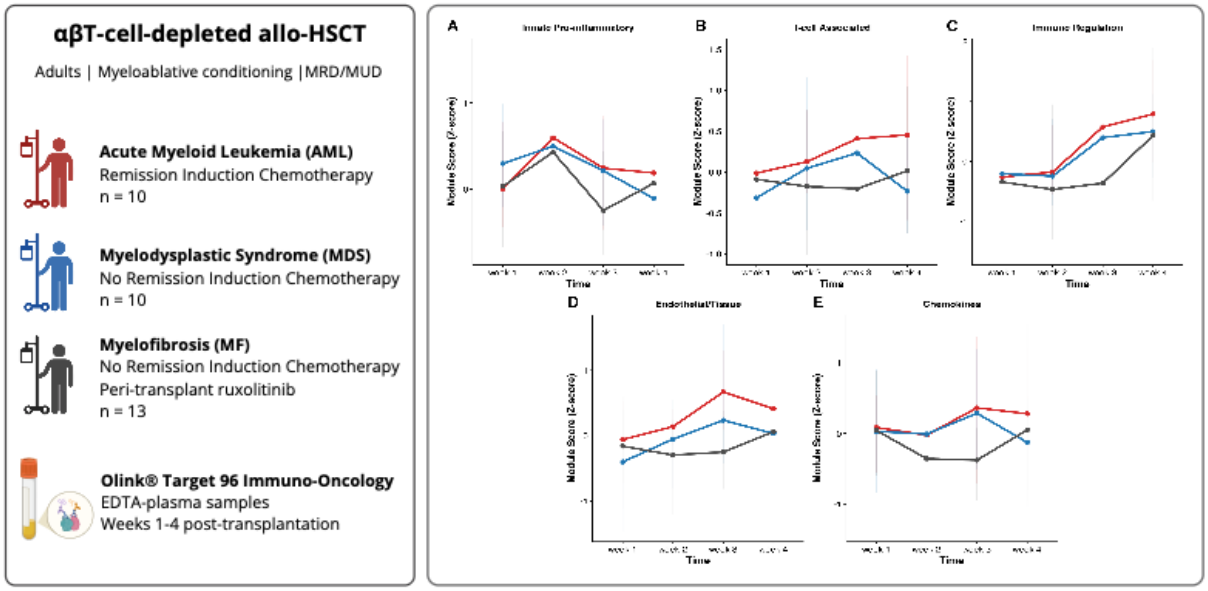
Anniek Stuut[1], *Pleun Schonewille*[1], *Coco de Koning*[1,2], *Klaartje Nijssen*[1], *Julia Drylewicz*[1], *Jurgen Kuball*[1], *Stefan Nierkens*[1,2], *Moniek de Witte*[1]
[1]*University Medical Center Utrecht, Utrecht, Netherlands (the),* [2]*Princess Máxima Center for Pediatric Oncology, Utrecht, Netherlands (the)*

Background: Allogeneic hematopoietic stem cell transplantation is the only curative treatment option for myeloid malignancies. Non-relapse mortality (NRM) remains high in myelodysplastic syndrome (MDS) and myelofibrosis (MF) but is lower in acute myeloid leukemia (AML). Peri-transplant ruxolitinib has been shown to reduce NRM in MF, suggesting that early immune events can be important drivers for later complications. We hypothesize that post-transplant immune dynamics can be initiated already before engraftment and are shaped by disease-specific host conditions. To investigate this, we profiled longitudinal changes in 92 immune-related proteins in patients with AML, MDS, and MF during the first four weeks after allogeneic transplantation.

Methods: We performed a single-center, retrospective analysis, including AML (n =10), MDS (n=10), and MF (n=13) patients who had undergone allogeneic stem cell transplantation. All patients received a myeloablative conditioning regimen and an *ex vivo* αβTCR +/- CD19-depleted allograft. MF patients received 5mg ruxolitinib twice daily from day -5 to day +14. We used the Olink® Target 96 Immuno-Oncology assay to measure 92 immune-related proteins in weekly EDTA-plasma samples (weeks 1-4 post-transplant). Using this method, protein expression was converted into normalized protein expression (NPX) units, expressed on a log2 scale. The data were corrected for batch effects before further analysis. We performed unsupervised analyses to assess global temporal and disease-associated patterns. Subsequently, based on biological function, proteins of interest were grouped into five predefined modules: pro-inflammatory cytokines, T-cell-associated cytokines, immune-regulatory proteins, endothelial/tissue injury-related proteins, and chemokines. For each module, a module score was calculated per sample by aggregating NPX values across proteins within the module (e.g., mean NPX), enabling longitudinal comparison of module trajectories across disease groups.

Results: The time point of sampling explained the largest source of variation in the PCA, suggesting that immune-related protein expression was mostly driven by the time after transplantation. Proteins driving the first principal components included pro-inflammatory cytokines (e.g. IL-6, IL-8), T-cell-associated proteins (e.g. IFN-γ, GZMB, GZMA), immune regulatory proteins (e.g. LAG-3, PD-L1), endothelial-related proteins (e.g. ANGPT1, ANGPT2), and chemokines (e.g. CX3CL1, CCL3). Module scores for these five protein groups highlighted marked time-dependent changes with distinct trajectories per disease group (Figure 1). While cytokine, immune regulation, and chemokine trajectories were similar in AML and MDS during the first three weeks post-transplantation, MDS module scores decreased in week four, diverging from AML. In contrast, module scores for all protein groups were lower in the MF group during weeks two and three but increased after week three.

Short-Term Post-Transplant Proteomics Reveal Temporal and Disease-Specific Trajectories in Myeloid Malignancies



Conclusions: Longitudinal profiling of 92 immune-related proteins indicates that early post-transplant immune dynamics are time-driven but modulated by underlying disease and peri-transplantation interventions. In MF patients treated with peri-transplant ruxolitinib, early module scores were lower but increased after week three, suggesting a transient dampening of the initial immune response. AML and MDS showed similar early trajectories that diverged at later time points. Overall, these results support the use of multiplex protein panels to capture disease-specific immune trajectories, which should be linked to clinical outcomes in future studies.

IMMUNE PROFILE AND PROTEOME OF PLASMA EXTRACELLULAR VESICLES REVEAL A MYELOID-DRIVEN SIGNATURE ASSOCIATED WITH THE RISK OF RELAPSE AFTER CD19.CAR-T CELL THERAPY

Serena De Matteis[1], *Gianluca Storci*[1], *Salvatore Nicola Bertuccio*[1], *Anna Maria Giudetti*[2], *Francesco De Felice*[3], *Beatrice Casadei*[1], *Enrico Maffini*[1], *Sadia Falcioni*[1], *Marcello Roberto*[3], *Enrica Tomassini*[1], *Gabriele Sales*[4], *Francesca Vaglio*[1], *Maria Naddeo*[1], *Irene Salamon*[1], *Daria Messelodi*[1], *Renèe Concetta Duardo*[1], *Francesco Iannotta*[1], *Elisa Bisconti*[2], *Federica Ardizzoia*[3], *Gabriele Fontana*[3], *Michele Loffredo*[1], *Elisa Dan*[1], *Barbara Sinigaglia*[1], *Pier Luigi Zinzani*[1], *Manuela Ferracin*[3], *Massimiliano Bonafè*[3], *Francesca Bonifazi*[1]
[1]*IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy,* [2]*University of Salento, Lecce, Italy,* [3]*University of Bologna, Bologna, Italy,* [4]*University of Padua, Padua, Italy*

Background: The therapeutic success obtained with immunotherapies, including chimeric antigen receptor T-cell (CAR-T) therapy, represents the results of many years of research based on the understanding of T-cell biology. However, the complex immunosuppressive tumor microenvironment poses significant challenges to their efficacy. Extracellular vesicles (EVs) have emerged as promising biomarkers in immunotherapy due to their stability in circulation, their ability to reflect the molecular state of their cells of origin, and their suitability for noninvasive liquid biopsy. This strategy aimed to characterize the immune cell subsets, transcriptional and proteomic features associated with clinical response.

Methods: This is a monocenter prospective tissue study conducted on 40 patients receiving AIFA-approved CD19.CAR-T cell products for relapsed/refractory B-cell lymphomas at IRCCS-Azienda Ospedaliero-Universitaria of Bologna. Nineteen patients were in complete response at 1-year after infusion. The others (n=21) had a disease progression during the follow-up. The study was approved by the local Ethical Committee in agreement with the Helsinki Declaration. We used a combining approach integrating multiparametric flow cytometry, single cell-transcriptomic (scRNAseq) analysis and mass spectrometry analysis of EVs. Specifically, we performed:

1. Immune profile on fresh peripheral blood mononuclear cells (PBMCs) before lymphodepletion (PLD) to day+30 after CAR-T cell therapy.
2. scRNAseq on PBMCs at CAR-T cell expansion peak (day+7) and day+90.
3. Proteomic characterization of EVs isolated from plasma by size exclusion chromatography at day+3 after infusion.

Results: Among all cell subsets analyzed, the most striking finding was the abundance of an inflammatory $CD8^+$ T cell subset (defined as $CD45RA^+CD57^+$) and polymorphonuclear (PMN)-MDSC ($CD11b^+CD14^-CD15^+HLA\text{-}DR^{-/low}CD33^+$) at PLD time point in patients who did not respond to treatment compared to those achieving a durable response. Correlation heatmaps revealed a positive association among PMN-MDSC and biochemical parameters. Specifically, PMN-MDSC positively correlated with inflammatory markers including triglycerides, ferritin,

and C-reactive protein. Consistently, the transcriptomic analysis showed an enrichment of myeloid genes attributable to MDSC signature in patients who relapsed immediately or later, in contrast with those who achieved a durable response.
Proteomic analysis of plasma EVs further underscored a clear stratification of the patient cohort according to clinical outcome. Patients achieving a durable response exhibited higher levels of peroxisome proliferation-activated receptor delta (PPARδ), a regulator of myeloid-cell immunosuppressive programs, together with increased expression of the insulin-like growth factors IGF1 and IGF2 and their binding proteins IGFBP3 and IGFBP5, pointing to a role for insulin signaling in mediating clinical benefit. In contrast, non-responders displayed markedly elevated levels of inflammatory markers, including serum amyloid A-4 (SAA4) and Orosomucoid 2 (ORM2).

Conclusions: Our data provides preliminary insights on how the interplay between inflammation, myeloid immunosuppression, and metabolic programs may critically shape clinical outcomes and inform the development of predictive biomarkers and targeted interventions.

IMPACT OF CELLULAR COMPOSITION OF LEUKAPHERESIS PRODUCT ON OVERALL NUCLEATED CELL VIABILITY AFTER CRYOPRESERVATION

Vadim Spitsyn[1], *Islam Nakastoev*[1], *Maxim Telyashov*[1], *Olga Bayteryakova*[1], *Yulia Chabayeva*[1], *Irina Galtseva*[1], *Sergey Kulikov*[1], *Tatyana Gaponova*[1]
[1]*National Medical Research Center for Hematology, Moscow, Russian Federation (the)*

Background: According to the recommendations of the European Society for Blood and Marrow Transplantation (EBMT), a key quality parameter of a cryopreserved hematopoietic stem cell (HSC) graft is the overall viability of nucleated cells (NC), which should be ≥70%. However, this integral parameter is comprised of the viability of various cell populations (neutrophils, lymphocytes, monocytes, CD34+ cells), which may have different resistance to cryopreservation.

Methods: We analyzed 75 leukapheresis products. NC viability was assessed by flow cytometry using 7-aminoactinomycin D staining. The cellular composition was determined on a hematology analyzer.

Results: It was established that different cell populations of the leukapheresis product tolerate low-temperature storage differently. Post-thaw viability parameters are presented in Table 1.

Table 1. Viability (%) of cell populations in the leukapheresis product after cryopreservation

Parameter	N	Minimum	Median	Maximum	Mean	Std Dev
NEUTR in product	75	4.00	29.60	72.50	30.74	17.40
MONO in product	75	38.10	88.30	98.30	82.75	15.52
LYMPH in product	75	26.80	86.80	99.00	83.63	13.83
CD34+ in product	75	16.30	90.70	99.50	82.86	19.43

No statistically significant associations were found between the viability of different fractions ($R^2 < 0.34$ for all pairs), indicating independent mechanisms of their cryodamage. A key finding was the direct dependence of the overall NC viability indicator on the initial neutrophil proportion: in containers with NC viability <50%, the initial neutrophil proportion exceeded 60%.

Conclusions:

1. Neutrophils are the population most vulnerable to cryogenic damage in the leukapheresis product; their mean viability does not exceed 31%.
2. The overall NC viability mandated by the EBMT may critically depend on the cellular composition of the graft. A high initial proportion of neutrophils (>60%) may cause the overall viability to fall below the 70% threshold.
3. Thus, assessment of the cellular composition and individual viability of cell populations may provide a more accurate and informative characterization of cryopreserved graft quality compared to using only the integral parameter.

Disclosure: Nothing to declare

A024

THE IMPACT OF INFUSED LYMPHOCYTES SUBSETS ON CLINICAL OUTCOMES IN MUD/HAPLO HCT SETTING WITH CD34+ POSITIVE SELECTION AND COINFUSION OF A CONTROLLED NUMBER OF CD3+

*Stefano Rossi[1], Marta Comini[2], Elena Soncini[1], **Marianna Maffeis**[1], Giulia Baresi[1], Federica Bolda[2], Stefania Fontana[2], Arnalda Lanfranchi[2], Fulvio Porta[1]*
[1]ASST Spedali Civili / Pediatric Oncohematology Unit and Pediatric Bone Marrow Transplant Center, Brescia, Italy, [2]ASST Spedali Civili / Stem Cell Laboratory, Section of Hematology and Blood Coagulation, Clinical Chemistry, Brescia, Italy

Background: The most frequent technique used for counterbalance partial incompatible HCT is CD34+ selection, mostly to minimizes GvHD, but his approach could delay immune reconstitution and increase risk of viral and fungal infection. On the other hand, the use of PBSC implies the infusion of a relevant higher number of T cells 5 to 10 times more as compared with Bone Marrow (BM). Since in our centre most part of our patients are primary immunodeficiencies, we applied a procedure to minimize the risk of severe GvHD infusing a controlled number of CD3 positive cells. More recently we have applied this approach also in the haploidentical setting.

Methods: We report on 34 HCT procedures (15 from MUD and 19 Haploidentical donor) in 33 pediatric patients (1 patient received 2 HCT) between 2021 and 2025 in the BMT Unit of the Children's Hospital of Brescia. CD34+ selection has been realized by a Milteny column with an ideal coinfusion of CD3 positive cells of $30x10^6$/Kg. We hypothesized that a different lymphocyte subset distribution in the infused product could have an impact on the incidence of GVHD and analyzed lymphocytes distribution in the infused product in patients who later developed aGVHD grade II-IV (group A) and patient who did not (group B). Mann-Whitney test was used for comparison between groups.

Results: 2-y overall survival was 92.9% for MUD compared with 85.1% for haplo. All HCT engrafted except for 2 cases of primary graft failure (2 patients transplanted for TBD) in the haplo group; these patients were excluded from the analysis on GVHD incidence. 3/15 (20.0%) patients experienced aGVHD grade II-IV in the MUD group in contrast to 5/17 (29.4%) in the haplo group. 1/15 (6.7%) and 2/17 (11.8) developed cGVHD in the MUD and haplo groups, respectively.
The median number of infused CD3+ TCR a/b cells was 27.2*10^6/Kg for the MUD group and 27.5*10^6/Kg for the haplo group. No differences were found in the distribution of lymphocytes subsets in patients who later developed aGVHD grade II-IV. In particular median numbers (*10^6/ Kg R) of infused cells for group A and B were: CD4+ 13.8 vs 17.7 (p 0.34), CD8+ 10.0 VS 9.8 (P 0.30); CD20+ 5.5 vs 6.1 (p 0.72); CD56+CD16+ 1.5 vs 2.1 (p 0.62). No difference was observed in the percentage of CD45RA+ and CD45RO+ (% of infused CD3+) that were 54.3 vs 58.0 and 45.7 vs 42.1 respectively, or in the percentage of γδ T cells (4 vs 2.8).

Conclusions: Our results show that MUD and Haploidentical donor guarantee a similar follow up, with similar control of severity of GvHD, with only few children with limited chronic GvHD. The method allows to graft primary immunodeficiencies patients while limiting the

number of infused CD3+ cells. Moreover, our data, though on a limited number of patients, show that differences in lymphocyte subset distribution on the infused graft do not have an impact on the incidence of GVHD. More extensive analysis are needed to determine the optimal number of CD3+ in different settings of HCT.

Disclosure: Nothing to declare.

A025

RELEVANCE OF HLA-B LEADER DIMORPHISM AND MOLECULAR COMPATIBILITY IN HAPLOIDENTICAL HSCT WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE: EXPERIENCE OF A SPANISH COHORT

Francisco Javier Gil-Etayo[1], *Rodrigo Gil-Manso*[1], *Marta Fonseca*[1], *Pilar Terradillos-Sánchez*[1], *Isabel Jiménez-Hernaz*[1], *Ariadna Vicente-Parra*[1], *Nuria Calzada*[1], *Juan López-Pérez*[1], *Estefania Pérez*[1], *Sara Marcos Asensio*[1], *Monica Cabrero*[1], *Almudena Navarro-Bailón*[1], *Fermin Sánchez-Guijo*[1], *Ramón García-Sanz*[2], *Lucía López-Corral*[1], *Amalia Tejeda Velarde*[1]
[1]*Hospital Universitario de Salamanca, Salamanca, Spain,* [2]*Hospital Universitario Gregorio Marañon, Madrid, Spain*

Background: The shortage of fully HLA-matched donors for hematopoietic stem cell transplantation (HSCT) has driven the expansion of alternative donor strategies, notably haploidentical HSCT (haplo-HSCT) using post-transplant cyclophosphamide (PTCy). This approach has significantly improved the feasibility and safety of transplantation by mitigating the detrimental effects of HLA mismatches. However, the immunological criteria for selecting the most suitable donor remain a matter of debate, particularly regarding the contribution of molecular HLA compatibility and the influence of HLA-B leader dimorphism on transplant outcomes.
The present study aimed to evaluate the immunogenic impact of HLA mismatches and the role of HLA-B leader dimorphism in haplo-HSCT with PTCy, focusing on their association with chronic graft-versus-host disease (cGvHD) and graft-versus-host disease–free/relapse-free survival (GRFS).

Methods: A retrospective single-center analysis was conducted on a cohort of 190 patients who underwent haplo-HSCT and their respective donors. High-resolution typing of HLA-A, -B, -C, -DRB1, -DQB1, and -DPB1 loci was performed using PCR-SSOP and/or next-generation sequencing (NGS) methodologies. The degree of HLA compatibility was assessed using the Predicted Indirectly Recognizable HLA Epitopes (PIRCHE) algorithm, expressed as the PIRCHE Score (PS). Additionally, HLA-B leader dimorphism and matching were determined through BLEAT and IPD-IMGT/HLA databases.

Results: The median age of the patients was 57 years, with 56% being male. The predominant indications for transplantation were acute myeloid leukemia and myelodysplastic syndromes, accounting for 52% of the cases. The median follow-up period was 36 months.
Receiver Operating Characteristic (ROC) curve analysis demonstrated that patients with a

PIRCHE Score for HLA-B (PS-B) greater than 1 showed a higher incidence of cGvHD (hazard ratio [HR]: 1.81, p = 0.038). A similar trend was observed in cases with HLA-B leader mismatching (HR: 1.69, p = 0.065) and when the TM dimorphism was present in the recipient's HLA-B leader (HR: 2.21, p = 0.021). Both variables remained independent risk factors for cGvHD in multivariate analysis.
Furthermore, patients with a total PIRCHE Score (PS) exceeding 49, as defined by ROC curve cut-off, presented a significantly reduced GRFS (HR: 2.01, p < 0.001). Comparable results were obtained for patients with a hematopoietic cell transplantation-comorbidity index (HCT-CI) ≥ 3 (HR: 1.85, p = 0.004) and for donor–recipient combinations characterized by the HLA-B leader MTM variant (HR: 2.16, p = 0.029). In the multivariate model, both the PIRCHE algorithm–derived score and the HLA-B leader matching status were identified as independent predictors of inferior GRFS.

Conclusions: In conclusion, this study highlights the potential clinical relevance of molecular HLA compatibility parameters in haploidentical HSCT with PTCy. The integration of PIRCHE-based assessments and HLA-B leader dimorphism analysis may enhance donor selection strategies by identifying patients at increased risk of developing cGvHD or experiencing reduced GRFS. These molecular markers could serve as valuable prognostic tools, contributing to more precise immunogenetic matching and improved transplant outcomes in the context of haploidentical transplantation.

GENERATION OF CHIMERIC ANTIGEN RECEPTORS AGAINST MURINE CD123 ALLOWS BIOLOGIC ASSESSMENTS IN IMMUNOLOGICALLY COHERENT IN VIVO SYSTEMS

Martin Sauer[1], *Franziska Baatz*[2], *Jessica Herbst*[1], *Axel Schambach*[1], *Tobias Mätzig*[1], *Hust Michael*[3]
[1]*Pediatric Hematology and Oncology, Medizinische Hochschule Hannover, Hannover, Germany,* [2]*Pediatric Hematology and Oncolopgy, Medizinische Hochschule Hannover, Hannover, Germany,* [3]*Department of Biotechnology, Technical University of Braunschweig, Braunschweig, Germany*

Background: The remarkable early success of CD19-directed CAR T cells in humans reduced the perceived need for detailed mechanistic studies in murine systems. However, emerging limitations now raise critical questions that cannot be adequately addressed in humans or humanized mouse models. To overcome this, we generated CARs targeting murine CD123 (mCD123), an AML-associated antigen, enabling in vivo studies within an immunologically coherent system.

Methods: Antibody selection was performed via phage display. A synthetic murine CD123 peptide, designed from genetic sequence data, was immobilized on high-binding 96-well plates. Additionally, 4 µg of recombinant murine CD123 with a human Fc tag in PBS was

coated onto 96-well plates. Before exposure to the coated wells, HAL9/10 libraries (5×10^{10} phage particles) were preincubated with 4 µg of an unrelated human Fc–tagged protein to deplete Fc-binding phage. The supernatant was then transferred to antigen-coated wells, and bound phage were eluted for subsequent panning rounds. Eluted phage were transferred to 96-deep-well plates for infection, followed by centrifugation and resuspension of the pellets. Three rounds of panning were completed. After the third round, single-clone plates were screened via ELISA. Soluble scFv fragments were produced in 96-well polypropylene MTPs, and supernatants containing monoclonal scFvs were applied to CD123-coated plates. Binding was detected using murine mAb 9E10, which recognizes the C-terminal c-myc tag.

Results: Binders were screened against the murine $CD123^{+}$ myeloid leukemia cell line C1498-mCD123-GFP (Figure 1A). Three candidates—SH1836b-C2, -A11, and -A8—were selected and cloned into a murine second-generation CAR backbone containing a CD28 co-stimulatory domain, a CD3ζ signaling domain, and a single functional ITAM, termed im12328z1 (Figure 1B). CAR expression was regulated by a tetracycline-inducible (Tet-on) T11 promoter and linked to an IRES-driven dTomato (iTom) reporter. Despite sharing an identical backbone, the resulting CARs exhibited distinct functional profiles. im12328z1-A11 showed the highest expression levels (Figure 1C). When stimulated in vitro with mCD123-expressing target cells, im12328z1-A11–transduced murine primary T cells displayed stronger antigen-specific activation compared with SH1836b-C2 and -A8 (Figure 1D). In NFAT reporter cells expressing a GFP-based inducible system, im12328z1-A11 triggered the strongest antigen-dependent response with minimal tonic signaling (Figure 1E). im12328z1-A11 also mediated potent antigen-dependent cytotoxicity against C1498-mCD123 cells in vitro (Figure 2H). In vivo, co-transfer of im12328z1-transduced murine primary T cells rescued syngeneic hematopoietic stem cell recipients from a lethal dose of mCD123-expressing leukemia.

Conclusions: Antigen-display is a powerful approach for generating CARs against non-human antigens with human equivalents, enabling thorough evaluation of their biological properties in vivo. Early identification of limitations or unexpected toxicities in such models may significantly inform and improve the design of future human CAR T-cell trials.

THE RATIO THAT MATTERS - HOW CD4:CD8 BALANCE SHAPES CAR T-CELL EFFICACY AND SAFETY

Bastian Zinkel[1,2,3], *Sara Gamali*[1,2,3], *Tea Gogishvili*[4], *Marc-Aurele Brun*[5], *Andreas Mackensen*[1,2,3], *Gloria Lutzny-Geier*[1,2,3], *Michael Aigner*[1,2,3]
[1]*Universitätsklinikum Erlangen, Erlangen, Germany,* [2]*Deutsches Zentrum Immuntherapie (DZI), Erlangen, Germany,* [3]*Bayrisches Zentrum für Krebsforschung (BZKF), Erlangen, Germany,* [4]*Sony Biotechnology Europe, Sony Europe B.V, Weybridge, United Kingdom of Great Britain and Northern Ireland (the),* [5]*Sony Corporation, Tokyo, Japan*

Background: The growing number of CAR T-cell therapies reported to the EBMT Registry highlights the expanding clinical relevance of this modality. Alongside its therapeutic success, cytokine release syndrome (CRS) remains key treatment-limiting toxicity. Emerging evidence indicates that the CD4:CD8 composition of CAR-T products may influence both therapeutic responses and toxicity profiles. Therefore, we systematically evaluated defined CD4:CD8 CAR-T cell ratios to explore their potential impact on functional behavior and cytokine profiles, as well as the use of new manufacturing technologies that would make such strategy viable in a GMP setting.

Methods: To assess the impact of CD4:CD8 CAR T-cell composition on cytokine secretion, target-cell killing and cytotoxicity profiles, defined CAR T-cell ratios were co-cultured with tumor cell lines. Functional analyses included flow-cytometric characterization of CAR T-cell differentiation, viability and activation profile, as well as multiplex cytokine secretion analyses, and exploratory cytotoxicity in short term cultures. To demonstrate the feasibility in a closed GMP manufacturing workflow, CAR T-cells were generated from PBMCs of healthy donors and subsequently sorted into defined CD4:CD8 ratios using a fully GMP compatible Sony CGX10 Cell Isolation System.

Results: Across CD4:CD8 CAR T-cell ratios ranging from 1:10 to 10:1, no significant differences were observed in CAR T-cell viability or survival after tumor cell contact. In contrast, tumor-cell apoptosis increased in a CD8-dependent manner, with higher proportions of $CD8^+$ CAR T-cells producing correspondingly higher apoptotic indices, and the inverse pattern observed for CD4-enriched ratios. Phenotypic analysis showed that expression of activation (CD25) and exhaustion markers (PD-1, TIM-3, LAG-3) remained comparable across all tested ratios. However, cytokine secretion profiles differed markedly. Increasing the proportion of $CD8^+$ CAR T-cells was associated with elevated secretion of Perforin and Granzyme-B, consistent with FACS data showing enhanced tumor-cell killing in CD8-enriched ratios. Rising proportions of $CD4^+$ CAR T-cells were associated with elevated release of multiple inflammatory cytokines. Finally, clinical scale apheresis products and CAR T-cell products were successfully sorted to defined CD4:CD8 ratios in a closed system utilizing the Sony CGX10, further allowing for the addition of stemness markers in the definition of the sorted cell populations.

Conclusions: Overall, our findings demonstrate that CD4:CD8 CAR T-cell composition is a critical determinant of functional activity and inflammatory potential. CD8-enriched ratios enhanced tumor-cell killing, whereas CD4-enriched ratios markedly amplified cytokine release profiles associated with severe immune toxicities. Although these ratios had minimal impact on CAR T-cell intrinsic phenotype, they shaped effector function and inflammatory output, suggesting that CD4:CD8 composition could serve as a potential parameter to consider when aiming to minimizing CRS-related risks. The Sony CGX10 Cell Isolation System offers a solution that supports translation of this approach while providing fully GMP compliant conditions. Using this setup, additional refinement of CAR T-cell products by definition and isolation of desirable subpopulations (e.g., CAR+, naïve, Tscm, non-exhausted) is feasible and can be explored further at clinical scale.

TRANSFORMING CAR-T ACCESSIBILITY: A PATHWAY TO AFFORDABLE CELL THERAPY FOR B-CELL MALIGNANCIES IN INDIA AND OTHER LMICS

Anupam Chhabra[1], *Neeraj Gupta*[2], *Boro Dropulić*[3], *Mike Kadan*[3], *Shashi Koduru*[3], *Indraneel Ghosh*[3], *Aadhar Gupta*[2], *Ravindra Rathi*[1], *Sumit Wadhwa*[1]
[1]*Cartogene Therapeutics, Gurgaon, India,* [2]*Genes2me, Gurgaon, India,* [3]*Vector BioMed, Gaithersburg, United States of America (the)*

Background: CAR-T cell therapy has transformed outcomes for relapsed or refractory B-cell malignancies, yet access in low- and middle-income countries (LMICs) remains extremely limited due to high costs, complex manufacturing requirements, and long vein-to-vein timelines. Cartogene Therapeutics aims to address this gap by in-licensing CGT19, a validated CD19 CAR-T construct from Vector BioMed, USA, and establishing a cost-efficient, scalable manufacturing platform in India. CGT19 is a third-generation construct incorporating FMC63 variable regions, CD8 hinge and transmembrane domains, a 4-1BB co-stimulatory domain, and a CD3ζ activation domain, designed to enhance persistence and cytotoxic activity. Preclinical evidence supports its suitability for deployment in resource-constrained regions.

Methods: Vector BioMed conducted in-vitro and in-vivo studies to characterize CGT19. Human T cells were transduced with a lentiviral vector encoding the CGT19 CAR, and assessed for transduction efficiency, vector copy number (VCN), phenotype, and CD19-specific tumor killing. In-vivo antitumor activity was evaluated in CD19-positive xenograft mouse models using serial bioluminescence imaging.
To translate CGT19 into an affordable therapeutic option for India, Cartogene Therapeutics will implement a rapid 7-day manufacturing platform adapted for LMIC settings. T-cell enrichment is performed using a proprietary negative selection method (IsoPure™), followed by Day-0 transduction on the Sepax C-Pro Cell Processing System. Expansion occurs in G-Rex 100M devices to ensure consistent yield with minimal manual handling. Final steps include harvest, wash, formulation, and cryopreservation, with release testing performed for Safety, Purity, Identity, and Potency (SPIP). The process is designed to reduce dependency on complex infrastructure, lower production costs, and support high operational reliability.

Results: In-vitro studies demonstrated high transduction efficiency, generating approximately 70% CAR-expressing T cells with a VCN of ~3. CGT19 exhibited potent CD19-specific cytotoxicity in tumor-killing assays. In xenograft models, CAR-T–treated mice achieved complete tumor clearance, with no detectable bioluminescent signal by Day 55 post-engraftment, confirming strong and durable antitumor activity.
The 7-day manufacturing platform offers major advantages for LMIC application. The substantially shortened production cycle enables a vein-to-vein time up to three-fold faster than many global commercial CAR-T products. Process automation and standardized expansion enhance reproducibility and reduce operator-dependent variability. Importantly, the streamlined workflow enables an estimated throughput of approximately 700 therapies per year, significantly increasing treatment accessibility in India. This high throughput,

combined with a reduced cost base, is expected to support broader patient access while maintaining clinical efficacy comparable to international reference products.

Conclusions: CGT19, supported by strong preclinical activity and a rapid, scalable 7-day manufacturing platform, represents a practical and affordable pathway to expand CAR-T access in India and other LMICs. By integrating a validated CD19 CAR construct with a high-throughput, resource-appropriate production system capable of delivering up to 700 therapies annually, Cartogene Therapeutics aims to reduce the global CAR-T access gap and establish a reproducible model for deploying advanced cell therapies in resource-limited healthcare settings.

COMPARATIVE IN VITRO EXPANSION OF REGULATORY T CELLS FROM CORD BLOOD AND MOBILIZED PERIPHERAL BLOOD STEM CELLS WITH RAPAMYCIN

Mona Tajrishi[1], Saeed Abroun[1], Saeed Mohammadi[2], Mohammad Ahmadvand[2], Mohammad Vaezi[2], Mahin Nikougoftar Zarif[3], Mohammadreza Ostadali[2], ***BibiShahin Shamsian***[4]
[1]Department of Hematology, Faculty of Medical Sciences, Tarbiat Modares University, Tehran, Iran (Islamic Republic of), [2]Cell Therapy and Hematopoietic Stem Cell Transplantation Research Center, Research Institute for Oncology, Hematology and Cell Therapy, Tehran University of Medical Sciences, Tehran, Iran (Islamic Republic of), [3]Center for Hematology and Regenerative Medicine, Karolinska Institutet, Department of Medicine, Karolinska University Hospital Huddinge, Stockholm, Sweden, [4]Shahid Beheshti University of Medical, Tehran, Iran (Islamic Republic of)

Background: Regulatory T cell (Treg)–based cellular therapies require reliable ex vivo expansion strategies; however, the comparative stability and functional quality of umbilical cord blood–derived (UCB) versus mobilized peripheral blood stem cell–derived Tregs (mPBSC), particularly under rapamycin-based conditions, remain incompletely defined.

Methods: $CD4^+CD25^+$ regulatory T cells were isolated from mobilized peripheral blood stem cells (mPBSC) and umbilical cord blood (CB) units (n=10; 5 mPBSC and 5 CB). Cells were expanded for 14 days with anti-CD3/anti-CD28 stimulation, IL-2 (1000 IU/mL), and with or without rapamycin (100 nM). Expansion rate, purity, viability, and suppressive function were assessed. Phenotypic and stability profiling included CD45RA/RO, FoxP3, CD69, CD27, PD-1, and TIM-3. FOXP3 TSDR methylation was evaluated as a marker of lineage stability. All parameters were compared between sources and culture conditions.

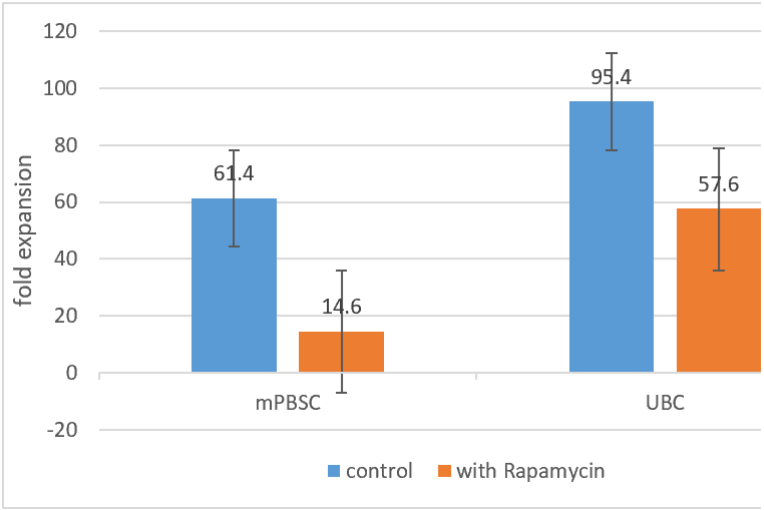
Results: CB-Tregs demonstrated higher post-expansion purity (94.8 ± 0.2% vs. 91.7 ± 0.3%) and significantly greater fold expansion (57.6 ± 19.8-fold vs. 14.6 ± 3.2-fold) compared with mPBSC-Tregs, particularly in the presence of rapamycin (Figure 1). The

characteristics of expanded Tregs derived from umbilical cord blood (CB) and mobilized peripheral blood stem cells (mPBSC) are summarized in Table 1. Cell viability after expansion was comparable between the two sources (98.5 ± 1.0% vs. 98.5 ± 0.6%). Phenotypic analysis showed that CB-Tregs predominantly expressed CD45RA, whereas mPBSC-Tregs exhibited increased CD45RO expression. CD69 expression was lower in CB-Tregs, while CD27 expression was higher compared with mPBSC-Tregs. PD-1 and TIM-3 expression levels were higher in mPBSC-Tregs and reduced in CB-Tregs expanded with rapamycin. Suppression assays demonstrated higher suppressive activity in CB-Tregs compared with mPBSC-Tregs. Analysis of FOXP3 methylation revealed an unmethylated pattern at the analyzed loci in CB-Tregs (n = 5), whereas among mPBSC-derived Treg products, methylation was detected in 2 of 5 samples and was not detected in the remaining 3 samples.

Table 1. Characteristics of Tregs expanded from mPBSC& UCB sources

	MPBSC (MEAN±sd)		UCB (MEAN±sd)	
	control	with Rapa	control	With Rapa
Absolute Treg yields(×103/μl)	6140±4719	1460±320	9540±2037	5760±1980
Fold expansion	61.4±47.1	14.6±3.2	95.4±20.3	57.6±19.8
Purity(%)	88.8±0.5	91.7±0.3	93.7±0.5	94.8±0.2
Viability (%)	98.6 ± 0.5	98.5±1.0	99.2 ± 0.4	98.5±0.6

Figure 1. Fold expansion difference of Treg derived from mPBSC and UBC in the presence and absence of rapamycin



Conclusions: In this study, our findings suggest that CB-Tregs represent a more stable and reliable source for ex vivo expansion, demonstrating superior proliferative capacity, phenotypic preservation, suppressive function, and epigenetic stability compared with mPBSC-Tregs. The reduced stability and function observed in mPBSC-Tregs may be partly influenced by the cytokine-rich inflammatory environment generated during G-CSF mobilization, which can transiently activate peripheral T cells and potentially predispose them to exhaustion or diminished regulatory stability. Together, these observations support the potential superiority of CB-Tregs for future clinical applications, particularly in the prevention of GVHD.

THE INFLUENCE OF LUSPATERCEPT ON BONE MARROW MESENCHYMAL STROMAL CELLS IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR PATIENTS WITH MYELODYSPLASTIC NEOPLASMS AND ACUTE MYELOID LEUKEMIA

Nikolai Tsvetkov[1], *Ksenia Tsvirko*[1], *Polina Polishchuk*[1], *Valeriia Laushkina*[1], *Artem Ivanov*[1], *Alena Shakirova*[1], *Kirill Lepik*[1], *Tatiana Rudakova*[1], *Elena Morozova*[1], *Ivan Moiseev*[1], *Alexander Kulagin*[1]
[1]*RM Gorbacheva Research Institute, Pavlov University, St. Petersburg, Russian Federation (the)*

Background: Myelodysplastic neoplasms (MDS) and acute myeloid leukemia (AML) are the most common indications for allogeneic hematopoietic stem cell transplantation (HSCT) in adult patients. Problems related to poor graft function and rejection are linked to the altered mesenchymal stromal cells (MSCs). Different genes are involved in this process encoding both soluble and cell surface proteins. Secreted factors include key hematopoietic cytokines thrombopoietin (THPO) and stem cell factor (KITLG) along with main stem cell homing chemokine CXCL12. Cell-cell and cell-matrix contacts are highly dependent on adhesion molecules like integrins (ITGB1), cadherins (CDH2), and immunoglobulin superfamily members (VCAM1). The drug luspatercept has demonstrated efficacy for anemia treatment in patients with MDS, affecting also the ability of MSCs to support normal hematopoiesis. It is assumed that these effects could be translated to the post-transplant period.

Methods: The study included 23 patients (11 men and 12 women) with established diagnoses of AML (n=8) and MDS (n=15). The median age was 52 years (19-65). The median time from diagnosis to HSCT was 303 days (73-5342). The median post-HSCT follow-up time was 476 days (79-855). MSCs were isolated from patients' bone marrow at two time points: before HSCT (median 17 days (7-38)) and after HSCT (median 57 days (20-101)). At both time points MSCs were cultured in duplicate: an experimental sample with luspatercept and a control sample without luspatercept. Quantitative PCR was performed to

assess the mRNA expression levels of the genes ITGB1, KITLG, CDH2, VCAM1, THPO, and CXCL12.

Results: When comparing gene expression levels before HSCT, an increase in the expression of ITGB1 ($p<0.02$), KITLG ($p<0.02$), VCAM1 ($p<0.03$), and CXCL12 ($p<0.007$) genes was revealed in the luspatercept group compared to the control. When comparing gene expression levels after HSCT, an increase in the expression of ITGB1 ($p<0.001$), KITLG ($p<0.001$), CDH2 ($p<0.003$), VCAM1 ($p<0.002$), THPO ($p<0.003$), and CXCL12 ($p<0.002$) genes was found in the luspatercept group compared to the control. When comparing control samples from the time points before and after HSCT, the expression level was significantly increased for the ITGB1 ($p<0.002$), KITLG ($p<0.001$), CDH2 ($p<0.02$), and VCAM1 ($p<0.001$) genes post-HSCT compared to pre-HSCT. When comparing samples with luspatercept from the time points before and after HSCT, the expression level was significantly increased for the KITLG gene ($p<0.05$) post-HSCT compared to pre-HSCT. No significant correlation was found between the expression of the studied genes and the time to blood count recovery or the number of transfusions after HSCT. No cases of graft failure were observed, and the incidence of severe poor graft function (the need for red blood cell and/or platelet transfusions after engraftment) was 61% (38-77) at 1 year after HSCT. In univariate proportional hazard model we found no significant association between gene expression levels and overall or progression-free survival.

Conclusions: The obtained in vitro data indicate the ability of luspatercept to enhance the expression of genes responsible for hematopoietic support in bone marrow MSCs of patients with MDS and AML. Further studies are needed to confirm these results and determine the clinical significance of luspatercept use after HSCT.

Disclosure: Authors declare no conflict of interest.
The study was supported by the grant from the Foundation for Cancer Research Support (RakFond, Competition of Research Projects in Oncology 2022-01).

A032

DEMONSTRATING THE FEASIBILITY OF REFREEZING PREVIOUSLY CRYOPRESERVED BONE MARROW FOLLOWING REPROCESSING

Erik Woods[1], *Nicholas Weinstein1 Weinstein*[1], *Max Jacobs*[1], *Sagar Munjal*[1], *Brian Johnstone*[1]
[1]*Ossium Health, San Fransisco, United States of America (the)*

Background: Cryopreserved cellular therapy products are typically maintained below −140 °C until infusion. However, circumstances may necessitate thawing and refreezing during the product life cycle, including additional testing, removal of cellular debris, adjustment of composition, or further manufacturing steps. The decision to reprocess rather than remanufacture must balance feasibility, cost, source material availability, and potential impact on product quality. Given the widespread perception that repeated freeze–thaw cycles severely reduce cell viability, limited evidence exists to guide the optimization of reprocessing techniques. This study evaluated the feasibility of recovering functional cells from thawed

and re-cryopreserved whole bone marrow (BM) and explored methods to minimize viability loss.

Methods: BM was isolated from vertebral bodies obtained from consented deceased organ donors. White blood cell (WBC) concentration was adjusted to 1.4×10^8 cells/mL. Samples were cryopreserved in 5% dimethyl sulfoxide (DMSO) at 65 mL per 270 mL cryostorage bag, cooled at −1 °C/minute in a −80 °C freezer, and transferred after 12 hours to vapor-phase liquid nitrogen. Thawing was performed using a Barkey Varitherm device, with DMSO dilution achieved using medium containing 2.5% human serum albumin (HSA) and 10 U Benzonase in Plasma-Lyte A. Re-cryopreservation was performed by adding 5% DMSO to the thawing medium, followed by filtration (Fresenius Kabi BM filtration kit), repackaging, passive freezing at −80 °C overnight, and transfer to liquid nitrogen storage.
Cell counts, viability, and colony-forming unit (CFU) assays were obtained before and after reprocessing. Viable $CD34^+$ cell enumeration followed the ISHAGE protocol using a Novocyte flow cytometer (Agilent). A refined thawing method was also tested, in which thawing medium was added gradually (13 mL/min for 5 minutes) to reduce osmotic shock.

Results: Initial evaluation of two cryopreserved BM lots demonstrated that reprocessing did not significantly compromise viability or clonogenicity, provided that the starting $CD34^+$ viability was ≥40% and CFU-GM frequency ≥10 CFU/10^5 WBC. Further testing on BM from three donors confirmed maintenance of functionality. Mean $CD34^+$ viability increased from 87.8 ± 5.6% to 93.2 ± 5.4% ($p = 0.2$), likely reflecting removal of nonviable cells during filtration. CFU frequency declined modestly from 60 ± 29.4 to 51.7 ± 11.8 CFU/10^5 WBC (<30% reduction), indicating preservation of the majority of hematopoietic progenitors. Implementation of the gradual-dilution thawing method further improved post-thaw outcomes. $CD34^+$ viability increased by 6.7 ± 10.1%, and CFU output decreased minimally by 1.1 ± 27.5% ($n = 3$) compared with immediately post-thaw samples, suggesting that HSA, Benzonase, and controlled dilution help mitigate thaw-related stress.

Conclusions: Reprocessing of previously cryopreserved BM is feasible and can be accomplished without substantial loss of cell viability or clonogenic function. Although modest yield reductions were observed, the recovered material retained sufficient functional capacity to justify reprocessing over remanufacture in appropriate cases. This approach offers operational and economic advantages in managing cellular therapy inventories. Ongoing investigations aim to refine thawing and refreezing parameters and to define standardized, validated conditions for safe reprocessing of cryopreserved BM products.

EXTRACORPOREAL PHOTOPHERESIS FOR DELAYED NEUROTOXICITY SYNDROME AFTER BCMA CAR T-CELL THERAPY

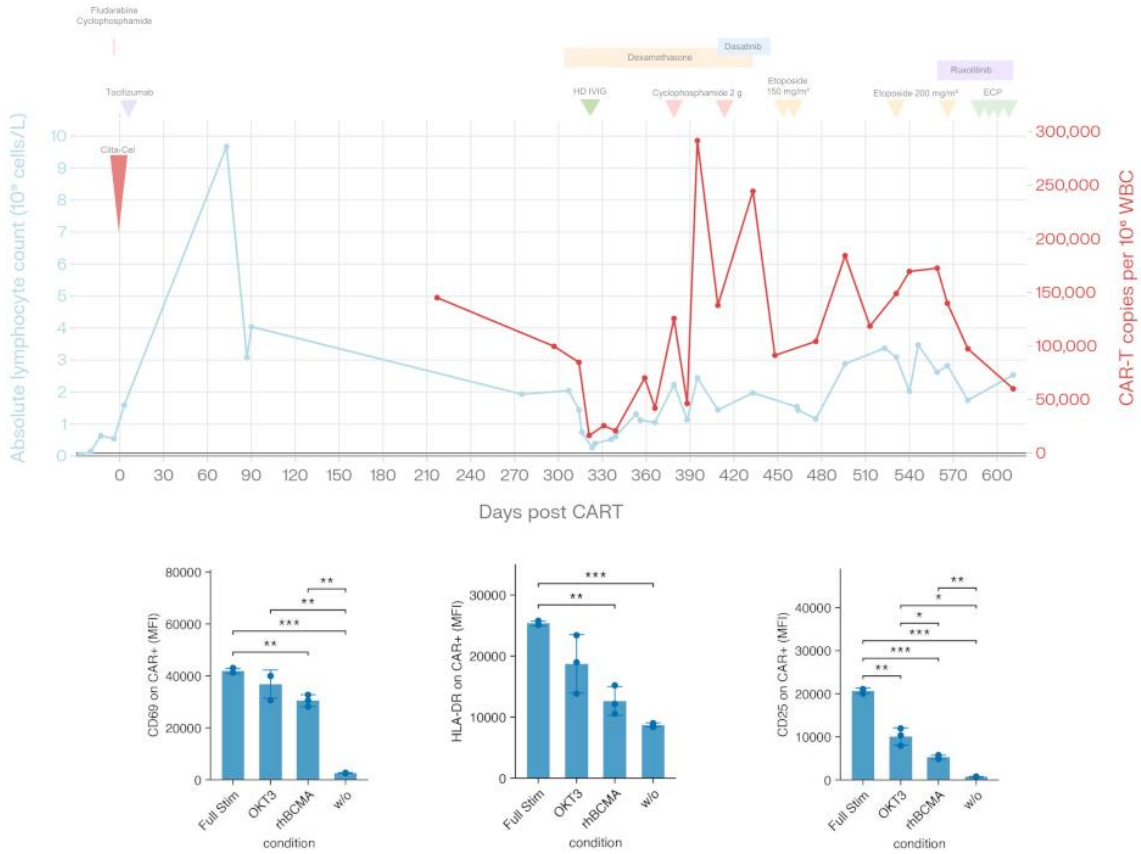
Philipp Gödel[1], *Udo Holtick*[1], *Lars Fabian Prinz*[1], *Markus Chmielewski*[1], *Tobias Riet*[1], *Hyatt Balke-Want*[1], *Ruth Flümann*[1], *Eva Heger*[1], *Jan-Michael Werner*[1], *Gilbert Wunderlich*[1], *Christof Scheid*[1], *Tim Richardson*[1]
[1]*University of Cologne, Cologne, Germany*

Background: Prolonged hyperexpansion and increased absolute lymphocyte counts after cilta-cel, a BCMA-targeting CAR-T cell (CART) product targeting multiple myeloma (MM) cells, are associated with potentially life-threatening immune-mediated neurotoxicity syndromes including movement and neurocognitive toxicity mimicking parkinsonism. Still, optimal treatment strategies remain undefined. Extracorporeal photopheresis (ECP) is an established treatment modality for graft-versus-host disease, (solid organ) transplant rejection and indolent leukemic T-cell neoplasms but has not been described for the treatment of autologous CART-related diseases.

Methods: We treated a previously neurologically unremarkable 44 yr old male patient with cilta-cel in 4th line for high-risk MM without acute complications despite of CRS °II that was readily controlled with tocilizumab. 3 months after CART infusion he developed an absolute lymphocytosis paralleled by a progressive hypokinetic-dystonic movement disorder with only marginal response to symptomatic pharmacotherapy diagnosed by an expert neurologist. Cranial MRI and CSF sampling with extensive workup showed no signs of infection or malignant disease but mild lymphocytic pleocytosis (12 cells/ul, no qPCR performed). Gradual worsening of neurologic symptoms was accompanied by high CART copy numbers (dPCR) in peripheral blood (pB) which prompted lymphotoxic therapy. However, neither CART hyperexpansion nor the clinical course were durably affected by high-dose steroids, intravenous immunoglobulins, cyclophosphamide, and dasatinib. Repeated therapy with etoposide (150-200 mg/m²) led to a transient decline of CART numbers with consecutive symptomatic improvement but rapid relapse and subsequent refractoriness. Ruxolitinib dosed at up to 20 mg BID did not meaningfully reduce CART copies nor led to relevant symptomatic improvement.
ECP was performed using the Therakos CellEx device according to standard protocols processing 1500 ml of whole blood per session. Methoxysalen (Uvadex) was used as UV radiosensitizer. CART qPCR detecting the lentiviral LTR sequence was multiplexed with RPP30 (housekeeping gene) to normalize cells to 10^6 peripheral blood white blood cells (WBC). qPCR was only available since late 2024. CARTs were detected by fluorochrome-labeled recombinant BCMA in flow cytometry. Short-term CART culture was performed according to published protocols. CARTs were ex vivo stimulated with recombinant BCMA (rhBCMA) or OKT3 as positive control.

Results: Extensive immunophenotyping demonstrated peripheral T-cell lymphocytosis without signs for malignant transformation before initiation of ECP and evidence of activated CART in pB that showed BCMA-specific upregulation of activation markers CD25, CD69 and HLA-DR in vitro, demonstrating inflammatory potential.
Around 20 months after CART infusion, we initiated ECP. Already after 4 sessions the patient

showed an improvement of symptoms and declining CART in pB despite discontinuation of ruxolitinib.
The patient retained complete remission of MM evidenced by ongoing suppression of free light chains and absence of extramedullary disease on PET/CT scan. He continues to receive ECP and extended follow up will be presented at the meeting.
Therapeutic interventions, CART copies and absolute lymphocyte counts and in vitro stimulation assay pre ECP are depicted in Fig. 1.



Conclusions: This preliminary data indicates that ECP might represent a promising therapeutic approach for toxicities related to hyperexpanding CARTs irresponsive to extensive lymphotoxic therapies.

Disclosure: Nothing to declare.

SINGLE-CELL MAPPING PORTRAYS THE LINEAGE SPECTRUM OF EPSTEIN-BARR VIRUS INFECTION AND UNVEILS CLINICAL IMPLICATIONS OF CD70 IN PATIENTS WITH PTLD

Xuehong Zhang[1,2], Jiayin Zhou[1], Dan Huang[1], Xijia Wang[1], Yuchao Hao[1], Furong Wang[1], Beibei Gao[1], Zhijie Hou[3], Dong Zhou[1,4], Fang Xie[1,4], ***Jinsong Yan***[1,4]
[1]*Department of Hematology, the Second Hospital of Dalian Medical University, Dalian, China,* [2]*Center of Genome and Personalized Medicine, Institute of Cancer Stem Cell, Dalian Medical University, Dalian, China,* [3]*Institute of Cancer Stem Cell, Dalian Medical University, Dalian, China,* [4]*Liaoning Medical Center for Hematopoietic Stem Cell Transplantation, Blood Stem Cell Transplantation Institute, Diamond Bay Institute of Hematology, The Second Hospital of Dalian Medical University, Dalian, China*

Background: Epstein-Barr virus (EBV)-related post-transplant lymphoproliferative disorder (EBV$^+$ PTLD) is a life-threatening complication that can occur as a result of immunosuppression after hematopoietic stem cell transplantation (HSCT). The remaining unclear pathogenesis and limited treatment options of EBV$^+$ PTLD result in the poor prognosis.

Methods: Bulk and single-cell RNA sequencing (scRNA-seq) were performed on bone marrow and peripheral cells derived from patients with EBV$^+$ PTLD and matched transplant donors. The expression of EBV genes and host genes was analyzed simultaneously by constructing a hybrid reference genome of EBV and human. The quantitative real-time polymerase chain reaction (qRT-PCR) method was employed to verify the differently expressed genes in PTLD.

Results: The bulk transcriptome analysis revealed the expression characteristics of EBV$^+$ PTLD patients, including the over-expressed CD70, uncontrolled proliferation, impaired apoptosis, activated innate immunity and suppressed adaptive immunity, and enhanced T-cell exhaustion. scRNA-seq analysis exhibited a comprehensive cell atlas of EBV$^+$ PTLD, and unveiled the broad EBV infection involving in the full spectrum of the hematopoietic system, even for the hematopoietic stem cells of the patients with PTLD. Further analysis confirmed the latency III/lytic expression program of EBV genes in patients with high infection burden, rather, latent type I/II in patients with low EBV infection. The overwhelming majority of infected B cells were derived from memory B cells, and presented universal and abnormal differentiation patterns, especially for the irregular generation of immunoglobulin antibody isotypes. Moreover, EBV-infected T cells showed significantly inhibited T cell receptors signal, reduced IL2 secretion capacity, and elevated T-cell exhaustion. The re-clustering analysis of B cells, T cells, natural killer cells, and myeloid cells uncovered the heterogeneous cell subpopulations, among which the most highly infected exhausted B cells were likely contributed to treatment evasion. The specifically over-expressed CD70 was recurrently proved by scRNA-seq data and qRT-PCR experiment in EBV$^+$ PTLD patients, illustrating its clinical implications as a biomarker for the diagnosis and immunotherapy in EBV$^+$ PTLD patients.

Conclusions: Collectively, scRNA-seq of EBV$^+$ PTLD provides valuable insights into the lineage distribution and latency programs of EBV infection and offers important candidate solutions for the diagnosis and targeted treatment in the future.

DECIPHERING THE HDAC6-MEDIATED REGULATION OF MLLT3 IN MYELOID PROGENITOR CELL FATE: INSIGHTS INTO STEM CELL DIFFERENTIATION DYNAMICS

Anil Aribandi[1], *Mabu Subahan*[2], *Ranjith Kumar CS*[1], *Arunasree M. Kalle*[2]
[1]*Sindhu Hospitals, Hyderabad, India,* [2]*University of Hyderabad, Hyderabad, India*

Background: Mixed-lineage leukemia translocated to 3 (MLLT3) is a critical factor in maintaining the stemness of hematopoietic stem cells. While it is established that the loss of MLLT3 in megakaryocyte-erythrocyte progenitor (MEP) cells drives differentiation into megakaryocytes (MKs), the specific regulatory mechanisms that govern MLLT3 during this differentiation process have remained unclear.

Methods: To address this gap, this study utilized single-cell data and bulk RNA sequencing, complemented by FACS, qPCR, and Western blot analyses, to investigate the molecular drivers of terminal differentiation. The research focused on the capacity of histone deacetylase 6 (HDAC6) to modulate MLLT3 levels via Heat Shock Protein 90 (Hsp90) activation during myeloid lineage differentiation into MKs, monocytes, and macrophages.

Results: The study demonstrated that HDAC6 plays a pivotal role by deacetylating and activating Hsp90. This activation enables Hsp90 to retain MLLT3 in the cytoplasm. Subsequently, Protein Kinase C (PKC) phosphorylates MLLT3 at serine residues, leading to the loss of MLLT3. Notably, this specific mechanism was observed during the differentiation of MKs and macrophages but was absent during monocyte differentiation.

Conclusions: Supported by transcriptomic evidence, these findings elucidate the regulatory mechanisms underlying myeloid lineage commitment. By identifying the interplay between HDAC6, Hsp90, and PKC in regulating MLLT3, this study offers valuable insights into stem cell biology and opens new avenues for future therapeutic applications.

PATENTING CORD BLOOD CELLS: AN HISTORICAL PERSPECTIVE

Antonio Bruno[1], *William Arcese*[2], *Annalisa Ruggeri*[3], *Eliane Gluckman*[4,5]
[1]*University Tor Vergata, Rome, Italy,* [2]*Policlinico Universitario Campus Bio-Medico, Rome, Italy,* [3]*Hematology and BMT Unit, San Raffaele Scientific Institute, Milan, Italy,* [4]*Eurocord, APHP, Hopital Saint-louis, Paris, France,* [5]*Monacord, Centre Scientifique de Monaco, Monaco, Monaco*

Background: Haematopoietic stem cell transplantation (HSCT) has undergone rapid and remarkable development over the past 75 years. Since the first cord blood HSCT was performed in 1988 at Saint-Louis Hospital in Paris by a French-American team on a child with Fanconi Anemia, cord blood has been widely used as a source of haematopoietic stem cells for transplant. However, in 1996 the biotechnology company Biocyte Corporation submitted a patent application to the European Patent Office (EPO) for the storage and use of cord blood for allogeneic transplants, gene therapy and clinical and research purposes. Fearing that the patent would increase the cost of transplants worldwide and limit the future use of cord blood, a prompt and strong opposition against the patent application raised from the scientific community, including Eurocord, Netcord, EBMT and the International Society for Cellular Therapy as well as from the wide academic world.

Methods: The president of Eurocord (EG), along with companies such as Thermogenesis and Astra Medica, filled an appeal against Biocyte Corporation with the European Patent Office (EPO) in Munich. The arguments against the patent were as follows : 1) commercial exploitation of parts of the human body ; 2) violation of the principle of free and anonymous donation ; 3) granting of monopolistic power to a single company ; 4) delay to cord blood research resulting from the payment of royalties ; and 5) lack of novelty.

Results: In 1999, the EPO accepted the argument concerning the lack of novelty as grounds for revoking Biocyte Corporation's patent. Previous studies, such as the 1983 study from Koike Kenichi on the viability of haematopoietic stem cells from cord blood and the 1985 Spanish thesis by Juan Besalduch Vidal, had shown that cord blood contains sufficient stem cells for non-HLA-identical transplants so that it can be stored in public cord blood banks and thawed for clinical use.

Conclusions: 1) Thanks to opposition from the scientific Community and work carried out prior to Biocyte Corporation's patent application, transplant centres, cord blood banks, and researchers around the world are not required to pay royalties to a company since unprocessed cord blood cannot be patented, in the same way as bone marrow or peripheral blood stem cells for transplant ; 2) it is a matter of discussion that on a strictly legal level, only the principle of scientific novelty and not an ethical principle, has been recognized as valid for the purposes of recognizing a patent even in the case of use of human biological material for therapeutic purposes. The public donation of stem cells from cord blood, bone marrow and peripheral blood should be supported and warranted worldwide.

ALTERED PRE-TRANSPLANT GUT MICROBIOTA PROFILES IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: TOWARD MICROBIOTA-INFORMED RISK STRATIFICATION

Lavinia-Eugenia Lipan[1,2], *Karina-Doris Vihta*[3], *Alexandra Marcoci*[1], *Iuliana Iordan*[1,4], *Simona Olimpia Dima*[1,2], *Dumitru Jardan*[3], *Anca Colita*[1,2], *Alina Daniela Tanase*[1,2]
[1]*University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania,* [2]*Fundeni Clinical Institute, Bucharest, Romania,* [3]*Medlife, Bucharest, Romania,* [4]*National Registry of Voluntary Hematopoietic Stem Cell Donors, Bucharest, Romania*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a potentially curative strategy for hematologic malignancies; however, transplant-related complications remain a significant determinant of outcome. The intestinal microbiota has emerged as an essential regulator of mucosal integrity and immune responses relevant to allo-HSCT. Patients with hematologic malignancies frequently enter transplantation with a markedly altered gut microbiota due to prior chemotherapy, recurrent antibiotic exposure, and disease-related factors, resulting in reduced microbial diversity and shifts in community structure. Such pre-transplant dysbiosis may predispose to adverse post-transplant outcomes,

including infectious complications, graft-versus-host disease (GVHD), and non-relapse mortality.
This study aimed to characterize alterations in gut microbiota composition and alpha diversity in patients before allo-HSCT compared to healthy controls, and to explore the relationship between pre-transplant therapeutic exposures and early post-transplant outcomes.

Methods: This prospective, observational study included adult patients with hematologic malignancies undergoing allo-HSCT at the Fundeni Clinical Institute. Fecal samples were collected from 56 patients before the initiation of conditioning therapy and from 27 healthy donors serving as controls. Microbial DNA was extracted from stool samples, and the V4–V5 hypervariable regions of the bacterial 16S rRNA gene were amplified by polymerase chain reaction (PCR) and sequenced on an Illumina platform. Bioinformatic processing was performed using QIIME 2, including demultiplexing, denoising with DADA2, and generation of amplicon sequence variant (ASV) tables. Wilcoxon rank-sum tests were used to compare alpha diversity between patients and controls. Beta diversity was assessed using Bray–Curtis dissimilarity, and Principal Coordinate Analysis was performed to explore clustering patterns. Baseline microbiota features were analyzed in relation to early post-transplant outcomes, with follow-up extending to day +100.

Results: The cohort comprised 56 adult patients undergoing allo-HSCT, with a median age of 42.4 years (IQR 17.2); 59.6% were male, and acute myeloid leukemia was the most frequent indication for transplantation (56.1%). Most patients had good performance status (ECOG 0–1 in 96.4%) and low-to-intermediate transplant risk (HCT-CI 0–2 in 92.9%). Before allo-HSCT and baseline stool sample collection, patients were heavily pretreated: 71.9% received cytotoxic chemotherapy, 35.1% immunotherapy, 31.6% hypomethylating agents, 19.3% venetoclax, and 12.3% monoclonal antibodies. Additionally, 54.4% were exposed to systemic antibiotics before transplantation, most commonly beta-lactams (35.1%), followed by aminoglycosides and anti-staphylococcal agents (24.6%). At baseline, patients exhibited significantly lower gut microbiota alpha diversity than healthy donors, as assessed by the Shannon index. Beta-diversity analysis demonstrated distinct clustering of patient and control samples on principal coordinate analysis, indicating substantial differences in microbial community structure.

Conclusions: Adult patients undergoing allo-HSCT present with a profoundly altered gut microbiota already before transplantation, likely reflecting extensive prior exposure to chemotherapy and antibiotics. These findings are consistent with previously published data and reinforce existing evidence that reduced baseline gut microbiota diversity may influence early post-transplant outcomes. Together, these observations support the rationale for microbiota-informed risk stratification and interventional strategies in allo-HSCT. Further prospective and longitudinal studies in larger cohorts are warranted better to define the clinical relevance of pre-transplant microbiota alterations.

Disclosure: This research was funded by the EU NextGenerationEU instrument through the National Recovery and Resilience Plan of Romania - Pillar III-C9-I, section I5. Establishment and operationalization of Competence Centers PNRR-III-C9-2022 – I5, managed by the Ministry of Research, Innovation and Digitalization, within the project entitled "Creation,

Operational and Development of the National Center of Competence in the field of Cancer", contract no. 760009/30.12.2022, code CF 14/16.11.2022.

THE ROLE OF SALVAGE ALLOGENEIC HEMATOPOIETIC STEMM CELL TRANSPLANTATION FOR RELAPSED OR REFRACTORY AML IN NON REMISSION: INSIGHTS FROM REAL-WORLD EXPERIENCE

Seungah Cha[1], *Dong-Yeop Shin*[2], *Junshik Hong*[2], *Youngil Koh*[2], *Ja Min Byun*[2], *Inho Kim*[2]
[1]*Asan Medical Center, Seoul, Korea (the Republic of),* [2]*Seoul National University/Seoul Uational University Hospital, Seoul, Korea (the Republic of)*

Background: Relapsed and refractory (R/R) acute myeloid leukemia (AML) represents a significant therapeutic challenge, with limited treatment options and poor survival outcomes. While salvage allogeneic hematopoietic stem cell transplantation (allo HSCT) remains the only curative strategy with potential efficacy for these patients, its application in patients who fail to achieve complete remission (CR) before transplantation remains controversial due to historically poor survival rates. To date, there is no consensus on how to optimize transplantation strategies for this high-risk cohort, necessitating urgent real-world evidence to guide clinical practice.

Methods: This retrospective study analyzed 120 R/R AML patients who underwent allo-HSCT in non-CR status at Seoul National University Hospital between 2005 and 2024. Overall survival (OS) was estimated using the Kaplan–Meier method, while relapse and non-relapse mortality (NRM) were assessed within a competing-risks framework. Prognostic factors were analyzed using univariate and multivariate Cox regression models.

Results: The median OS was 5.2 months, with a 3-year OS probability of 23%. At three years, the cumulative incidence of relapse was 45.7%, while NRM reached 51.1%. In multivariable analysis, several variables retained independent associations with poorer survival, including age ≥ 50 years (HR 2.90, 95% CI 1.59–5.29; P = 0.001), adverse cytogenetics (HR 2.39, 95% CI 1.46–3.91; P = 0.001), and a bone marrow blast count ≥ 20% at the time of transplantation (HR 1.86, 95% CI 1.15–3.02; P = 0.012). Patients receiving grafts from matched unrelated donors or 1–2 antigen–mismatched unrelated donors experienced higher mortality compared with those transplanted from matched sibling donors. Among post-transplant complications, severe acute graft-versus host disease (GVHD) was associated with markedly inferior survival, whereas chronic GVHD did not significantly affect OS.

Conclusions: Salvage allo-HSCT in non-CR R/R AML shows substantial variability in outcomes, highlighting the importance of careful patient and donor selection, particularly regarding age, cytogenetic risk, disease burden, and donor type. Severe aGVHD was clearly associated with markedly worse survival. These findings highlight the need for individualized donor choice and early control of aGVHD to improve outcomes in this high-risk group.

Disclosure: All authors declare that there are no actual or potential conflicts of interest related to this manuscript.

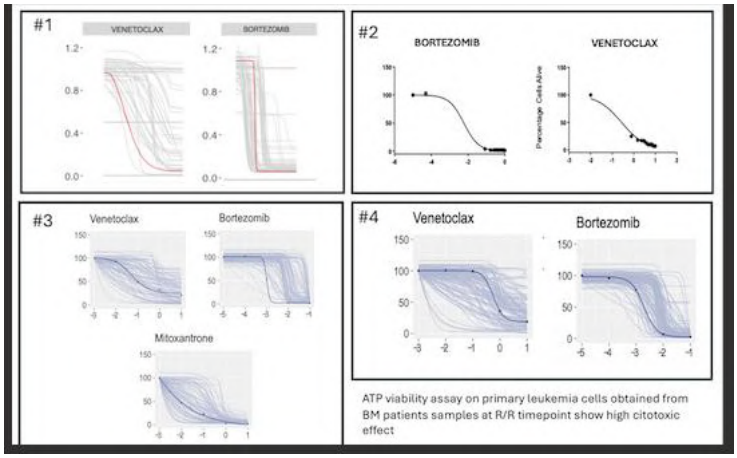
PERSONALIZED THERAPY GUIDED BY EX VIVO DRUG RESPONSE PROFILING ENABLES ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) IN RELAPSED/REFRACTORY ACUTE LEUKEMIA WITH IMMATURE PHENOTYPE

Lucia Prezioso[1], *Benedetta Cambò*[1], *Maria Teresa Giaimo*[1,2], *Amelia Rinaldi*[1], *Luca Pagliaro*[1,2], *Raffaella Zamponi*[1,2], *Anna Montanaro*[2], *Andrea Gherli*[2], *Giovanni Roti*[1,2]
[1]*Hospital University of Parma, Parma, Italy,* [2]*Translational Hematology and Chemogenomics AIRC Investigator Leukemia Research Foundation Hollis Brownstein Research Scholar, Parma, Italy*

Background: Disease status at the time of allogenic bone marrow transplantation (HSCT) significantly influences the outcome in high risk acute leukemia, with patients achieving complete remission pre HSCT demonstrating superior overall survival and reduced relapse rates compared to those with active disease. However, a substantial proportion of patients with highly refractory or relapsed (R/R) leukemia fail to achieve adequate disease control with conventional therapies, precluding them from proceeding to potentially curative transplantation. Therefore, identifying effective bridging strategies that can successfully reduce disease burden in relapsed/refractory (R/R) patients is crucial to expand transplant eligibility and offer this therapeutic option to a major proportion of patients . In this context an alternative strategy is to develop individualized approaches assessing susceptibility of leukemic cells to specific small molecules by performing ex vivo drug response profiling (DRP). DRP can be performed within an actionable timeframe and could predict in vivo response, leading to a personalized therapy and bridging to transplant.

Methods: We report a case series of 4 patients with R/R AL. Patient characteristics are summarized in Table 1. Treatment regimens were selected based on ex vivo drug sensitivity profiles: three patients received venetoclax plus bortezomib (VEBO), while one patient (pt#3) received VEBO plus mitoxantrone.



At the time of transplantation, two patients (pt#2 and pt#4) had achieved complete remission (CR); notably, one of these patients (pt#2) had previously undergone allogeneic HSCT. The remaining two patients demonstrated significant reduction in disease burden prior to transplantation. All patients received a myeloablative conditioning regimen, two of them Total Body Irradiation based (pt#1 and pt#3). One patient had a matched unrelated donor, three an haploidentical donor. The choice of T depleted o repleted haploidentical transplantation was guided by patient condition, disease status and HCT-CI at time of transplantation.

PT	age	diagnosis	CI-FISH	gene mutations	prior lines of therapy	disease status at DRP	DRP oriented therapy	disease status at HSCT	HSCT
#1	27	near ETP ALL	DDX3X-MLLT10	NOTCH1, JAK3, NRAS, SUZ12, PHF6, MED12	HyperCVAD, LAL0904	refractory	VEN800-Bortezomib	PR	MAC-MUD
#2	36	AUL	PICALM-MLLT10	FLT3 ITD	HyperCVAD,FLAI, HSCT (sibling)	relapse	VEN800-Bortezomib	CR	MAC-Haplo PTCy
#3	59	T-ALL (cortical) + ETP	trisomy 21, TRADrearrangement	/	LAL1913 (4 cycles)	relapse	VEN400-Bortezomib-Mitoxantrone	PR	MAC-Haplo abTCD

#4	37	near ETP ALL	PICALM-MLLT10, MECOM, monosomy7, ETV6-CDKN1B del, TRAD-NKX2	NOTCH1, RUNX1, SUX12, WT1, PTPN11	LAL1913 (9 cycles+maintenance)	relapse	VEN800-Bortezomib	CR	MAC-Haplo PTCy

Results: All four patients proceeded to allogeneic HSCT following two cycles of DRP-guided therapy. Patient #1 experienced fatal veno-occlusive disease (VOD) during the engraftment period of his second allogenic transplantation. Patient #2 maintained Complete response (CR) for 12 months post-transplant. Patient #3 experienced disease relapse at 6 months post-HSCT. Patient #4 remains in ongoing CR at 3 years post-transplantation.

Conclusions: Although limited to a small patient cohort, ex vivo drug screening platform successfully guided therapeutic option in R/R AL patients, with very high risk phenotype enabling successful bridging to allogeneic transplantation significantly reducing disease burden.

RETHINKING CONTAMINATION CONTROLS IN CHIMERISM TESTING: THE CASE AGAINST NTCS

Jesse Cox[1], Shelly Williams[1], Shannen Bishop[1], Brittany O. Deladillo[1], Sophie Hauxwell[1], Narin Tangprasertchai[2], ***Thierry Viard***[2]
[1]University of Nebraska Medical Center, Omaha, United States of America (the), [2]CareDx, Inc., Brisbane, United States of America (the)

Background: Modern next-generation sequencing (NGS)-based molecular assays offer a rich array of metrics and informatics tools to monitor assay performance. These advancements challenge the necessity of traditional quality control concept such as no-template controls (NTCs) and their application. In our laboratory's validation and clinical use of the CareDx AlloSeq HCT assay for chimerism monitoring, we evaluated the effectiveness of replacing NTCs with single-genome controls and contrived samples.
NTCs are conventionally used to detect contamination. However, in the context of chimerism testing, they frequently fail to generate sufficient read depth due to the absence of input material. This failure renders them uninformative, as any contamination present is unlikely to reach the detection threshold. A failed NTC result does not confirm assay integrity; it simply provides no usable data. In contrast, single-genome controls and sensitivity mixtures offer robust, interpretable metrics that can actively monitor assay performance and detect contamination.

Methods: We conducted twelve validation runs, nearly 200 clinical runs, and four additional study runs using single-genome controls and contrived mixtures. These included samples intentionally contaminated with bleach (a commonly used surface disinfectant and

decontaminant, but also a powerful PCR inhibitor) and unanticipated contributors. In each case, we recorded contributor proportions, software-detected genotype errors, and key assay metrics such as cluster density and read depth.

Results: Initial assessments revealed that including an NTC reduced read depth by approximately 30% across all batched samples compared to runs using single-genome contamination controls, probably due to the massice creation of non-specific products of amplification). Because the AlloSeq HCT software relies on defined donor and recipient genotypes, the detection of unexpected alleles serves as a reliable indicator of contamination. To test this, we spiked wipe samples from bleach-dampened and DNA-contaminated surfaces into single-genome controls. These samples either flagged errors for unanticipated genotypes or showed degraded performance, validating the sensitivity of this approach.

Conclusions: Over hundreds of runs, our contrived sensitivity controls have consistently enabled robust performance monitoring. The informatics systems in place are sufficiently sensitive to detect contamination and deviations in assay setup, eliminating the need for legacy NTCs and potentially redundant wipe tests. These findings support a streamlined, data-driven approach to quality control in chimerism testing, improving both assay reliability and operational efficiency.

Disclosure: Thierry Viard and Narin Tangprasertchai are CareDx employees and Stock holders.

TRACKING BACK INNOVATION IN DIFFERENT CLASSES OF NEWLY-DEVELOPED MEDICINAL PRODUCTS THROUGH THE LINKAGE BETWEEN NOBEL AND GALIEN PRIZES SUPPORTS A SPECIFIC STATUS FOR ADVANCED THERAPIES

Christian Chabannon[1], *Hashim Wamutitu*[2], *Valentin Roby*[3], *Aurélie Mahalatchimy*[3]
[1]*Institut Paoli-Calmettes & Aix-Marseille Université, Marseille, France,* [2]*Azenta Life Sciences GmbH, Griesheim, Germany,* [3]*Law Faculty, Aix Marseille Université, CNRS, DICE, CERIC, Aix-en-Provence, France*

Background: Advanced therapies – Advanced Therapy Medicinal Products or ATMPs as per EC Regulation 1394/2007 – are different in many aspects from other classes of medicinal products, whether chemically synthesized or manufactured through a biological process. By adopting a 'lex specialis' for ATMPs, the European Union has acknowledged the specificity of ATMPs, especially on the basis of the innovative dimension of their manufacturing process and of their interest for public health and economics. However, one can wonder about the origin and recognition of their innovativeness while innovation is a notion contingent to its context of use and ATMPs are facing several commercialization failures, although denoting that innovation does not always equal adoption..

Methods: In this study, we attempted to grade the levels of innovation that characterize different categories of medicinal products that were brought to the market over the last four decades.
As a proxy to the flow from "discovery" to "innovation", we have listed Nobel prizes in Physiology or Medicine or Nobel prizes in Biochemistry from 1920 on one hand, and Galien prizes awarded to innovations based on biological elements (biomedical innovations) on the other hand, and searched for links between the two categories of awards.
We subset the biomedical innovations that were most frequently awarded a Galien prize into three groups: "products of recombinant DNA technology", "products of antibody engineering" and "advanced therapies" (ATMPs).

Results: First, our study highlights that one Nobel prize can lead to several biomedical innovations.
Second, it is quite remarkable that the vast majority of Galien prizes has been awarded to biological medicinal products (biologicals).
Third, the links between Nobel prizes and Galien prizes are not homogenous among the three groups targeted in our analysis, showing difference in the recognition of innovation.
From 1999 onwards, "Products of antibody engineering" have received many Galien prizes – many of them in recent years - stemming from a quite low number of Nobel prizes. It continues to produce significant impacts in several medical fields.
"Products of recombinant DNA technology" have also received an important although smaller number of Galien Prizes; overall, these were awarded in an earlier period starting in 1987.
In 2017, a Gallien prize was awarded for the first time to an ATMP. In total, ATMPs have been awarded a smaller number of Galien prizes. However, their design and development can be tracked back to a higher number of Nobel prizes in physiology or chemistry, some of them that were awarded recently.

Conclusions: Our analysis suggests that the rapid incorporation of a combination of breakthrough technologies based on several scientific discoveries recognized by Nobel prizes is key to their development and manufacturing, supporting their recognition and regulation as a distinct class of therapeutics.

HARVESTING CD3 POSITIVE LYMPHOCYTES IN PEDIATRIC PATIENTS FOR CAR-T CELL MANUFACTURING

Volker Witt[1], *Andrea Lietz*[1], *Magdalena Russwurm*[1], *Michael Rittenschober*[1], *Herbert Pichler*[1]
[1]*St. Anna Kinderspital, Vienna, Austria*

Background: CD3+ are the targets for Leukapheresis in patients undergoing CAR-T cell therapy. We here report our inhouse experience to harvest T-cells form pediatric and adolescent patients with the AMICUS™ device.

Methods: We reviewed retrospectively the patients charts for the patients data and apheresis settings and results of the products harvested. All products were manufactured by Novartis Company (Kymriah™). Every patients and/or their relatives give written informed consent for the harvesting procedure, the treatment with CAR-T cells and the use of the data setting. We calculated the collection efficiency (CE) for Lymphocytes , Granulocytes, Monocytes, Erythrocytes and Thrombocytes taken blood smear immediately before and after the procedure. Products were than cryopreserved and shipped to Novartis facilities for CAR-T cell manufactoring. The specification form the manufacturer for the T-cell yield was 1 10^{09} cells in the product. (SD 1500 l

Results: From July 2016 to June 2025 we performed 23 procedures in 23 patients (14 male 9 female; median age 11.6y min 1.2 - max 19.4y; median bw 35 kg, min 10 - max 87 kg) with B-cell leukemias (n=22), Burkitt-Lymphoma (n=1). The setting of the AMICUS device in median 6 cycles with 1250 ml cycle volume, ACD-A ratio 1:12, MNC setpoint 0.6, RBC setpoint 6.8, MNC setpoint 1.5 - 2.3, PPP flush 10 ml. Due to the CD3+ cell count we managed the whole blood to be processed. In median 8737 ml (SD 1500 ml) whole blood were processed, corresponding to 240 ml (SD 25 ml) whole blood /kg bw, with a median CD3+ cell count before the procedure of 1250 cell/µl (SD 350cells/µl). For the CD3+ cells we calculated a CE of 55.3%, total Lymphocytes 55,2%, Monocytes 41.3%, Granulocytes 3.5%, Thrombocytes 19.4%, MNC 53.2%. In all patients we had a sufficient yield of more than 1x10^{09} CD3+ cells in the product, with one exeption. In one case it was 0.92x10^{09}. No side effects were noted in the patients during or after the procedure. Venous acces was central venous access only (n=11) and peripheral access only (n=4) or a combination of PVC and CVC. The content of Erythrocytes in the product is in median 8.5% (3.7 - 15%). With this preliminary data we now calculate the minimum whole blood to be processed by the formular: (1000.000.000 CD3+ cells/CD3+ cell count/ml)* (CE(=0.5)) = whole blood to processed.
One product could not be manufactured due to HCV positivity in the IDM at harvest, 2 products has not fullfilled the quality criteria after manufacturing.

Conclusions: We conclude, that Lymphcyte apheresis performed with the AMICUS device is feasable and results in good standard products for manufacturing CAR-T cells.

Disclosure: No conflict of interest.

Background: Exagamglogene autotemcel (exa-cel) is a one-time, *ex vivo* CRISPR/Cas9 gene-edited, autologous cell therapy approved for patients ≥12 years (y) old with transfusion-dependent β-thalassemia (TDT) or sickle cell disease (SCD) with recurrent vaso-occlusive crises (VOCs). We report long-term efficacy and safety from the phase 3 CLIMB THAL-111, CLIMB SCD-121, and CLIMB-131 trials.

Methods: CLIMB-111 (TDT) and CLIMB-121 (SCD) are 2-year, phase 3 studies of exa-cel in participants aged 12-35y. Participants then enroll in CLIMB-131 for up to 13 y follow-up. The CLIMB-111 primary endpoint is transfusion independence: proportion of participants maintaining a weighted average hemoglobin ≥9 g/dL without RBC transfusion for ≥12 consecutive months (TI12). The CLIMB-121 primary endpoint is the proportion of participants free of severe VOCs for ≥12 consecutive months (VF12); the key secondary endpoint is the proportion of participants free from inpatient hospitalization for severe VOCs for ≥12 consecutive months (HF12). As an ad hoc analysis, the overall survival (OS) rate (proportion who survived death from any cause) and event-free survival (EFS) rate as typically defined for allogeneic bone marrow transplant (proportion who survived death from any cause, graft-versus-host-disease [GVHD], or graft failure, whichever occurred earliest) were evaluated. Data are from July 20, 2025; final CLIMB-121 results are presented.

Results: In CLIMB-111, 56 participants (mean age: 21.2y) received exa-cel; median follow-up was 49.6 (19.4,78.6) months. All participants were evaluable for TI12; 98.2% (55/56) achieved TI12 in CLIMB-111/CLIMB-131. After exa-cel, all participants engrafted neutrophils and platelets at a median of 29 (12,56) days and 43.5 (20,200) days, respectively. As of July 2025, 69.6% (39/56) of CLIMB-111/CLIMB-131 participants had discontinued iron removal therapy (IRT) for ≥6 months with levels of serum ferritin, liver iron content, and T2* cardiac iron content generally stable with no increase over time post-IRT discontinuation.
In CLIMB-121, 46 participants (mean age: 21.4y) received exa-cel; median follow-up was 44.7 (8.9,73.7) months. Of 45 participants evaluable for VF12/HF12, 100% (45/45) achieved VF12 and HF12 in CLIMB-121/CLIMB-131. After exa-cel, all participants engrafted neutrophils and platelets at a median of 27 (15,40) and 34.5 (23,126) days, respectively. In SCD participants, clinically meaningful improvements in hemolysis markers (lactate dehydrogenase, haptoglobin, reticulocyte count, indirect bilirubin) were observed compared to baseline and were maintained over time.
In TDT and SCD, durable increases in total and fetal hemoglobin were observed. Allelic editing was stable over time in both bone marrow and peripheral blood. OS and EFS rates at 2 years were the same: 100% for TDT and 97.8% for SCD (1 death due to COVID-19, previously reported; individual was not immunized against SARS-CoV-2). There were no events of GVHD or graft failure in any participant.
Exa-cel safety profile was consistent with myeloablative conditioning and autologous transplant in both TDT and SCD. There were no malignancies through follow-up in CLIMB-131.

Conclusions: Exa-cel demonstrated durable clinical benefits for >6 years of follow-up in TDT and SCD participants. The safety profile was consistent with busulfan myeloablative conditioning and autologous transplant; there were no malignancies. These data continue to support exa-cel as a one-time functional cure for TDT and SCD.

Background: Non-relapse mortality (NRM) is a significant concern following CAR T-cell infusion, with a recent meta-analysis identifying NRM of 5-10% following CAR T-cell infusion for haematological malignancies (1). However, this study comprised pooled data from a mixture of clinical trials and real-world data reports, with varying reporting criteria and limited long-term follow-up (1). Therefore, disease- and product-specific estimates of NRM in large real-world cohorts remain needed.
This retrospective EBMT registry study evaluated the risk of NRM for different disease indications and CAR-T products and identified the leading causes of NRM.

Methods: We identified and included adult patients ≥18 years of age at the time of first CAR-T infusion, who received a licensed CAR-T product between 2019 and 2023 for a haematological malignancy.

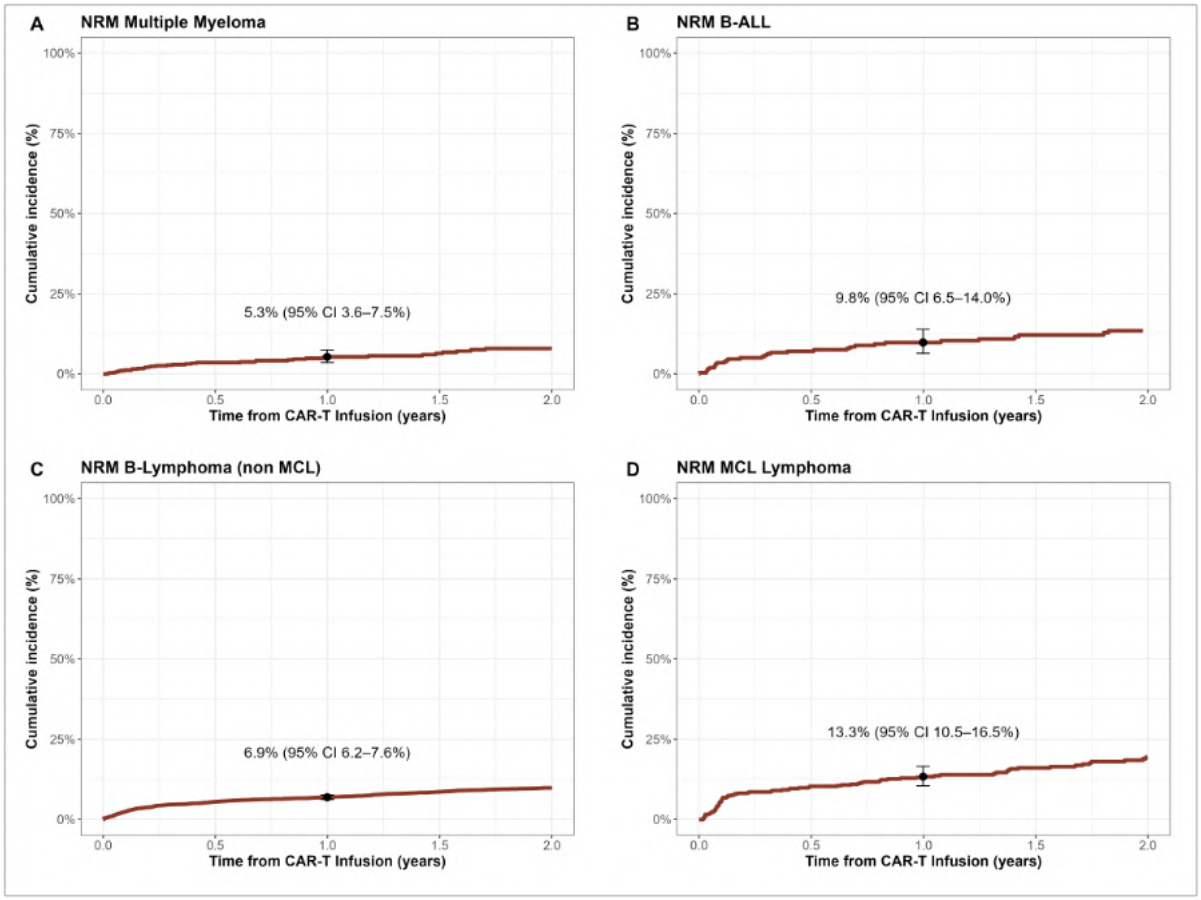
Results: 6928 patients were included, of whom 258 received CAR T-cell therapy for B-acute lymphoblastic leukaemia (B-ALL), 514 for mantle cell lymphoma (MCL), 5573 for B-cell lymphoma (BCL), and 583 for multiple myeloma (MM). There were 2,887 deaths, and the leading cause was disease progression/relapse (80.4%).
Table 1 summarizes NRM by disease indication and CAR-T product, and Figure 1 depicts the cumulative incidence of NRM by disease. The highest NRM at 1-year post-infusion was observed in MCL patients treated with brexu-cel (13.3%), followed by B-ALL patients treated with brexu-cel (11.4%). The lowest NRM at 1 year was seen in BCL patients treated with liso-cel (3.99%).

Table 1: Non-relapse mortality by disease indication and CAR T product

Diagnosis and CAR T product	NRM at 6 months (% (95% CI))	NRM at 1 year (% (95% CI))	NRM at 2 years (% (95% CI))

B-ALL Tisa-cel	6.90% (3.64%, 11.6%)	9.00% (5.14%, 14.2%)	10.9% (6.42%, 16.6%)
B-ALL Brexu-cel	7.45% (3.26%, 14.0%)	11.4% (5.74%, 19.1%)	19.0% (10.6%, 29.3%)
BCL Liso-cel	3.99% (1.29%, 9.19%)	3.99% (1.29%, 9.19%)	6.07% (2.05%, 13.3%)
BCL Tisa-cel	5.24% (4.23%, 6.39%)	6.31% (5.19%, 7.58%)	9.42% (7.93%, 11.1%)
BCL Axi-cel	5.68% (4.97%, 6.46%)	7.26% (6.44%, 8.14%)	10.1% (9.09%, 11.3%)
MCL Brexu-cel	10.3% (7.83%, 13.1%)	13.3% (10.5%, 16.5%)	19.4% (15.6%, 23.7%)
MM Ide-cel	3.24% (1.90%, 5.16%)	4.59% (2.89%, 6.87%)	Not Applicable (Insufficient FU)
MM Cilta-cel	4.85% (1.78%, 10.3%)	8.75% (4.01%, 15.8%)	Not Applicable (Insufficient FU)

In multivariable analysis, the risk of NRM was increased in B-ALL patients with ECOG ≥1 (HR 3.47, p=0.03), and in MM patients with active disease at lymphodepletion (HR [CR/PR vs. active disease] 0.42, p=0.05). Among BCL patients, higher NRM was associated with older age at CAR-T infusion (HR 1.16, p<0.001), male sex (HR 1.34, p=0.003), ECOG ≥1 (HR 2.00, p<0.001), and disease status (HR [PR vs. active disease] 0.75, p=0.01). The leading cause of NRM was infection (n=191, 35.4% of NRM), cell therapy-related causes (n=177, 32.8% of NRM), and secondary malignancies (n=51, 9.5% of NRM).



Conclusions: This study highlights the significant NRM associated with CAR T-cell therapy and differences across diseases and therapeutic products. Infections were the leading cause of NRM, underscoring the need for improved, product-specific strategies for infection prevention, surveillance, and management to further enhance CAR-T outcomes.

Background: Both axicabtagene ciloleucel (axi-cel) and lisocabtagene maraleucel (liso-cel) are approved for second line treatment of relapsed/refratory (r/r) large b-cell lymphoma (LBCL). Differences in the design of the pivotal trials complicate direct comparisons of their efficacy. In the ≥3rd-line setting, real-world analyses have significantly influenced the use of the approved CAR T-cell products. This EBMT analysis evaluates potential differences in efficacy between axi-cel and liso-cel in the second-line treatment of r/r LBCL.

Methods: Patients with LBCL registered in the EBMT registry from 01/2022 until 12/2024 receiving either axi- or liso-cel in second line were included. Kaplan-Meyer estimates were used to calculate overall (OS) and progression-free survival (PFS) from the day of CAR T-cell infusion, cumulative incidences were applied for relapse incidence (RI) and non-relapse mortality (NRM). To mitigate selection bias, propensity score matching (PSM) was employed, including the following variables: treatment year, disease status at CAR T-cell infusion, HCT-CI, time between diagnosis and infusion and lymphodepleting regimen.

Results: Of 515 included patients, 44 were treated with liso-cel and 471 received axi-cel. Median age of the whole cohort was 63 years (range 54 - 70) and the majority of patients were male (64%). At cell therapy, 91% of patients had an ECOG performance status of 0-1, 77% presented with Ann Arbor stage III-IV and 41% had elevated LDH. The majority of patients had refractory disease at the time of CAR T-cell infusion (58%). The two cohorts differed significantly only in the frequency of extranodal involvement (39% in the axi-cel group vs 21% for liso-cel patients, p = 0.048) and the year of CAR T-cell infusion (76% of axi-cel infusions in 2022 and 2023 vs 45.5% of liso-cel infusions in this period). With a

median follow-up of 1.1 years, OS at 1 year for all patients was 77.9% (95% CI 73.6-81.6), 77.5% (95% CI 73-81.4) for axi-cel patients and 81.9% (95% CI 65.5-91) for liso-cel patients. PFS at 1 year was 60.7% (95% CI 55.6-65.3) for the entire cohort and 60.3% (95% CI 55-65.2) for patients who received axi-cel vs 64.4% (95% CI 47.2-77.3) for patients treated with liso-cel. The relapse incidence was 35.9% (95% CI 30.9-41) 1 year after axi-cel infusion and 30.3% (95% CI 16.6-45.1) after liso-cel treatment. One-year NRM was 3.7% (95% CI 2.1-6) and 5.3% (95% CI 0.9-16) for axi-cel and liso-cel, respectively. Propensity score matching confirmed similar results for both productsfor OS, PFS, RI and NRM.

Conclusions: In this real-world analysis, patients with r/r LBCL receiving axi-cel or liso-cel infusion in the second line setting achieved excellent 1-year survival outcomes, consistent with pivotal trial data. Both products demonstrated similar results in terms of OS, PFS and RI. NRM is notably low for both axi- and liso-cel, highlighting that both products are not only highly efficacious but also safe. Treatment selection can therefore be tailored to individual patient characteristics, such as comorbidities and other clinical factors. Ongoing data collection on toxicity profiles, including the incidence of ICANS and CRS, will further inform treatment decisions.

Background: CD19-directed CAR T-cell therapy (CART) induces durable remissions in a subset of patients with relapsed/refractory large B-cell lymphoma (R/R LBCL). Bridging therapy (BT) between leukapheresis and lymphodepletion is used in many patients, but the optimal modality and its impact on outcomes remain uncertain. Here, we evaluated the impact of BT modality and disease status at lymphodepletion on the outcomes following CART in a large international cohort.

Methods: We analyzed 1,134 adults with R/R LBCL treated with commercial CD19-directed CART cells (axicabtagene ciloleucel or tisagenlecleucel) at 38 EBMT centers (2018–2023). BT was defined as any anti-lymphoma treatment between leukapheresis and lymphodepletion and was categorized into Pola-BR, low-dose regimens, classical salvage chemo-immunotherapy, or radiotherapy (RT). Outcomes were analyzed using Kaplan-Meier plots and multivariable Cox models adjusted for clinical covariates and CART product, with changes in disease status from apheresis to lymphodepletion classified as improved, stable, or worse.

Results: Of 1,134 patients, 900 pts (79%) received BT and 234 (21%) proceeded to CART without BT. BT usage marked a higher-risk population at lymphodepletion, with significantly increased LDH levels (49.3% vs 39.1%), bulky disease (17.0% vs 6.8%), and ECOG ≥2 (16.9% vs 7.9%). With a median follow-up of 36.2 vs 35.1 months, the 3-year PFS was 34.3% vs 44.7% and the OS 44.4% vs 57.4% in the BT versus No-BT groups, respectively. In multivariable models adjusting for age, sex, transformed histology, prior auto-HCT, number of prior treatment lines, disease status at apheresis, LDH at lymphodepletion, ECOG at CART, and CART product, absence of BT remained associated with more favorable outcomes (OS HR 0.63, 95%CI 0.49–0.82; PFS HR 0.69, 95%CI 0.55–0.87), mostly caused by lower RI in these patients. Overall, 25.6% of patients improved their disease status between apheresis and lymphodepletion (28.2% in BT vs. 9.9% in No-BT, $p<0.001$). Patients with improvement of the disease status had a 3-year OS of 63.2% vs 41.8% (stable) and 39.8% (worsened; $p<0.0001$) and a 3-year PFS of 48.6% vs 32.1% and 34.2%, respectively ($p<0.0001$). This was particularly pronounced among BT recipients, with 3-year PFS rates of 47.5%, 28.9%, and 27.7% for improved, stable, and worsened disease status, respectively. BT modality influenced conversion rates and rates of progression (highest/lowest with Pola-BR and RT), but in multivariable analyses using the same covariates, no BT modality was associated with OS, PFS, RI, or NRM. Toxicity profiles, including CRS, ICANS, were comparable between BT and No-BT cohorts.

Conclusions: In this large registry cohort, BT was used in 79% of patients intended for CART and identified patients with a higher risk of failure following CART. BT exposure was associated with inferior survival even after adjustment for baseline disease and patient characteristics, and no individual BT modality conferred a clear survival advantage. Improvement in disease status before lymphodepletion was a significant determinant of outcome. These data support the use of BT when necessary, aiming to improve the disease status at lymphodepletion. Our data underscore the need for prospective studies to refine BT strategies that safely achieve disease control without compromising CART efficacy.

Background: In the primary analysis of TRANSCEND FL (NCT04245839), an open-label, pivotal study, liso-cel showed high response rates and favorable safety in patients with R/R FL. Here, we report 3-year follow-up results in patients with 3L+ FL, including efficacy, safety, and longitudinal safety analyses for key AEs.

Methods: Patients were eligible if they had R/R FL after ≥ 2 prior lines of combination systemic therapy, including an anti-CD20 antibody and an alkylator. Patients received liso-cel after lymphodepleting chemotherapy (LDC). Bridging therapy was allowed with reconfirmation of PET-positive disease before LDC. The primary endpoint was ORR per independent review committee by PET/CT using Lugano 2014 criteria. Secondary endpoints included CR rate, duration of response, PFS, OS, and safety. Additional post hoc analyses included time to next treatment and efficacy by progression of disease ≤ 24 months from

first-line chemoimmunotherapy (POD24) status (yes vs no) and by prior bendamustine exposure before leukapheresis (yes vs no). Incidences of infections, second primary malignancies (SPM), hypogammaglobulinemia, and grade ≥ 3 cytopenia (overall and by lineage) were assessed over time from Day 0–15, Day 16–30, at 3-month intervals until Month 12, at 6-month intervals until Month 36, and from Month 37 until end of study.

Results: At data cutoff (03/31/2025), 107 patients with 3L+ FL received liso-cel and were evaluable for safety; 103 were efficacy evaluable. Median (range) age was 62 years (23–80); 95 (89%) had Ann Arbor stage III/IV disease; and 61 (57%) were high risk per Follicular Lymphoma International Prognostic Index. Fifty-nine patients (55%) had POD24, 69 (64%) were double refractory to anti-CD20 antibody and an alkylator, and 65 (61%) had prior bendamustine exposure.
Median (range) on-study follow-up was 41.5 months (0.3–54.0). Response rates were high overall and regardless of POD24 status or prior bendamustine exposure (**Table 1**). Treatment-emergent (TE) AE rates were consistent with the primary and 2-year follow-up analyses. Grade 3 cytokine release syndrome was reported in 1% (no grade 4/5), grade 3 neurological events in 2% (no grade 4/5). SPMs were reported in 11 patients (10%; 4 additional patients since the 2-year follow-up analysis; no secondary T-cell malignancies). Grade ≥ 3 infections were reported in 13 (12%) patients, including 7 (7%) in the TE period (≤ 90 d after infusion) and 8 (7%) in the post-TE period (3 more patients since the 2-year analysis). AE incidences over time are shown in **Table 2.**

Conclusions: In patients with 3L+ FL, a single infusion of liso-cel demonstrated remarkable efficacy, with durable responses and high 3-year survival rates, regardless of POD24 status or prior bendamustine exposure. No new safety signals were identified. Grade ≥ 3 neutropenia and hypogammaglobulinemia decreased over time and severe infections remained low, further underscoring the favorable long-term safety profile of liso-cel in patients with 3L+ FL.

Table 1. Efficacy outcomes

	3L+ FL (n = 103)	**POD24 (n = 57)**	**Non-POD24 (n = 46)**	**Prior bendamustine exposure (n = 61)**	**No prior bendamustine exposure (n = 42)**

[a]Proportions for grade ≥ 3 cytopenias and hypogammaglobulinemia were calculated using the denominator as the number of patients with a laboratory parameter assessment in each time period. From M25—M36, > 50% of patients on study had missing values for laboratory parameters. Proportions for infections were calculated using the number of patients on study in each time period: D0—D15, n = 107; D16—D30, n = 106; M2—M3, n = 106; M4—M6, n = 105; M7—M9, n = 100; M10—M12, n = 97; M13—M18, n = 97; M19—M24, n = 94; M25—M30, n = 90; M31—M36, n = 85; M37—EOS, n = 81.
Monthly ranges start on the first day of the first month and end on the last day of the last month. Each patient is counted once in each time period but is counted again if having an event in another time period. Results are consistent when patients who started subsequent antilymphoma therapy were excluded at the initiation of subsequent therapy.
D, Day; EOS, end of study; liso-cel, lisocabtagene maraleucel; M, Month.

OS02-03

AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION COMBINED WITH CAR-T CELL THERAPY SIGNIFICANTLY IMPROVES PROGRESSION-FREE SURVIVAL IN RELAPSED REFRACTORY CENTRAL NERVOUS SYSTEM LYMPHOMA

Rui Liu[1], Zhonghua Fu[1], Lixia Ma[1], Fan Yang[1], Danyang Li[1], Miaomiao Cao[1], Yuelu Guo[1], Biping Deng[2], Alex H. Chang[3], Xiaoyan Ke[1], Kai Hu[1], ***Yan Gao***[1]

Background: Relapsed or refractory Central nervous system lymphoma(R/R CNSL) is challenging to manage clinically. CAR-T therapy has demonstrated efficacy in relapsed and refractory large B-cell lymphoma, with some studies indicating a favourable response rate for R/R CNSL. Nevertheless, disease-free survival and long-term outcomes are suboptimal.Our study aims to explore the efficacy of CAR-T and the factors affecting its long-term survival in R/R CNSL. Additionally, we analysed the safety and effectiveness of ASCT combined with CAR-T therapy.

Methods: This single-centre retrospective study included 153 patients with relapsed/refractory CNS lymphoma (R/R CNSL) treated with CAR-T therapy at Beijing GoBroad Hospital from September 2019 to September 2025. Overall, 51% were male, and the median age was 56 years (range, 19–79). PCNSL accounted for 53% of cases (81/153)

and SCNSL for 47% (72/153), The common histology in SCNSL was DLBCL(n=55), followed by HGBL(n=5), PMBL(n=3) and others.
A total of 83 patients had received ≥3 prior treatment lines. IELSG (PCNSL) or IPI (SCNSL) scoring identified 27% as low-risk, 59% intermediate-risk, and 14% high-risk. Most patients were refractory to HD-MTX (85%), and 58% had received MTX within 6 months before CAR-T. BTKi resistance was present in 64%, and 18% had failed prior ASCT.
Parenchymal involvement occurred in 74%, cerebrospinal fluid in 8%, and both in 18%.
Patients received a median of 2 cycles (0–5) of bridging therapy, achieving a 71% objective response rate (CR 84; PR 24). Based on bridging response, patients were classified into Bridging-Effective (CR/PR) and Bridging-Ineffective (SD/PD) groups. In the BE group, 49%(53/108) underwent ASCT combined with CAR-T therapy.

Table 1:Baseline of different treatment in the effective group after bridging therapy

Variable	CAR-T(N=55)	ASCT+CAR-T(N=53)	p-value
Age(>60)	27/55(49.1%)	6/53(11.3%)	0.736
Sex(male)	26/55(47.3%)	26/53(49.1%)	0.278
Risk category -Low risk -Intermediate risk -High risk	14/55(25.5) 34/55(61.8%) 7/55(12.7%)	21/53(39.6%) 28/53(52.8%) 4/53(7.5%)	0.118
ECOG ≥2	20/55(37.7%)	21/53(39.6%)	**0.0001**
Histology -PCNSL -SCNSL	20/55(36.4%) 35/55(63.6%)	23/53(43.4%) 30/53(56.6%)	**0.005**
TP53 mutation	6/55(10.9%)	8/53(15.1%)	0.272
Previous HD-MTX resistance	48/55(87.3%)	51/53(96.2%)	**0.001**
Previous BTK inhibitor resistance	35/55(63.6%)	35/53(66.0%)	0.761
Previous auto-HCT	14/55(25.5%)	9/53(17.0%)	0.067
Previous regimen lines≥3	28/55(50.9%)	31/53(58.5%)	0.833

Results: The 3-month ORR was 79% (121/153), and CRR is 69% (106/153). Incidences of any-grade CRS and ICANS were 69% (105/153) and 14% (21/153), with severe (≥3) CRS and ICANS at 6% (6/105) and 24 % (5/21), respectively. BE group exhibited significantly higher 3-month ORR (91% vs. 56%) and CRR (87% vs. 33%) compared to BI group. Median follow-up time was 26months. Median Progression-Free Survival (PFS) for BE group was 49 months, significantly longer than BI group's 6 months (P<0.0001).
Median Overall Survival (OS) was not reached for BE group, while it was 13 months for BI group (P<0.0001).1-year OS rates were 93% vs. 57% (P<0.01), and 1-year PFS rates were 75% vs. 27% (P<0.01) for BE and BI groups, respectively.
2-year OS rates were 78.5%vs. 29% (P<0.01), and 1-year PFS rates were 67% vs. 14% (P<0.01) for BE and BI groups, respectively.
Among the 108 BE group patients, Median PFS in ASCT combined with CAR-T cohort was significantly prolonged (57.11 vs. 27.35 months, p=0.001). Median OS was not reached in both cohort（p=0.053). No statistical difference was observed in CRS and ICANS between the two cohorts.

Conclusions: Effective bridging therapy can significantly improve the efficacy of CART in the treatment of R/R CNSL. After bridging therapy is effective, the treatment model of ASCT combined with CAR-T can significantly improve Progression-free survival.

Disclosure: Nothing to declare.

Background: B-cell-directed immunotherapies (BCDI), such as CD19 chimeric antigen receptor T-cell therapy (CAR-T), antibody-drug conjugates including polatuzumab vedotin (pola), and bispecific antibodies (BSA) have revolutionized the treatment of large B-cell lymphoma (LBCL). The optimal sequencing of BCDI and CAR-T remains unclear, while prolonged B-cell depletion may contribute to CAR-T-associated non-relapse mortality (NRM). In a collaborative analysis by the EBMT and the GoCART coalition, we evaluated the impact of prior BCDI exposure on outcomes after CD19 CAR-T in a large retrospective cohort.

Methods: We analyzed 1128 adult patients with LBCL who underwent CD19 CAR-T between 2018 and July 2023 at 38 European centers reported to the EBMT registry. BCDI exposure (excluding rituximab) prior to CAR-T, including bridging therapy, was categorized as BSA, pola-based regimens, and other BCDI, including obinutuzumab, brentuximab vedotin, and loncastixumab tesirine.

Results: Among 1,128 patients, 376 (33.2%) received BCDI other than rituximab before CAR-T (BCDI group) and 752 (66.7%) did not (non-BCDI group). Within the BCDI group, 189 (50.3%) received BCDI as bridging only and 187 (49.7%) prior to apheresis (median of 3 lines including BCDI). BCDI-exposed patients more often had ≥3 prior treatment lines (54.8% vs. 43.0%, p<0.001), more frequent axicabtagene ciloleucel usage (63.8% vs. 56.0%, p=0.012), and higher complete/partial remission (CR/PR) rates at lymphodepletion (40.2% vs. 29.1%, p<0.001).
Three-year overall survival (OS) was numerically inferior with prior BCDI (41.3% vs. 49.7%, p=0.07), without differences in progression-free survival (PFS) (35.0% vs. 37.2%), relapse incidence (52.0% vs. 51.5%), or NRM (13.0% vs. 11.3%). Post–CAR-T CR rates (51.8% vs. 54.8%) and overall response rate (73.8% vs. 73.1%) were not statistically different, as were cytokine release syndrome (83.9% vs. 84.8%), Immune Effector Cell-Associated Neurotoxicity Syndrome (31.3% vs. 32.9%), and 2-year grade III/IV infections (22.2% vs. 21.8%). In multivariable analysis, prior BCDI showed a borderline association with inferior OS (HR 1.21, 95% CI 1.00–1.47, p=0.06).
Within BCDI-exposed patients, BCDI type was associated with different 2.5-year OS (BSA 48.0%, pola-based (often including bendamustine) 39.8%, other BCDI 59.9%; p=0.03). After matching patients, OS was lower with pola than with BSA (HR 1.84 [0.95–3.57], p=0.07), and favored other BCDI over pola (HR 0.61, p=0.11), with a trend toward improved PFS (HR 0.63, p=0.09). Analysis of BCDI administration timing is under way but shows different univariable 3-year OS by BCDI exposure relative to apheresis (post-apheresis only 47.1%, pre-apheresis only 41.2%, both pre- and post-apheresis 22.6%).

Conclusions: Our data suggest that prior BCDI exposure may be associated with inferior OS after CAR-T without affecting NRM, with this effect potentially confined to patients receiving BCDI before apheresis. Matched analyses indicated a signal toward inferior OS with pola-based regimens; however, these findings are hypothesis-generating and limited by residual confounding (e.g. bendamustine use with pola), retrospective design, and small subgroup sizes.

DO 2 YEAR PATIENT OUTCOMES DIFFER BY DONOR TYPE USING CONTEMPORARY GRAFT VS HOST DISEASE PROPHYLAXIS POST-TRANSPLANT? A CIBMTR RETROSPECTIVE ANALYSIS

Steven M. Devine[1], *Igor Litvinovich*[1], *Varuna Astha*[1], *Kwang Woo Ahn*[2], *Caitrin Bupp*[1], *Rajat Bansal*[3], *Javier Bolaños-Meade*[4], *Aleksandr Lazaryan*[5], *Mahasweta Gooptu*[6], *Bronwen E. Shaw*[2], *Heather E. Stefanski*[1], *Stephen R. Spellman*[1], *Jeffery J. Auletta*[1]

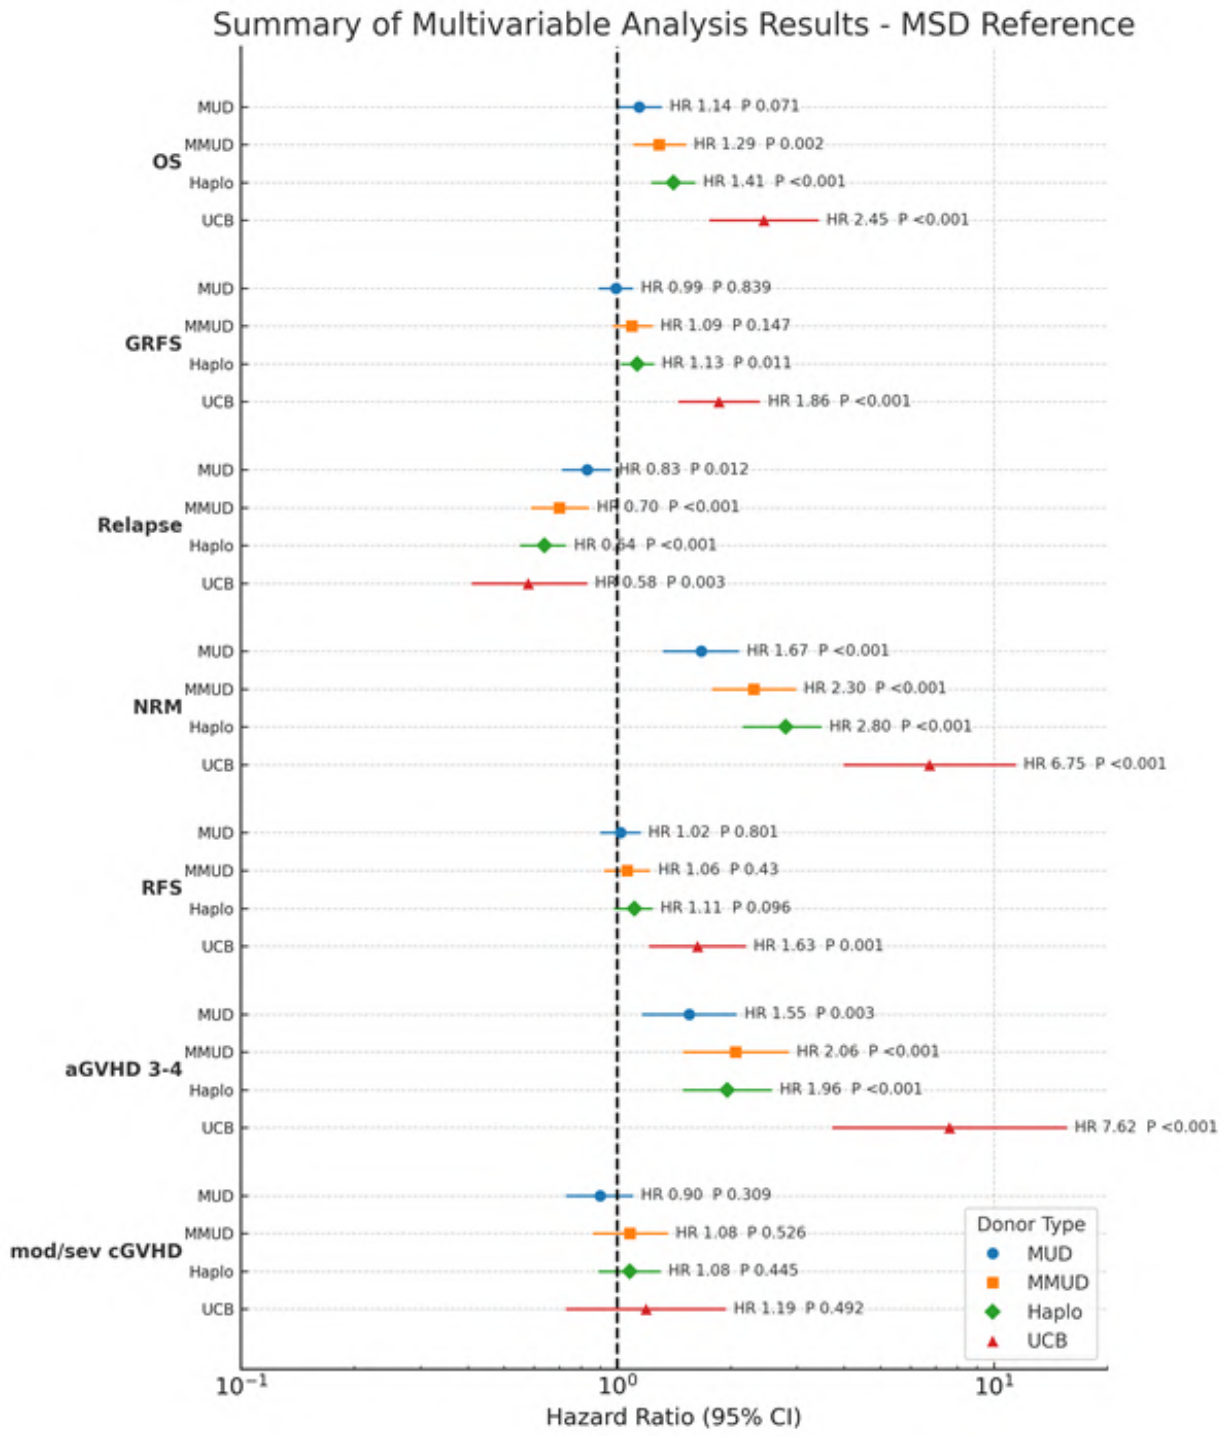
Background: Post-transplant cyclophosphamide (PTCy) based graft vs host disease (GvHD) prophylaxis expands access to allogeneic hematopoietic cell transplantation (HCT) through the safe and effective use of mismatched related (haplo) and unrelated donors (MMUD). A previous analysis from our group evaluating HCTs from 2017-2022 demonstrated that outcome disparities persist at 1-year post-HCT between matched (sibling/related [MSD] and unrelated [MUD]) donors compared to mismatched sources, but such differences have diminished in magnitude using contemporary GVHD prophylaxis. We sought to expand the population (adding cases from 2023) and evaluate longer term outcomes to determine if differences persist beyond one year of follow-up.

Methods: We conducted a retrospective registry analysis of all contemporary donor types using the Center for International Blood and Marrow Transplant Research (CIBMTR) database. The primary objective was to compare overall and GVHD-free, relapse-free survival (GRFS) at 2 years post HCT among donor types. Secondary objectives were to compare cumulative incidence of relapse, disease-free survival (DFS), non-relapse mortality (NRM), acute GVHD (aGVHD) grades 2-4 and 3-4 and moderate/severe chronic GVHD (cGVHD). The cohort included adult patients (≥18 years old) with acute leukemia (ALL and AML) or myelodysplastic syndrome (MDS) transplanted in the U.S. from 2017-2023. Donor types included MSD, 8/8 HLA MUD, 7/8 HLA MMUD, haplo and umbilical cord blood (UCB). All patients received PTCy without ATG with the exception of UCB recipients who received CNI-based GVHD prophylaxis without ATG as standard of care per current American Society for Transplantation and Cellular Therapy (ASTCT) guidelines.

Results: The study cohort included 13,336 patients from 166 centers. The distribution by donor type and disease were as follows: MSD=1263, MUD=4117, MMUD=1426, Haplo=5811, UCB=719 and ALL=2551, AML=7305, MDS=3480, respectively. Median donor age in years differed by type and was older for related donor sources: MSD=53, MUD=27, MMUD=28 and haplo=35. Peripheral blood allografts were used in 89% of MSD/MUD/MMUD/haplo HCT. 40% received myeloablative conditioning with >50% in both the MSD and UCB groups. Median survival time was 23.2 months (interquartile range 11.0-39.7 months) and analysis limited to 24 months. In multivariable analyses (Figure), OS was highest in MSD and MUD and lowest in UCB. Compared to MSD (reference), GRFS was worse in haplo and UCB and did not differ with MUD or MMUD. Relapse was lower in MUD, MMUD, haplo and UCB compared to MSD, but offset by higher NRM. aGVHD 3-4 risk was higher in MUD, MMUD, haplo and UCB, but cGVHD risk did not differ among groups.



Conclusions: In this extended follow-up analysis of recipients of alloHCT in the contemporary PTCy era, outcomes still vary by donor type at two years post-HCT. MSD and

MUD result in similar OS and GRFS. MMUD and haplo compare favorably. Conventional UCB had worse outcomes overall. Results suggest donor selection strategies should favor MSD and MUD, if available, followed by MMUD and haplo over UCB.

NOVEL COMPOSITE END-POINTS TOXICITY/PROGRESSION-FREE SURVIVAL (TFPFS) AND TOXICITY-FREE COMPLETE REMISSION (TFCR) AFTER CART19 CELL THERAPY FOR LARGE B CELL LYMPHOMA (LBCL): CELL THERAPY CONSORTIUM ANALYSIS

Veronika Bachanova[1], *Qing Cao*[1], *Marie Hu*[1], *Supryia Gupta*[1], *Miguel-Angel Perales*[2], *Olalekan Oluwole*[3], *Richard Maziarz*[4], *Joseph McGuirk*[5], *Andy Chen*[4], *Saraih Ahmed*[6], *Stephen Schuster*[7], *Gunjan Shah*[2], *Michael Bishop*[8], *Jamie Brower*[7], *David Porter*[7], *Peter Riedell*[8]
[1]*University of Minnesota, Minneapolis, United States of America (the),* [2]*MSKCC, New York, United States of America (the),* [3]*Vanderbilt Medical Center, Nashville,, United States of America (the),* [4]*Oregon Health and Science University, Portland, United States of America (the),* [5]*University of Kansas Medical Center, Kansas, United States of America (the),* [6]*MD Anderson Medical Center, Houston, United States of America (the),* [7]*University of Pennsylvania, Philadelphia, United States of America (the),* [8]*University of Chicago, Chicago, United States of America (the)*

Background:

The success of any CAR-T product is typically assessed by disease response and rates of immune complications; both vary significantly among CART19 products for patients with LBCL. We explored the utility of integrated efficacy/toxicity composite end-points to yield insights into net clinical benefit.

Methods: To evaluate the combined contribution of efficacy and toxicity in first 100 days post CAR19-T, we defined a novel composite end-point: toxicity-progression free survival at day 100 (tPFS100). Events included relapse/progression, death and grade ≥3 cytokine release syndrome (CRS) or grade ≥3 immune effector-associated encephalopathy (ICANS). In addition, at day 100, each patient was assigned to one of 3 groups: non CR group, toxicity-free complete response at day 100 (tfCR100) and CR group with grade ≥3 CRS or ICANS toxicity (CRwt).

Results:

We included 627 consecutive CAR19-T cell recipients with LBCL reported to Cell Therapy Consortium (CTC) between 2017-2023; median age was 64 yrs (18-86), 12% had ECOG≥2 and 57% had refractory disease. Most common product infused was axi-cel (53%) followed by tisa-cel (33%) and liso-cel (13%).

At day 100 post CAR19-T, composite tPFS100 in entire cohort was 61% (95% CI: 57-65%). Product specific tPFS100 was highest for liso-cel 70% (95%CI 62-80%) compared to 53% (47-60%) for tisa-cel and 46% (95%CI 41-51%) for axi-cel. In MVA, high LDH (2.40; 95%CI 1.87-3.09; p=0.01) and advanced stage III-IV (HR 1.38; 1-1.9; p=0.04) were risk factors for inferior tfPFS100. Liso-cel/age >65 yrs and tisa-cell/age >65yrs were protective (HR 0.21 and HR 0.7).
We determined that 242 pts (49%) achieved tfCR100, 66 patients (10%) experienced CRwt and 320 (51%) did not achieve CR by day 100.
The tfCR100 rates were similar by age and differed significantly by CAR-T product: 32.9 % (Axi-cel), 37.2% (Tisa-cel) and 65.1% (Liso-cel; p<0.01). Factors favorably associated with tfCR included normal LDH and ECOG £1. After CART19 therapy, tfCR group had lower rates of neutropenia <500, thrombocytopenia, infection rates, peak CRP and ferritin, ICU utilization and shorter length of hospital stay compared to CRwt patients.
At a median follow-up of 22.4 months (range 21-80.7), adjusted 2-year OS among tfCR100 group was 86% (95% 80-91) compared to 63% (49-75%) for the CRwt group (p=0.01). Among patients without CR100, 31% (25-36%; p<0.01) survived to 2 years post CAR19-T. Notably, non-relapse mortality was significantly lower in the tfCR100 group (5%; 95% CI: 2–9%) compared to CRwt (26%; 95% CI: 14–38%; p < 0.01). The 2-year cumulative incidence of relapse did not differ significantly between two CR groups (26%; vs. 21%; p = 0.44). As a result, tfCR100 group yield significantly better PFS (72%; 95%CI(64-79%) compared to CRwt group (54; 95% CI 43-64%; p<0.01).

Conclusions:

Our data demonstrate that about half of CAR19-T recipients experience CR without advanced CRS or ICANS; thus, products differ significantly in early endpoint tfPFS100 with observed superiority of liso-cel. The emergence of these novel tools that may be valuable in benchmarking cell therapies, health economic modeling, and guiding future strategies to optimize safety and efficacy of CAR-T therapy.

OS07-02

FRAILTY ASSESSMENT AND THEIR PROGNOSTIC SIGNIFICANCE IN CAR T-CELL THERAPY. RESULTS FROM A PROSPECTIVE AND LONGITUDINAL SINGLE-CENTER STUDY

Rubén Solís Armenta[1], *Pilar Ayora*[1], *Carla Ramos*[1], *Nuria Martínez*[1], *Nil Abiol Zamora*[1], *Aina Olvier Calders*[1], *Valentín Ortíz Maldonado*[1], *Mercedes Montoro Lorite*[1], *Ana García*[1], *Raquel Salinas*[1], *Maite Antonio*[1], *Pedro Castro*[1,2], *Carlos Fernández de Larrea*[1], *Julio Delgado*[1], *Francesc Fernández Avilés*[1], *María Queralt Salas*[1]
[1]*Hospital Clínic Barcelona, Barcelona, Spain,* [2]*IDIBAPS, University of Barcelona, Barcelona, Spain*

Background: Frailty syndrome in patients with hematological malignancies has been increasingly associated with inferior outcomes. Based on this evidence, our institution launched a prospective, longitudinal, observational study in April 2023 to evaluate frailty in all candidates for CAR T-cell therapy and to assess its impact on clinical outcomes. This analysis summarizes the results obtained during this investigation.

Methods: All patients with lymphoproliferative disorders (LPD) or acute lymphoblastic leukemia (ALL) eligible for commercial (axicabtagene autoleucel) or academic (ARI0001) CD19 CAR T-cell therapy were prospectively included after providing informed consent. Frailty was assessed using the HCT Frailty Scale (Salas et al., 2023) at first consultation (prior to leukapheresis) and before lymphodepletion for CAR T-cell infusion. Quality of life (QoL) was evaluated using the EQ-5D-3L questionnaire before lymphodepletion. All assessments were integrated into clinical practice and conducted by nursing staff, requiring a median of 10–15 minutes per patient, and no additional resources. The study had no funding, and no interventions were implemented based on frailty status during the study period.

Results: A total of 132 consecutive patients were included, 44 (33%) with ALL and 88 (67%) with LPD. At first consultation, 28 (21%) patients were classified as fit, 86 (65%) as pre-frail, and 18 (13%) as frail. Frail patients were older than fit and pre-frail patients (median age 62 vs. 52 and 55 years; p=0.015) and more frequently female (44.4% vs. 10.7% and 38.3%; p=0.015) (Table 1).
Before lymphodepletion, frailty distribution changed significantly, confirming its dynamic nature: 39 (29.5%) patients were fit, 67 (50.9%) pre-frail, and 26 (19.7%) frail (Figure 1). Frail patients remained older, more frequently female (61.5% vs. 25.6% and 26.9%; p=0.003), and more often had ECOG ≥1 (49.9% vs. 13.9% and 22.2%; p=0.042). No differences were observed regarding baseline diagnosis, disease status, bridging therapy, or CAR T-cell product (Table 1).
Outcome analyses were performed according to frailty status before lymphodepletion (Table 1). Rates of cytokine release syndrome and immune effector cell–associated neurotoxicity syndrome (ICANS) were similar across groups. However, proportions of ICU admission were higher in frail patients (26.4%) than in fit (15.2%) and pre-frail (13.4%) patients (P=0.163). QoL was significantly worse in frail patients across all EQ-5D domains (mobility, self-care, usual activities, pain/discomfort, and anxiety (all p<0.05). With a median follow-up of 251

days, frailty was associated with inferior overall survival (OS): 1-year OS rates were 96.3% in fit, 83.2% in pre-frail, and 73.3% in frail patients (p=0.044) (Figure 1). Relapse rates were similar across groups (30.8% vs. 15.4% and 22.4%, p=0.338). The main cause of death was relapse, while non-relapse mortality occurred in 1 of 39 fit patients and 1 of 26 frail patients.

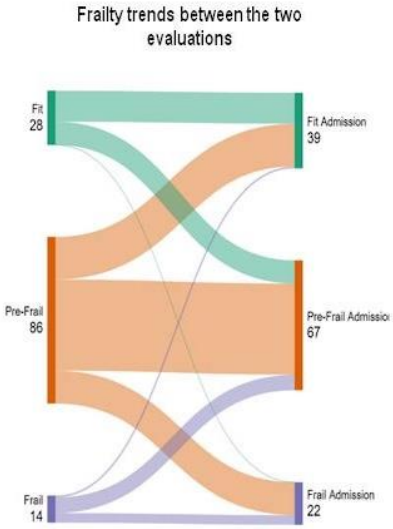
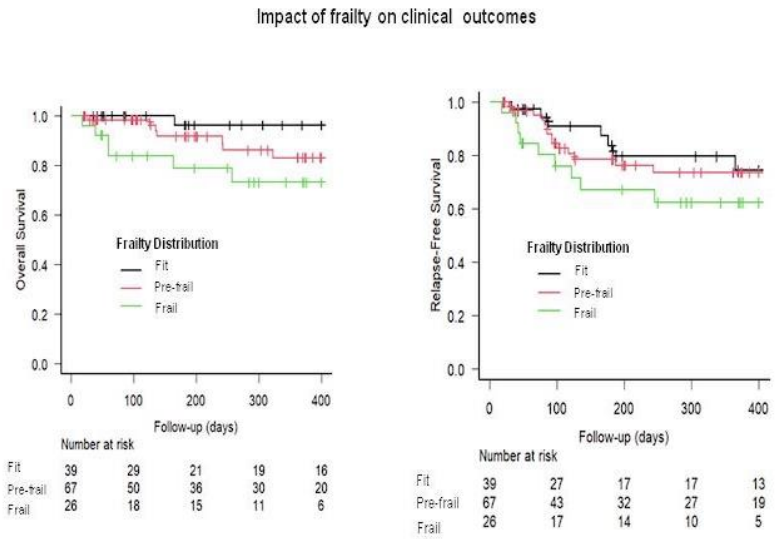
ICANS Any grade Grade 2-5	 33 (25.0) 19 (14.3)	 10 (25.6) 7 (17.9)	 15 (22.3) 8 (11.9)	 8 (30.8) 4 (15.3)	 0.7 0.714
ICU Admission	20 (15.2)	4 (10.3)	9 (13.4)	7 (26.9)	0.163
Disease Relapse (Yes)	29 (22.0)	6 (15.4)	15 (22.4)	8 (30.8)	0.338
Death **NRM**	14 (10.6) 3 (2.3)	1 (2.6) 1 (2.6)	7 (10.4) 0	6 (23.1) 2 (7.7)	0.031





Conclusions: Frailty was prevalent and dynamic among CAR T-cell candidates. Frailty was associated with poorer QoL and inferior survival. These findings suggest that routine frailty assessment and consideration of interventions to address frailty prior to CAR T-cell therapy may be beneficial in this group of patients.

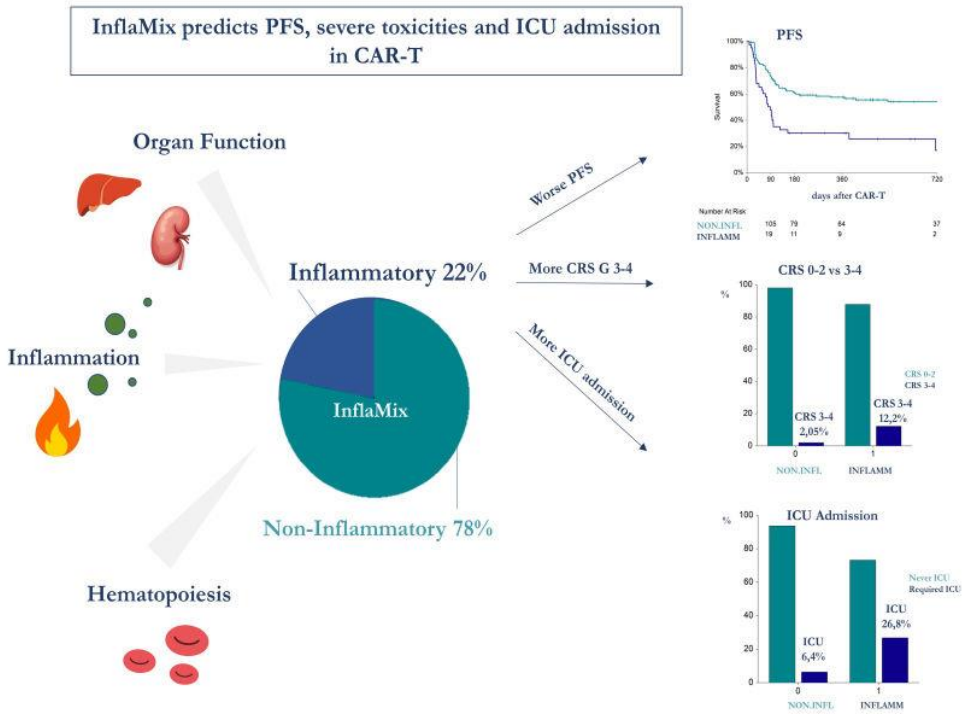
Background: InflaMix is a multiparametric inflammation-based score developed to characterize pre-infusion inflammatory profiles and organ function in candidates for CAR-T therapy. InflaMix can be calculated online from at least two of the following values (hemoglobin, albumin, LDH, CRP, ALP, AST, cytokines (IL-6, IL-10, TNFα), ferritin, D-dimer, WBCs and platelets) and dichotomize patients in Inflammatory and Non-Inflammatory. Early studies suggested a role in predicting toxicity and clinical outcomes. Despite significant advances in CAR-T cell therapy for relapsed/refractory large B-cell lymphoma (R/R LBCL), early prediction of severe inflammatory toxicities and poor outcomes remains challenging. We report a real-world validation of InflaMix in relapsed/refractory large B-cell lymphoma (LBCL), with some insight on prediction of severe toxicities and Intensive Care (ICU) admission, useful for empowering resources allocation strategies.

Methods: A total of 188 LBCL patients infused with commercial anti-CD19 CAR-T cells in two hub centers were retrospectively evaluated and categorized as Non-Inflammatory (n=147, 78%) or Inflammatory (n=41, 22%) according to the InflaMix obtained ≤48 hours before infusion. Clinical endpoints included CRS/ICANS severity, use of tocilizumab and corticosteroids, ICU admission, early infections (day 0–30), cytopenias (early/late ICAHT), progression-free survival (PFS), and competing-risk cumulative incidence of relapse and non-relapse mortality (NRM).

Results: InflaMix confirmed a strong prognostic relevance: inflammatory patients had inferior PFS compared to the non-inflammatory group, with 1-year PFS of 30% vs 57% (HR 2.38; 95% CI 1.54–3.67; p<0.001). Competing-risk analysis showed higher relapse incidence in the inflammatory group (Gray's p=0.004), while NRM stood around 7.5% at 1 year and did not differ significantly (Gray's p=0.722).
Inflammatory patients showed a significantly higher incidence of grade 3–4 CRS (12.2% vs 2.05%, OR 3.13; 95% CI 1.70–5.76, p<0.001,) and an increased risk of ICU admission (26.8% vs 6.4%, OR 2.95, 95% CI 1.77–4.92; p<0.001). In contrast, the association with grade ≥2 ICANS did not reach statistical significance (OR 1.51, CI 0.78-2.89; p=0.215).



No significant correlations were found with the use of tocilizumab (OR 1.55, CI 0.76-3.12; p=0.223), the use of corticosteroids (OR 1.33, CI 0.77-2.27; p=0.299), early infections (OR 1.55, CI 0.86-2.78; p=0.141), or cytopenias (early/late ICAHT) (OR 0.92 CI 0.51-166, p=0.803; OR 0.59 CI 0.15-2.2, p=0.432, respectively).

Conclusions: These results confirm InflaMix as a powerful baseline prognostic tool capable of predicting high-grade CRS (which require vasopressors and/or high flow respiratory support), the need for ICU-level care and inferior PFS. By capturing multidimensional aspects of systemic inflammation and organ function at pre-infusion, InflaMix provides clinically meaningful risk stratification relevant for patient counseling, toxicity mitigation strategies, and optimization of critical-care resource allocation in high-volume CAR-T programs.

Disclosure: Nothing to disclose.

OS07-04

A BASELINE INFLAMMATORY SIGNATURE IDENTIFIES IMPAIRED CD8⁺ T-CELL RECONSTITUTION AND RELAPSE RISK AFTER ALLOHCT IN AML, INDEPENDENT OF TP53 MUTATION AND MRD

Natalia Tijaro Ovalle[1], *Maria Baez Vientos*[1], *Moataz Ellithi*[2], *Ilan Goldstein*[1], *Amethyst Saldia*[1], *Jonathan Peled*[1], *Pulkit Jain*[1], *Esperanza Papadopoulos*[1], *Doris Ponce*[1], *Brian Shaffer*[1], *Roni Tamari*[1], *James Young*[1], *Ioannis Politikos*[1], *Mohammad Alhomoud*[1], *Gagan Raju*[1], *Parastoo Dahi*[1], *Aaron Goldberg*[1], *Ellin Berman*[1], *Xin Wang*[1], *Susan DeWolf*[1], *Eytan Stein*[1], *Teng Fei*[1], *Ann Jakubowski*[1], *Richard Lin*[1], *Miguel-Angel Perales*[1], *Sergio Giralt*[1], *Roni Shouval*[1], *Sandeep Raj*[1]
[1]*Memorial Sloan Kettering Cancer Center, New York, United States of America (the),*
[2]*University of Nebraska Medical Center, Omaha, United States of America (the)*

Background:

Maladaptive inflammation confers adverse risk to T cell immunotherapies including immune checkpoint inhibition and CAR-T. However, its effects on hematopoietic cell transplant (HCT) allograft function and efficacy are unknown. *InflaMix*, a point of care tool developed using an unsupervised computational approach in CAR-T cohorts (Raj, *Nat Med* 2025), provides a pragmatic method to quantify deleterious inflammatory states. We hypothesized that *InflaMix* classification before allogeneic HCT (alloHCT) identifies AML patients at risk of treatment failure independent of other high-risk factors such as *TP53* mutation.

Methods: We conducted a single center observational analysis of adults undergoing first standard of care alloHCT for AML between 2014–2024 (n=421). *InflaMix* was derived from laboratory and cytokine variables obtained within 14 days pre-alloHCT (including IL-6, IL-10, TNF, albumin, LDH, hemoglobin, AST, alkaline phosphatase, and CRP). Patients were then classified in inflammatory vs non-inflammatory clusters. Primary endpoints were overall survival (OS), cumulative incidence of measurable residual disease (MRD) relapse assessed by multiparameter flow cytometry (MFC), and non-relapse mortality (NRM). Multivariable Cox models and Fine-Gray models were adjusted for age, conditioning intensity, HLA match, GVHD prophylaxis, *TP53* status, cord blood use, and baseline MRD. *TP53* status was defined by either *TP53* mutation of copy number loss noted by next generation sequencing or 17p chromosomal loss by cytogenetics. Secondary endpoints included graft-versus-host disease-free, relapse-free survival (GRFS) and immune reconstitution.

Results: *InflaMix* classified 43 patients (10.2%) as inflammatory and 378 (89.8%) as non-inflammatory (Table 1). In our multivariable analysis, inflammatory status was independently associated with inferior overall survival (HR 1.59, 95% CI 1.01–2.52, p=0.047). In a competing risks analysis, inflammatory status was associated with a higher cumulative incidence of MRD-defined relapse (sHR 1.59, 95% CI 1.03–2.45, p=0.037) and a trend toward increased non-relapse mortality that did not reach statistical significance (sHR 1.86, 95% CI 0.97–3.56, p=0.060) (Fig. 1A-C). Longitudinal immune profiling demonstrated persistently impaired CD8⁺ T-cell reconstitution following alloHCT among inflammatory patients compared with non-inflammatory patients (Fig. 1D). Consistent with these findings,

inflammatory status was associated with inferior graft-versus-host disease-free, relapse-free survival (HR 1.47, 95% CI 1.04–2.09, p=0.030).

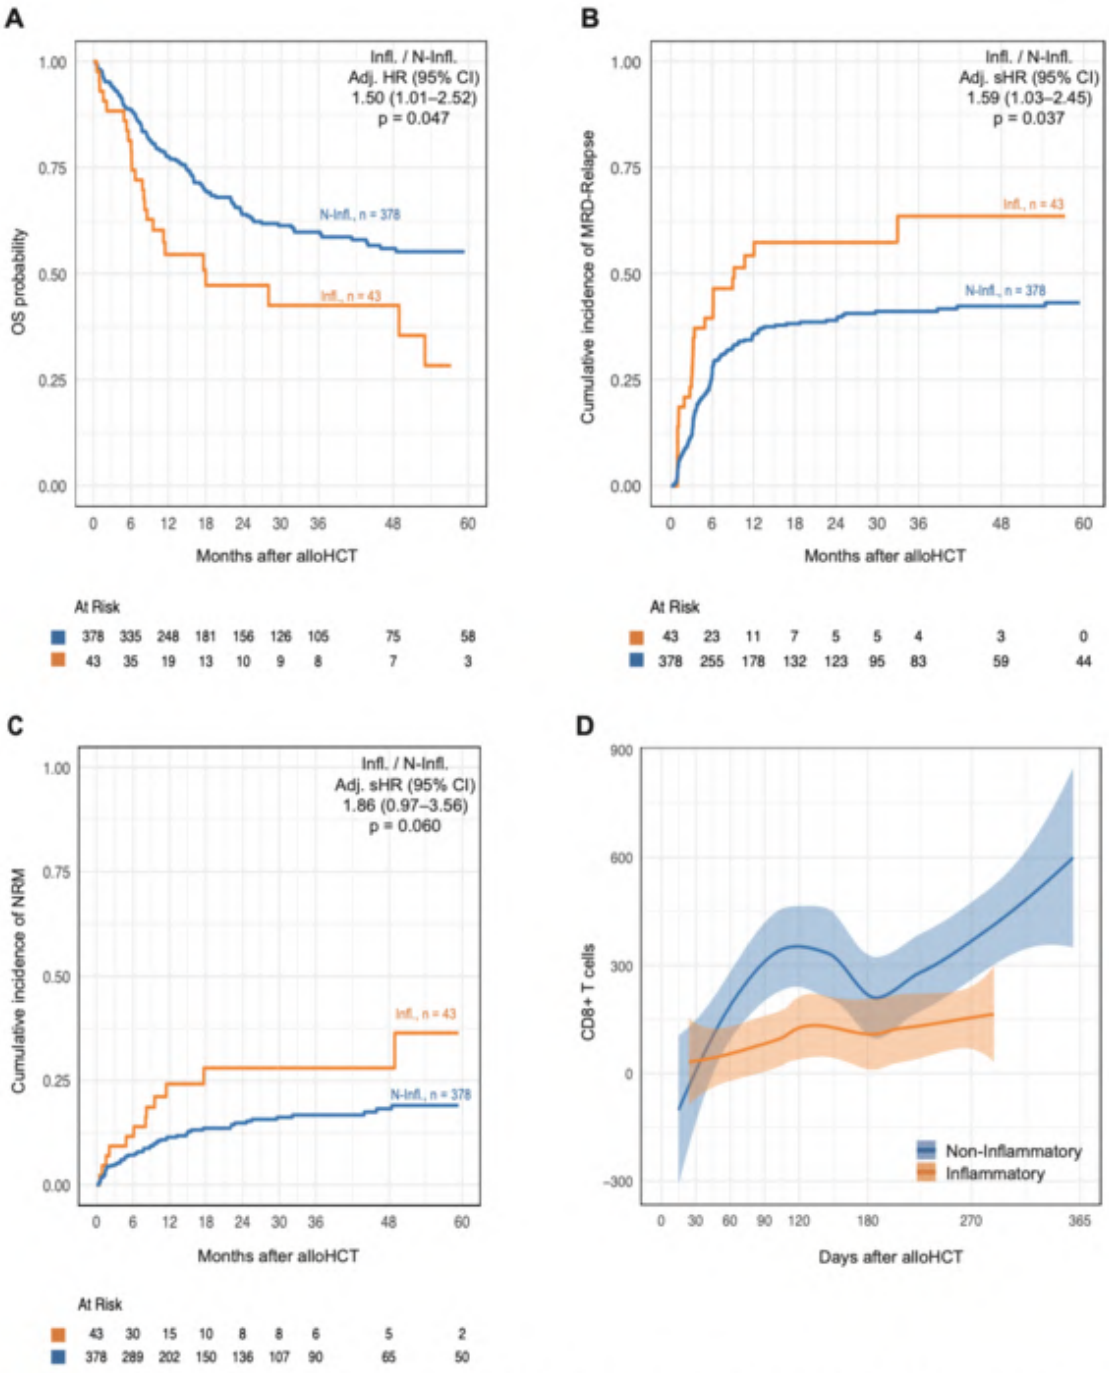

Figure 1 | Pre-transplant inflammatory status is associated with overall survival, relapse risk, non-relapse mortality, and immune reconstitution following alloHCT in AML. (A) Kaplan–Meier estimates of overall survival (OS) stratified by inflammatory (Infl.) versus non-inflammatory (N-Infl.) status following allogeneic hematopoietic cell transplantation (alloHCT). **(B)** Cumulative incidence of MRD-defined relapse and **(C)** cumulative incidence of non-relapse mortality (NRM), accounting for competing risks and stratified by inflammatory status. **(D)** Smoothed trajectories of CD8+ T-cell reconstitution over time following alloHCT, stratified by inflammatory status. Hazard ratios (HRs) for OS and subdistribution hazard ratios (sHRs) for competing-risks endpoints were estimated using multivariable Cox and Fine–Gray models, respectively.

Conclusions: A pre-alloHCT inflammatory state captured by *InflaMix* confers prognostic value over *TP53* mutation status and pre-transplant MRD, independently identifying adults with AML at increased risk of post-transplant relapse and mortality. Notably, inflammatory clustering correlated with impaired post-transplant $CD8^+$ T-cell reconstitution, potentially explaining the heightened risk of relapse and non-relapse mortality. These findings suggest that systemic inflammation prior to transplant may link relapse biology and post-transplant immune dysfunction, identifying a high-risk population that may benefit from inflammation-informed risk stratification and targeted interventions.

CARE-BMT RISK SCORE: CARDIOVASCULAR RISK STRATIFICATION IN 104 CONSECUTIVE PATIENTS UNDERGOING ALLOGENIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Ambra Fumagalli[1,2], *Andrea Acerbis*[2], *Chiara Gandossi*[2], *Simona Piemontese*[2], *Anna Francesio*[1,2], *Alessandro Criscimanna*[1,2], *Lorenzo Lazzari*[2], *Luca Saliani*[1,2], *Maria Helena Parrinello*[1,2], *Alessandro Bruno*[2], *Elisa Diral*[2], *Fabio Giglio*[2], *Sarah Marktel*[2], *Raffaella Greco*[2], *Consuelo Corti*[2], *Andrea Assanelli*[2], *Annalisa Ruggeri*[2], *Maria Teresa Lupo-Stanghellini*[2], *Fabio Ciceri*[1,2]

Background: Cardiovascular complications remain a major cause of morbidity and mortality after allogenic stem cell transplantation (allo-HCT). Identifying high-risk patients during pre-transplant assessment is essential, especially in the context of PTCy-based GvHD prophylaxis, which carries potential cardiotoxicity. The recent American Heart Association (AHA) scientific statement recommends the use of CARE-BMT Risk Score to improve cardiovascular risk stratification and to guide management in transplant candidates. We aimed to evaluate the predictive performance of the CARE-BMT Risk Score in a cohort of patients undergoing allo-HCT with PTCy and to describe the main characteristics of early and late cardiovascular events (CE).

Methods: We retrospectively analyzed all consecutive adult patients who underwent allo-HCT with PTCy as GvHD prophylaxis at our center between April 2023 and September 2024. Patients were stratified into CARE-BMT risk categories according to AHA recommendations. CE were evaluated at day +100 and 1-year post-transplant. CE included cardiovascular death, non-fatal myocardial infarction, stroke, new-onset heart failure, new atrial fibrillation/flutter and sustained ventricular tachycardia. Pre-transplant cardiologic evaluation included baseline pro-BNP and T-troponin, measured before conditioning.

Results: Patients and transplant characteristics are reported in Table 1. A total of 104 patients were included, with a median age of 54 years (range 19-74). According to the CARE-BMT Risk Score, 53 patients (51%) were classified as high-risk and 51 (49%) as intermediate-risk. PTCy was administered at 50 mg/kg in 94 patients, while 10 (2 intermediate- and 8 high-risk) received a reduced dose of 40 mg/kg according to institutional policy.
Overall, 8 patients (7.7%) experienced CE after HCT, all among the high-risk group. Within the first 100 days after allo-HCT, CE included 1 stroke and 5 arrhythmias (4 atrial fibrillation and 1 atrial flutter). At 1-year, 1 cardiovascular death and 1 paroxysmal supraventricular tachycardia were observed. 15.1% of high-risk patients and 0% of intermediate-risk experienced a CE (p<0.01).
Baseline elevation of both pro-BNP and T-troponin was detected in 17 patients, 15 of whom belonged to the high-risk category. High-risk patients with baseline elevation of both pro-BNP and T-troponin showed a higher incidence of CE (33.3% *vs* 7.9%, p=0.03).

Table 1. Patient and allo-HCT characteristics

Characteristics of patients	Overall population, n	%
Age		
<50 y	31	30
50-54 y	12	11
55-64 y	34	33
≥ 65 y	27	26
Disease		
Acute myeloid leukemia	50	48
Acute lymphoblastic leukemia	12	11
Chronic lymphocytic leukemia	3	3
Myelodysplasia and Myeloproliferative neoplasms	29	28
Lymphoma and Myeloma	9	9
Non-malignant disease	1	1
Disease status at transplant		
Complete/partial remission	70	67
Active disease	34	33
Donor type		
Matched-related donor (MRD)	12	12
Matched-unrelated donor (MUD)	72	69
Mismatched-related donor (MMRD)	20	19
Cardiovascular history		

Arrhythmias	4	4
Cerebrovascular event	2	2
Dyslipidemia/diabetes	13	12
Heart failure	3	3
Hypertension	22	21
Peripheral arterial disease	2	2
Acute coronary syndrome	6	6
CARE-BMT risk score		
High (≥5)	53	51
5 point	28	
6 point	14	
7 point	9	
8 point	2	
Intermediate (2-4)	51	49
2 point	14	
3 point	13	
4 point	24	
Low (≤2)	0	

Conclusions: The CARE-BMT Risk Score confirmed its ability to identify patients at increased cardiovascular risk after allo-HCT in our single center experience. Moreover, baseline pro-BNP and T-troponin further improved our ability to stratify these high-risk patients, suggesting that combined biomarker assessment may provide additional predictive value beyond the CARE-BMT Risk Score. Additional studies are warranted to optimize cardiovascular risk prediction, guide individualized transplant strategies (including PTCy dose modulation), and assess long-term outcomes.

OS08-04

CD19 CHIMERIC ANTIGEN RECEPTOR T CELLS GENERATED USING A PIGGYBAC TRANSPOSON VECTOR FOR ACUTE LYMPHOBLASTIC LEUKEMIA: A PHASE I STUDY

Kotaro Narita[1], *Seitaro Terakura*[1], *Ryo Hanajiri*[1], *Shinsuke Kataoka*[1], *Hideki Muramatsu*[1], *Nobuhiro Nishio*[1], *Yoshiyuki Takahashi*[1]
[1]*Nagoya University, Nagoya, Japan*

Background: CD19-directed chimeric antigen receptor T cell (CD19 CAR-T cell) therapy achieves high remission rates in patients with relapsed or refractory B-cell hematologic malignancies. However, its widespread implementation is hampered by the substantial manufacturing costs associated with viral vector-based production. To overcome this issue, we developed a clinically effective, cost-efficient CAR-T platform by generating CAR-T cells

using a nonviral piggyBac transposon gene-transfer system and initiated a Phase I clinical trial to evaluate toxicity, the maximum tolerated dose, and clinical efficacy. Here, we report the trial findings.

Methods: CD19 CAR-T cells were generated using a CD19 CAR-expressing transposon vector together with a piggyBac transposase expression vector. The Phase I trial employed a modified 3+3 dose-escalation design, enrolling pediatric and adult patients with relapsed or refractory B-precursor acute lymphoblastic leukemia. Patients in Cohort 1 (age: 16–60 years) and 2 (age: 1–15 years) received 1×10^5 CAR-T cells/kg, while patients in Cohorts 3 and 4 (age: 1–60 years) received 3×10^5 CAR-T cells/kg and 1×10^6 CAR-T cells/kg, respectively. All patients underwent lymphodepletion (fludarabine [25 mg/m²/day] and cyclophosphamide [250 mg/m²/day] for 3 consecutive days), followed by a single infusion of the CAR-T cell product. Safety, cytokine release syndrome (CRS), neurotoxicity, expansion kinetics, early antileukemic responses, and long-term outcomes were systematically assessed.

Results: As of December 2025, a total of 12 patients (n = 3 in each cohort) had received the CAR-T cell infusion. Flow cytometry analysis confirmed CAR-T cell expansion, with detectable circulating CAR-T cells in all patients. Generally, peak expansion occurred approximately 7–10 days after infusion, demonstrating expansion kinetics comparable to those reported for conventional viral vector-derived CAR-T products, with no evidence of delayed or impaired proliferation associated with our nonviral piggyBac platform. No dose-limiting toxicities (DLTs; defined as [1] Grade ≥4 nonhematologic toxicities, [2] Grade ≥4 CRS, [3] Grade 4 graft-versus-host disease, or [4] Grade 3 nonhematologic toxicities or Grade 3 CRS that failed to improve to Grade 2 within 4 weeks of infusion) were observed. CRS occurred in six patients (Grade 3, n = 1; Grade 1–2, n = 5). At 28 days after infusion, four patients achieved complete remission, seven achieved complete remission with incomplete hematologic recovery, and one showed no response. The median follow-up was 33 months (range, 3–70), with a 2-year disease-free survival (DFS) of 73.3% (n = 12), including three documented relapses. Among the nine patients who had isolated extramedullary relapse at enrollment, the 2-year DFS was 75.0%.

Conclusions: In this first-in-human trial, piggyBac transposon-engineered CD19 CAR-T therapy demonstrated an excellent safety profile, with no DLTs or severe adverse events. The therapy achieved high remission rates and durable disease control, even in individuals with isolated extramedullary relapse. Collectively, these findings support the safety, biological robustness, and long-term efficacy of this nonviral CAR-T platform, highlighting its potential as a scalable, low-cost alternative suitable for broader clinical implementation.

OS08-05

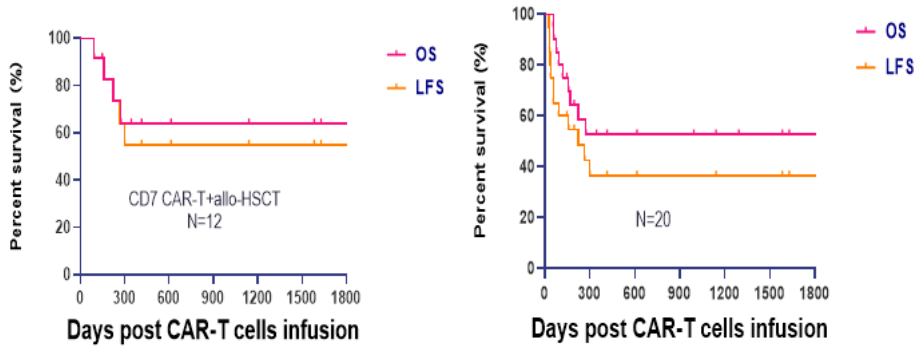
CD7-TARGETED CHIMERIC ANTIGEN RECEPTOR (CAR)-T CELL THERAPY SHOWS GOOD EFFICACY AND SAFETY IN REFRACTORY/RELAPSED MIXED PHENOTYPE ACUTE LEUKEMIA (MPAL)

Junfang Yang[1], Xian Zhang[1], Jingjing Li[1], Liyuan Qiu[1], Jiarui Zhou[1], Jianping Zhang[1], Yue Lu[1], ***Peihua Lu***[1]
[1]*Hebei Yanda Lu Daopei Hospital, Langfang, China*

Background: Mixed-phenotype acute leukemia (MPAL) is a rare and aggressive malignancy. Patients with relapsed or refractory (r/r) disease have limited therapeutic options. Here, we report the safety and efficacy of CD7CAR-T for r/r CD7-positive MPAL from our phase I clinical trial (https://clinicaltrials.gov NCT04938115).

Methods: Peripheral blood (PB) mononuclear cells were collected from 19 patients and 1 from prior transplant donor. A novel approach was used to generate "naturally selected" CD7 CAR (NS7CAR) T cells that overcome CD7-directed fratricide without gene editing. NS7CAR is a second-generation murine-based CAR containing 4-1BB and CD3ζ co-stimulatory domains. Before CAR-T cell infusion, patients received bridging chemotherapy to control rapid disease progression, followed by a lymphodepleting regimen of fludarabine (30 mg/m^2/d) and cyclophosphamide (300 mg/m^2/d) for three days (day -5 to day -3). The median production time for NS7CAR-T was 14 days.

Results: Twenty patients with CD7-positive expression ≥ 80% MAPL were enrolled and received NS7CAR-T therapy. The median age was 26.5(8-58) years. At enrollment, the median bone marrow (BM) blasts by flow cytometry (FCM) were 12.0% (0.08-74.4%), and 8 patients had extramedullary disease (EMD). Six patients were relapsed from prior allogeneic hematopoietic stem cell transplantation (allo-HSCT). All patients received a single NS7CAR-T infusion, 5 with a low d
ose (1-5 × 10^5/kg) and 15 with a medium dose (1.0 × 10^6/kg). The median transduction efficiency was 96.6% (32.0-99.1%).
About 1-month post-infusion, in BM, 18/20 (90%) patients achieved minimal residual disease (MRD)-negative complete remission (CR). Among the 8 patients with EMD, the overall response rate was 6/8 (75%), including 5 CR and 1 partial response, and 2 showed no response. Overall, 15/20 patients achieved CR both in BM and EMD.
With a median follow-up of 248 days (range: 55–1810), the 3-year overall survival (OS) and leukemia-free survival (LFS) for the entire cohort were 52.6% and 36.4%. Within 3 months after CAR-T, 12 patients in CR underwent consolidative allo-HSCT (including 3 second transplants), resulting in a 3-year OS and LFS of 64.2% and 55%, respectively. For the remaining 3 CR patients, 1 remained leukemia-free till 194 days, and 2 died.



Among the other 7 patients less than CR, 3 died from disease progression, and 4 received salvage transplantation, of whom 2 died.
Following NS7CAR-T infusion, most patients developed mild cytokine release syndrome (CRS) (95% ≤ grade II), and only 1 experienced grade III CRS. None had neurotoxicity. Two of the 6 patients with prior transplant history developed GVHD (1 grade I, 1 grade IV).
The median peak proportion of circulating CD7 CAR-T cells in PB by FCM was 82.5% (25.8–96.5%), occurring on day 14 (7–25). By qPCR, the median peak CAR-T copy number was 3.64 × 10^5 copies/μg DNA (0.28–15.7 × 10^5), observed on day 19 (10–29).

Conclusions: This study demonstrates that NS7CAR-T cells are a promising therapeutic option for CD7-positive MPAL, including patients who relapsed after transplantation. Consolidative allo-HSCT further improves survival outcomes. Further studies with longer follow-up and larger cohorts are warranted to confirm the long-term efficacy and durability of NS7CAR-T therapy in MPAL.

LONG-TERM OUTCOMES OF SEQUENTIAL CD7 CAR-T THERAPY AND SECOND ALLOGENEIC TRANSPLANTATION FOR T-ALL/LBL RELAPSED AFTER A PRIOR ALLO-TRANSPLANT

Xing-yu Cao[1], *Jian-ping Zhang*[1], *Zhi-jie Wei*[1], *Yue Lu*[1], *Yan-li Zhao*[1], *Min Xiong*[1], *Jia-rui Zhou*[1], *Yu Wang*[2], *Jun-fang Yang*[1], *Xian Zhang*[1], *Peihua Lu*[1]
[1]*Hebei Yanda Lu Daopei Hospital, Langfang, China,* [2]*Peking University People's Hospital, Peking University Institute of Hematology, National Clinical Research Center for Hematologic Disease, Beijing, China*

Background: Relapsed T-cell acute lymphoblastic leukemia/lymphoma (T-ALL/LBL) after allogeneic hematopoietic stem cell transplantation (allo-HSCT) has a poor prognosis with limited therapeutic options. While CD7-targeted chimeric antigen receptor (CAR) T-cell therapy can induce remission, the long-term outcomes remain suboptimal. The role of a

consolidative second allo-HSCT following CAR-T-induced remission is not well defined. The purpose of this study is to evaluate the long-term efficacy and safety of a second allo-HSCT performed following CD7 CAR-T therapy for T-ALL/LBL patients who relapsed after a prior transplant.

Methods: This study included 18 patients (16 T-ALL, 2 T-LBL) who, after post-first-transplant relapse, achieved bone marrow minimal residual disease (MRD)-negative complete remission (CR) with CD7 CAR-T therapy and proceeded to a second allo-HSCT at our centers between January 2021 and January 2021. Outcomes including survival, relapse, and transplant-related complications were analyzed. Follow-up was until September 30, 2025, with a median post-second-transplant follow-up of 510 days (range: 32-1352).

Results: Their first allo-HSCT was performed using matched sibling (n=4), haploidentical (n=13), or unrelated (n=1) donors. Following the first transplant, 16 patients experienced morphological relapse and 2 patients had MRD-positive. Extramedullary disease was present in 12 patients at the time of relapse. Prior to the second transplant, CD7 CAR-T cells were administered, derived from the original transplant donor in 5 patients and from the recipient in 13 patients.
The median age at second HSCT was 29.7 years (range: 13.8-55.4). Prior to second HSCT, all 18 patients (100%) achieved MRD-negative CR in bone marrow. Of 12 patients with extramedullary disease, 11 (91.7%) achieved CR and 1 achieved partial remission (PR) after CD7 CAR-T. All patients received a transplant from a different donor at the time of the second HSCT. Donors for the second transplant were haploidentical (n=15) or matched unrelated (n=3). Conditioning regimens were TBI-based (n=10), busulfan/ melphalan -based (n=8). The estimated 3-year overall survival (OS) and leukemia-free survival (LFS) after the second transplant were 46.4% (95% CI: 21.9-71.0%) and 44.4% (95% CI: 21.5-67.4%), respectively. The 3-year cumulative incidence of relapse (CIR) and non-relapse mortality (NRM) were 16.7% (95% CI: 5.9-46.8%) and 48.0% (95% CI: 28.8-80.2%), respectively. The day-100 cumulative incidences of grade II-IV and grade III-IV acute graft-versus-host disease (aGVHD) were 66.7% (95% CI: 48.1-92.4%) and 44.4% (95% CI: 26.5-74.5%), respectively. The 1-year cumulative incidence of chronic GVHD (cGVHD) and moderate-severe cGVHD was 34.7% (95% CI: 18.1-66.5%) and 11.1% (95% CI: 3.0-41.0%), respectively. The day-100 cumulative incidences of CMV and EBV viremia were 66.7% (95% CI: 48.1-92.4%) and 22.2% (95% CI: 9.4-52.7%), respectively.
Nine patients died after the second transplant: 3 from infection, 2 from GVHD, 1 from TA-TMA, 1 from relapse, 1 from kidney failure, and 1 from intracranial hemorrhage.

Characteristics	Patients(n=18)
ETP-ALL/LBL	
Yes	4(22.2%)
No	18(77.8%)
Relapse/MRD involvements site when CD7-CAR-T therapy enrollment; n (%)	

BM MRD positive only	2(11.1%)
BM morphological relapse alone	4(22.2%)
BM+EMD relapse	11(61.1%)
EMD relapse alone	1(5.6%)
Lines of treatment prior to NS7CAR-T after relapse following the first allo-HSCT; median (range)	2(1-4)
Number of chemotherapy cycles prior to NS7CAR-T after relapse following the first allo-HSCT; median (range)	2(0-7)
BM blasts before CAR-T enrollment by FCM; median (range)	5.4%(0-91.0%)
BM blasts before CAR-T infusion by FCM; median(range)	0.8%(0-94.5%)
Dose of CD7-CAR-T cells; n (%)	
5×10^5/kg	6(33.3%)
1×10^6/kg	12(66.7%)
Transfection rate of CAR; median (range)	96.4%(59.4%-99.1%)

Conclusions: For T-ALL/LBL patients relapsing after a first allo-HSCT, CD7 CAR-T therapy can effectively induce remission, making a consolidative second allo-HSCT feasible. This sequential approach offers a potential curative strategy for this high-risk population. However, significant transplant-related mortality, primarily from infections and GVHD, remains a major challenge. Further investigation with larger cohorts and longer follow-up is warranted to optimize this treatment strategy.

Disclosure: Nothing to declare.

OS08-08

FIRST-IN-HUMAN TRIAL OF IL15-ACTIVATED CIK CELL THERAPY POST-HCT: DURABLE REMISSION AND SEROTHERAPY-ASSOCIATED IMMUNE RECONSTITUTION IN HIGH-RISK HEMATOLOGIC MALIGNANCIES

Eva Rettinger[1], *Dirk Heckl*[2], *Emilia Salzmann-Manrique*[1], *Martin Hutter*[1], *Marie Luedtke*[1], *Sabine Huenecke*[1], *Melanie Bremm*[1], *Claudia Cappel*[1], *Gesine Bug*[3], *Johann Greil*[4], *Roland Meisel*[5], *Eva Maria Wagner-Drouet*[6], *Hubert Serve*[3], *Tayfun Güngör*[7], *Jan-Henning Klusmann*[1], *Thomas Klingebiel*[1], *Peter Bader*[1], *Halvard Bonig*[8]
[1]*Department of Pediatrics, Goethe University, Frankfurt, Germany,* [2]*Institute for Experimental Pediatric Hematology and Oncology (EPHO), Frankfurt, Germany,* [3]*Medical*

Clinical II, Goethe University, Frankfurt, Germany, [4]University Children's Hospital, Heidelberg, Germany, [5]Division of Pediatric Stem Cell Therapy, Department of Pediatric Oncology, Hematology and Clinical Immunology, Medical Faculty, Heinrich-Heine-University, Duesseldorf, Germany, [6]III. Department of Medicine, Johannes Gutenberg-University, Mainz, Germany, [7]Department of Pediatric Stem Cell Transplantation and Hematology, Children's Research Center, University Children's Hospital, Zurich, Switzerland, [8]Institute of Transfusion Medicine and Immunohematology, and German Red Cross Blood Center Frankfurt, Goethe University, Frankfurt, Germany

Background: Early relapse after allogeneic hematopoietic stem cell transplantation (HCT) remains a major cause of treatment failure and poor survival, particularly in pediatric patients and individuals with substantial treatment-related toxicity, for whom effective salvage options are often unavailable or unapproved. This clinical gap underscores the need for preventive, well-tolerated, and broadly accessible post-HCT immunotherapies. We conducted a first-in-human, disease-burden–guided study to evaluate the feasibility, safety, and efficacy of donor-derived IL-15–activated cytokine-induced killer cells (IL15-CIK), which combine T-cell and natural killer cell properties, for post-HCT disease control.

Methods: Combined outcomes from a prospective, multicenter phase I/II trial (EudraCT 2013-005446-11) and a parallel pilot study are reported, comprising 56 cases with high-risk leukemia treated with IL15-CIK monotherapy for relapse prevention or relapse management following HLA-matched or HLA-mismatched transplantation (n=28 each). According to disease status at first infusion, cases were stratified into consolidation (n=7; complete molecular remission [CMR]), preemptive (n=34; complete remission [CR] with impending relapse and <5% bone marrow blasts), or salvage cohorts (n=15; overt relapse with ≥5% bone marrow blasts). In total, 169 IL15-CIK infusions were administered without lymphodepletion or graft-versus-host disease (GvHD) prophylaxis, either as single infusions (29%) or within predefined dose-escalation regimens (71%).

Results: Centralized, on-demand IL15-CIK manufacturing and shipment to five centers in Germany proved feasible and scalable, with treatment being well tolerated. Therapy-related adverse events and GvHD were infrequent, predominantly mild, and clinically manageable. Acute GvHD grades 1–2 and grade 3 occurred in 27% and 4% of patients, respectively, with no extensive chronic GvHD or treatment-related mortality observed. Beyond early responses at day 100, the cumulative incidence of CMR at day 700 reached 74% in the preemptive cohort compared with 13% in the salvage cohort, highlighting the advantage of early, preventive intervention. After a median follow-up of 7.3 years (range, 6.8–8.7), 5-year overall survival (OS) was 71% in the consolidation cohort, 61% in the preemptive cohort, and 20% in the salvage cohort. Five-year progression-free survival was 50% overall and reached 69% in pediatric acute myeloid leukemia, a population with substantial unmet clinical need. To inform future risk-adapted strategies, predictors of outcome were analyzed. In multivariable analysis, myeloid malignancy (vs lymphoblastic) was independently associated with superior OS (p=0.036), whereas high leukemic burden at first IL15-CIK infusion (≥5% bone marrow blasts; p=0.004) and refractory disease at HCT (p=0.024) were associated with inferior OS. Prior serotherapy emerged as the only factor significantly associated with cumulative incidence of relapse (p=0.021), with lower relapse rates observed after Campath compared with ATG.

Conclusions: Donor-derived IL15-CIK monotherapy is feasible, safe, and confers durable relapse-preventive activity after allogeneic HCT. Treatment efficacy is primarily determined by disease burden at the time of intervention, while prior serotherapy emerges as a key modulator of post-HCT relapse risk. Beyond the IL15-CIK platform, these findings have broader implications for post-transplant immunotherapy and support IL15-CIK as a viable alternative to donor lymphocyte infusion.

OS12-02

COST-EFFECTIVENESS OF ORCA-T VS ALLO-HCT WITH CONVENTIONAL GVHD PROPHYLAXIS FOR THE TREATMENT OF ADVANCED HEMATOLOGIC MALIGNANCIES IN THE UNITED STATES

Rawan Faramand[1], *James Scott McClellan*[2], *Anna Pavlova*[2], *Rocio Manghani*[2], *Andrea Blank*[2], *Matia Saeedian*[3], *Shivani Yadav*[3], *Miguel-Angel Perales*[4]
[1]*Moffitt Cancer Center, Tampa, United States of America (the),* [2]*Orca Bio, Menlo Park, United States of America (the),* [3]*Blue Path Solutions, Los Angeles, United States of America (the),* [4]*Memorial Sloan Kettering Cancer Center, New York, NY, United States of America (the)*

Background: Allogeneic hematopoietic cell transplantation (allo-HCT) is a potentially curative therapy for patients with hematologic malignancies, but its success is limited by GVHD, which is associated with substantial morbidity, mortality, and economic burden. Orca-T, an investigational, high-precision cell therapy, demonstrated improvement in survival free

of moderate-to-severe chronic GVHD compared to conventional allo-HCT with tacrolimus/methotrexate (TAC/MTX) in the pivotal Phase 3 Precision- T trial. Given the rising costs of GVHD therapies and the long-term care burden, assessing the economic value of Orca-T is essential. To assess the cost effectiveness of Orca-T compared to conventional allo-HCT with TAC/MTX GVHD prophylaxis from a US health system perspective.

Methods: A three-state partitioned survival model (relapse-free, relapsed, and dead) with monthly cycles and a lifetime horizon was developed. The intervention arm included Orca-T with single-agent tacrolimus, while the comparator arm included conventional allo-HCT with TAC/MTX GVHD prophylaxis. Overall survival and relapse-free survival data from the Phase 3 Precision-T study were incorporated using a cure-mixture modeling approach to estimate long-term survival and relapse status for patients. Costs included conditioning regimens, index procedure length of stay, Orca-T acquisition, donor procurement (conventional allo-HCT with TAC/MTX only), acute GVHD (aGVHD) and chronic GVHD (cGVHD) management, infection management, and terminal care. Model outcomes included life-years, quality-adjusted life-years (QALYs), and direct healthcare costs. Both costs and outcomes were discounted at 3% annually.

Results: Orca-T was associated with lower lifetime costs of $1,412,864 compared to $2,253,413 for conventional allo-HCT with TAC/MTX with a lifetime cost savings of $840,548 per patient. The costs associated with Orca-T acquisition were offset by savings from aGVHD, infection, and cGVHD management costs. The cGVHD management costs were $797,650 for Orca-T compared to $2,068,847 for conventional allo-HCT with TAC/MTX. Orca-T was also associated with 15.80 QALYs compared to 11.45 QALYs with conventional allo-HCT with TAC/MTX over a patient's lifetime. Given the combination of cost savings and QALY gains, Orca-T is dominant over conventional allo-HCT with TAC/MTX.

Conclusions: Over a patient's lifetime, the model demonstrated that Orca-T can reduce the overall economic burden compared to conventional allo-HCT with TAC/MTX, with the majority of cost savings driven by reductions in aGVHD, infection, and cGVHD management costs. Given the considerable clinical and economic impact of these complications, Orca-T represents a high value therapeutic option for adults with advanced hematologic malignancies, offering both superior clinical outcomes and economic benefits.

OS13-03

HOSPITAL EXEMPTION FOR HEIDAGENLECLEUCEL (HEIDI-CEL), A THIRD GENERATION CD19.CAR T CELL PRODUCT IN GERMANY

Anita Schmitt[1], Maria-Luisa Schubert[2], Angela Hückelhoven-Kraus[2], Brigitte Neuber[2], Anthony D. Ho[2], Carsten Müller-Tidow[2], Peter Dreger[2], ***Michael Schmitt***[2]
[1]Michael Schmitt, Heidelberg, Germany, [2]Heidelberg University Hospital, Heidelberg, Germany

Background: Chimeric antigen receptor (CAR)-transduced T cells have become an important instrument in the armamentarium of the hematologist for the treatment of CD19+ disease in patients. Hitherto, no commerical CAR-T-cell product has been approved on the market for patients with chronic lymphatic leukemia (CLL). In a lengthy and cumbersome process, we established in-house manufacturing of CD19.CAR-T-cell products for CLL patients in accordance with Good Manufacturing Practice (GMP). Here, we describe the entire way from an investigator-initiated trial (IIT) up to the achievement of a hospital exemption which enables us to open new medical and financial strategies in current clinical practice in Germany.

Methods: In our investigator-initiated trial (IIT) HD-CAR-1 trial (NCT03676504 (clinicaltrials.gov); EudraCT-No. 2016-004808-60), 43 patients with CD19+ leukemias and non-Hodgkin's lymphoma consented treatment by our in house-product heidagenlecleucel (Heidi-cel). Subsequently, the patients underwent leukapheresis. In our GMP core facility, we manufactured 3rd generation Heidi-cel, i.e. (CD28/4-1BB) CAR-T-cells. Patients obtained the CAR-T-cells after standard conditioning with fludarabine and cyclophosphamide, and were followed-up clinically.
To obtain a hospital exemption, we submitted non-clinical and clinical data, quality data, a risk mitigation plan (RMP), a pharmacovigilance surveillance master file (PSMF) as well as a product information (PI) to the federal regulatory authority Paul-Ehrlich-Institut (PEI).

Results: For all patients undergoing leukapheresis, a CAR-T-cell product was successfully manufactured. Nine heavily pretreated patients with refractory or relapsed CLL obtained CD19.CAR-T cells at escalated dose levels up to 200 × 10^6 CAR-T-cells/m^2. In-house CD19.CAR-T-cell manufacturing was successful for all patients. Not even a single case of neurotoxicity (ICANS) was observed. One case of grade 3 cytokine release syndrome was reported. By day 90, six patients (67%) achieved a CR, five of these (83%) with undetectable MRD. With a median follow-up of 27 months, 2-year PFS and OS were 30% and 69%, respectively.
Based on these encouraging results, we started a harsh and meticulous review process with our regulators at the PEI. After 2.5 years of a responsorial submission process, we eventually obtained a hospital exemption for r/r CLL patients from the PEI.

Conclusions: This is a report on the definitively first time in Germany, that the PEI issued a hospital exemption for an ATMP, i.e. for our in-house manufactured CAR T cell product, designated heidagenlecleucel (Heidi-cel). This is remarkable for various reasons: simplification of logistics, increased flexibility, development and clinical testing of own approaches, achievement of autarky by strengthening of know-how in vector design and

production of genetically modified cells and thus cost reduction in the German healthcare system.

Background: In the MCL cohort of TRANSCEND NHL 001 (NCT02631044), the CD19-directed CAR T cell product liso-cel demonstrated high CR rate and deep, durable responses in heavily pretreated patients with 3L+ R/R MCL (Wang M, et al. *J Clin Oncol* 2024). This study compared efficacy outcomes observed with liso-cel in the MCL cohort with standard-of-care (SOC) treatments used in routine clinical practice.

Methods: An ECA cohort was developed using real-world data from the United States (Flatiron Health database; data cutoff: 02/28/2024) and clinical/hospital sites in 4 European countries (France, Germany, Spain, and United Kingdom; data cutoff: 06/30/2024), applying key eligibility criteria from the MCL cohort of TRANSCEND NHL 001. Propensity score methodologies balanced the ECA to the TRANSCEND NHL 001 MCL cohort by prespecified baseline characteristics and prognostic factors (age, refractory to last therapy, ECOG score, MCL morphology, number of prior therapies, prior ASCT, refractory to Bruton tyrosine kinase inhibitor [BTKi] therapy, and simplified mantle cell lymphoma International Prognostic Index score). Balancing was performed using trimmed, stabilized inverse probability of treatment weighting (IPTW).
The primary analysis utilized the liso-cel–treated efficacy analysis cohort (LTEAC [n=75]; patients with PET-positive disease who failed ≥2 prior lines of systemic therapy, including a BTKi, alkylating agent, and rituximab [or other CD20-targeted agent] and received liso-cel at a target dose of 100×10^6 CAR^+ T cells). Sensitivity analyses included: the liso-cel efficacy

analysis cohort (LEAC [n=81]; the LTEAC plus 6 patients who received liso-cel at a target dose of 50×10^6 CAR^+ T cells) and the leukapheresed cohort (LKC [n=104]; all eligible patients who underwent leukapheresis).
The primary endpoint was ORR. Secondary endpoints included CR rate, PFS, time to next treatment (TTNT), OS, and duration of response (DOR). Response data were by investigator assessment. Generalized linear models estimated relative risk for ORR and CR rate, and Cox proportional hazards models estimated HR for PFS, TTNT, OS, and DOR.

Results: A total of 457 patients (Europe, n=197; United States, n=260) were included in the ECA. SOC regimens used in the 3L+ R/R MCL setting included chemoimmunotherapy (22.1%), covalent BTKi (19.7%), lenalidomide-based regimens (17.7%), bortezomib-based regimens (10.9%), CD19 CAR T cell therapy (brexucabtagene autoleucel; 10.1%), venetoclax-based regimens (6.3%), noncovalent BTKi (4.2%), chemotherapy (3.9%), and HSCT (2.6%).
After IPTW adjustment, liso-cel treatment was associated with statistically significant improved outcomes versus SOC for the primary (ORR) and secondary endpoints (CR rate, PFS, and OS; **Table**). Notably, patients who received liso-cel achieved an ORR approximately twice as high (79.6%) and a CR rate nearly 3 times greater (64.5%) than those treated with SOC (39.4% and 21.6%, respectively). Liso-cel reduced the risk of progression or death by 35.0% and the risk of death by 40.0%. TTNT and DOR also numerically favored liso-cel. Sensitivity analyses were consistent with the primary analysis.

Conclusions: Liso-cel demonstrated significantly better efficacy than SOC therapies, establishing its role as an important new treatment for patients with 3L+ R/R MCL who have received a minimum of 2 prior lines of systemic therapy, including treatment with a BTKi.

Table. Comparison of efficacy endpoints adjusted for trimmed, stabilized IPTW between the LTEAC, LEAC, LKC, and ECA cohort

	LTEAC (n=75) vs ECA cohort (n=457)	**LEAC (n=81) vs ECA cohort (n=457)**	**LKC (n=104) vs ECA cohort (n=457)**
ORR	***RR, 2.0 (1.7–2.5)***	***RR, 2.0 (1.7–2.5)***	***RR, 1.7 (1.4–2.2)***
CR rate	***RR, 3.0 (2.3–4.0)***	***RR, 3.1 (2.3–4.1)***	***RR, 2.7 (2.0–3.6)***
PFS	***HR, 0.65 (0.44–0.97)***	***HR, 0.63 (0.43–0.93)***	***HR, 0.57 (0.39–0.84)***

Table. Comparison of efficacy endpoints adjusted for trimmed, stabilized IPTW between the LTEAC, LEAC, LKC, and ECA cohort

DOR[a]	HR, 0.92 (0.57–1.47)	HR, 0.88 (0.55–1.43)	–

Results are RR or HR (95% CI). RR >1 or HR <1 indicate favorable results for liso-cel versus SOC treatments. Statistically significant results are bolded and *italicized*.
[a]DOR was calculated among responders (n=64 [85.3%] in the LTEAC, n=67 [82.7%] in the LEAC, and n=180 [39.4%] in the ECA cohort). DOR was not prespecified to be analyzed in the sensitivity analysis between leukapheresed cohort and ECA cohort.
LTEAC (n=75): included patients with MCL who had PET-positive disease at the time of liso-cel administration or after bridging therapy had failed ≥2 prior lines of systemic therapy, including an alkylating agent, a BTKi, and rituximab (or other CD20-targeted agent) and were treated at a target dose of 100×10^6 CAR^+ T cells (DL2) with conforming product. LTEAC is the PAS in the TRANSCEND NHL 001 MCL cohort.
LEAC (n=81): included patients with MCL who had PET-positive disease at baseline or after bridging therapy and had failed ≥2 prior lines of systemic therapy, including an alkylating agent, a BTKi, and rituximab (or other CD20-targeted agent) and were treated at DL2 and DL1 (a target dose of 50×10^6 CAR^+ T cells) with conforming product.
LKC (n=104): included all patients with MCL who met all inclusion/exclusion criteria, underwent leukapheresis, and had disease that failed ≥2 prior lines of systemic therapy, including an alkylating agent, a BTKi, and rituximab (or other CD20-targeted agent).
DL, dose level; PAS, primary analysis set; RR, relative risk.

Background: Liso-cel is an autologous, CD19-directed CAR T cell product with consistent efficacy across B-cell malignancies, including R/R LBCL. Its well-established safety profile has made outpatient delivery commonplace. Here, we describe real-world outcomes for patients with R/R LBCL who received liso-cel as standard of care (SOC) therapy in the inpatient or outpatient setting.

Methods: This observational study included patients in the United States with R/R LBCL who received commercial liso-cel as second-line or later treatment in the inpatient or outpatient setting between 02/2021 and 02/2025 and had ≥ 1 postinfusion assessment reported in the Center for International Blood & Marrow Transplant Research (CIBMTR). Outcomes included rates of AEs of special interest, nonrelapse mortality (NRM), postinfusion hospitalizations in the outpatient group, ORR, CR rate, duration of response (DOR), PFS, and OS. Results are reported descriptively.

Results: Of 1116 eligible patients, 34% (n=375) were intended for outpatient treatment, as reported to the CIBMTR, including 82 of 195 (42%) patients who received liso-cel as second-line treatment. Among patients treated in the inpatient versus outpatient setting, respectively, median (range) age was 71.5 years (21.5–91.2) and 69.8 years (25.0–86.1), most patients were male (59% and 61%), 16% and 12% had high-grade B-cell lymphoma,

26% and 26% had ≥ 2 extranodal involvement sites, and 5% and 4% had secondary CNS involvement, while 48% versus 37% had elevated LDH before infusion, and 10% versus 3% had ECOG PS ≥ 2; ≥ 1 comorbidities were reported for 72% and 65% (including cardiac, 36% and 32%; pulmonary, 30% and 26%; active infections requiring ongoing treatment, 6% and 3%) of patients in the inpatient and outpatient groups, respectively. Median (range) number of prior lines of therapy was 3 (1–13) and 3 (1–16) in the inpatient and outpatient groups, and 65% and 62% received bridging therapy, respectively. Median (95% CI) follow-up was 12.7 months (12.5–13) and 12.6 months (12.4–12.8) in the inpatient and outpatient groups, respectively.
Overall incidences of cytokine release syndrome (CRS) and immune effector cell–associated neurotoxicity syndrome (ICANS) events were similar between groups; most CRS and ICANS events were low grade (**Table 1**). Incidences of other AEs of special interest were also similar. Among outpatients, 46% were not hospitalized after infusion; of those hospitalized, median (IQR) time to hospitalization was 5 days (3–8) and duration of stay was 5 days (3–9).
Response rates were high in both the inpatient (ORR, 80%; CR rate, 70%) and outpatient settings (ORR, 83%; CR rate, 74%), with consistent 12-month DOR (59% and 63%), PFS (49% and 56%), and OS (65% and 74%) rates, respectively (**Table 2**).

Conclusions: These results continue to demonstrate that one-time treatment with liso-cel results in deep, clinically meaningful efficacy in the SOC setting across a broad population of patients with R/R LBCL. Despite the few differences in baseline characteristics, outcomes were consistent across inpatient and outpatient care settings. The well-established safety profile of liso-cel is conducive to outpatient treatment, allowing ~50% of patients to remain out of the hospital after infusion.

QUANTIFYING DAY-TO-DAY RISK OF CYTOKINE RELEASE SYNDROME (CRS) AND NEUROLOGICAL EVENTS (NE) AFTER LISOCABTAGENE MARALEUCEL (LISO-CEL) INFUSION: POOLED ANALYSIS FROM 7 CLINICAL TRIALS

Valentin Ortiz-Maldonado[1], *Pere Barba*[2], *Robert Lown*[3], *Pim Mutsaers*[4], *Kirit Ardeshna*[5], *Peter Borchmann*[6], *Paolo Corradini*[7], *Michael Northend*[5], *David Bernasconi*[8], *Stefanie Buschor*[8], *Peter J. Mueller*[8], *Franck Morschhauser*[9]
[1]*Hospital Clinic of Barcelona, University of Barcelona, Barcelona, Spain,* [2]*Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain,* [3]*University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom of Great Britain and Northern Ireland (the),* [4]*Erasmus University Medical Center, Rotterdam, Netherlands (the),* [5]*University College London Hospitals NHS Foundation Trust, London, United Kingdom of Great Britain and Northern Ireland (the),* [6]*Universität zu Köln, Köln, Germany,* [7]*University of Milano, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy,* [8]*Bristol Myers Squibb, Boudry, Switzerland,* [9]*Centre Hospitalier Universitaire de Lille, Groupe de Recherche sur les Formes Injectables et les Technologies Associées, Lille, France*

Background: CRS and NEs are adverse events associated with CAR T cell therapy. Regulatory authorities such as the FDA and EMA recently reduced the time patients are

required to remain close to the healthcare facility after infusion from 4 to 2 weeks. Here, we quantify the probability of new onset CRS or NEs at specific time points after liso-cel infusion.

Methods: Time to first onset of CRS or NE data were pooled for liso-cel–treated patients from clinical trials in second-line (2L) or third-line or later (3L+) large B-cell lymphoma (LBCL; TRANSCEND NHL 001, TRANSCEND WORLD, PLATFORM, OUTREACH, TRANSFORM, PILOT) and 2L or later (2L+) FL (TRANSCEND FL). We estimated, for Days 1–30 after infusion (Day 1=infusion day), the probability of future CRS/NE onset at each landmark as the proportion of patients under observation with onset on that day or later, divided by those still at risk (alive and in study), regardless of prior onset.
Additional analyses estimated the future risk of CRS/NEs within the same time period (Days 1–30 after infusion) based on prior occurrence of CRS/NEs and the probability of CRS/NEs within the first 15 days after infusion (the close monitoring period) in patients without prior CRS/NEs. All analyses are descriptive; no formal hypothesis testing was performed.

Results: Of 691 patients who received liso-cel across 7 clinical trials, 51% (n=355) did not experience CRS/NEs. For patients with any-grade CRS/NEs (n=336; grade ≥3 at first onset, n=12), 96% occurred on or before Day 15 after infusion; median time to onset of CRS and NEs was 5 and 8 days, respectively, and median time to resolution was 4 and 7 days. The risk of future any-grade CRS/NEs decreased steadily over time to 1% on Day 30 (**Table**, **Figure**), and the risk of experiencing a maximum grade ≥3 CRS/NE remained low throughout the 30-day period (≤8%).
Patients without prior CRS/NEs had numerically lower risks of experiencing any-grade CRS/NEs within 30 days after infusion compared with patients who previously experienced CRS/NEs (Day 15, 4% vs 7%, respectively; **Table**). The overall risk of grade ≥3 CRS/NEs was ≤8% and ≤13%, respectively, for patients without versus with prior CRS/NEs, and decreased to ≤1% by Day 15 regardless of prior CRS/NE status.
From Day 1, risk of any-grade or maximum grade ≥3 CRS/NEs within 15 days of infusion for patients without prior CRS/NEs decreased over time (**Table**). On Day 7, the probability of future grade ≥3 CRS/NEs was 3%, suggesting patients without prior CRS/NEs may be candidates for early discharge before Day 15, contingent on institutional protocols and risk tolerance.

Conclusions: Data from liso-cel clinical trials in patients with 2L/3L+ LBCL and 2L+ FL indicate that 96% of CRS/NEs occurred within 15 days after infusion and were predominantly low grade. The risk of future CRS/NEs decreased progressively over time, with an estimated 4% risk at Day 15 in patients without prior events. These findings provide quantitative residual risk estimates that may help physicians decide when to discharge patients after liso-cel infusion, particularly from inpatient settings.

OS14-01

ORCA-T DEMONSTRATES FAVORABLE QUALITY OF LIFE AND HEALTHCARE RESOURCE USE COMPARED TO STANDARD ALLOHSCT PLUS TAC/MTX FOR GVHD PREVENTION IN RANDOMIZED PHASE3 CLINICAL TRIAL (PRECISION-T)

Arpita Gandhi[1], *Anna Purdum*[2], *Anna Pavlova*[2], *Ai Li*[2], *James Scott McClellan*[2], *Bronwen Shaw,*[3], *Rachel Cusatis*[3]
[1]*Oregon Health Sciences University, Portland, United States of America (the),* [2]*Orca Bio, Menlo Park, United States of America (the),* [3]*Center for International Blood and Marrow Transplant Research, Medical College of Wisconsin, Milwaukee, United States of America (the)*

Background: Conventional allogeneic hematopoietic stem cell transplantation (alloHSCT) is associated with increased toxicity and infections due to multiagent immunosuppression. Orca-T, a high-precision engineered allogeneic T cell immunotherapy utilizing single-agent GVHD prophylaxis, demonstrated superior survival free of chronic GVHD (HR = 0.26; p < 0.00001), significantly lower moderate to severe chronic GVHD (12.6% vs 44.0%; p < 0.001), and fewer serious infections and deaths at 1 year versus alloHSCT in a phase 3 trial. This study compares health-related quality of life (HRQoL) and hospitalization patterns between arms.

Methods: Adults aged 18–65 undergoing myeloablative alloHSCT for acute leukemia in remission or high-risk MDS (≤10% BM blasts) with matched related or unrelated donors were randomized 1:1 to Orca-T + tacrolimus or unmanipulated PBSC + Tac/MTX. Exploratory outcomes included HRQoL and hospitalization. HRQoL was measured using the FACT-BMT instrument (0–164 scale; higher scores indicate better HRQoL) at baseline and predefined intervals. A repeated measures model assessed change over time. Duration of initial hospitalization, rehospitalization rates, total hospitalized days, and rehospitalization-free survival were compared between arms.

Results: Safety analyses included 88 Orca-T and 94 Tac/MTX patients, with grade 3–4 acute GVHD rates of 5.7% vs 9.6% and moderate–severe chronic GVHD of 12.5% vs 34.0%. Survey completion was >85% at baseline and ~66% at 1 year. FACT-BMT scores were consistently higher for Orca-T, with smaller declines at day 14 (−7.74 vs −13.69) and recovery above baseline by day 100 (1.34 vs −3.12), sustained through day 365. Subscale scores exceeded baseline earlier and were ≥2-fold higher by day 365. Median hospitalization was 24.5 vs 24.0 days; rehospitalizations 27.3% vs 45.7%; total hospitalized days 30.6 vs 40.8; ICU admissions 1 vs 4. Rehospitalization-free survival at 18 months was 66.4% (95% CI 54.0–76.2) vs 33.8% (95% CI 18.5–49.9) (p = 0.0096; HR 0.53 [0.32–0.86]).

Conclusions: Orca-T recipients experienced higher HRQoL, faster recovery, fewer ICU stays, lower rehospitalization rates, and improved rehospitalization-free survival compared to Tac/MTX, suggesting improved early post-transplant recovery and reduced GVHD symptom burden.

Background: Orca-T is an investigational precision cell therapy for allogeneic treatment of hematological disorders. In a Phase 1b clinical trial (NCT04013685) with patients having acute leukemias or MDS, Orca-T exhibited an excellent safety profile and low rates of severe Graft-versus-Host Disease (GVHD). In a Phase 3 randomized trial (NCT05316701), in comparison to calcineurin inhibitor/methotrexate prophylaxis, Orca-T met the primary endpoint of improving moderate-to-severe chronic GVHD-free survival (cGFS). Here we retrospectively compared the clinical outcomes of Orca-T patients to those receiving post-transplant cyclophosphamide (PTCy) for GVHD prophylaxis.

Methods: The Orca-T patients in this study (n=164) included all participants in the Ph3 trial who received Orca-T (n=88), as well as participants in the ph1b trial who met the Ph3 eligibility criteria (n=76). The PTCy patients (n=380) included those in the CIBMTR registry who received PTCy + tacrolimus ± mmf and had pre-transplant demographic and clinical profiles that were similar to the Orca-T patients. Additional inclusion criteria were ages 18-65, intermediate- to high-risk AML or ALL in CR or MDS, rmyeloablative conditioning, and an 8/8 HLA-matched donor. The endpoints compared were overall survival (OS), relapse-free survival (RFS), cGFS, and the cumulative incidences of non-relapse mortality (NRM), relapse, gr. 3-4 acute GVHD, and moderate-severe chronic GVHD. Competing risks were death for the cumulative incidences of relapse and GVHD, and relapse for NRM. Time-to-event outcomes were analyzed from the transplantation date until the first event or date of last contact. Standard survival and competing risk methods were used; $p<.05$ defined significance.

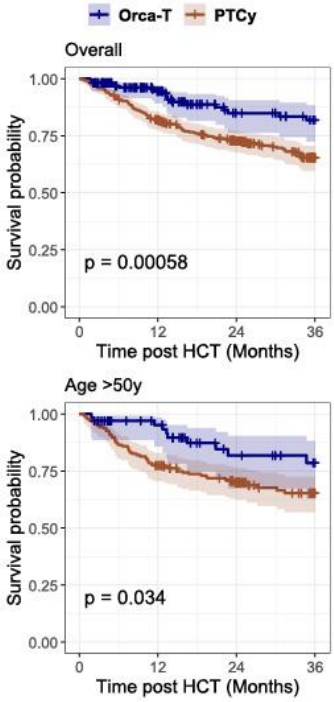
Results: Orca-T patients, in comparison to the PTCy patients, exhibited increased OS ($p<.001$), increased RFS ($p=.045$), and decreased NRM ($p=.033$) (Table 1 and Fig. 1). GRFS, relapse, and aGVHD grades 3-4 estimates did not significantly differ between the treatment groups. The 1-year cumulative incidence of moderate-severe cGVHD was lower in the PTCy group, but the cGFS rates were not significantly different.
The increased OS effect of Orca-T was consistently observed in subgroups of patients (e.g., age, HCT-CI, DRI, disease type) that can be associated with disparate clinical outcomes. Noteworthy was the increased OS ($p=.034$) and decreased NRM ($p=.048$) in patients >50 years of age.

Table 1. Clinical Outcomes.

	Orca-T	PTCy	P-value[2]
Overall Estimates (N)	164	380	
Overall survival			**<.001**
1-year	94% (89-97%) [1]	82% (78-86%)	
2-year	85% (76-90%)	73% (68-77%)	
3-year	82% (72-88%)	65% (60-70%)	
RFS			**0.045**
1-year	78% (70-84%)	70% (65-74%)	
NRM			**0.033**
1-year	2.7% (0.87-6.4%)	7.7% (5.3-11%)	
Age group >50y (N)	67	177	
Overall survival			**0.034**
1-year	95% (86-98%)	77% (71-83%)	
2-year	82% (67- 90%)	70% (62-76%)	
3-year	79% (63- 88%)	65% (57-72%)	
RFS			0.2
1-year	76% (63-85%)	68% (60-74%)	
NRM			**0.048**
1-year	3.0% (0.56-9.4%)	12% (7.7-17%)	

[1] Point estimate (95% CI)
[2] Log-rank test (survival) or Gray's test (cumulative incidence)

Figure 1. Overall Survival.



Conclusions: In conclusion, Orca-T patients, in comparison to PTCy patients in the CIBMTR registry, exhibited increased OS, increased RFS, and decreased NRM. These observations were consistently observed in stratified analyses, with further separation in clinical effect between Orca-T and PTCy in patients >50 years of age.

Background: ACCESS is a CIBMTR run phase II, non-randomized, multicenter trial that assessed peripheral blood graft (PBSC) use in the setting of a GVHD prophylaxis regimen of cyclophosphamide, tacrolimus, and mycophenolate mofetil (PTCy) in two adult strata: myeloablative conditioning (MAC) and reduced-intensity or nonmyeloablative (RIC) conditioning before HCT from a ≤35 year old MMUD (4-7/8 match at HLA-A, B, C and -DRB1). The primary outcome was overall survival (OS) at 1-year post-HCT and was 83.8% and 78.6% in MAC and RIC, respectively (Al Malki et al. JCO 2025). Here we present longer term outcomes and compared to two similar trials also using PTCy GVHD prophylaxis.

Methods: In the current analysis using long term outcome data reported as standard to the CIBMTR registry, we evaluated 2-year outcomes for the patients enrolled on and reported in the primary ACCESS results publication along with comparative cohorts from the 15-MMUD

phase II trial (15-MMUD) (Shaw et al. JCO 2021), bone marrow in MMUD MAC and RIC, and the Blood and Marrow Transplant Clinical Trials Network 1703 randomized phase III trial (1703) (Bolanos-Meade et al. NEJM 2023), PBSC using PTCy in matched related and unrelated RIC.

Results: A total of 145 patients on ACCESS (n=75 MAC, n=70 RIC) were included, 80 on 15-MMUD (n=40 MAC, n=40 RIC) and 208 on 1703 (all RIC) with 59%, 48% and 13% self-identifying within an underrepresented group, respectively. Median follow-up on ACCESS was 24.2 months (range: 0.4-40.3 months). Primary disease was predominately acute leukemia in all cohorts. HLA matching varied by cohort: ACCESS – 7/8=68%, <7/8=32%; 15-MMUD – 7/8=61%, <7/8=39%; and 1703 – 7/8=3%, <7/8=0%.
In the MAC groups, the 2-year OS was 72.5% (95% Confidence Interval, 60.7-81.3%) and 62.4% (45.6-75.4%) (Figure) and GVHD-free, relapse-free survival (GRFS) was 32.7% (22.2-43.5%) and 28.0% (15.0-42.5%) for ACCESS and 15-MMUD, respectively. Relapse at 2 years was 31.4% (21.1-42.2%) on ACCESS and 27.6% (14.7-42.1%) on 15-MMUD. Chronic GVHD requiring immunosuppression (cGVHD IST) at 2 years was 26.5% (16.8-37.1%) and 25.6% (13.1-40.2%) on ACCESS and 15-MMUD, respectively.
In the RIC groups, the 2-year OS was 72.8% (60.7-81.7%), 74.8% (58.2-85.6%) and 67.2% (60.3-73.1%) (Figure) and GRFS was 41.5% (29.8-52.8%), 38.0% (23.0-52.9%) and 36.5% (29.8-43.3%) for ACCESS ,15-MMUD and 1703, respectively. Relapse at 2-years was 26.5% (16.6-37.4%) on ACCESS, 32.8% (18.7-47.6%) on 15-MMUD and 33.2% (26.7-39.8%) on 1703. cGVHD IST at 2 years was 17.1% (9.4-26.9%), 17.5% (7.6-30.8%) and 18.9% (13.8-24.6%) on ACCESS, 15-MMUD and 1703, respectively. Additional outcomes at 2 years and acute GVHD at 6 months are shown in the table.

Figure: Overall Survival following HCT for MAC (A) and RIC (B) cohorts from ACCESS, 15-MMUD and BMT CTN 1703

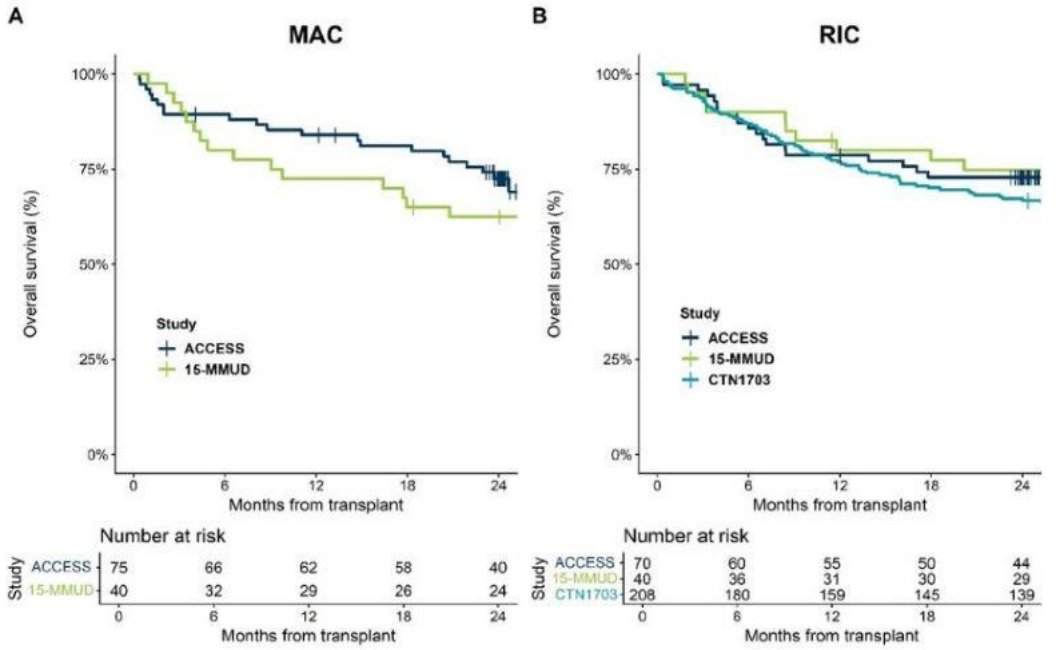

Table: Estimates for OS, GRFS, cGVHD, cGVHD requiring IST, relapse/progression, and relapse/progression-free survival at 2 years post-transplant – MAC cohorts from ACCESS and 15-MMUD and RIC cohorts from ACCESS, 15-MMUD and BMT CTN 1703

	Myeloablative Conditioning (MAC)		Reduced Intensity Conditioning (RIC)		
	ACCESS MAC PBSC (N = 75)	**15-MMUD MAC BM (N=40)**	**ACCESS RIC PBSC (N = 70)**	**15-MMUD RIC BM (N=40)**	**BMT CTN 1703 RIC PBSC (N=208)**
Outcomes	**Prob (95% CI)**	**Prob (95% CI)**	**Prob (95% CI)**	**Prob (95% CI)**	**Prob (95% CI)**
Overall Survival	72.5 (60.7-81.3)%	62.4 (45.6-75.4)%	72.8 (60.7-81.7)%	74.8 (58.2-85.6)%	67.2 (60.3-73.1)%

Table: Estimates for OS, GRFS, cGVHD, cGVHD requiring IST, relapse/progression, and relapse/progression-free survival at 2 years post-transplant – MAC cohorts from ACCESS and 15-MMUD and RIC cohorts from ACCESS, 15-MMUD and BMT CTN 1703

Chronic GVHD	44.6 (31.3-56.9)%	46.8 (29-62.9)%		28.7 (17.3-41.2)%	21.5 (9.3-37.1)%	33.5 (26-41.1)%
cGVHD requiring IST	26.5 (16.8-37.1)%	25.6 (13.1-40.2)%		17.1 (9.4-26.9)%	17.5 (7.6-30.8)%	18.9 (13.8-24.6)%
Relapse	31.4 (21.1-42.2)%	27.6 (14.7-42.1)%		26.5 (16.6-37.4)%	32.8 (18.7-47.6)%	33.2 (26.7-39.8)%
Relapse-free survival	55.1 (43-65.6)%	54.9 (38.3-68.7)%		57.5 (44.9-68.2)%	59.7 (42.9-73.1)%	53.8 (46.6-60.4)%
GRFS	32.7 (22.2-43.5)%	28.0 (15.0-42.5)%		41.5 (29.8-52.8)%	38.0 (23.0-52.9)%	36.5 (29.8-43.3)%
Non-relapse mortality	13.5 (6.9-22.4%)	17.5 (7.6-30.8)%		16.0 (8.5-25.7)%	7.5 (1.9-18.4)%	13.0 (8.8-18.1)%
6mo Grade 2-4 aGVHD	30.7 (20.6-41.3)%	47.5 (34.5-60.7)%		44.3 (32.4-55.5)%	35 (23.1-48)%	54.8 (47.7-61.3)%
6mo Grade 3-4 aGVHD	8.0 (3.2-15.6)%	20 (10.6-31.5)%		10.0 (4.4-18.4)%	2.5 (0.1-8.2)%	6.8 (3.9-10.8)%

Conclusions: PTCy-based GVHD prophylaxis after MMUD HSCT with PBSC grafts results in favorable 2-year OS, GRFS and other outcomes. The results on ACCESS are comparable to those observed on the 1703 trial utilizing matched related and unrelated donors and 15-MMUD using MMUD with bone marrow grafts. Using MMUDs at all match levels expands donor availability to all patients regardless of ancestry and should be considered as a viable alternative when fully matched related or unrelated donors are unavailable.

Background: Disease relapse is a major challenge for acute myeloid leukemia patients after allogeneic hematopoietic cell transplantation (allo-HCT). The risk of post-transplant relapse significantly increases in patients who are transplanted in complete remission with detectable measurable disease (MRD positive) as opposed to MRD negative. Haploidentical donor (HAPLO) grafts may exert a higher graft-versus-leukemia effect than human leukocyte antigen (HLA)-matched donors. In a European Society for Blood and Marrow Transplantation (EBMT) global multi-center, registry-based analysis, we compared the outcomes following allo-HCT from either a HAPLO, matched sibling donor (MSD), or a 10/10 HLA-matched unrelated donor (MUD).

Methods: Data from 3385 adult AML patients receiving a first allo-HCT in first or second complete remission (CR1/CR2) from 269 EBMT centers between 2015 and 2022 were analyzed. 2765 patients were transplanted in CR1 and 620 in CR2. All had detectable measurable residual disease by molecular biology (MRD positive). Transplants from HLA-mismatched UD (<10/10), umbilical cord blood, or grafts with *ex*-vivo manipulation were excluded. HAPLOs were restricted to recipients with post-transplant cyclophosphamide (PTCy) as graft-versus-host disease (GVHD) prophylaxis. Multivariable Cox regression models were used to evaluate the impact of donor types on outcomes.

Results: Results from 3385 HCTs were analyzed comprising 609 (18%) HAPLO, 1057 (31%) MSD and 1719 (51%) MUD. For the entire study population, the median age was 55 years (range: 18-83). In the HAPLO group, the proportion of patients transplanted in CR2 was higher (22%) than in the MSD (15%) or MUD (18%) groups (p< 0.001). Peripheral blood was the major graft source (91%) and reduced-intensity conditioning (RIC) was usedfor approximately half (49%) of the study population. Primary disease relapse was the major cause of death in each of the three cohorts.
On multivariable analysis, compared with HAPLO HCT (as reference group), MSD HCT (hazard ratio [HR]=1.55, 95% CI 1.26-1.91; p<0.001) was associated with a significantly higher risk of disease relapse (HR=1.55, 95% CI 1.26-1.91; p<0.001)and lower non-relapse mortality (NRM) (HR=0.63, 95% CI 0.46-0.86; p=0.004) leading to an inferior LFS (HR=1.19, 95% CI 1.01-1.41; p=0.048) and a lower GVHD/relapse free survival (GRFS) (HR=1.22, 95% CI 1.05-1.41; p=0.01). Interestingly, in reference to HAPLO, although MUD HCT was associated with a higher incidence of disease relapse (HR=1.26, 95% CI 1.03-1.54; p=0.03), there was no significant differences concerning LFS, GRFS and OS.
We also found, as expected, that HCT at CR2 was associated with a significantly higher incidence of relapse (HR=1.5, 95% CI 1.27-1.78; p<0.001) compared with at CR1 and therefore significantly poorer survival outcomes (OS, LFS and GRFS). Myeloablative conditioning regimen was associated with a significantly lower relapse incidence (HR=0.75, 95% CI 0.64-0.87; p<0.001) and significantly superior survival outcomes (OS, LFS and GRFS) compared with reduced intensity conditioning. Finally, older patient age (by 10-year intervals) was associated with higher NRM (HR=1.23, 95% CI 1.12-1.36; p<0.001) and poorer OS (HR=1.10, 95% CI 1.04-1.17; p<0.001).

Conclusions: For AML patients transplanted in MRD positive complete remission, HAPLO HCTs were associated with better LFS and GRFS than MSD HCTs, primarily due to better relapse prevention.

Disclosure: Nothing to declare.

Background: ABO incompatibility occurs in approximately 40% of all allogeneic hematopoietic stem cell transplants (allo-HSCT) in Caucasian populations. Inferior outcomes after ABO major-incompatible transplantation have been reported, although findings across studies are inconsistent. Suggested adverse effects include delayed engraftment, increased graft rejection, higher incidence or severity of graft-versus-host disease (GvHD), and increased transplant-related mortality (TRM). The clinical significance of ABO incompatibility in pediatric populations remains insufficiently defined due to limited data. The FORUM trial offers a unique opportunity to evaluate this question in a large, prospectively conducted and well-controlled pediatric cohort. We therefore assessed the impact of ABO incompatibility on transplantation outcomes in children with acute lymphoblastic leukemia (ALL) enrolled in the international FORUM trial.

Methods: The FORUM (For Omitting Radiation Under Majority Age) trial is a prospective, global, multicenter, open-label phase III study (EudraCT 2012-003032-22; ClinicalTrials.gov: NCT01949129). We retrospectively analyzed 1,564 pediatric patients who received allo-HSCT from matched sibling or matched unrelated donors to determine the influence of ABO incompatibility on safety, efficacy, and survival outcomes. The data cut-off was November 2025. Patients were stratified into two cohorts based on age: (1) ≥4 years with matched sibling or matched donors (MSD/MD; n=1,328) and (2) <4 years with MSD/MD donors (n=236). Transplants were further hierarchically categorized as ABO-compatible, ABO major-incompatible, or ABO minor-incompatible. In Cohort 1, 650, 376, and 302 patients were included in each respective group; in Cohort 2, 105, 78, and 53 patients were included. Stem

cell sources included bone marrow, peripheral blood stem cells, and cord blood. Three-year overall survival (OS) and event-free survival (EFS) were assessed.

Results: The median follow-up was 3 years.
In Cohort 1 (≥4 years, MSD/MD), ABO incompatibility was not significantly associated with survival. OS and EFS were similar across ABO groups (OS: 0.77 for ABO-compatible, 0.80 for major-incompatible, 0.79 for minor-incompatible; p=0.722; EFS: 0.70, 0.68, 0.69; p=0.850).
In Cohort 2 (<4 years, MSD/MD), major ABO incompatibility showed a non-significant trend toward lower survival, while minor-incompatible transplants showed outcomes comparable to ABO-compatible transplants (OS: 0.74, 0.67, 0.79; p=0.246; EFS: 0.58, 0.50, 0.59; p=0.222).
Across both cohorts, ABO incompatibility had no impact on rates of acute GvHD or engraftment.

Conclusions: Our large study showed no impact of ABO incompatibility on outcomes in children ≥4 years undergoing allo-HSCT. In children <4 years, major ABO incompatibility was associated with a slight, non-significant reduction in OS and EFS, while outcomes after minor-incompatible transplantation were comparable to ABO-compatible procedures. Overall, major ABO mismatches should not limit donor selection in pediatric allo-HSCT.

Clinical Trial Registry: The FORUM (For Omitting Radiation Under Majority Age) trial is a prospective, global, multicenter, open-label phase III study (EudraCT 2012-003032-22; ClinicalTrials.gov: NCT01949129).

Background: Anti-CD19 CAR T-cells have transformed the prognosis of relapsed/refractory (R/R) B-cell acute lymphoblastic leukemia (B-ALL) in children, adolescents and young adults (AYA). Despite initial response rates exceeding 90%, durability of remission remains uncertain and more than 50% of patients relapse. These results required to optimize the post CAR T-cells management strategies and specifically asking the role of a consolidation treatment with allogeneic hematopoietic stem cell transplantation (allo-HSCT). Efficacy and toxicity of this procedure after CAR T-cells remain underreported. Here, we present the French experience of pediatric and AYA patients undergoing allo-HSCT after CAR T-cells for R/R B-ALL.

Methods: This national SFGM-TC retrospective study included children and AYA who received allo-HSCT after tisagenlecleucel for R/R B-ALL in SFCE or AYA centers (2016–2023). Data were collected from the PROMISE registry and patient records.

Results: Forty patients underwent allo-HSCT after a median of 6.3 months (range: 2–28.5) post CAR T-cells for early failure/relapse (n=23), early B-cell recovery (BCR) (n=13) and pre-planned consolidation or persistent cytopenia (n=4).Twenty-nine patients received treatment between CAR T-cells therapy and allo-HSCT (immunotherapy: n=19, chemotherapy: n=10).
At 2 year, EFS was 46% (95% CI: 32–66%), OS 57% (95% CI: 43–76%), CIR 31% (95% CI: 16–47%), and NRM 23% (95% CI: 11–37%).
Allogeneic HSCT toxicity was not different according to indication, with a rate of aGVHD of 43% (grade 3+: 13%), SOS of 33% (grade 3+: 13%) and cGVHD of 17%. In the whole cohort, the 2y GRFS was 36% (95%CI: 23%-56%).
Among the 18 deceased patients (45%), 10 died in complete remission from allo-HSCT complications, after a median time of 1.4 months (range: 0–25.4 months).
In multivariate analysis, early BCR was associated with better OS (77%, 95% CI: 57–100%; HR = 0.17; p = 0.027) and lower CIR (16%, 95% CI: 2–42%).
Twelve patients had previously undergone a 1st allo-HSCT (median interval between transplants: 29 months, range: 12–100). Prior allo-HSCT did not significantly impact survival (2-y OS: 58% for 1st allo HSCT vs 55% for 2nd allo HSCT) or toxicity profile after allo-HSCT (2-y NRM: 25% for 1st allo HSCT vs 18% for 2nd allo HSCT).
Among the 11 patients who relapsed after allo-HSCT the 2-year OS was 24% (95%CI: 9-74%). Two patients were successfully re-treated with subsequent CD19-directed CAR T cells therapy.

Conclusions: In this real-world analysis, allo-HSCT after CAR T-cells is associated with high NRM even after 1st allo-HSCT comparing to historically results for patients receiving allo-HSCT without previous CAR T-cells. This result is similar with a single center retrospective analysis where pre-transplant CAR T-cell therapy was associated with inferior survival and increased NRM compared to patients receiving only allo-HSCT (Chok et al, ASH 2025).

Importantly, indications of allo-HSCT lead the prognosis of patients in terms of survival offering a curative perspective for patients with early BCR precising the favorable results of allo-HSCT after CAR T-cells published by the CHOP (Myers et al., Haematologica, 2025).

Disclosure: Nothing to declare.

Background: Allogeneic hematopoietic stem cell transplantation (allo-HCT) is a key consolidation strategy for intermediate- and high-risk acute myeloid leukemia (AML) in first complete remission (CR1). However, whether specific genomic subgroups derive true therapeutic benefit from allo-HCT—rather than simply reflecting adverse prognosis—remains unclear. Most prior studies rely on static survival comparisons, which are susceptible to immortal-time bias, and do not formally test whether transplant benefit differs by mutational status. We applied a time-dependent interaction framework to identify molecular predictors of relapse-free survival (RFS) and overall survival (OS) benefit from allo-HCT.

Methods: We conducted a multicenter, retrospective study of 1,228 adult AML patients who achieved CR1, with next-generation sequencing data at diagnosis across five academic centers. Allo-HCT was modelled as a time-dependent covariate to minimize immortal time bias. Multivariable Cox regression models adjusted for age, white blood cell count, and cytogenetic risk. Somatic mutations were grouped into molecular clusters using pairwise Fisher's exact tests with false discovery rate correction, defining a co-mutated cluster 4 (ASXL1, RUNX1, BCOR, BCORL1). Interaction terms between mutation status and the time-dependent transplant variable were used to test whether transplant benefit differed by genomic subgroup formally.

Results: Among 1,228 patients, 593 (48.3%) underwent allo-HCT at a median of 107 days post-CR1. In time-dependent models, allo-HCT conferred marked RFS benefit in ASXL1-mutated patients (hazard ratio [HR] 0.22) with significant interaction (interaction HR 0.26,

p=0.004), indicating substantially greater benefit versus ASXL1-unmutated patients (HR 0.82). Similarly, RUNX1-mutated AML showed significant RFS improvement with allo-HCT (HR 0.29; interaction HR 0.35, p=0.01) versus RUNX1-unmutated disease (HR 0.81). At the pathway level, chromatin modifier mutations (interaction HR 0.53, p=0.02) and MDS-related gene mutations (interaction HR 0.62, p=0.03) predicted significant RFS benefit. Cluster 4 analysis showed pronounced RFS benefit from allo-HCT (interaction HR 0.45, p<0.01), Figure 1.For OS, significant interactions were observed in ASXL1-mutated (interaction HR 0.28, p=0.01) and RUNX1-mutated patients (interaction HR 0.37, p=0.0), with neutral transplant effects in unmutated groups. Cluster 4 demonstrated a significant OS benefit (interaction HR 0.50, p=0.01). Improvements were primarily driven by reduced relapse incidence.

Using time-dependent interaction analysis, we demonstrate that ASXL1, RUNX1, chromatin modifiers, and MDS-related mutations—and a mutated ASXL1/RUNX1/BCOR/BCORL1 cluster—identify AML patients deriving substantial survival benefit from allo-HCT in CR1. These mutations function as predictive biomarkers of transplant response, not merely adverse prognostic markers, supporting genomically guided transplant decision-making in AML.

Background: Chimeric antigen receptor (CAR)-T cell therapy has transformed the management of relapsed/refractory (R/R) diffuse large B-cell lymphoma (DLBCL), yet suboptimal complete remission (CR) rates and limited T-cell persistence remain major challenges. IL-10 engineering enhances CAR-T cell function in solid tumor models, but its clinical relevance in lymphoma remains unknown. To address this, we conducted an open-label, single-arm, investigator-initiated phase I trial (NCT06120166) evaluating the IL-10-expressing CD19 CAR-T product, META 10-19, in patients with R/R DLBCL.
The primary objective was to assess the safety and tolerability of META 10-19. Secondary

objectives included the characterization of pharmacokinetics, *in vivo* expansion, cytokine profiles and preliminary antitumor efficacy.

Methods: Between December 2023 and April 2025, 13 patients with R/R DLBCL were enrolled and received a single infusion of META 10-19 across three dose levels (DLs): DL1 (2.0×10^4 cells/kg; n=3), DL2 (2.0×10^3 cells/kg; n=7, including 4 in dose expansion), and DL3 (5.0×10^3 cells/kg; n=3). All patients received standard fludarabine/ cyclophosphamide lymphodepletion. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) were graded using Lee 2014 and ASTCT 2019 criteria. Adverse events were assessed through CTCAE 5.0. Pharmacokinetics and immune correlates were evaluated through flow cytometry, serum cytokine analyses, and single-cell RNA sequencing (scRNA-Seq).

Results: As of November 15th, 2025, the objective response rate was 100%, comprising 11 patients achieving CR (91.7%) and 1 achieving partial remission (PR, 8.3%). CRS occurred in 12 patients (Grade 1: 8; Grade 2: 3; Grade 3: 1), while ICANS in 2 patients (Grade 1: 1; Grade 2: 1). All patients exhibited robust *in vivo* expansion of META 10-19 (median peak: 660.7 cells/μL), accompanied by marked increases in serum IL-10 levels (median peak: 1,221.59 pg/mL). scRNA-Seq showed that IL-10^+ $CD8^+$ CAR-T cells displayed transcriptional programs with heightened proliferation, activation, type 2 immune response, and IL-10 signaling, compared to IL-10^- $CD8^+$ CAR-T cells.

Conclusions: Ultra-low-dose of META 10-19 demonstrated potent antitumor activity, manageable safety, and exceptional proliferative capacity in R/R DLBCL. The doses used (2×10^3 - 2×10^4 CAR-T cells/kg) are the lowest reported in clinical CAR-T therapy to date, defining a new benchmark for potency and clinical scalability. As one of the first cytokine-engineered CAR-T products evaluated in R/R DLBCL patients, META 10-19 introduces a novel therapeutic paradigm for aggressive B-cell malignancies. Larger studies with extended follow-up are warranted to validate long-term durability and broader applications across hematologic and solid tumors.

Background: CAR-T cell therapies have transformed the treatment landscape of relapsed/refractory (R/R) large B cell lymphoma (LBCL). However, >50% of patients relapse, in part due to CD19 tumor antigen escape. Dual targeting of two validated B-cell antigens, CD20 and CD19, may prevent relapses associated with CD19 antigen loss.
Prizlo-cel is an investigational dual targeting CD20/CD19 CAR-T cell therapy with an optimized CAR design and a differentiated CD20 binder. We report preliminary efficacy, safety, and biomarker analyses from the first global phase 1b (NCT05421663) study of prizlo-cel in CAR-T naive patients with R/R LBCL.

Methods: Prizlo-cel dose levels tested were 2.0 million (M) CAR-T cells/kg (n=18), 150M (n=8) and 75M (n=25) CAR-T cells. Primary objectives include safety and recommended phase 2 dose. Secondary objectives include preliminary efficacy and pharmacokinetics. Biomarker analyses include peripheral blood T cell expansion and B-cell depletion, tumor-

based CD20 and CD19 target expression and gene expression-based tumor microenvironment (TME; LymphoMAP) analysis.

Results: As of April 2025, 51 patients with R/R LBCL were infused; 39% had ≥2 prior lines of therapy; 67% had bridging therapy. Median follow-up was 8mo.
Across all doses, Grade 3 ICANS were reported in 4 (8%) of patients. Grade 3 CRS events were observed in 2 (4%) patients. All events were in the absence of prophylactic steroids.
Across all doses in 44 evaluable patients, ORR was 91% and CR rate was 75%. High response rates were achieved irrespective of number of prior lines of therapy.
Cellular kinetics showed comparable CAR-T cellular expansion, including CD4+ and CD8+ CAR-T cells at peak expansion, and comparable B-cell depletion across doses. Moreover, few Grade 3 ICANS and CRS events were observed with comparable CAR-T expansion across doses.
High response rates were observed across varying levels of CD20 or CD19 expression. In 31 patients with CD20 and CD19 high/medium (H-score >100), ORR and CR rates were 100% and 90%, respectively. In 11 patients with low expression of one or both antigens (CD20 or CD19 H-score <100), ORR and CR rates were 82% and 73%, respectively. Initial findings from 30 patients with available gene expression data showed 100% ORR across all LymphoMAP archetypes, with high CR rates across lymph node (94%), fibroblast/macrophage (83%), and T exhausted (80%) TME archetypes.

Conclusions: Initial findings from this global phase 1b study showed that prizlo-cel has a favorable safety profile, with low and manageable rates of Grade 3 CRS and ICANS, and high CR rates in CAR-T–naïve patients with R/R LBCL. High response rates were observed across a range of CD20 and CD19 expression levels and immunosuppressive TME archetypes. Taken together, these data suggest that dual antigen targeting of CD20 and CD19 with prizlo-cel via an optimized CAR-T construct may overcome the limitations of single-antigen CAR-T cell therapies, with the potential of improving clinical outcomes.

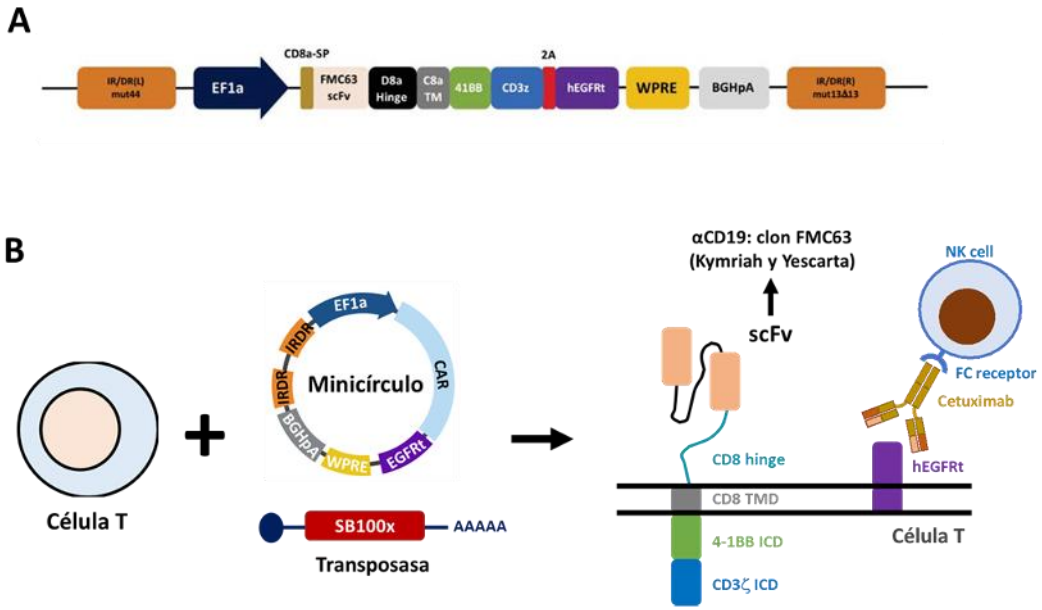
Background:



TranspoCART19 is an academic project designed to develop an innovative, virus-free CAR-T cell therapy for adults with relapsed/refractory (R/R) B-cell lymphomas. Using the *Sleeping Beauty* transposon system, the TranspoCART19 product encodes a 4-1BB-costimulated anti-CD19 CAR together with a truncated EGFR safety switch. Following successful preclinical development and regulatory approval, a multicenter phase I/IIa clinical trial (NCT06378190) was initiated in May 2023.

Methods: This is an open-label, multicenter, non-randomized phase I/IIa trial evaluating safety, feasibility, and preliminary efficacy. Dose escalation follows a 3+3 design with three dose levels (1, 3, and 5 $\times 10^6$ CAR-T/kg), followed by an expansion cohort at the recommended phase II dose. The CAR-T product is infused fractionally (10%, 30%, 60% on days 0, +1, +4). This abstract summarizes safety and preliminary efficacy findings from patients treated in the first two dose levels of the ongoing dose-escalation phase.

Results: As of November 2025, 10 patients were enrolled and seven received TranspoCART19 (four at 1×10^6/kg; three at 3×10^6/kg), while three additional patients have completed apheresis and manufacturing and are pending infusion (Dose Level 3). Manufacturing was successful for all apheresed patients, with no manufacturing failures or out-of-specification products. Patient-level characteristics and outcomes are summarized in the Table.
Safety: No DLTs were reported. Across all infused patients, CRS occurred in 3/7 cases, all grade 1 and self-limited except for one requiring a single dose of tocilizumab. The only patient who developed ICANS was the one with rapidly progressive primary CNS lymphoma, who progressed early and was withdrawn on day +20, subsequently dying from progressive disease on day +31 (he was replaced per DSMB rules to complete dose level 1). He had a possible grade 3 ICANS, although grading was unreliable due to markedly abnormal neurological status at baseline (ICE 5–8). No other patient developed ICANS or any neurological adverse events. There were no cases of IEC-HS. Cytopenias were transient or intermittent, responsive to supportive care, and no patient developed an aplastic phenotype. After a median follow-up of 199 days (range, 62–519), four SAEs have been reported: two febrile neutropenia, one abdominal sepsis, and one papillary thyroid carcinoma in a patient with a pre-CAR-T benign thyroid lesion. No treatment-related deaths occurred.
Efficacy: With the exception of the patient with rapidly progressive primary CNS lymphoma who experienced early disease progression, all six remaining patients achieved complete metabolic response at first assessment (day +28), which has been maintained in subsequent evaluations. In-vivo expansion of TranspoCART19 was detected in all patients, with CAR-T peaks at day +14 and detectable persistence up to day +56 in three out of four patients with available data.

Baseline Characteristics and Outcomes of TranspoCART19-Treated Patients (n = 7)

Variable	Patient 002-1	Patient 001-1	Patient 001-2	Patient 001-3	Patient 001-4	Patient 004-1	Patient 004-2
Dose level	1×10^6/kg	1×10^6/kg	1×10^6/kg	1×10^6/kg	3×10^6/kg	3×10^6/kg	3×10^6/kg

Variable	Patient 002-1	Patient 001-1	Patient 001-2	Patient 001-3	Patient 001-4	Patient 004-1	Patient 004-2
Age (years)	53	53	67	73	74	68	68

Diagnosis	Marginal zone lymphoma	Primary CNS lymphoma	Difuse large B-cell lymphoma	Follicular lymphoma	Follicular lymphoma	Follicular lymphoma	Follicular lymphoma
Lines of prior therapy	8	3	2	2	4	3	2
Bridging therapy	R-GemOx	Dex + ibrutinib; R-IE; Dex maintenance	Pola-GemOx	None	None	None	R-CVP
Disease preLD	PR	PD	PD	PD	PD	PD	PR
Hematotox score	2	2	0	1	1	NA	NA
CRS (grade)	0	1 (toci x 1)	0	0	1	0	1
ICANS (grade)	0	3 (grading was not reliable)	0	0	0	0	0
Infections (grade ≥3)	Febrile neutropenia	None	Abdominal sepsis and papillary thyroid carcinoma	None	None	None	None

Variable	Patient 002-1	Patient 001-1	Patient 001-2	Patient 001-3	Patient 001-4	Patient 004-1	Patient 004-2
Day +28 response	CR	PD	CR	CR	CR	CR	CR
Day +100 response	CR	NA	CR	CR	CR	Not due yet	Not due yet
Day +180 response	CR	NA	CR	CR	Not due yet		
Day +365 response	CR	NA	CR	Not due yet			
Status at last follow-up	Ongoing CR	Dead due PD	Ongoing CR	Ongoing CR	Ongoing CR	Ongoing CR	Ongoing CR

Conclusions: Manufacturing feasibility was confirmed, with all apheresed patients producing a product that met release criteria. TranspoCART19 also demonstrated a highly favorable safety profile across two dose levels and promising early efficacy, with sustained metabolic complete responses in all evaluable patients. These results support continuation of dose escalation and subsequent expansion.

EXTENDED CLINICAL AND GENOMIC EVALUATION OF CTX130, A CD70-DIRECTED ALLOGENEIC CAR T THERAPY, IN ADULT T-CELL LEUKEMIA/LYMPHOMA: RESULTS FROM THE FIRST-IN-HUMAN COBALT-LYM PHASE I TRIAL

Emma Cordover[1], Kimberly Seymour[2], Buse Eglenen Polat[2], Santiago Beltran[2], Ankit Tanwar[1], Sidney Hwang[1], Nicholas Li[1], Ella Wesson[1], Ridhi Gupta[2], ***R. Alejandro Sica***[2]
[1]*Albert Einstein College of Medicine, New York City, United States of America (the),*
[2]*Montefiore Medical Center, New York City, United States of America (the)*

Background: Adult T-cell leukemia/lymphoma (ATLL) is a rare, aggressive $CD4^+$ T-cell malignancy driven by HTLV-I infection and associated with poor outcomes, particularly in the relapsed/refractory setting where effective therapies are lacking. CD70 is aberrantly expressed in ATLL and contributes to immune escape through CD27-mediated signaling, making it a compelling immunotherapeutic target. CTX130 is an allogeneic CRISPR-Cas9–

engineered CAR T-cell product directed against CD70. We report clinical outcomes and genomic correlates from six patients with relapsed/refractory ATLL treated with CTX130 in the Phase I COBALT-LYM trial, including next-generation sequencing (NGS) findings from four patients.

Methods: This single-arm, open-label Phase I study evaluated CTX130 in patients with relapsed or refractory T-cell malignancies at sites in the USA, Australia, and Canada. We describe the experience from our center's ATLL cohort. Patients were required to have received ≥1 prior systemic therapy and have ECOG 0–1. All underwent lymphodepletion with fludarabine and cyclophosphamide before CTX130 infusion; repeat dosing was allowed per protocol. The primary endpoint was safety. Secondary endpoints included overall response rate (ORR), progression-free survival (PFS), and overall survival (OS). NGS was performed (NeoGenomics) on peripheral blood samples from four patients to characterize mutational profiles and assess clonal dynamics pre- and post-treatment.

Results: Six patients with previously treated ATLL received CTX130 between August 28, 2020, and May 30, 2023, with follow-up through July 2025. Median age was 54 years (range 33–72), with a median of one prior therapy (range 1–5). Two patients (29%) had acute/leukemic ATLL and four (71%) had lymphomatous disease. CTX130 dose levels ranged from 3×10^7 to 9×10^8 CAR T cells; three patients received a second infusion. No cytokine release syndrome (CRS) or ICANS was observed. Grade ≥3 adverse events consisted primarily of infections and neutropenia.
The ORR was 50% (three of six patients), including two complete responses (CRs) and one partial response (PR). Median PFS was 2.5 months, and median OS was 7.8 months. Two patients remained alive as of July 2025, with one achieving prolonged survival of 37.5 months. NGS demonstrated dynamic genomic changes in two patients with paired samples, including shifts in variant allele frequencies and acquisition of new mutations. A STAT3 mutation emerged post-therapy in one long-term responder, consistent with reports associating STAT3 alterations with more indolent ATLL biology. These findings suggest that CAR T-cell–mediated immune pressure may drive clonal remodeling and, in select patients, contribute to more favorable disease trajectories.

Conclusions: CTX130 showed encouraging activity and manageable toxicity in relapsed/refractory ATLL, producing a 50% ORR in a population with historically limited treatment options. The presence of two long-term survivors represents the first documented durable remissions from our center's ATLL CAR T program. Genomic analyses indicate that ATLL can undergo clonal adaptation under CAR T-cell pressure, warranting deeper investigation into predictors of response. These results support ongoing development of CD70-targeted therapies, including next-generation CTX131, and highlight the need for larger studies to refine patient selection and integrate molecular biomarkers into therapeutic decision-making.

ADOPTIVE TRANSFER OF MULTIVIRUS-SPECIFIC T CELLS AGAINST REFRACTORY CMV, ADV AND EBV INFECTIONS AFTER STEM CELL TRANSPLANTATION – INTERIM RESULTS FROM THE "TRACE" PHASE-III TRIAL

Theresa Kaeuferle[1,2], *Federica Galaverna*[3], *Maria Giuseppina Cefalo*[3], *Peter van Balen*[4], *Tessa Kerre*[5], *Daniele Bensoussan*[6], *Peter Lang*[7], *Brigitte Strahm*[1], *Giuseppina LiPira*[3], *Chiara Agrati*[3], *Rosa de Groot*[4], *Mira Reger*[2], *Elvira Bodien*[1], *Markus Pfirrmann*[8], *Anna Tortolini*[9], *Linda Hanssens*[10], *Franco Locatelli*[3,11], *Tobias Feuchtinger*[1,2]
[1]*University Medical Center Freiburg, Freiburg, Germany,* [2]*LMU Klinikum, Munich, Germany,* [3]*IRCCS Ospedale Pediatrico Bambino Gesù, Roma, Italy,* [4]*Leiden University Medical Center, Leiden, Netherlands (the),* [5]*Ghent University Hospital, Ghent, Belgium,* [6]*Université de Lorraine, Vandoeuvre-les-Nancy, France,* [7]*University of Tuebingen, Tuebingen, Germany,* [8]*Ludwig-Maximilians-Universitaet Muenchen, Munich, Germany,* [9]*Simbec-Orion, Merthyr Tydfil, United Kingdom of Great Britain and Northern Ireland (the),* [10]*Miltenyi Biomedicine, Bergisch Gladbach, Germany,* [11]*Catholic University of the Sacred Heart, Roma, Italy*

Background: Patients with chemo-refractory CMV, EBV, or AdV infections following allogeneic stem cell transplantation (SCT) are exposed to a high morbidity and mortality, with limited approved treatment options. Adoptive transfer of multivirus-specific T cells has shown promising results in early studies. TRACE was the first placebo-controlled phase-III trial evaluating the efficacy and safety of multivirus-specific T-cell infusion in this patient population. The primary endpoints are viral clearance (two consecutive negative PCRs) and progression rates between Day 7 and Week 8 after investigational medical product (IMP) infusion. Incidence and severity of graft-versus-host disease (GvHD) as well as the frequency of *in vivo* expanded virus-specific T-cells are amongst the secondary endpoints.

Methods: TRACE is a prospective, multicentre, double-blind, placebo-controlled randomized phase-III trial conducted across 33 European centres. The IMP is produced in 7 decentralized academic GMP units. Patients can be included, if viremia is resistant to at least two weeks of antiviral first-line therapy. Only IMPs produced using cells from the original SCT donor are accepted. The IMP consists of donor-derived CD4+ and CD8+ T lymphocytes enriched for CMV, EBV, and AdV specificity using the CliniMACS IFNy-Capture System after exposure to overlapping peptide mix. Patients are randomized 2:1 (verum:placebo). The pre-planned interim analysis was performed after 39 evaluable patients (57% of the aimed total). Significance levels were adjusted for multiple testing.

Results: Harmonization of academic GMP production across all participating countries (Italy, Germany, the Netherlands, Belgium, France and Spain) was successful, including diagnostic methods and reproducible quality control, to allow inter-center-comparability. In the interim analysis, 2 primary efficacy endpoints were assessed in 39 evaluable patients across the 2 treatment groups (placebo or verum) in a blinded manner. First, viral clearance showed a remarkable clearance rate of 56% in group A compared to only 36% in group B. Second, 76% of patients did not progress in group A compared to 57% in group B. Neither test was statistically significant, therefore the clinical trial continues with both treatment arms. Of the

39 evaluable patients, 26% were enrolled due to AdV, 51% due to CMV and 3% due to EBV infection, and 20% presented with multiple viral infections. Induction of a virus-specific T cell response *in vivo* could be successfully detected. Safety analysis was performed, with GvHD as AE of special interest and no safety concerns have been raised. In light of this last evidence, the independent advisory board ("Scientific Ethics Advisory and Data Safety Monitoring Board") recommended the study to continue.

Conclusions: Set-up and conduct of a phase-III IIT aimed at restoring pathogen-specific immunity is feasible. TRACE is designed to provide evidence for the efficacy and safety of multivirus-specific T-cell infusion in patients with chemo-refractory viral infections post-SCT. Given the high need to generate efficacy data, this approach may represent a novel therapeutic option for this vulnerable patient population.

Background: The role of T-cell depletion/modulation by serotherapy in cord blood hematopoietic stem cell transplantation (CB-HSCT) has not been fully elucidated, and recent studies suggest that CB-HSCT without serotherapy may be the optimal option in high-risk

and relapsed/refractory pediatric myeloid malignancies, because of an acceptable non-relapse mortality (NRM) combined to a strong graft-versus-leukemia effect.

Methods: In this multicenter study, we retrospectively analyzed the outcome of a cohort of pediatric patients (n=289) with malignant diseases undergoing unrelated CB-HSCT from 01/01/2000 to 31/12/2022 who did (ATG; n=252) or did not receive (no-ATG; n=37) serotherapy as part of their GvHD prophylaxis. Overall, 88 patients (30%) underwent transplant in advanced disease phase defined as either after the failure of a previous transplant or without heamatological remission at the time conditioning was initiated.

Results: The study involved 21 centers. The median duration of the follow-up of the entire study population was of 9 years (IQR 5,3-12,6) with no differences in the two subgroups. Median time to neutrophil engraftment was 24 days (range 12-76) in ATG group and 28 days (range 10-47) in no-ATG group (p=0.44). At day + 45 the cumulative incidence of graft failure was 2,4% (95%CI 1,1-5,3) in ATG group and 5,5% (95%CI 1,4-21,3) in no-ATG group (p=0,28).
In univariable analysis, the composite endpoint of 5-year chronic GvHD-free, relapse-free survival (cGRFS) was 47,2% (95% CI: 39–55%) and 60% (95% CI:38 –81%) in ATG and no-ATG group, respectively (p = 0.39). In multivariable analysis, only disease phase showed a statistically significant correlation with cGRFS [early disease phase RR 0,67 (95%CI 0,52-0,88) p=0.004]The cumulative incidence of NRM was 30% (95%CI 24-36) in ATG patients and 36% (95%CI 22-57) in no-ATG patients (p=0.6), while the cumulative incidence of relapse (CIR) was 19% (95%CI 14-25) and 25% (95%CI 14-45) in ATG patients and non-ATG patients, respectively (p= 0.34). In patients with advanced disease phase, a CIR of 29% (95% CI: 21–40) was observed. In multivariable analysis, disease phase and year of HSCT were related to NRM (early disease phase RR 0.34 95%CI 0.16-0.71 p= 0.004, transplant year before 2010 RR 0.38 95%CI 0.19-0.75 p= 0.005); disease phase correlated with relapse (early disease phase RR 0.52 95%CI 0.32-0.85 p= 0.001).
Cumulative incidence of grade II-IV aGvHD was 32% (95%CI 26-38) and 26% (95%CI 15-48) in ATG and no ATG subgroups (p=0.63), respectively. Cumulative incidence of cGVHD was 16% (95%CI 11-23) in ATG patients and 8% (95%CI 1-50) in no-ATG patients (p=0.43).

Conclusions: In conclusion our study suggests that the use of ATG for GvHD prophylaxis in CB-HSCT from unrelated donors, differently from transplantation using bone marrow or peripheral blood as stem cell source, does not correlate with a better outcome, and confirms a strong graft-versus-leukemia effects of this stem cell source, as previously demonstrated by other studies.

Disclosure: Nothing to declare.

Paed4-07

TREOSULFAN-BASED REDUCED-TOXICITY CONDITIONING IN CHILDREN WITH INBORN ERRORS OF IMMUNITY: REPORT OF RETROSPECTIVE STUDY FROM A SINGLE CENTER IN CANADA

Ayshah AlOtaibi[1], *Alexandra Espinosa Pousa*[1], *Edbert Khong*[1], *Tal Schechter*[1], *Muhammad Ali*[1], *Vy Kim*[1], *Julia Upton*[1], *Joerg Krueger*[1], *Eyal Grunebaum*[1], *Donna Wall*[1], *Yogi Chopra*[1]
[1]*University of Toronto-Sickkids Hospital, Toronto, Canada*

Background: Children with inborn errors of immunity (IEI) display diverse symptoms. Allogeneic hematopoeitic stem cell transplant (HSCT) is the main cure, with traditional myeloablative conditioning (busulfan and cyclophosphamide) providing good engraftment but high toxicity (veno-oclussive disease) and long-term risks. Since 2016, the Hospital for Sick Children in Toronto has used Treosulfan-based conditioning for IEI patients. We performed a retrospective review to assess outcomes and survival with this regimen.

Methods: We retrospectively reviewed charts of IEI patients under 18 years who received allogeneic HSCT with Treosulfan-based reduced-toxicity conditioning at Sick Children's Hospital from July 2016 to June 2025, following REB approval. Outcomes were compared to published North American Busulfan-based cohorts. We evaluated overall survival, transplant-related mortality, acute and chronic complications, chimerism, immune reconstitution, IVIG independence, and vaccine response.

Results: Between July 2016 and June 2025, ninety-four children diagnosed with inborn errors of immunity (IEI) underwent allogeneic hematopoietic stem cell transplantation (HSCT) at The Hospital for Sick Children. The median follow-up period was 36 months, ranging from 3 months to 8 years. The median age at transplant was 2 years (range: 2 months to 17 years), with males comprising 62% of the cohort.
The IEI diagnoses included haemophagocytic lymphohistiocytosis (HLH; n=20), severe combined immunodeficiency (SCID; n=18), chronic granulomatous disease (CGD; n=12), combined immunodeficiency (CID; n=5), and other IEI disorders (n=39). All patients received a Treosulfan-based conditioning regimen, predominantly Treosulfan/Fludarabine/Cyclophosphamide (n=79), Treosulfan/Fludarabine (n=14), or Treosulfan/Fludarabine/Thiotepa (n=1). Serotherapy with antithymocyte globulin (ATG) was administered to all individuals.
Donor types included cord unrelated donors (CURD; n=38), matched unrelated donors (MUD; n=21), matched sibling donors (MSD; n=19), mismatched unrelated donors (MMUD; n=9), and haploidentical donors (n=7). Sources of stem cells were peripheral blood (n=37), bone marrow grafts (n=19), and cord blood (n=38).
The overall survival rate was 91%, similar to the historical PIDTC range (67%-95%). There were eight deaths: survival rates were 83% in SCID, 85% in HLH, and 91% in CGD groups. Acute GVHD occurred in 51% of patients (44/86), with grade III-IV seen in 6.8% (6/86). Chronic GVHD was reported in 41% (36/86), but severe cases comprised only 4%. VOD developed in 3.6% (3/86). Chimerism analysis showed full donor chimerism in 51% (44/86) and mixed in 48% (42/86). Most patients (94%) were off IVIG at analysis.

Conclusions: This is the first North American study of IEI children receiving Treosulfan-based conditioning, demonstrating excellent results with reduced transplant mortality, lower VOD rates, acceptable GVHD rates, and IVIG independence.

EMAPALUMAB INDUCES RAPID, DURABLE RESPONSES AND RELIABLE BRIDGING TO CURATIVE HSCT IN PATIENTS WITH PRIMARY HLH: POOLED ANALYSIS OF PROSPECTIVE TRIALS NI-0501-04, NI-0501-05 AND NI-0501-09

*Michael Jordan[1], **Franco Locatelli**[2,3], Didier Halimi[4], Elena Burillo[5], Brian D. Jamieson[6], Andrew Danquah[5], Emmanuel Monnet[4]*
[1]Divisions of Immunobiology, and Bone Marrow Transplantation and Immune Deficiency, Department of Pediatrics Cincinnati Children's Hospital Medical Center, University of Cincinnati Medical School, Cincinnati, United States of America (the), [2]IRCCS, Ospedale Pediatrico Bambino Gesù, Rome, Italy, [3]Catholic University of the Sacred Heart, Rome, Italy, [4]Sobi, Basel, Switzerland, [5]Sobi, Stockholm, Sweden, [6]Sobi, Inc., Morrisville, United States of America (the)

Background: Emapalumab, a fully human anti-interferon-γ (IFNγ) monoclonal antibody, is FDA-approved for adult/paediatric patients with pHLH with refractory, recurrent or progressive disease or intolerance to conventional HLH therapy. Primary hemophagocytic lymphohistiocytosis (pHLH) is a life-threatening, genetically driven, IFNγ–mediated hyperinflammatory disorder. Allogeneic hematopoietic stem-cell transplantation (HSCT) still remains the only potentially curative therapy, but optimal conditioning and transplant success depend on achieving adequate disease control beforehand. The pivotal NI-0501-04 study first showed, and the NI-0501-09 study later confirmed, that emapalumab rapidly controls hyperinflammation and enables successful HSCT in patients with pHLH (Locatelli et al., 2020, 2025).

Methods: We conducted a pooled analysis of 3 prospective studies (NI-0501-04 [2013 to 2019; n=45], NI-0501-05 [2021; n=37 of 45 in NI-0501-04], NI-0501-09 [2019 to 2022; n=35] for a total of 80 emapalumab-treated patients. Clinical responses were based on an investigator's global assessment, classified as complete response [CR] (complete response or non-active disease), partial response [PR] (partial response or HLH improvement) or no response [NR] (progressive disease, reactivation, worsening or death). Investigator-assessed OR was defined as achieving either CR or PR. Patients who received ≥3 emapalumab doses with investigator assessments made up the response-evaluable set at week 8 or EOT (n=62) and the best-response set (n=71); those with ≥3-month follow-up formed the bridging-success survival set (n=73). Safety was not evaluated in this pooled analysis. Analyses were descriptive.

Results: At baseline, the median age was 0.8 years (range 0.01–16.67); 54% (43/80) were males; 31% (25/80) had central nervous system involvement and 66% (53/80) had received prior HLH therapy. At Week 8/EOT, 55/62 evaluable patients achieved OR (89%), including CR in 14/62 (23%). Considering best response up to Week 8/EOT, 67/71 patients responded (94%) and 23/71 attained CR (32%). Median time to first OR was 16 days.
Bridging-success survival was achieved by 57/73 patients (78%): 51 proceeded to HSCT and 6, without HSCT, were alive ≥3 months after EOT (median 358 days; [95% CI 109-380]). An assessment of CR or PR by Week 8 conferred a greater probability of bridging success than NR (93% and 90%, respectively vs 43%).
GC tapering by at least 25% and 50% from baseline occurred within 14 days for 29/73 patients (40%) and 19/73 patients (26%), respectively. By EOT, 35/73 (48%) and 26/73 (36%) achieved those same reductions.

Conclusions: In pHLH, emapalumab rapidly achieves clinically meaningful and durable disease control, enables GC reduction, and successfully bridges to HSCT or ≥3 months survival without HSCT in 78% of patients. These findings reinforce emapalumab's role as an effective IFNγ neutralizing bridge to curative HSCT in a high-risk pediatric population.

INTERIM CLINICAL OUTCOMES IN ORCA-T WITH REDUCED INTENSITY CONDITIONING: AN OBSERVATIONAL COMPARISON TO REGISTRY-BASED POST-TRANSPLANT CYCLOPHOSPHAMIDE PATIENTS

*Alejandro Villar-Prados[1], **Anna Pavlova**[2], Nathaniel B. Fernhoff[2], James Scott McClellan[2], Scott Killian[2], Robert S. Negrin[1], Everett H. Meyer[1]*
[1]Division of Blood and Marrow Transplantation & Cellular Therapy, Stanford University School of Medicine, Stanford, United States of America (the), [2]Orca Bio, Menlo Park, United States of America (the)

Background: Orca-T is an investigational precision cell therapy that has been evaluated in the context of myeloablative conditioning for allogeneic treatment of hematological disorders. In a ph1b clinical trial (NCT04013685) in patients with acute leukemias and MDS, Orca-T exhibited an excellent safety profile and low rates of serious graft-versus-host disease (GVHD). In a ph3 randomized trial (NCT05316701), in comparison to calcineurin inhibitor/methotrexate prophylaxis, Orca-T met the primary endpoint of improving moderate-to-severe chronic GVHD-free survival. Studies of Orca-T combined with reduced intensity conditioning (RIC) are ongoing. Here we report interim clinical outcomes in Orca-T patients who received RIC in comparison to a registry cohort who received RIC plus post-transplant cyclophosphamide (PTCy).

Methods: Patients on a single-center ph1 study (NCT05088356) of Orca T in RIC who were diagnosed with ALL, AML, or MDS (n=46) were included in this evaluation. The other patients with myelofibrosis or a haploidentical donor were excluded (n=7). Contemporaneous patient level data were obtained from CIBMTR-NMDP. The comparator group included adults in the CIBMTR registry treated with RIC + PTCy + tacrolimus ± mycophenolate (n=587). The pre-transplant demographic and clinical characteristics were similar between cohorts. The included participants were adults ages 60-75, had intermediate- to high-risk AML, ALL or MDS, received RIC, and had a 7/8 or 8/8 HLA-matched donor. We studied the following endpoints: overall survival (OS), relapse-free survival (RFS), GVHD and relapse-free survival (GRFS), moderate-severe chronic GVHD-free survival (cGFS), and the cumulative incidences of non-relapse mortality (NRM), relapse, grades 3-4 acute GVHD and moderate-severe chronic GVHD. Standard survival and competing risk methods were used; $p<.05$ defined significance.

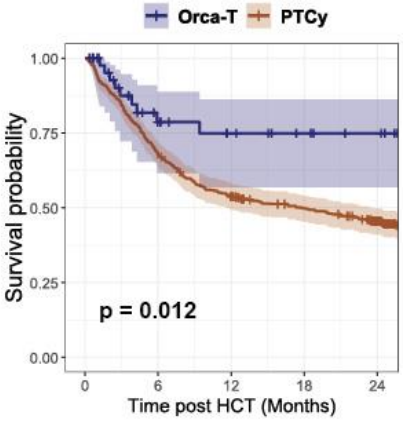
Results: Although this is a retrospective analysis, each of the clinical outcome estimates strongly favored Orca-T, with RFS (p=.034), GRFS (p=.012), and cGFS (p=.034) (Table 1). Notably, the 1-year GRFS estimate for Orca-T of 75% (95% CI = 57-86%) was remarkably high (Figure 1). While the cumulative incidence estimates of serious GVHD were low in both groups, none of the Orca-T patients experienced gr. 3-4 aGVHD.

Table 1. Clinical Outcomes.

Outcome[1]	Orca-T (N=46)	PTCy (N=587)	P-value[2]
Overall survival	86% (70-94%)	72% (68-75%)	0.066
RFS	81% (65-91%)	61% (57-65%)	**0.034**
GRFS	75% (57-86%)	54% (49-58%)	**0.012**
cGFS	79% (61-90%)	64% (60-67%)	**0.034**
NRM	8.1% (2.0-20%)	16% (13-19%)	0.4
Relapse	10% (3.2-23%)	23% (20-27%)	0.067
aGVHD gr.3-4	0.00% (—%)	5.8% (4.1-7.9%)	0.12
cGVHD mod-sev	6.9% (1.1-20%)	10% (7.9-13%)	0.4

[1] 1-year estimate (95% CI)
[2] Log-rank test (survival) or Gray's test (cumulative incidence)

Figure 1. GRFS.



Conclusions: Interim analyses of RIC + Orca-T patients revealed low GVHD, relapse, and NRM rates. Comparison to RIC + PTCy patients in the CIBMTR registry suggested a clinical benefit of RIC + Orca-T. These findings provide insight for improving clinical outcomes in older patients and high comorbidity patients unable to receive myeloablative conditioning regimens.

Background: A retrospective analysis of all paediatric patients undergoing allogeneic hematopoietic stem cell transplant (HSCT) in all 13 British Society of Bone Marrow Transplant and Cellular Therapies (BSBMTCT) centres from 2017 to 2023 was performed to determine the contemporary rate and causes of TRM.

Methods: Data from annual national audit meetings were reviewed for cause of death, which was then classified as relapse or TRM. The proportion of TRM was compared across groups.

Results: A total of 2312 patients (0 – 19 years, median = 7y) received allogeneic HSCT during the study period. Follow-up time varied from 10 months to 21 months depending on date of transplant and the annual data collection cut-off.
Overall mortality was 14% (334/2312 patients). Relapse rate was 5% at time of analysis although this is likely to increase with longer follow-up. The overall TRM was 9% (213/2312 patients). Over time, this fell from 12.5% in 2017 to 6.9% in 2023 (p = 0.44). Patients with TRM died at a median of 80 (+/-54) days after transplant.
The main causes of TRM are shown in Figure 1. Infection accounted for almost half of TRM. Viral infections predominated (27% of TRM), particularly adenovirus [29 patients (14%

overall TRM), cytomegalovirus [15 (7%)], and parainfluenza [11 (5%)]. Graft-versus-host disease (GVHD) by itself or in combination with other diagnoses was the cause of TRM in 33 patients (14.3 %). The "other causes" category (11%) mostly included cases of directed organ or systemic drug toxicity.
When analysing the difference in TRM proportion across groups (table 1) we observed a higher TRM in patients with a diagnosis of inborn errors of metabolism (15.4%) and inborn errors of immunity (IEI) (11.3%), whereas TRM in patients with haemoglobinopathies (4.2%) and bone marrow failure (3.7%) was very low. In patients with leukaemia, TRM was lower in those transplanted in CR1 than with advanced disease (p< 0.01). In terms of donor type, MSD had the lowest TRM (5.7%), and haploidentical transplants the highest (16.4%) (p <0.01). Difference between MSD (5.7%) and MUD (9.3%) was borderline significant (p = 0.05). Use of bone marrow as graft source was associated with a significantly lower TRM (7%) compared to PBSC (11.9%) and umbilical cord (11.7%) (p = <0.01). TRM was comparable in recipients of myeloablative (10.7%) and reduced intensity conditioning (11%), but significantly lower in those who received non-myeloablative conditioning (4.1%) (p<0.05). TRM was significantly higher in second transplants (p<0.01).

For statistical comparison, Chi-square test or Fisher's exact test (if <5 events in any outcome) were applied using RStudio software. Matching symbols indicate subgroups with statistical significance within a group. +For conditioning regimens, the most prevalent drug combinations are shown in parenthesis. *Bu: Busulfan; CR: complete remission; Cy: cyclophosphamide; Flu: fludarabine; HSCT: hematopoietic stem cell transplant; MA: myeloablative; MFD: matched family donor; MSD: matched sibling donor; NMA: non-myeloablative; PBSC: peripheral blood stem cells; RIC: reduced intensity conditioning; RTC: reduced toxicity conditioning; SCD: sickle-cell disease; TBI: total body irradiation; Treo: treosulfan; TRM: transplant-related mortality*			

Conclusions: TRM in children undergoing HSCT has reduced over time but remains significant. Overall TRM in our cohort is comparable to published series but shows a higher proportion of infectious deaths. Our data identify key areas to focus resources on to improve outcomes. Infections, particularly viral infections are currently the leading cause of TRM,

highlighting the need for novel anti-virals and strategies to enhance immune reconstitution. Further work is needed to understand the pathogenesis of IPS and TA-TMA enabling prevention of these complications.

CLINICAL BENEFITS OF RUXOLITINIB IN MODERATE-TO-SEVERE CRS: REDUCED SEVERE ICANS AND STEROID USE WITH PRESERVED SURVIVAL AFTER PEDIATRIC CAR-T THERAPY

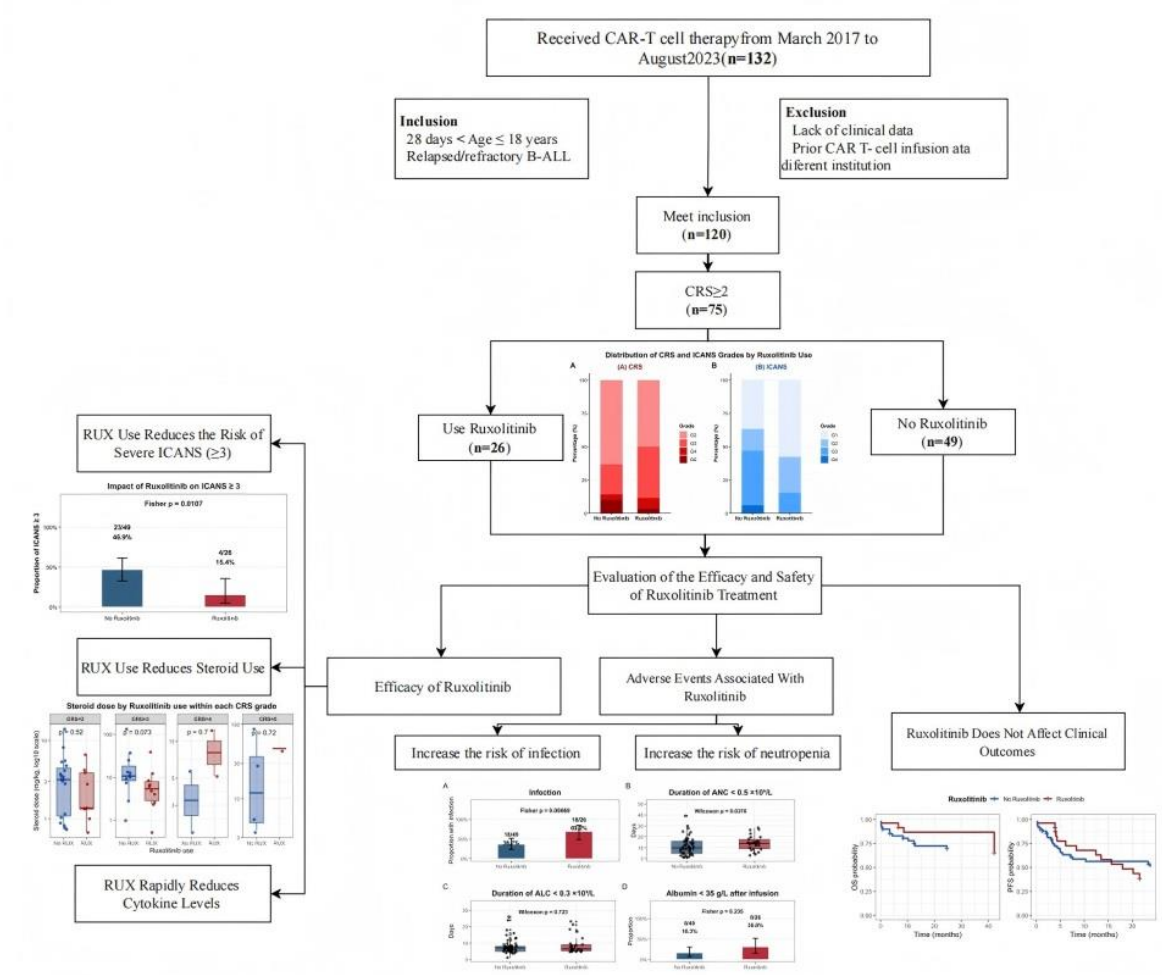
Qi Ji[1], Senlin Zhang[1], Qingwei Wang[1], Shuiyan Wu[1], Peifang Xiao[1], Yizhen Li[1], Jun Lu[1], ***Shaoyan Hu***[1]
[1]*Children's Hospital of Soochow University, Suzhou, China*

Background: Cytokine release syndrome (CRS) and immune effector cell–associated neurotoxicity syndrome (ICANS) remain major complications in children with relapsed or refractory B-cell acute lymphoblastic leukemia (B-ALL) undergoing CAR-T-cell therapy. Ruxolitinib (RUX), a JAK1/2 inhibitor, has recently been incorporated into CRS management protocols, yet its impact on neurotoxicity, steroid exposure, and clinical outcomes has not been clearly defined. This study evaluated the efficacy and safety of RUX in patients who developed CRS of grade 2 or higher following CAR-T infusion.

Methods: From a cohort of 132 pediatric CAR-T recipients, 75 patients who experienced CRS ≥ grade 2 were included. Clinical characteristics, ICANS grade, cumulative steroid exposure, neutropenia duration, infection, and long-term survival were compared between patients who received RUX and those who did not. Steroid dose was further analyzed within individual CRS severity strata to assess potential differences in RUX responsiveness.

Results: Ruxolitinib use was associated with a marked reduction in severe neurotoxicity. The incidence of ICANS ≥ grade 3 was 15.4% in the RUX group compared with 46.9% in the non-RUX group (Fisher p = 0.0107), demonstrating a significant protective effect. In analyses stratified by CRS grade, patients with CRS = 2 showed lower steroid doses in the RUX group, although the difference was not statistically significant (median 1.37 vs 3.18 mg/kg, p = 0.52). Patients with CRS = 3 exhibited a more pronounced reduction, with RUX users receiving substantially lower steroid amounts compared with controls (median 4.44 vs 10.66 mg/kg), and the difference approached statistical significance (p = 0.073). Steroid comparisons within CRS grades 4 and 5 were limited by very small sample sizes, permitting descriptive reporting only. Ruxolitinib use was associated with prolonged myelosuppression, with a significantly longer duration of neutropenia (median 14 vs 10 days, p = 0.0188) and a numerically increased infection rate. Importantly, RUX did not negatively impact long-term efficacy. One-, two-, and three-year overall survival rates were 86.5%, 86.5%, and 86.5% in the RUX group, compared with 77.7%, 72.3%, and 69.3% among non-RUX patients. Progression-free survival was likewise comparable between groups at all time points,

indicating no detrimental survival effect.



Conclusions: Among pediatric B-ALL patients who developed CRS ≥ grade 2 after CAR-T therapy, ruxolitinib significantly reduced the risk of severe ICANS and demonstrated a consistent steroid-sparing trend, particularly in CRS = 3 patients. Although RUX increased the duration of neutropenia and infection risk, these effects did not compromise overall or progression-free survival. These findings support ruxolitinib as a promising adjunctive strategy for CRS management with meaningful neuroprotective benefits and acceptable safety in the context of CAR-T–related toxicity.

Background: Epstein Barr virus associated post-transplant lymphoproliferative disease (EBV+PTLD) is a rare complication occurring after either stem cell (HSCT) or solid organ transplantation (SOT), with a very poor outcome if first line therapy fails, ranging from 1-4 months. Tabelecleucel is an allogeneic EBV-specific T-cell immunotherapy that targets EBV-positive cells selectively based on human leukocyte antigen (HLA) restriction. The phase 3 ALLELE study demonstrated an overall response rate (ORR) of 51%, with a complete remission (CR) rate of 28% and an overall survival (OS) of 84% at 12 months for responding patients, without significant toxicities. In Italy Tabelecleucel became available as monotherapy in adult and pediatric patients with R/R EBV-related PTLD, who have received at least one prior therapy, from February 2023 as compassionate use and from March 2025 as commercial use.

Methods: This retrospective observational analysis describes the preliminary Italian real-life experience with use of tabelecleucel. Adult patients diagnosed with R/R PTLD candidated and referred to treatment with tebelecleucel used both compassionately and commercially were included.

Results: From January 2024 to September 2025, 19 patients were enrolled across 8 Italian centers. The median age at the time of immunotherapy was 49 years (range 29–76), with a predominance of male patients (63.2%) and good performance status. Seven patients (36.8%) received prior HSCT and 12 (63.2%) received SOT: 6 heart, 2 lung, 2 kidney, 1 combined, and 1 liver transplant. Sixteen patients (84.2%) had monomorphic PTLD (mostly DLBCL). PTLD-adapted prognostic index was high in 10 patients (52.6%), 16 cases (84.2%)

had an extranodal localization, 2 (10.5%) with central nervous system involvement, 13 (68.4%) with IV stage disease. In 17 out of 19 cases the origin of the PTLD was documented (10 from patient, 7 from the donor). In 8 cases this attribution was made on the basis of high-resolution HLA typing. The median time from transplant to PTLD onset was 21 months (range 1-227) and 11 cases (58.0%) had early-onset. The median time from PTLD diagnosis to tabelecleucel treatment was 3 months (range 0.9–131). Sixteen patients (84.2%) received rituximab monotherapy as first line treatment. The median number of tabelecleucel cycles was 2 (range 0–6): 3 patients did not receive tabelecleucel (1 death, 2 unavailability of tabelecleucel lots). Two lot switchs were required. No significant toxicity was reported. The ORR was 37.5%, with 5 of 16 treated cases (31.3%) achieving CR. In the subcohort of SOT recipients, ORR was 60%, with 5 of 10 patients (50%) achieving CR; while, among HSCT recipients ORR was 0%. After a median follow-up of 11 months, 11 of 19 patients were alive.

Conclusions: The preliminary Italian experience supports the efficacy and safety of tabelecleucel, consistent with the results of the ALLELE trial in SOT. In our cohort no response to tabelecleucel was observed in PTLD after HSCT, remarkably 3 of these patients did not meet ALLELE inclusion criteria. It is essential to identify early potential candidates for this promising new therapy, which is now readily accessible in our country.

LISOCABTAGENE MARALEUCEL VERSUS AXICABTAGENE CILOLEUCEL IN R/R LARGE B-CELL LYMPHOMA: A META-ANALYSIS OF REAL-WORLD COMPARATIVE STUDIES

Fernando Gibran-Nunes[1], *Henrique Nunes Pêcego*[2], *Juliana Bosco Santos*[1], *Igor Mello*[3], *Meire da Silva*[4], *Marcos Fogale*[1], *Jacqueline Rena*[1], *Anita Cortez*[1], *Aliana Ferreira*[1], *Maria*

Seiwald[1], Ana Fonseca[1], Mariana Serpa[1], Erick Xavier[1], Luciana Tucunduva[1], Yana Novis[1], Michael Scordo[5], Xavier Deschênes-Simard[6]
[1]Hospital Sirio Libanês, São Paulo, Brazil, [2]D'Or Institute for Research and Education, Rio de Janeiro, Brazil, [3]University of Valença, Valença, Brazil, [4]Independent Researcher, São Paulo, Brazil, [5]Memorial Sloan Kettering Cancer Center, New York, United States of America (the), [6]Centre Hospitalier de l'Université de Montréal (CHUM), Montreal, Canada

Background: Axicabtagene ciloleucel (axi-cel) and lisocabtagene maraleucel (liso-cel) are standard-of-care CAR T-cell therapies for R/R LBCL. In the absence of head-to-head randomized controlled trials (RCTs), real-world evidence (RWE) studies have emerged.

Methods: We conducted a systematic review and meta-analysis to synthesize the available RWE (both fully published studies and recently presented abstracts) comparing the efficacy and safety of liso-cel versus axi-cel in patients with R/R LBCL.Following a pre-registered protocol (PROSPERO CRD420251218794), we searched PubMed, Embase, Cochrane, and major conference abstracts for comparative studies of liso-cel vs. axi-cel in R/R LBCL. Dichotomous safety and efficacy outcomes were pooled via random-effects meta-analysis. Time-to-event outcomes were extracted or calculated from reconstructed individual patient data (IPD) from published Kaplan-Meier curves.

Results: Five studies were included, totaling 2,205 patients. When comparing liso-cel to axi-cel,the meta-analysis of efficacy demonstrated no statistical difference in overall response rate (ORR) (OR 1.34, 95% CI: 0.63–2.83) or complete response rate (CRR) (OR 1.18, 95% CI: 0.96–1.45). Liso-cel was associated with lower odds of any-grade cytokine release syndrome (CRS) (OR 0.15, 95% CI: 0.09–0.26) and lower grade ≥3 CRS (OR 0.24, 95% CI: 0.08–0.69). Liso-cel was also associated with lower odds of any-grade immune effector cell-associated neurotoxicity syndrome (ICANS) (OR 0.30, 95% CI: 0.23–0.39) and, notably, significantly lower odds of grade ≥3 ICANS (OR 0.42, 95% CI: 0.19–0.93). Survival analyses, restricted to the 729 patients with extractable IPD from fully published studies, showed comparable outcomes: progression-free survival (PFS) (HR 1.07, 95% CI: 0.86-1.33), overall survival (OS) (HR 1.02, 95% CI: 0.78-1.33), and duration of response (DOR) (HR 1.03, 95% CI: 0.79-1.35).

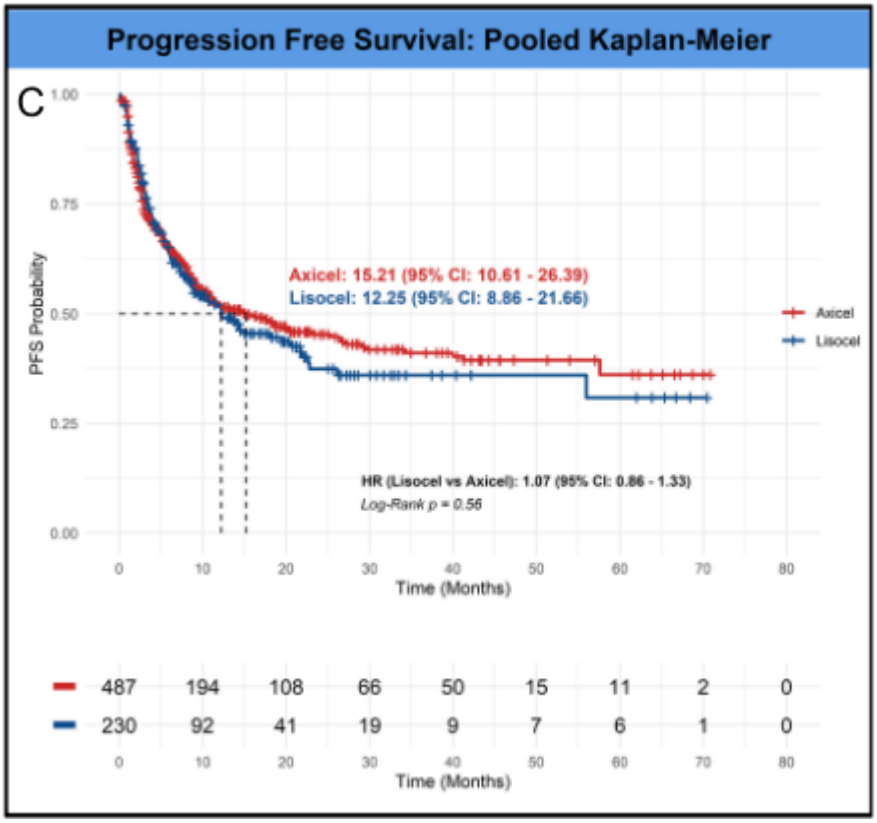
Progression Free Survival: Pooled Kaplan-Meier



Conclusions: This meta-analysis of RWE suggests that liso-cel and axi-cel offer comparable efficacy and survival outcomes in the treatment of R/R LBCL. Liso-cel was, however, associated with a substantially better toxicity profile, including significantly lower rates of CRS and ICANS.

PRELIMINARY SAFETY AND EFFICACY OF MYELOABLATIVE ORCA-Q IN PATIENTS WITH HAPLOIDENTICAL DONORS

Amandeep Salhotra[1], *Samer A. Srour*[2], *Mehrdad Abedi*[3], *Edmund K. Waller*[4], *Hannah Choe*[5], *Anna Pavlova*[6], *Tamara Zharkevich*[6], *Scott Killian*[6], *James Scott McClellan*[6], *Nathaniel B. Fernhoff*[6], *Robert Lowsky*[7]
[1]*Department of Hematology/HCT, City of Hope National Medical Center, Duarte, United States of America (the),* [2]*Division of Cancer Medicine, The University of Texas MD Anderson Cancer Center, Houston, United States of America (the),* [3]*Comprehensive Cancer Center, University of California, Davis, Sacramento, United States of America (the),* [4]*Bone Marrow and Stem Cell Transplant Center, Emory University Winship Cancer Institute, Atlanta, United States of America (the),* [5]*James Cancer Hospital, The Ohio State University, Columbus, United States of America (the),* [6]*Orca Bio, Menlo Park, United States of America (the),* [7]*Division of Blood and Marrow Transplantation & Cellular Therapy, Stanford University School of Medicine, Stanford, United States of America (the)*

Background: Haploidentical hematopoietic stem cell transplantation (haplo-HSCT) is an option for patients without matched donors. Despite advances, outcomes remain limited by immunological barriers, leading to higher risks of graft-versus-host disease (GVHD), delayed immune recovery, and variable relapse rates. Orca-Q is a precision-engineered, immune cell therapy designed to facilitate immune recovery and maintain GVL while reducing GVHD. with less immunosuppression. This study reports interim results from an ongoing study (NCT03802695).

Methods: Adult patients with high-risk hematologic malignancies who were eligible for myeloablative conditioning (MAC) alloHSCT with a haploidentical donor were enrolled in a dose expansion study using single agent tacrolimus for GVHD prevention. Inclusion criteria were broad, 44 patients in total were treated, and here, we report data for 39 patients age

<65 with AML, ALL, or MDS. Orca-Q was centrally manufactured at an Orca Bio GMP facility (Sacramento, CA) from GCSF-mobilized peripheral blood apheresis products. Patients were followed for GVHD and relapse for one year and for overall survival (OS) thereafter. GVHD-free, relapse-free survival (GRFS) was defined as the time from transplant to the first occurrence of grade 3-4 acute GVHD (aGVHD), moderate to severe chronic GVHD (cGVHD), relapse or death.

Results: Orca-Q was successfully manufactured and administered with a vein-to-vein time of less than 72 hours. 39 patients were treated, baseline characteristics were as follows: Median age 44 years (range 21-64), 77% male; median follow-up was 937 days (range 19-1825). All patients received MAC with one of the following regimens: Bu/Flu/Thio-based, TBI/Flu/Thio, TBI/Flu. Patients who received TBI/Flu/Thio were also analyzed separately. Orca-Q was well-tolerated and all patients engrafted neutrophils by day +19 (median 11 days). Two patients with busulfan-based conditioning experienced secondary graft failure. Clinical outcomes were as follows:

	All patients	Patients with TFT regimen
n=	39	14
Median f/u, days	937	1244
OS at 1, 2, 3 years	80%, 77%, 77%	85%, 85%, 85%
RFS at 1 year	77%	85%
GRFS at 1 year	72%	85%
NRM at 1 year	5.8%	7.7%
Relapse incidence at 1 year	18.2%	8.4%
aGHVD gr3-4 at D+180	8.1%	0%
Mod-to-severe cGVHD at 1 year	0%	0%
BMT CTN Grade 3+ infections at 1-year	5.3%	7.1%

Mean cumulative number of serious adverse events (SAEs) at 1 year was 0.43 for patients with TFT regimen compared to 1.08 for patients with other regimens.

Conclusions: The study demonstrated high engraftment rates, encouraging OS and RFS, and low incidences of severe aGVHD and cGVHD. Notably, outcomes appeared favorable in the TFT subgroup, with improved survival, GRFS, and lower relapse incidence compared to other regimens. These findings support the safety and efficacy of Orca-Q in reducing GVHD

and achieving durable remissions. The Phase 1 study continues to enroll patients to confirm these results.

Background: With expanding use of CAR-T-cell therapy, clinicians report adverse events beyond classical toxicities. Pseudoprogression, a phenomenon known from immune checkpoint inhibition, may occur rapidly with CAR-T-cell therapy. Further to mimicking early malignant progression, it can induce inflammatory swelling that may cause complications depending on the anatomical site. This entity—termed CAR-T-cell-therapy–induced pseudoprogression (CARTiPP)—has been described in small single-center reports and remains insufficiently understood. Characterizing its frequency, clinical presentation and prognostic significance is crucial to guide management. We collected multicentric EBMT data to define clinical features, diagnostic patterns, management strategies and outcomes of CARTiPP across European centers.

Methods: All adult patients (≥18 years) receiving first CAR-T-cell therapy reported to EBMT until June 2024 were eligible if they developed CARTiPP, defined as a transient increase in volume of malignant manifestations within 30 days of infusion followed by regression. Complicated CARTiPP (cCARTiPP) was defined by organ dysfunction, tissue damage or the need for any new therapeutic intervention initiated due to CARTiPP. Data was collected from 2024 until 2025 through two EBMT forms: An initial case-identification form, sent out to 221 EBMT centres and a second, detailed form capturing clinical characteristics, diagnostics, treatments, and outcomes.

Results: 41 patients with CARTiPP from 16 European centres were included. Median age was 57.4 years (53.7% male, 48.8% ECOG 1). Most underlying diseases were diffuse large B-cell lymphoma (DLBCL, 53.7%), mantle cell lymphoma (MCL, 9.8%), and primary mediastinal large B-cell lymphoma (PMBCL, 9.8%). Before lymphodepletion, most patients had relapse or progression, including primary refractory disease (58.5%). Median CARTiPP occurrence was five days (Q1–Q3, 4–7) after infusion. CARTiPP was detected by clinical observation (36.6%), imaging (34.1%), or both (29.3%). 56.1% developed cCARTiPP. In 81.1%, CARTiPP resembled prior disease presentations. Before CARTiPP, 82.9% received anti-inflammatory treatment for CAR-T toxicities, mainly tocilizumab alone (53.7%) or in combination (24.4%). CRS occurred in 37 (90.2%) cases, mostly (89.7%, n=35) before CARTiPP onset. Fifteen patients (36.6%) developed ICANS, mostly (n=11, 73.3%) after CARTiPP onset. CARTiPP-triggered interventions occurred in 34.1% of patients, mainly glucocorticoids (57.1%), suggesting some episodes resolved without escalation. The median follow-up of patients alive was 21.6 months (95% CI, 12–33.6). Relapse incidence at one year after CAR-T infusion was 36.3% (95% CI, 21.2–51.5). One-year overall survival (OS) was 68.6% (95% CI, 51.0–81.0) two-year OS 57.5% (95% CI, 38.9–72.4) (Figure 1). One-year progression-free survival (PFS) was 57.3% (95% CI, 40.5–71.1). One-year non-relapse mortality (NRM) was 7.3% (95% CI, 1.9–18.0).

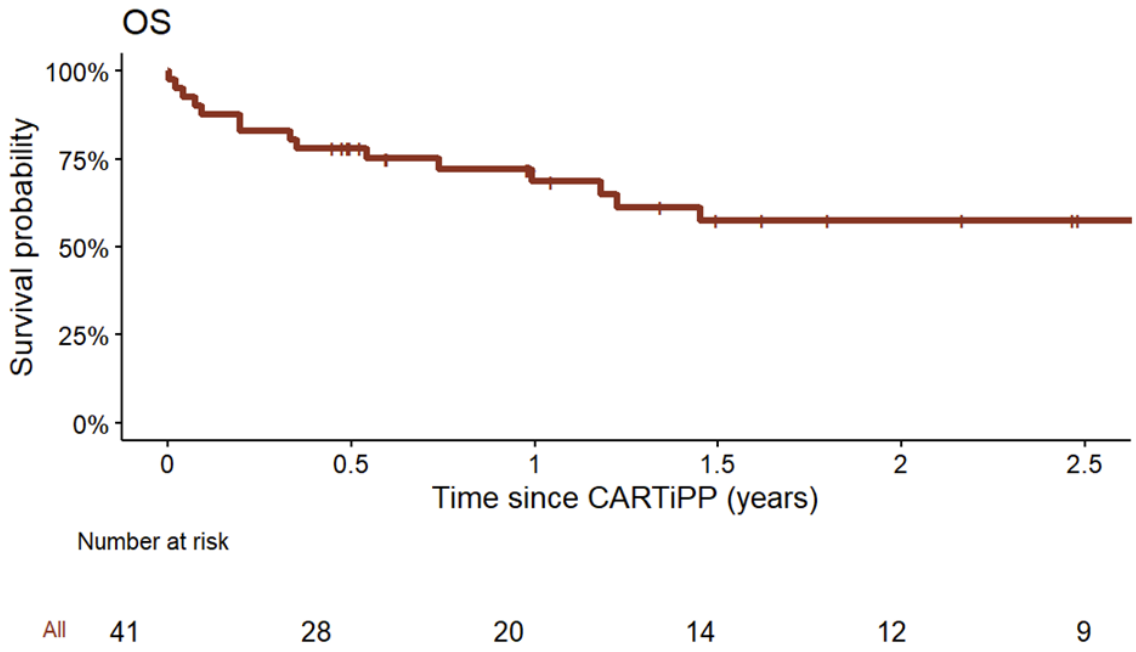

Figure 1: OS after CARTiPP.

Conclusions: This is to our knowledge the first multicenter report of CARTiPP as an early inflammatory flare occurring within days after infusion mimicking disease progression. CARTiPP-patients showed PFS, OS and NRM comparable to published real-world CAR-T cohorts, suggesting CARTiPP may not impact prognosis. Some cases resolved spontaneously, although complicated presentations required timely intervention. CARTiPP may be an often self-limiting phenomenon, needing more standardized diagnostic criteria, imaging confirmation whenever feasible, and structured management recommendations across centres. For lesions near critical anatomical structures, mindful anticipation of transient inflammatory enlargement may help mitigate risks.

Disclosure: Nothing to declare.

CLINICAL BIOMARKERS FOR EARLY RECOGNITION OF SUBOPTIMAL ECULIZUMAB RESPONSE IN TRANSPLANT-ASSOCIATED THROMBOTIC MICROANGIOPATHY

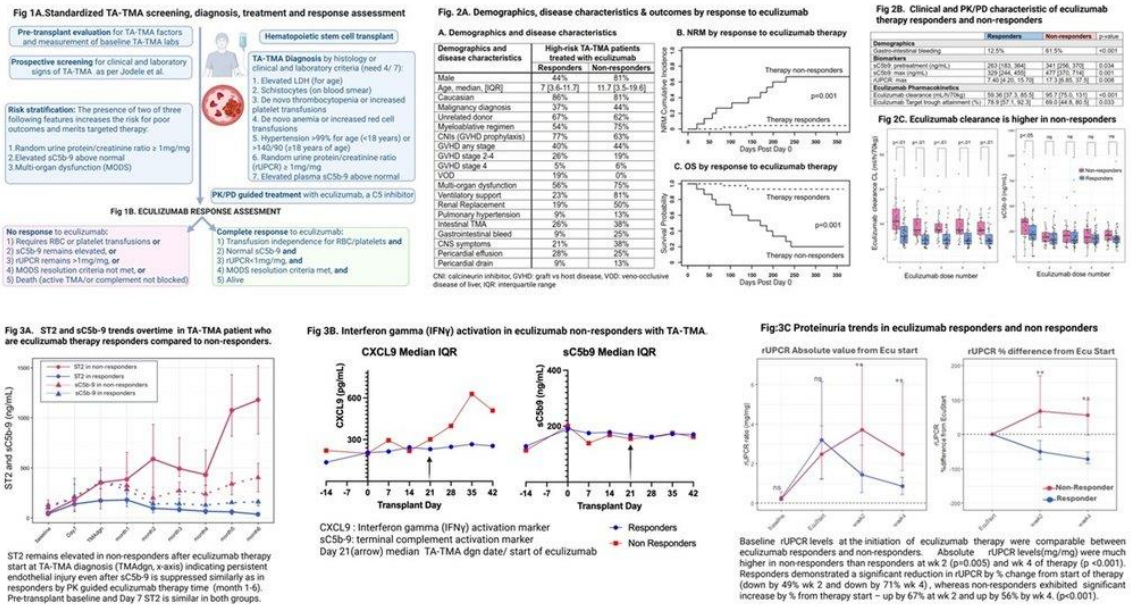
Sonata Jodele[1], Kana Mizuno[1], Anthony Sabulski[1], Christopher Dandoy[1], ***Kristie Ramos***[1]*, Aaron Webster[1], Stella Davies[1]*
[1]Cincinnati Children's Hospital Medical Center, Cincinnati, United States of America (the)

Background: Transplant-associated thrombotic microangiopathy (TA-TMA) is a life-threatening complication of hematopoietic stem cell transplantation (HSCT), driven by endothelial injury and complement activation. Eculizumab, a terminal complement C5 inhibitor, improves survival in high-risk TA-TMA, yet one-third of patients fail to respond. Our study objective was to determine mechanisms of eculizumab non-response and early predictors of outcome in TA-TMA that are critical for improving therapy.

Methods: We prospectively studied 90 children and young adults with high-risk TA-TMA, comparing eculizumab responders (n=60) and non-responders (n=30). All HSCT recipients were prospectively screened for TA-TMA. TA-TMA risk group and response to eculizumab was determined based on published criteria (Fig1). All patients with high-risk TA-TMA received PK/PD-guided eculizumab dosing. We performed novel PK/PD modeling to determine complete complement blockade ("equilibrium"). Complement blockade, PK/PD dynamics, biomarker trajectories for sC5b-9, CXCL9, ST2, proteinuria by random urine protein/creatine ratio (rUPCR), and outcomes were compared in responders and non-responders.

Results: Non-responders displayed greater systemic organ injury and worse survival despite optimized eculizumab dosing and PK/PD monitoring (Fig 2A). PK/PD modeling confirmed that complement blockade can be achieved with intensified dosing, but steady blockade state (equilibrium) requires approximately six weeks of therapy, underscoring that short-term biomarker normalization is not sufficient to declare response (Fig 2B). Importantly, non-responders exhibited persistently elevated rUPCR and rising ST2 despite suppression of sC5b-9, indicating ongoing complement-independent endothelial injury. Longitudinal biomarker profiling showed that non-responders had progressive CXCL9 elevation despite sC5b-9 control, and that adding IFNγ blockade with emapalumab improved eculizumab PK/PD, accelerated complement suppression, and enhanced survival, underscoring the pathogenic role of the complement-interferon loop (Fig3). We showed that elevated sC5b-9 is associated with TA-TMA risk, higher therapy needs and poor outcomes, whereas comprehensive profiling of other complement components did not differentiate responders, and normal C3/C4 values did not exclude TA-TMA highlighting the need for functional biomarkers.

Figures: Determinants of Eculizumab Response in High-Risk Transplant-Associated Thrombotic Microangiopathy



Conclusions: These findings reveal that eculizumab non-response reflects complement independent persistent endothelial injury. Early monitoring of ST2, CXCL9, rUPCR, may identify patients at risk for suboptimal eculizumab response and guide precision therapies that can be integrated with complement blockade. Such strategies will be essential to improve survival and prevent irreversible vascular injury in high-risk TA-TMA.

Clinical Trial Registry: Not applicable.

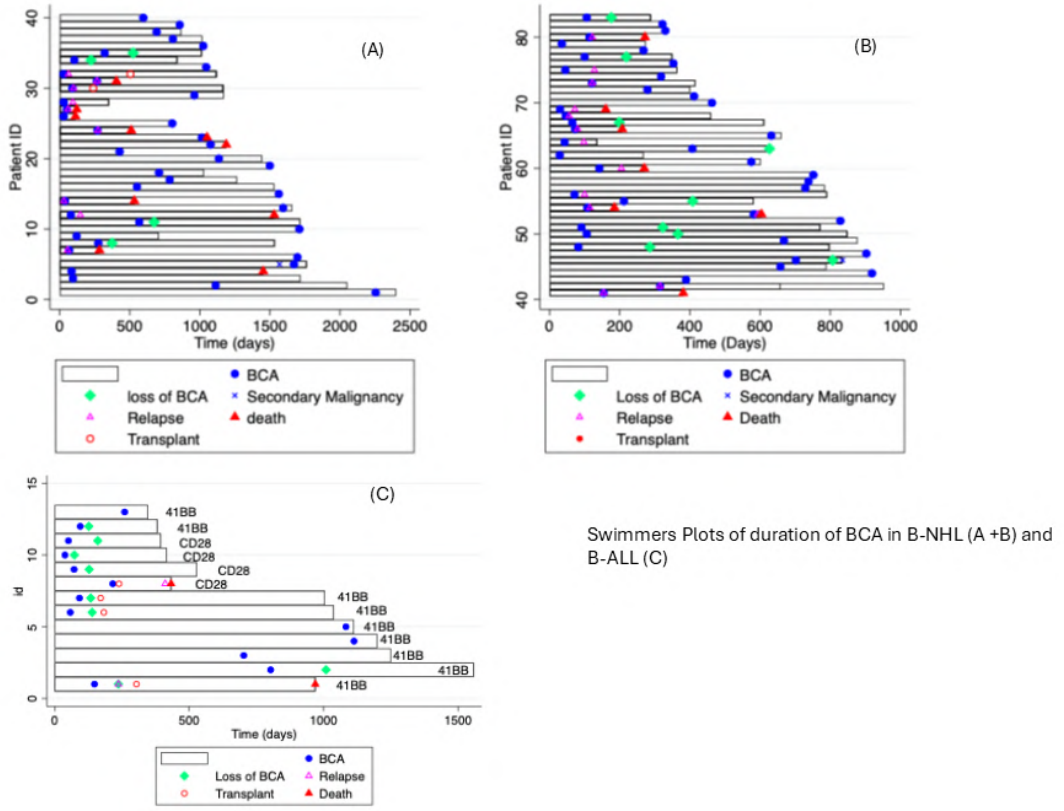
Background: B cell aplasia(BCA) is often used as a surrogate marker for CAR-T persistence. BCA in the setting of CD28 containing CAR-T cell and it's impact on remission duration is less well defined than 41BB.

Methods: This retrospective study analysed outcomes of 115 consecutive CAR-T patients. Probability of Overall Survival(OS), Progression Free Survival(PFS) were calculated by Kaplan Meier. Cumulative Incidence(CI) of relapse risk, non relapse mortality (NRM) and B cell recovery was calculated using competing risk analysis.

Results:



Swimmers Plots of duration of BCA in B-NHL (A +B) and B-ALL (C)

102 patients with B-Non-Hodgkins Lymphoma(B-NHL) and 13 patients with B-Acute Lymphoblastic Leukaemia(B-ALL) were reviewed. Patient characteristics are in Table 1. BCA was assessed at regular time points pre and post CAR-T infusion. Patients who had no immunophenotyping performed or progressed/died before day 100 were not included in BCA and CD4 analysis. BCA was not assessed beyond time of relapse. For B-NHL, 54/83(65%) had BCA pre infusion. All patients were in BCA at least once post CAR-T up until a median of 1.59 years(IQR 0.27-2.11). Of these, 81/83(96%) had received CD28 containing CAR-T cell therapy. 13/83(15.7%) subsequently had loss of BCA at a median of 1 year post infusion(IQR 0.61-1.44). 42/83(50.6%) patients remained in CR with ongoing BCA at time of analysis with a median duration of BCA of 2.21 years(IQR 1.2-2.76). Median OS was 2.12 years (range 0.31-6.68) with estimated 2 year OS and PFS of 79% (95% CI 67-87) and 69%

(57-77). 2 year CI of relapse was 27%(18-37) in those in ongoing BCA vs 0% for those with loss of BCA, p=0.09). 2 year NRM was low in this cohort (ongoing BCA 2% (1-10) vs Loss of BCA 0%.)In the B-ALL cohort where 9/13(69%), 6/13(46.1%) had pre-existing BCA pre infusion. 13/13(100%) had detectable BCA post CAR-T up until a median of 0.41 years(IQR 0.2-0.96) post infusion. 8/13(61.5%) subsequently lost BCA at a median of 0.37 years post CAR-T(IQR 0.35-0.49). 4/13(30.8%) patients were in remission and in ongoing BCA at time of last follow up. Median OS was 2.65 years(range 0.95-4.27) with estimated 2 year OS and PFS of 89% (43-98) and 81% (41-95).
CI of B cell recovery at 6 months was 3%(1-10) for B-NHL patients versus 46%(19-69) for B-ALL patients(p=0.003). CI of CD4 recovery at 1 year was 43%(30-54) in B-NHL compared to 64%(37-87) in B-ALL(p=0.22).

PR	5(4.9)	
PD/relapse	17(16.7)	
SD	0(0)	
Not available	11(10.8)	

Conclusions: Prolonged BCA was demonstrated in B-NHL patients in long term remission treated with CD28 containing CAR-T and no excess risk of relapse was seen in those who lost BCA. B cell recovery was seen more frequently in B-ALL patients and this happened at earlier time points. Despite early B cell recovery, durable remissions were seen in the B-ALL cohort. The finding of faster B cell recovery in B-ALL may reflect younger age, higher proportion of prior Allo-SCT and fewer lines of therapy pre CAR-T. A high proportion of patients have BCA pre CAR-T and this calls into question it's utility as a marker for CAR-T persistence in isolation and should be used with immunophenotype-based and ddPCR CAR-T persistence assays.

Clinical Trial Registry: None.

LONG-TERM CLINICAL OUTCOMES IN PATIENTS WITH RELAPSED OR REFRACTORY B-CELL NON-HODGKIN LYMPHOMA TREATED WITH PRIZLONCABTAGENE AUTOLEUCEL

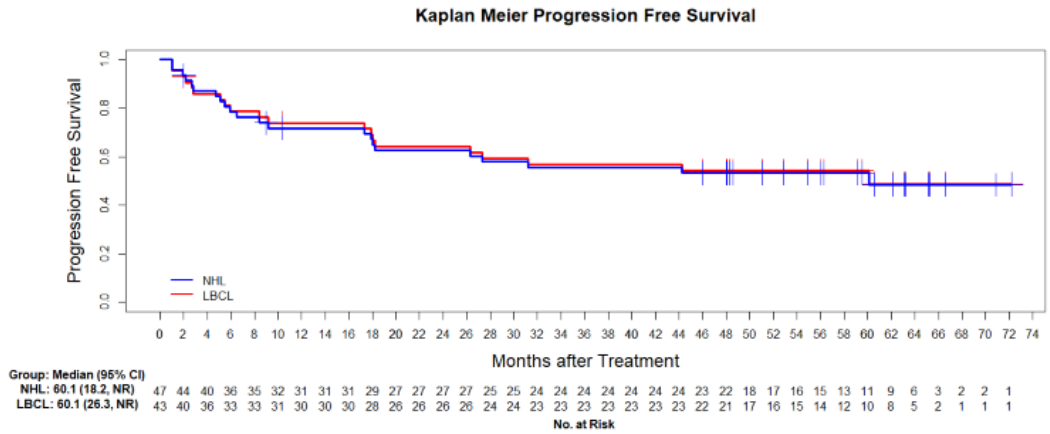
Aibin Liang[1], *Wenjuan Yu*[2], *Ping Li*[1], *Lili Zhou*[1], *Min Yang*[2], *Shiguang Ye*[1], *Judy Zhu*[3], *Jiaqi Huang*[4], *Xin Yao*[4], *Yan Zhang*[5], *Lanfang Li*[6], *Jing Zhao*[6], *Kevin Zhu*[7], *Jing Li*[3], *Chengxiao Zheng*[3], *Liping Lan*[3], *Yihong Yao*[4], *Huilai Zhang*[6], *Daobin Zhou*[5], *Jie Jin*[2]
[1]*School of Medicine, Tongji Hospital of Tongji University, Shanghai, China,* [2]*The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China,* [3]*Shanghai AbelZeta Ltd., Shanghai, China,* [4]*AbelZeta Inc., Rockville, United States of America (the),* [5]*Peking Union Medical College Hospital, Beijing, China,* [6]*Tianjin Medical University Cancer Insitute & Hospital, Tianjin, China,* [7]*University of Vermont Medical Center, Vermont, United States of America (the)*

Background: Recent studies have highlighted the curative potential of chimeric antigen receptor T-cell (CAR-T) therapy for large B-cell lymphoma (LBCL). Prizloncabtagene autoleucel, previously known as C-CAR039, is an autologous anti-CD20/CD19 dual-antigen targeting CAR-T therapy for the treatment of patients with relapsed or refractory (r/r) B-cell non-Hodgkin lymphoma (B-NHL). We previously reported the outcomes of 48 patients with r/r B-NHL treated with C-CAR039 at the 2025 EHA Congress (Yu et al. Abstract PS2159). At a median follow-up (mFU) of 45.5 months, the overall response rate (ORR) was 91.5%, with a

complete response (CR) rate of 85.1%. Median progression-free survival (PFS) and overall survival (OS) were not reached, and the estimated 4-year PFS and OS rates were 52.5% and 65.4%, respectively. Here, we report the long-term results with a mFU of 53.9 months.

Methods: Eligible patients had r/r diffuse large B-cell lymphoma (DLBCL), primary mediastinal large B-cell lymphoma (PMBCL), follicular lymphoma (FL), and mantle cell lymphoma (MCL) after ≥2 lines of therapy including an anti-CD20 monoclonal antibody plus an alkylating agent. Patients underwent leukapheresis, followed by lymphodepletion chemotherapy and infusion of C-CAR039 (1.0-5.0×10^6 CAR-T cells/kg). Primary endpoints include safety and tolerability. Secondary endpoints include efficacy and pharmacokinetics.

Results: As of Nov 26, 2025, mFU was 53.9 months (range: 3.1-72.2). Of the 48 infused patients, 44 were LBCL (DLBCL, n = 37; transformed FL, n = 4; PMBCL, n = 3), 3 were FL, and 1 was MCL. One DLBCL patient who had no measurable disease at baseline was excluded from the efficacy analysis. 45 out of 48 (93.8%) patients experienced cytokine release syndrome, with only one being grade 3. Three patients experienced immune effector cell-associated neurotoxicity syndrome, with two cases of grade 1 and one case of grade 2, all at the dose of 5.0×10^6 CAR-T cells/kg.
The clinical response for all patients was matured and consistent with the last report, with 91.5% ORR (95% CI, 79.6-97.6) and 85.1% CR (95% CI, 71.7-93.8). Median PFS was 60.1 months (95% CI, 18.2-NR), median OS was not reached. The estimated 4-year PFS and OS rates were 53.3% (95%CI, 40.4-70.2) and 65.9% (95%CI, 53.6-81.0), respectively.
Among 43 efficacy-evaluable LBCL patients, the ORR was 90.7%, with 86.0% CR. Median PFS was 60.1 months (95% CI, 26.3-NR), median OS was not reached. The estimated 4-year PFS and OS rates were 54.2% (95%CI, 41.0-71.8) and 67.4% (95%CI, 54.7-83.0), respectively. 20/43 (46.5%) remained CR and 28 patients (65.1%) remained alive at this data cutoff date. Notably, no disease progression occurred in any patients beyond 3 years.



Conclusions: With more than 4 years of follow-up, median PFS reached 60.1 months and median OS was not reached. Among LBCL patients, 20 patients (46.5%) maintained response without treatment and 28 patients (65.1%) remained alive. Together, these data

demonstrated excellent durable efficacy and manageable safety profiles. Pivotal studies are ongoing in the US and China, respectively.

OUTCOME OF AGGRESSIVE B-CELL LYMPHOMA ADMINISTERED WITH CAR T-CELL ALONE OR IN COMBINATION WITH ASCT: A PROPENSITY SCORE MATCHING COHORT STUDY

Yang Fan[1], Rui Liu[1], Zhonghua Fu[1], Yuelu Guo[1], Lixia Ma[1], Miaomiao Cao[1], Biping Deng[2], Shilin Gan[3], Xiaoyan Ke[1], Kai Hu[1], ***Yan Gao***[1]
[1]*Beijing Gobroad Hospital, Beijing, China,* [2]*Beijing Gobroad Boren Hospital, Beijing, China,* [3]*GoBroad Research Center, Beijing, China*

Background: Anti-CD19 chimeric antigen receptor T-cell therapy approved for relapsed or refractory large B-cell lymphoma (RR-LBCL) after at least two treatment lines.Autologous hematopoietic stem cell transplantation (ASCT) combined with CAR-T cell therapy is effective against multiple subtypes of RR-LBCL.

Methods: This single-center, propensity score matching (PSM) cohort study analyzed 64 R/R NHL patients. 32 patients received ASCT combined with CAR-T cell therapy, matched 1:1 with 32 patients receiving CAR-T alone based on 10 baseline characteristics (Table 1). The two groups were well balanced across all baseline characteristics after PSM, and were appropriate for further comparative analysis of outcomes.Patients who had previously received CAR-T therapy or ASCT were excluded.The conditioning regimen for the ASCT+CAR-T group was standard BEAM (bis-carmustine, etoposide, cytarabine, and melphalan) , while CAR-T cells were transfused within two days after transfusion of CD34+ HSCs in ASCT+CAR-T.

Results: The dose of CD34+ hematopoietic stem cells (HSCs) ranged from 2.4 to $9.5*10^6$/kg in ASCT+CAR-T group .The median numbers of CAR-T cell reinfusions were 2.2×10^6/kg (range: 0.3-4.5) and 2.8×10^6/kg (range: 0.4-3.5) in the CAR-T group and ASCT+CAR-T group, respectively.
Stem cell engraftment in the ASCT+CAR-T group was unaffected.CAR T-cell expansion did not appear to differ in terms of therapeutic efficacy.
In the ASCT+CAR-T and the CART group, the incidences of grade ≥3 CRS was 12% vs. 6.8%, respectively, while the incidences of grade ≥3 ICANS was 0 vs. 1.4%, respectively.
A response at 3 month occurred in 68.8% of the patients in the ASCT+CAR-T group and in

55.2% of those in the CAR-T group(P=0.302) (with a complete response in 62.5% and 41.4%, respectively)(P=0.127).
The median follow-up period was 38.4 months (95% CI: 0.36,71.67).The 3-year PFS and OS rates for the overall population were 51.58%(95% CI: 37.74,63.77) and 63.73%(95% CI: 49.53,74.91)respectively. Patients who received ASCT+CAR-T had an improving trend in PFS [3-year PFS 60.66%(95% CI: 40.87,75.64) vs. 44.20%(95% CI: 26.11,60.87); P=0.082] ,and OS [3-year OS 74.22%(95% CI: 54.82,86.25) vs. 52.22%(95% CI: 31.23,69.58); P=0.082] compared to patients in the CAR-T group. (Fig.1A,B).
The 3-year incidence of relapse/progression for ASCT+CAR-T was 32.17%(95% CI: 16.45,49.03) compared to 43.15%(95% CI: 24.75,60.30)in the CAR-T group (P=0.316)).
The non-relapse mortality (NRM) rate was 7.17% (95% CI: 1.16,21.07) with ASCT+CAR-T compared to 12.65% (95% CI: 3.87,26.85) in the CAR-T group (P=0.250).(Fig.1C,D)

Table 1 Baseline characteristics-PSM

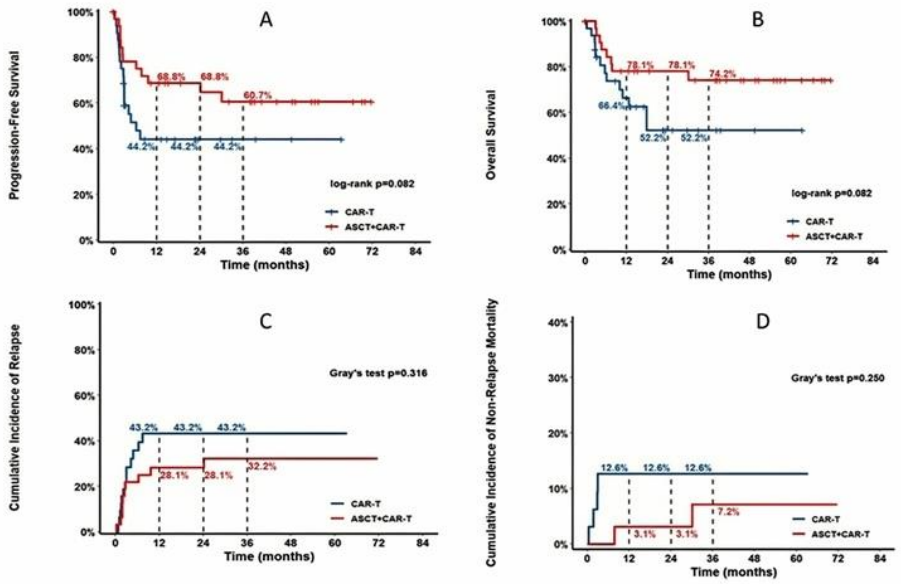

Figure 1 Kaplan–Meier curves comparing progression-free survival (A), overall survival (B), cumulative incidence of relapse (C), and non-relapse mortality (D) between patients with relapsed/refractory large B-cell lymphoma (RR-LBCL) treated with CD19 CAR-T therapy versus ASCT combined with CAR-T (ASCT+CAR-T).

Conclusions: Compared to CAR-T therapy alone, the combination of ASCT and CAR-T therapy showed a trend of improved survival outcomes in patients with relapsed/refractory (R/R) B-cell lymphoma. However, a larger study is required to confirm these findings.

INFLUENCE OF THE HLA MISMATCHED LOCUS ON OUTCOMES IN MISMATCHED UNRELATED DONOR HEMATOPOIETIC CELL TRANSPLANTATION USING POST-TRANSPLANT CYCLOPHOSPHAMIDE GVHD PROPHYLAXIS: A CIBMTR RETROSPECTIVE ANALYSIS

Stephen R. Spellman[1], *Varuna Astha*[1], *Kwang Woo Ahn*[2], *Caitrin Bupp*[1], *Antonio Jimenez Jimenez*[3], *Shannon McCurdy*[4], *Brian Shaffer*[5], *Bronwen E. Shaw*[2], *Heather E. Stefanski*[1], *Jeffery J. Auletta*[1], *Steven M. Devine*[1]
[1]*CIBMTR® (Center for International Blood and Marrow Transplant Research), NMDP, Minneapolis, United States of America (the),* [2]*CIBMTR® (Center for International Blood and Marrow Transplant Research), Medical College of Wisconsin, Milwaukee, United States of America (the),* [3]*University of Miami Miller School of Medicine, Miami, United States of America (the),* [4]*Hospital of the University of Pennsylvania, Philadelphia, United States of America (the),* [5]*Memorial Sloan Kettering Cancer Center, New York, United States of America (the)*

Background: The adoption of post-transplant cyclophosphamide (PTCy) has expanded the use of mismatched unrelated donors (MMUD) in allogeneic HCT. A prior CIBMTR study noted equivalent outcomes between 8/8 matched unrelated donors (MUD) and 7/8 MMUD when PTCy is used. Class I and II MMUD recipients had similar outcomes, whereas a report from the EBMT (Arrieta-Bolaños et al., JCO 2024) reported worse outcomes with class I mismatched donors are associated with an increased risk of mortality even in the PTCy setting. We therefore examined whether the mismatched HLA locus affects outcomes after 7/8 MMUD HCT with PTCy in a large, contemporary U.S. cohort.

Methods: We conducted a retrospective CIBMTR registry analysis of adults (≥18 years) undergoing first allogeneic HCT in the US from 2017-2023 using a 7/8 MMUD and PTCy-based GVHD prophylaxis. The primary objective was to compare overall and GVHD-free, relapse-free survival (GRFS) at 2 years post HCT between MMUD based mismatched HLA locus. Secondary objectives included evaluating relapse, disease-free survival (DFS), non-relapse mortality (NRM), acute GVHD (aGVHD) grades 2-4 and 3-4, moderate/severe chronic GVHD (cGVHD) and primary graft failure (PGF) by mismatched locus. Eligible diagnoses included acute myeloid leukemia (AML), acute lymphoblastic leukemia (ALL) and myelodysplastic syndromes (MDS).

Results: Included were 1,255 patients from 114 centers with AML (n=692), ALL (n=235) and MDS (n=328). Median (range) recipient and donor age was 59.4 (18.7-78.4) and 27.7 years (18.4-61.2), respectively. Fifty two percent of recipients were female, 32% were ethnically diverse and most received peripheral blood grafts (93.2%). The distribution of single-locus mismatches was HLA-A (n=591), HLA-B (n=279), HLA-C (n=128) and HLA-DRB1(n=257). HLA-DQB1 and -DPB1 T cell epitope (TCE) data were available for 99.2% and 96.8% of recipients, respectively. DQB1 mismatches were more common among DRB1 mismatched pairs (49%) versus HLA-A (6%), -B (8%) and -C (7%) MMUD. HLA-DPB1 TCE

matching was similar across groups (20-27% non-permissive). Neither DQB1 mismatching nor DPB1 TCE status was associated with any clinical outcomes in multivariable models. Using the largest group (HLA-A) as the reference mismatched locus, no significant differences were observed in OS, GRFS, relapse, DFS, NRM, aGVHD 2-4 or 3-4 and moderate-severe cGVHD across mismatched loci (table and figure). Primary graft failure (PGF) was higher among DRB1 mismatched pairs (HR 1.94, 95% CI 1.10-3.40, p=0.0211). Whether donor specific antibodies (DSA) were present is not available, limiting interpretation of PGF findings.

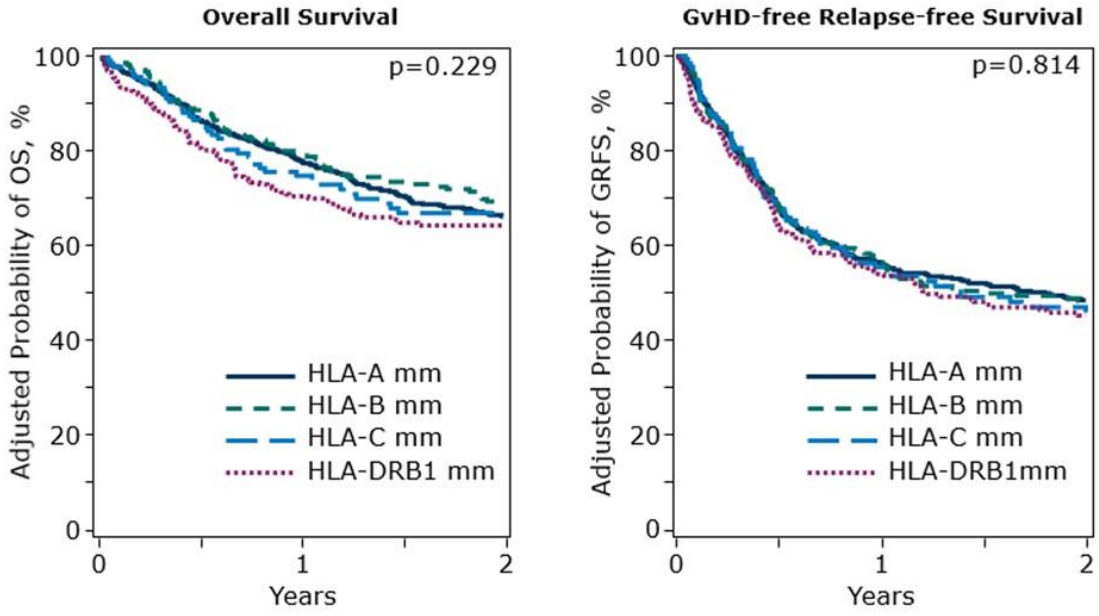
Primary Graft Failure	1	0.014	0.56(0.25-1.23)	0.148	1.33(0.61-2.90)	0.468	1.94(1.10-3.40)

Figure: 2-year Probability of overall survival and GVHD-free, relapse-free survival by HLA-mismatched locus in 7/8 MMUD HCT using PTCy-based GVHD prophylaxis



Conclusions: In this large contemporary cohort of 7/8 MMUD HCT with PTCy, we did not observe significant differences in OS, GRFS, relapse, DFS, NRM, aGVHD and cGVHD according to the mismatched HLA locus. PGF risk was higher with HLA-DRB1 mismatched pairs, although this finding is difficult to interpret in the absence of DSA data and should be considered exploratory. DSA to class II molecules have been historically associated with less effective desensitization than DSA to class I. These results support MMUD donor selection strategies that prioritize non-HLA donor characteristics, such as younger donor age rather than the specific HLA mismatched locus. Studies in larger cohorts will be required to confirm these results.

DONOR SELECTION AND CLINICAL OUTCOMES OF ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION IN ADULTS OLDER THAN 50 YEARS - A SINGLE CENTRE RETROSPECTIVE REVIEW

*Garret Leung[1], Joycelyn Sim[1], **Thomas Chan**[1], Albert Lie[1], Yok-Lam Kwong[1], Harinder Gill[1]*
[1]The University of Hong Kong, Hong Kong, China

Background: Optimal donor selection for older patients undergoing allogeneic haematopoietic stem cell transplantation (allo-HSCT) remains controversial. While matched sibling donors (MSD) have traditionally been considered standard, the benefits of younger alternative donors and the impact of post-transplantation cyclophosphamide (PTCy) prophylaxis remain unclear in this population. To address these issues, we compared the clinical outcomes of four donor types in allo-HSCT patients >50 years old.

Methods: We conducted a retrospective analysis of 493 consecutive patients >50 years old with malignant haematological diseases undergoing MSD, matched unrelated donor (MUD), mismatched unrelated donor (MMUD), or haploidentical allo-HSCT between January 2014 and December 2023. Patients received either PTCy-based (40mg/kg/day on days +3 to +4 with cyclosporine A and mycophenolate mofetil) or conventional calcineurin inhibitor-based graft-*versus*-host-disease (GVHD) prophylaxis. Outcomes analyzed included engraftment, GVHD, non-relapse mortality (NRM), relapse-free survival (RFS), overall survival (OS), and GVHD-free, relapse-free survival (GRFS). Univariate and multivariate analyses with Cox proportional hazards regression and Fine-Gray models were used to identify significant prognostic factors.

Results: Four hundred and ninety-three patients (median age: 57 years; male: 51%) undergoing allo-HSCT (MSD, N=198; MUD, N=101; MMUD, N=58; haploidentical, N=136) were analyzed (Table 1). Haploidentical recipients and MSD donors were significantly older, whereas MMUD and haploidentical recipients had higher disease risk indices. All haploidentical recipients received PTCy prophylaxis and 99% received peripheral blood HSC grafts. Engraftment rates were comparable (94–99% at day 28). The 180-day incidence of grade II-IV acute GVHD was significantly higher in MMUD (42%) compared with MSD (22%), MUD (31%), and haploidentical (16%) groups (P<0.001) (Figure 1A). In multivariate analysis, MMUD and non-PTCy prophylaxis were associated with increased risk of acute GVHD. At 2 years, the incidence of moderate to severe chronic GVHD was highest in MUD (49%) and MSD (43%) *versus* MMUD (25%) and haploidentical (17%) allo-HSCT (P<0.001) (Figure 1B). Risk factors for chronic GVHD included donor age >50 years, female-to-male donation, peripheral blood HSC grafts, and conventional GVHD prophylaxis. NRM was comparable (9–13% at 2 years). Importantly, haploidentical showed superior RFS (72% at 2 years; hazard ratio: 0.62; P=0.016) compared with MSD allo-HSCT. Haploidentical also demonstrated significantly superior GRFS (58% at 2 years) compared with other allo-HSCT (23–30%) (P<0.001) (Figure 1C). However, this advantage was primarily attributable to PTCy prophylaxis in multivariate analysis. OS was similar (62–74% at 2 years). In the high disease risk subgroup, haploidentical showed improved RFS compared with MSD allo-HSCT (62% *versus* 36%; P=0.051) (Figure 1D). Male sex and high disease risk index

independently predicted worse survival outcomes.

Haplo	0	10	12	12	12	12

Conclusions: In patients > 50 years old, MUD allo-HSCT with younger donors and conventional GVHD prophylaxis achieved outcomes comparable with those of older MSD allo-HSCT. Notably, haploidentical allo-HSCT with PTCy demonstrated superior RFS and GRFS compared with MSD allo-HSCT with conventional GVHD prophylaxis, suggesting that alternative donor approaches with optimized GVHD prophylaxis might be advantageous in this older population. Disease risk index remained an important independent predictor of outcomes in all donor types.

BCMA CAR T-CELL THERAPY DEMONSTRATES EARLY SAFETY AND EFFICACY SIGNALS IN REFRACTORY SYSTEMIC SCLEROSIS AND ANTIPHOSPHOLIPID SYNDROME: PHASE I RESULTS IN AUTOIMMUNE DISEASES

Shlomo Elias[1], *Shlomit Kfir-Erenfeld*[1], *Hadass Pri Chen*[1], *Nathalie Asherie*[1], *Emilie Bohbot*[1], *Rim Elmikawy*[1], *Alaa Shaheen*[1], *Ahmad Bazbaz*[1], *Isam Hendy*[1], *Yaakov Naparstek*[1], *Sigal Grisariu*[1], *Batia Avni*[1], *Eran Zimran*[1], *Eyal Lebel*[1], *Miri Assayag*[1], *Nomi Zalcman*[1], *Alaa Shehadeh*[1], *Aseel Ishtay*[1], *Shelly Regev*[1], *Miriam Schlossberg*[1], *Elina Zorde-Khevalevsky*[1], *Elena Karger*[1], *Marina Krizhevskaya*[1], *Hagit Peleg*[1], *Dror Mevorach*[1], *Chamutal Gur*[1], *Polina Stepensky*[1]
[1]*Hebrew University - Hadassah Medical Center, Jerusalem, Israel*

Background: Chimeric antigen receptor (CAR) T-cell therapy offers a targeted strategy to eliminate autoreactive B cells in severe autoimmune diseases. B-cell maturation antigen (BCMA), expressed on plasmablasts and plasma cells, represents a promising therapeutic target. We report updated safety and preliminary efficacy data from an ongoing Phase 1 trial of BCMA-directed CAR T cells (HBI0101) in patients with refractory autoimmune rheumatic diseases (ARDs) (NCT07085676).

Methods: HBI0101 is an autologous BCMA-targeted CAR T-cell product generated by retroviral transduction of patient-derived T cells. The construct, developed at Hadassah Medical Center, has previously been administered to 145 patients with relapsed/refractory multiple myeloma and 20 patients with amyloidosis. In the initial safety phase (October 2024–November 2025), eight patients with refractory systemic lupus erythematosus (SLE), systemic sclerosis (SSc), idiopathic inflammatory myopathy (IIM), and antiphospholipid syndrome (APS) coexisting with SLE received lymphodepleting chemotherapy followed by infusion of 450×10^6 CAR-positive (CAR^+) T cells (n=6) or 800×10^6 CAR^+ T cells (n=2). Adverse events (AEs) and clinical responses were prospectively monitored.

Results:

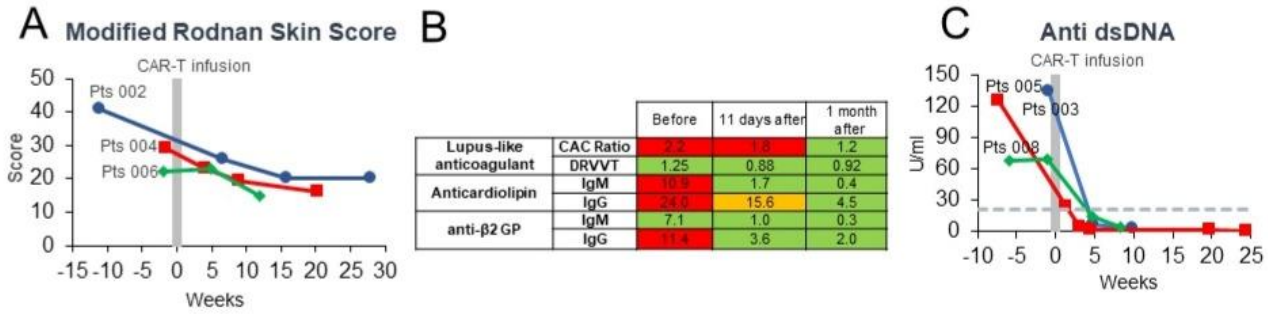

Figure 1. Representative laboratory and clinical responses following BCMA-directed CAR T-cell therapy. (A) Changes in Modified Rodnan Skin Score (mRSS) in three patients with systemic sclerosis. (B) Longitudinal changes in lupus anticoagulant assays in a patient with antiphospholipid syndrome who received CAR-T BCMA (red = above reference range; orange = above reference range with improvement; green = within normal range). (C) Longitudinal changes in anti–double-stranded DNA (anti-dsDNA) antibody levels in patients with systemic lupus erythematosus.

Clinical responses were observed across multiple autoimmune phenotypes, with a maximum follow-up of 12 months (mean: 169 days). Three patients with SSc showed rapid reductions in skin fibrosis, with Modified Rodnan Skin Score improving from 41 and 34 to 20, and from 27 to 15 within 2 months (Figure 1A); skin biopsy in one patient demonstrated early histological resolution of fibrosis. A patient with severe APS and diffuse alveolar hemorrhage showed cessation of pulmonary bleeding, improved oxygen dependence, and gradual corticosteroid tapering; antiphospholipid antibodies normalized (Figure 1B). SLE patients showed marked clinical improvement, including normalization of anti–double-stranded DNA antibodies (Figure 1C). One patient with severe SLE and lupus nephritis experienced resolution of edema and systemic symptoms, normalization of complement, serum albumin, hemoglobin, and anti-dsDNA titers, along with progressive improvement in proteinuria and serum creatinine, permitting corticosteroid and antihypertensive tapering. A patient with IIM showed improved muscle strength (iliopsoas manual muscle testing from 2/2+ to 5−/4+) and sustained decline in serum creatine phosphokinase; however, disease relapse occurred at 9 months.BCMA-directed CAR T-cell therapy was generally well tolerated. Lymphopenia from chemotherapy occurred in all patients. Grade 3–4 neutropenia occurred in 2 patients and was managed supportively. Cytokine release syndrome (CRS) was limited to Grade 1–2 events (Grade 2 in 4 patients; Grade 1 in 2 patients); two patients experienced no CRS. Tocilizumab was administered to 6 patients (median dose 1.5, range 1–3), and high-dose corticosteroids were required in one patient. No immune effector cell–associated neurotoxicity syndrome (ICANS) was observed.

Conclusions: BCMA-targeted CAR T-cell therapy demonstrated a favorable safety profile with no dose-limiting toxicities or unexpected adverse events. All treated patients showed clinical or biological responses lasting up to 9 months. Notably, we report the first clinical responses to BCMA-directed CAR T-cell therapy in SSc and APS. These interim data support the safety, feasibility, and therapeutic potential of BCMA-targeted CAR T cells as a novel, antigen-specific treatment strategy for refractory autoimmune diseases.

FLUDARABINE EXPOSURE IMPACTS BCMA-DIRECTED CAR-T THERAPY EFFICACY IN RELAPSED OR REFRACTORY MULTIPLE MYELOMA

Eugene Brailovski[1], *Sarah Samorodnitsky*[1], *Sandeep Raj*[1], *Hamza Hashmi*[1], *Natalie Brumwell*[1], *Melinda Cook*[1], *Andrew Lin*[1], *Jacqueline Dela Pena*[1], *Sergio Giralt*[1], *Alexander Lesokhin*[1], *Sham Mailankody*[1], *Sridevi Rajeeve*[1], *Gunjan Shah*[1], *Saad Usmani*[1], *Michael Scordo*[1], *Heather Landau*[1]
[1]*Memorial Sloan Kettering Cancer Center, New York City, United States of America (the)*

Background: Fludarabine (Flu) dosing is based on the body surface area. Adjustments for patients with reduced creatinine clearance (CrCl) are based on the package insert and are not tailored to CAR-T. While Flu exposure (area under the curve, AUC) has been linked with CAR-T outcomes in large B-cell lymphoma (Scordo, 2023) and B-cell acute lymphoblastic leukemia (Dekker, 2022), its significance in relapsed/refractory multiple myeloma (RRMM) remains to be fully established.

Methods: This retrospective study included patients with RRMM treated with CAR-T directed at the B-cell maturation antigen (BCMA). To estimate the Flu AUC using clinically available parameters, a validated pharmacokinetic model was used (Langenhorst, 2019). Absolute lymphocyte count (ALC; days 0-30) was used as a surrogate for CAR-T expansion (Saldarriaga, 2024). Overall response was defined as a partial response or better based on the International Myeloma Working Group response criteria. Cox proportional hazard models were used to estimate the association between Flu AUC and progression-free survival (PFS) and overall survival (OS). The relationship between Flu AUC and overall response rate (ORR), cytokine release syndrome (CRS), and immune effector cell-associated neurotoxicity syndrome (ICANS) was examined using logistic regression. Associations with blood counts were estimated using linear regression. Multivariable analyses (MVA) included age, sex, CAR-T product, cytogenetics and extra-medullary disease.

Results: We included 161 patients: 119 (74%) were treated with cilta-cel and 42 (26%) with ide-cel (Table 1). Flu AUC ranged from 11.2 to 22.25 mg*h/L (Figure 1A). Patients with a CrCl <80mL/min had higher Flu AUC than those with a CrCl≥80mL/min (17.37 vs 15.48mg*h/L, p<0.001; Figure 1B). On univariable analysis (UVA), higher Flu AUC was associated with more day 0-30 thrombocytopenia (p=0.019) and higher day 0-30 peak ALC (p=0.033). There was no association on UVA with ICANS, CRS, day 30-90 thrombocytopenia or day 0-90 neutropenia. On MVA, higher Flu AUC was associated with increased ORR (OR 1.37, 95%CI 1.03-1.89, p=0.038), MRD negativity (OR 0.65, 95%CI 0.49-0.85, p=0.003) and PFS (HR 0.78, 95%CI 0.68-0.91, p<0.001), but not OS (p=0.39). Analyzing each cell product individually, the impact of Flu AUC on PFS was observed in cilta-cel (HR 0.72, 95% CI 0.56-0.91, p=0.007) but was not statistically significant in ide-cel (HR 0.83, 95% CI 0.68-

1.02, p=0.077). Optimal Flu AUC to minimize relapse risk in cilta-cel was > 16.1 mg*h/L (Figure 1C).

Table 1: Baseline characteristics, stratified by creatinine clearance

Characteristics	CrCl<80mL/min (N=63)	CrCl≥80mL/min (N=98)	P-value
Age, mean [min, max]	70 [46, 86]	61 [42, 80]	<0.001
Female sex	27 (43%)	44 (45%)	0.9
High-risk cytogenetics	31 (49%)	49 (50%)	>0.9
Extra-medullary disease	10 (16%)	30 (31%)	0.04
Bone marrow plasma cell >50%	5 (8.1%)	16 (16%)	0.2
Cilta-cel	45 (71%)	74 (76%)	0.6
Ide-cel	18 (29%)	24 (24%)	0.6
Fludarabine exposure (mg*h/L), mean [min, max]	17.4 [12.3, 22.5]	15.48 [11.2, 20.2]	<0.001

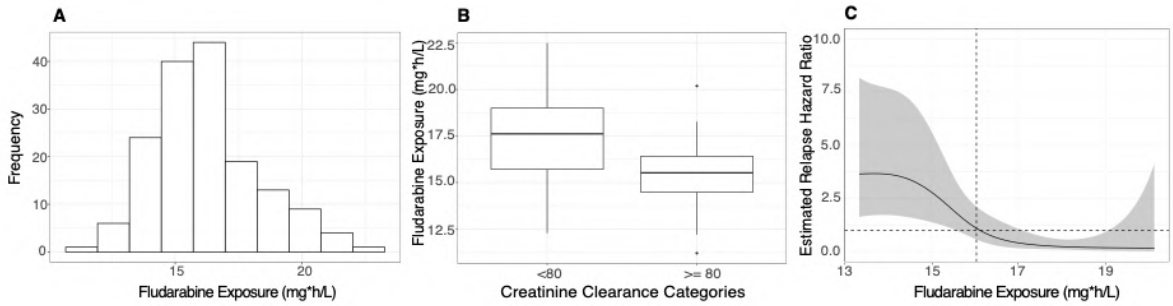

Figure 1: Fludarabine exposure prior to BCMA-directed CAR-T (A) Estimated fludarabine distribution; (B) Estimated fludarabine exposure is higher in the group with CrCl<80mL/min than CrCl≥80mL/min (C) Increased fludarabine exposure reduces risk of relapse in cilta-cel.

Conclusions: Flu AUC varies across CrCl despite standard dose adjustments. Higher Flu AUC is associated with improved CAR-T efficacy, which was particularly notable in cilta-cel, potentially suggesting product-specific differences between BCMA-directed CAR-T therapies.

However, limited ide-cel sample size may have reduced the power to detect an effect. The correlation between higher Flu AUC and ALC suggests a potential effect on CAR-T expansion. Personalized Flu dosing may represent a simple intervention to improve outcomes in RRMM.

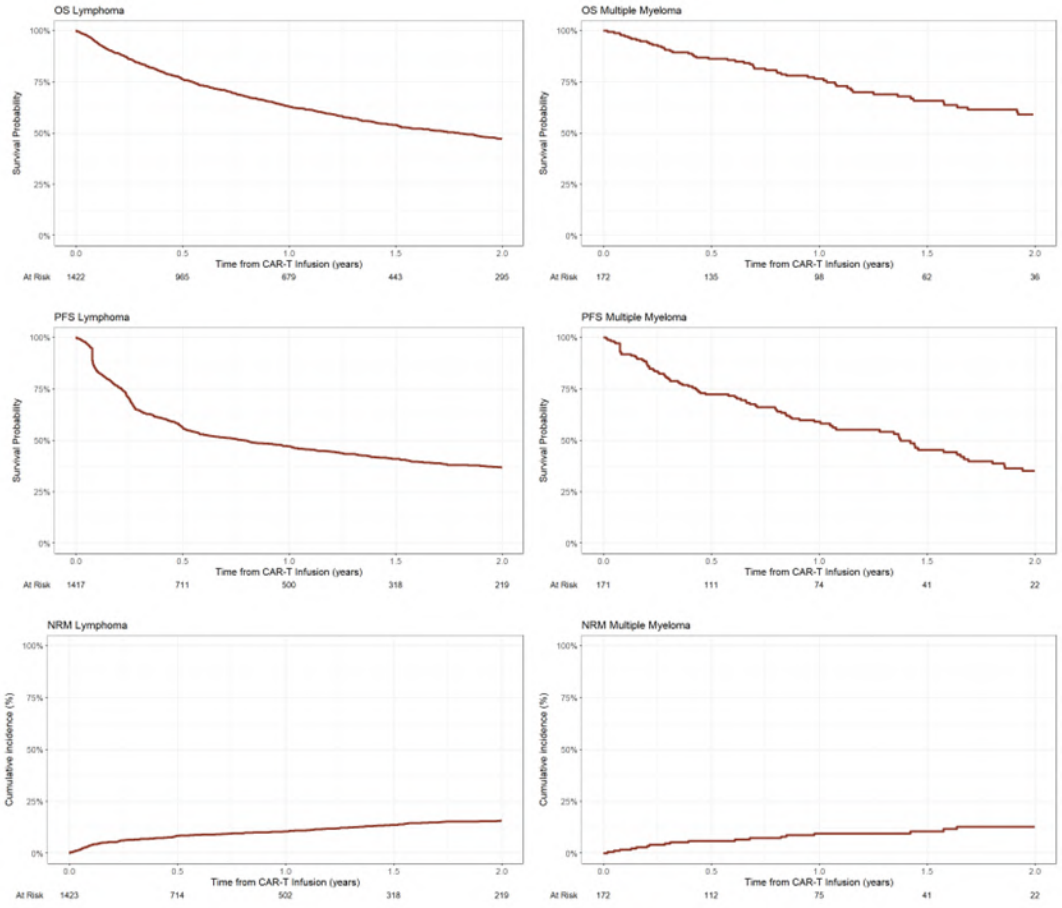
Background: CAR T-cell therapy has transformed the management of B-cell malignancies. Early clinical trial eligibility criteria and toxicity profiles suggested that advanced age might limit access. Although later studies confirmed feasibility, real-world data in patients ≥70 years remain limited. We evaluated outcomes and safety of CAR T-cell therapy in this population using the EBMT registry.

Methods: We included all patients aged ≥70 years at infusion who received a licensed CAR-T cell product between 2019 and 2023. Univariable analyses used Kaplan–Meier and cumulative incidence (CI) functions; multivariable analyses used Cox cause-specific models.

Results: We included 1,595 patients, of whom 1,423 had non-Hodgkin lymphoma (NHL, including mantle-cell lymphoma, n=197) and 172 had multiple myeloma (MM). Median age at infusion was 73.7 years (range 70.0–91.3). Most patients had an ECOG of 0–1 (91.5%). Prior autologous HCT was more frequent in MM (73
.2%) than in NHL (14.8%). At infusion, 35.1% of NHL patients and 38.3% of MM patients were in complete or partial remission.In univariable analyses, NHL patients showed an OS of 63.0% (95% CI: 60.4–65.7%) and PFS was 47.1% (95% CI: 44.3–49.7%) at 1 year. For MM, OS was 76.5% (95% CI: 70.0–83.5%) and PFS was 59.0% (95% CI: 50.8–66.3%) at 1 year. The CI of relapse at 1 year was 42.4% (95% CI: 39.8–45.1%) for NHL and 31.3% (95% CI: 24.2–38.6%) for MM. NRM at 1 year was similar, reaching 10.6% (95% CI: 9.0–12.3%) in NHL, and 9.5% (95% CI: 5.5–14.7%) in MM. Disease progression accounted for 75.6% and 71.4% of deaths in NHL and MM.
Multivariable analyses showed that treatment with axi-cel was associated with superior OS (HR 1.28, 95% CI:1.07–1.53; p=0.006), PFS (HR 1.41, 95% CI: 1.20–1.64; p<0.001), and lower relapse incidence (RI) compared with axi-cel. Male sex was associated with shorter OS (HR 1.21, 95% CI: 1.01–1.45; p=0.04) and higher NRM. ECOG ≥1 was similarly linked to poorer OS (HR 1.52, 95% CI: 1.27–1.81; p<0.001), PFS (HR: 1.34, 95% CI: 1.15–1.56; p<0.001), NRM and RI. Compared to patients in active disease, achieving a PR or a CR at infusion was associated with improved OS, (HR: 0.66, 95% CI: 0.54–0.82; p<0.001) and (HR: 0.52, 95% CI: 0.37–0.73; p<0.001) respectively, as were PFS and RI. Finally, a longer interval between initial diagnosis and CAR T-cell infusion is associated with better OS (HR [1-year]: 0.96, 95% CI:0.94–0.98; p<0.001), PFS (HR: 0.96, 95% CI: 0.95–0.98; p<0.001). In the MM subgroup, the use of ide-cel was associated with worse PFS (HR: 2.52, 95% CI: 1.19–5.30; p=0.02) and RI, while an ECOG≥1 was associated with shorter OS (HR: 2.80, 95% CI: 1.35–5.79; p=0.006), PFS (HR: 2.54, 95% CI: 1.49–4.33; p<0.001) and higher RI.



Conclusions: In this large real-world cohort of patients aged ≥70 years, CAR T-cell therapy showed marginally higher NRM and lower RI compared with younger populations in other studies. This suggests efficacity and safety of CAR-T in older populations.

HAPLOIDENTICAL DONOR-DERIVED CAR-T CELLS CO-INFUSED WITH THE ALLOGENIC GRAFT ON THE PLATFORM OF T CELL DEPLETION OR POST-TRANSPLANT CYCLOPHOSPHAMIDE IN CHILDREN WITH ADVANCED B-CELL NEOPLASMS

Larisa Shelikhova[1], *Olga Molostova*[1], *Maria Ilushina*[1], *Ekaterina Malakhova*[1], *Margarita Perminova*[1], *Yakov Muzalevsky*[1], *Dmitriy Pershin*[1], *Maria Fadeeva*[1], *Alexander Popov*[1], *Alexei Maschan*[1], *Michael Maschan*[1]
[1]*Dmitry Rogachev Federal Research Centre of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation (the)*

Background: Autologous CAR T cells induce high rate of deep remissions among children with rR/R B-ALL. In a significant proportion of cases cure is achieved only with HSCT as post-CAR-T consolidation. Seeking to combine the cytoreductive and curative power of HSCT with the antigen-specific activity of CAR-T we devised an approach with simultaneous infusion of hematopoietic stem cell graft and CAR-T cells, derived from the same donor. Two GVHD prevention platforms were used: ex-vivo T cell depletion and PtCy. We report here pooled analysis of prospective trial patients and compassionate use program.

Methods: A total of 38 pts with R/R BCP-ALL and B-NHL/leukemia were enrolled. The main characteristics of the group are presented in Table 1.

Table1 Clinical Characteristics of Patients

38 patients	
median age	9,6 y
Sex Male female	 23 15
Diagnosis BCP-ALL B-NHL/leukemia	 34 4
Remission status **AD** BM >5% BM>5%+ExD ExD **MRD positive** **CR (MRD negative)**	 **24** 10 7 7 **11** **3**
Previous therapy HSCT	 13

blinatumomab inotuzumab blinatumomab+inotuzumab CAR-T cell infusion	23 1 5 11
Conditioning regimen TBI Treosulfan	 19 19
ex-vivo T cell depletion	27
post-transplant cyclophosphamide	11
Donor type Haploidentical	 38

27 patients received T-cell depleted graft, GVHD prophylaxis included abatacept. In this subgroup CAR-T products included CD19 CAR- T (n=5), CD1922 tandem CAR-T (n=19), and cocktail CD19 and CD22 CAR-T (n=3). Eleven pts were transplanted with PtCy-based GVHD prophylaxis, in this subgroup CAR-T cells were infused on day +5 after HSCT and were represented by either by CD19-22 tandem CAR- T (n=1), CD19 CAR- T(n=1) or by CD19 and CD22 cocktail product (n=9). In the PtCy group GVHD prophylaxis included abatacept, vedolizumab and CsA or baricitinib.

Results: There was no suspected conflict between the graft and CAR-T cells. Primary engraftment was observed in 36 of 38 pts (one pt died before engraftment and one relapsed early), all engrafted patients achieved MRD-negative CR at day +28 after HSCT. The median time to CAR-T cell peak expansion was 14 days regardless of depletion platform.
CRS occurred in 21 (55%) patients and only two pts had grade 3 CRS. Also 21 patients had neurologic events (ICANS grade 1, n=13, grade 2, n=6 and grade 3, n=2). Twelve patients had aGvHD, grade 2 (n=10), grade 3(n=1) and grade 4 (n=1), 5 patients had mild chronic GvHD. There were no significant differences in CAR-T toxicity between depletion and PtCy groups.
Six patients died in CR and one before engraftment due to infection and VOD.
Leukemia relapse was observed in nine children (8 from HD burden and one from MRD group) at a median time of 174 days after allograft, 3 pts had CD 19 negative relapse.
23 (58%) patients are alive (22 in CR, 1 with disease progression) with a median follow-up of 2,9 years (0,33-5,8). EFS and OS in patients with high disease burden was 45% and 41%, in MRD group 82% and 81%. EFS and OS at 2,6 years in whole group are 59% and 57%, respectively, without differences between T-cell depletion and ptCy groups.

Conclusions: Our early experience suggests that allogenic CAR-T cells can be safely infused simultaneously with the HSC graft both on the platform of T cell depletion and PtCy-based GVHD prophylaxis. The infusions did not compromise engraftment and GvHD control, while specific CAR-T toxicity was mild and manageable. We have documented CAR-T expansion and persistence. Prospective testing of the approach is warranted.

Disclosure: Nothing to declare.

COMPARATIVE VALIDATION OF NEUTROPHIL-BASED MODELS (CAR-HEMATOTOX, ALL-HEMATOTOX, AND E-IPM) FOR PREDICTING EARLY T-ICAHT–DEFINED PLATELET RECOVERY AFTER CAR-T THERAPY

Tong Su[1,2,3], Xin-Le Wang[1], Ao-Ran Zhang[1], Yi-Han Yang[1], Ya Luo[1], Xiao-Han Su[1], Su-Xuan Liu[1], Ming-Kun Wang[1], Xu-Ying Pei[1], Xiao-Jun Huang[1,2,3], Xiang-Yu Zhao[1,2,3], ***Meng Lv****[1,2,3]*
[1]Peking University People's Hospital, Beijing, China, [2]Peking University Institute of Hematology, Beijing, China, [3]National Clinical Research Center for Hematologic Disease, Beijing, China

Background: Immune effector cell–associated hematotoxicity (ICAHT) is a common complication after CAR-T therapy. A thrombocytopenia-focused ICAHT grading system (T-ICAHT) has recently been developed to standardize the assessment of platelet recovery (Kai Rejeski, et al. Blood 2025). Whether established neutrophil-centered models—CAR-HEMATOTOX (CAR-HT), ALL-HEMATOTOX (ALL-HT), and the early Inflammatory Prognostic Model (eIPM) for N-ICAHT—can be repurposed to effectively predict T-ICAHT across different hematologic malignancies treated with CAR-T remains unknown.

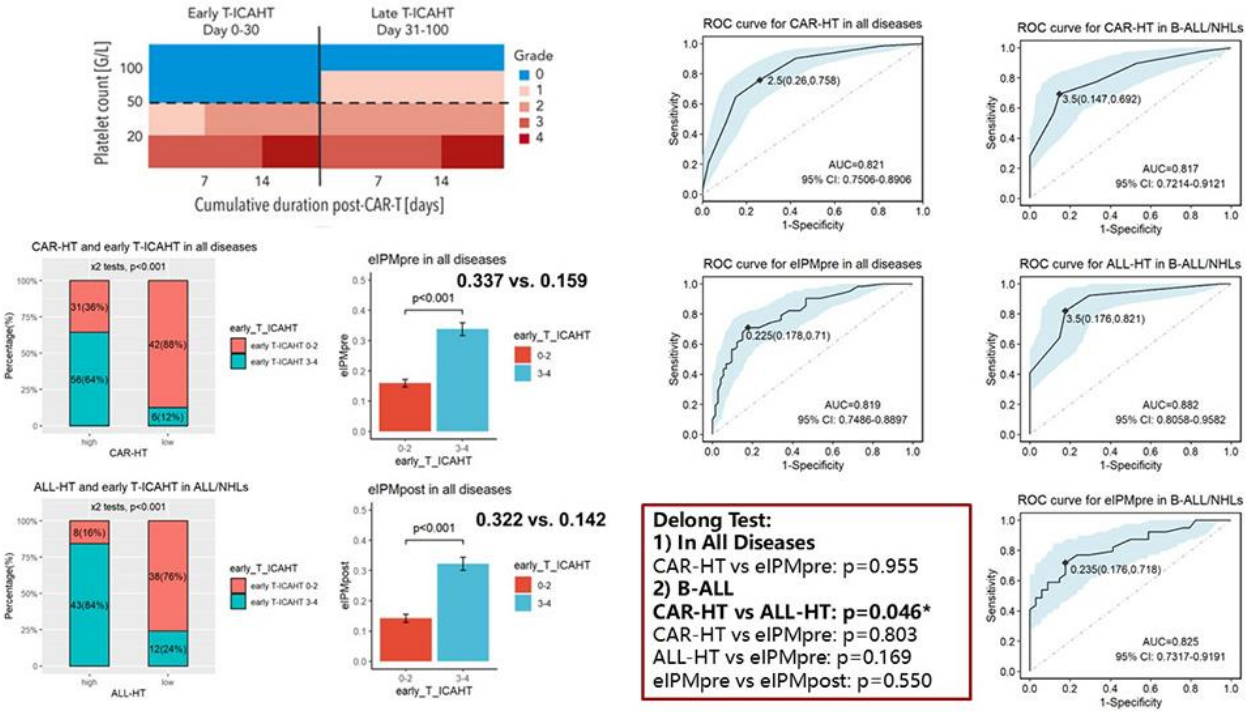
Methods: In this prospective cohort, 135 patients received CAR-T therapy between 2022 and 2025, including autologous CD19 CAR-T (brexucabtagene autoleucel or academic 4-1BB–based CAR-T) for B-ALL/B-cell non-Hodgkin lymphoma (n=73), CD7 CAR-T for T-ALL/T-cell NHL (n=28), and BCMA CAR-T for multiple myeloma (n=34). Early T-ICAHT was graded on a four-grade scale according to the cumulative depth and duration of thrombocytopenia within 30 days after infusion, and late T-ICAHT was defined by thrombocytopenia severity between days 31 and 100. Patients were censored at the time of subsequent allo-HSCT. The predictive performance of CAR-HT, ALL-HT, and eIPM for early T-ICAHT was compared, with ROC curves evaluated using DeLong's test.

Results: Grade 3–4 early T-ICAHT occurred in 39/73 (53.4%) of B-ALL/NHL, 16/28 (57.1%) of T-ALL/NHL, and 7/34 (20.6%) of MM patients. In the overall cohort, grade 3–4 early T-ICAHT was associated with significantly inferior outcomes, including inferior 1-year OS (63% vs. 97%, $P<0.001$) and DFS (43% vs. 80%, $P<0.001$) compared with grade 0–2. The prognostic impact on OS was disease-specific: grade 3–4 early T-ICAHT predicted inferior 1-year OS in T-ALL/NHL (0% vs. 100%, $P=0.004$) but not in B-ALL/NHL (94% vs. 92%, $P=0.50$). In contrast, early T-ICAHT was consistently associated with inferior DFS in both B-ALL/NHL (45% vs. 72%, $P=0.039$) and T-ALL/NHL (0% vs. 73%, $P=0.053$).
CAR-HT classified 64.4% of patients as high risk, and ALL-HT identified 50.5% of ALL/NHL patients as high risk. CAR-HT effectively discriminated patients at high risk for grade 3–4 early T-ICAHT (high risk: grade 3–4, 64% vs. grade 0–2, 36%; low risk: grade 3–4, 12% vs. grade 0–2, 88%; $P<0.001$), with consistent performance in B-ALL/NHL ($P<0.001$) and T-ALL/NHL ($P=0.031$). ALL-HT similarly distinguished high- and low-risk early T-ICAHT in ALL/NHL (high risk: grade 3–4, 84% vs. grade 0–2, 16%; low risk: grade 3–4, 24% vs. grade 0–2, 76%; $P<0.001$), with consistent performance in B-ALL/NHL ($P<0.001$) and T-

ALL/NHL (*P*=0.019). Both eIPM_pre and eIPM_post were strongly associated with grade 3–4 early T-ICAHT in the overall cohort (*P*<0.001), in B-ALL/NHL (*P*<0.001), and in MM (eIPM_pre, *P*=0.010; eIPM_post, *P*=0.006), but showed reduced discriminatory ability in T-ALL/NHL (eIPM_pre, *P*=0.029; eIPM_post, *P*=0.057).
ROC analysis for grade 3-4 early T-ICAHT demonstrated comparable predictive performance of CAR-HT, eIPM_pre, and eIPM_post in MM and T-ALL/NHL. In B-ALL/NHL, ALL-HT showed higher discrimination than CAR-HT (AUC 0.882 vs. 0.817), with a significant difference by DeLong's test (P=0.046).

Characteristics		Characteristics		ICAHT	B-ALL/NHL (N=73)	T-ALL/NHL (N=28)	MM (N=34)	Avg. PLT Infusion Units
Age, Median (Range)	41 (6-83)	Prior allo-HSCT, yes, n(%)	49 (36.3%)	N-ICAHT 1, n (%)	15(20.6%)	7 (25.0%)	19 (55.9%)	0.2
Sex, Male, n(%)	80 (59.3%)	Prior allo-HSCT, no, n(%)	86 (63.7%)	N-ICAHT 2, n(%)	12 (16.4%)	5 (17.9%)	5 (14.7%)	0.7
Sex, Female, n(%)	55 (40.7%)	Median BM blasts Before FC	Median (Interquartile range)	N-ICAHT 3, n (%)	26 (35.6%)	11 (39.2%)	10 (29.4%)	3.9
Disease and Target, n(%)		B-ALL/NHL	25.0%(6.0%-65.0%)	N-ICAHT 4, n (%)	20 (27.4%)	5 (17.9%)	0 (0.0%)	13.4
B-ALL/NHL, CD19 or CD19-22	73(54.1%)	T-ALL/NHL	7.0% (0%-55.5%)	T-ICAHT 0, n(%)	20 (27.4%)	5 (17.9%)	17 (50.0%)	0
T-ALL/NHL, CD7	28 (20.7%)	CRS 0-1, n(%)	81（60.0%)	T-ICAHT 1,	5 (6.9%)	2 (7.1%)	6 (17.6%)	0.1

				n (%)				
MM, BCMA	34 (25.2%)	CRS 2+, n(%)	54（40.0%)	T-ICAHT 2, n (%)	9 (12.3%)	5 (17.9 %)	4 (11.8 %)	0.1
Co-stimulatory CD28, n(%)	13 (9.6%)	ICANS 0-1, n(%)	128 (94.8%)	T-ICAHT 3, n (%)	17 (23.3%)	10 (35.7 %)	4 (11.8 %)	2.7
Co-stimulatory 4-1BB, n(%)	122 (90.4%)	ICANS 2+, n(%)	7 (5.2%)	T-ICAHT 4, n (%)	22 (30.1%)	6 (21.4 %)	3 (8.8%)	13.4



Conclusions: CAR-HT, ALL-HT, and eIPM effectively identify patients at higher risk of post-infusion thrombocytopenia within 30 days after CAR-T therapy. In ALL with predominant bone marrow blast involvement, ALL-HT may provide superior predictive performance.

Disclosure: ML received grants from Beijing Research Ward Excellence Program(BRWEP2024W134080103) and National key research and development plan of China (2021YFA1100902)

IMPACT OF THIOTEPA-BUSULFAN CONDITIONING ON CMML TRANSPLANT SCORE PERFORMANCE

Maraike Harfmann[1], *Radwan Massoud*[1], *Nico Gagelmann*[1], *Evgeny Klychnikov*[1], *Ina Rudolph*[1], *Silke Heidenreich*[1], *Rusudan Sabauri*[1], *Claudia Langebrake*[1], *Adrin Dadkhah*[1], *Rolf Krause*[1], *Christian Niederwieser*[1], *Mathias Schäfersküpper*[1], *Franziska Marquard*[1], *Mirjam Reichard*[1], *Sofia Oechsler*[1], *Benno Lickefett*[1], *Jette Lüdersen*[1], *Gunnar Weise*[1], *Kristin Rathje*[1], *Johanna Richter*[1], *Catherina Lück*[1], *Christine Wolschke*[1], *Nicolaus Kröger*[1], *Francis Ayuk*[1]
[1]*University Medical Center Hamburg Eppendorf, Hamburg, Germany*

Background: Allogeneic stem cell transplantation (allo-SCT) remains the only curative therapy for patients with CMML. Given the high transplant-related mortality and morbidity (Kröger et al., 2002), risk scores are essential to identify patients who most likely benefit. The CMML transplant score, developed by Gagelmann et al., incorporates ASXL1/NRAS mutations, bone marrow blasts >2%, and comorbidity index.
While predictive of overall survival (OS) and non-relapse mortality (NRM), the effect of conditioning regimen on score performance remains unknown. Recently, thiotepa–busulfan (TB) conditioning has been associated with markedly reduced relapse rates and improved Survival in CMML, (Massoud et al., 2024), raising the question whether intensified disease control may alter the prognostic relevance of established transplant risk scores.

Methods: A retrospective cohort analysis was performed including 54 consecutive patients who underwent allo-SCT for CMML between 2019 and October 2025 at the University Medical Center Hamburg-Eppendorf. The CMML transplant score was applied to all patients.
Primary analysis evaluated score discrimination in the entire cohort. Secondary analysis focused on the TB conditioning subgroup (n=30) to assess whether this conditioning modifies score prognostic value. The CMML transplant score was calculated according to Gagelmann et al. For analysis, we dichotomized at ≥5 points, representing the most relevant prognostic inflection in the original model (transition from scores 0–4 to 5–7). Patients were classified as lower-risk (0–4) or higher-risk (≥5).

Results: In the overall cohort (median age 66 years, 74% male), the CMML transplant score retained prognostic discrimination for OS (p=0.02) and PFS (p=0.04). In the TB conditioning subgroup (n=30, 58% of total cohort) no patient relapsed regardless of risk score However, OS varied by score group: at 1 year 100% for lower-risk (n=9) and 51% for higher-risk n=21) patients, p = 0.11. Though not reaching statistical significance, probably due to

sample size, the numerical differences indicate the CMML transplant score may retain its prognostic performance in CMML patients conditioned using TB. Survival differences were driven entirely by NRM rather than disease progression.
The most frequent main cause of death of TB patients was septic shock (7), followed by unknown (2), cardiac arrest (1), respiratory (1) and multiorgan failure (1). Comorbidity burden may contribute substantially, as 83% of deceased patients (10 of 12) had impaired lung function pre-transplant (DLCO < 65%), compared with 50% in the overall TB group and 48% in the full cohort.

Table Patients donor and transplant Characteristics

Variable	Overall cohort (N = 54)	TB subgroup (N = 30)
CPSS-Mol risk group Low	0 (0%)	0 (0%)
CPSS-Mol risk group Intermediate-1	10 (19%)	6 (20%)
CPSS-Mol risk group Intermediate-2	24 (44%)	13 (43%)
CPSS-Mol risk group High	18 (33%)	10 (33%)
CPSS-Mol risk group Very high	2 (4%)	1 (3%)
Transplant year, median (range)	2022 (2019-2025)	2024 (2019-2025)
MRD	7 (13%)	4 (13%)
Haplo	8 (15%)	0 (0%)
MUD	35 (65%)	24 (80%)
MMUD	4 (7%)	2 (7%)
Conditioning Thiotepa-busulfan (TB)	30 (56%)	30 (100%)
Conditioning Fludarabine-busulfan (FB)	7 (13%)	0 (0%)
Conditioning Treosulfan-fludarabine	12 (22%)	0 (0%)
Other	5 (9%)	0 (0%)
Male	40 (74%)	23 (77%)
Female	14 (26%)	7 (23%)

Patient age, years, median (range)	66 (41-80)	64 (42-76)
CMV Negative	20 (37%)	15 (50%)
CMV Positive	34 (63%)	15 (50%)

Conclusions: TB conditioning eliminates relapse risk across all risk groups of the CMML transplant score, validating our previous comparative study findings. While this intensive approach achieves superior disease control, the risk-benefit equation shifts from disease progression to treatment-related toxicity. The CMML Transplant score however appears to retain its prognostic performance.

Disclosure: Nothing to declare.

TRUNCATING GENE ALTERATIONS AND PROMOTER HYPERMETHYLATION DRIVE CD7⁻ RELAPSE AFTER CD7 CAR-T THERAPY: A PATIENT-INFORMED MECHANISM STUDY

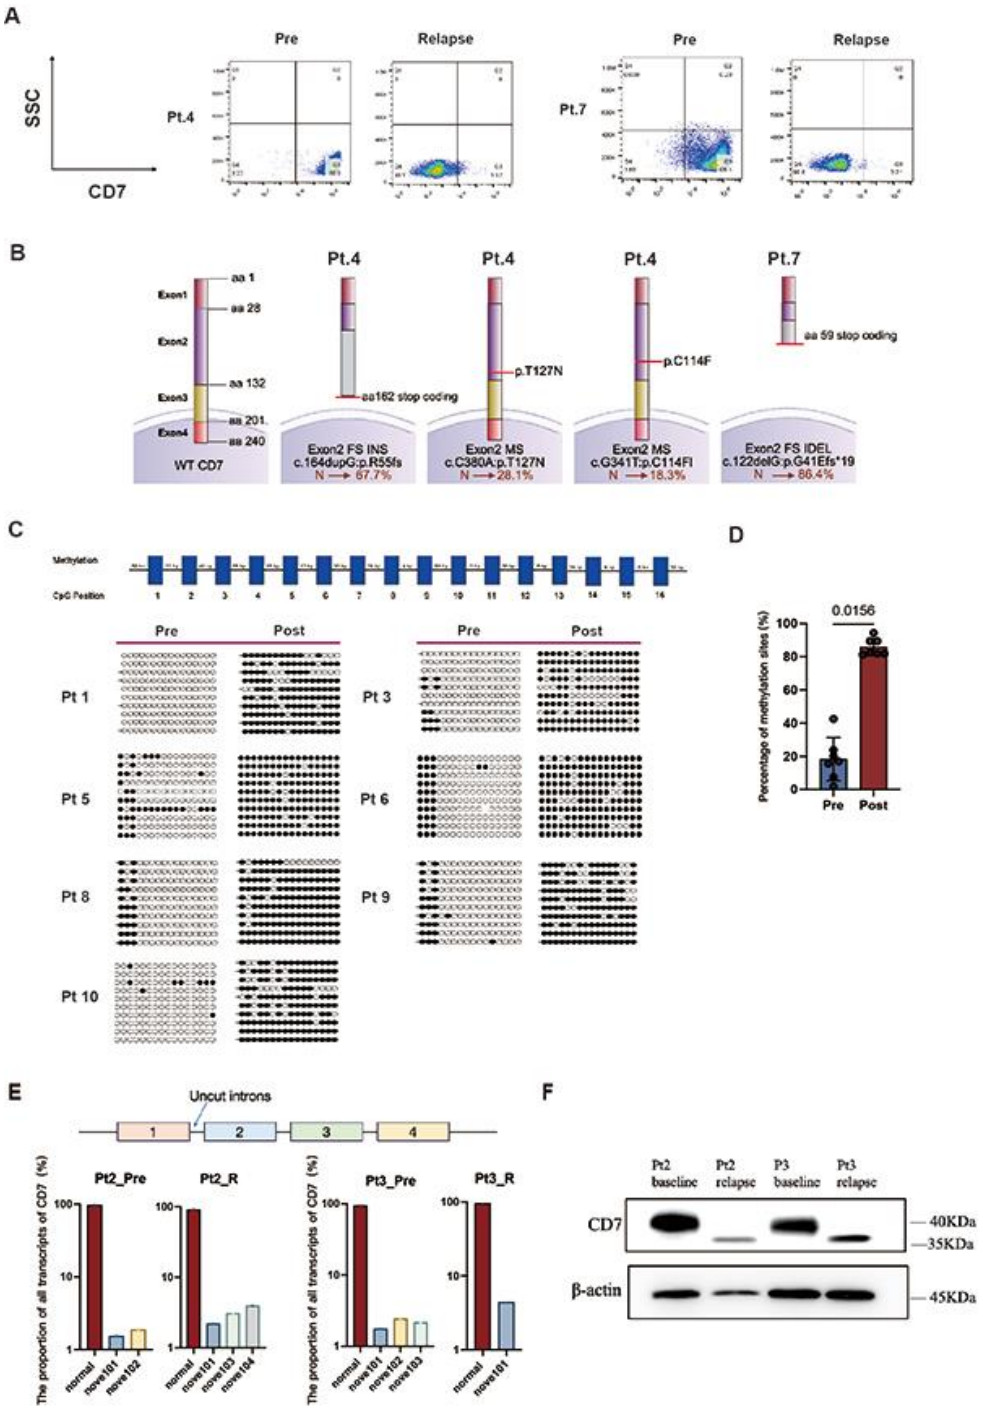
Rongrong Chen[1], *Haiqiong Zheng*[1], *Wenxin Wang*[1], *He Huang*[1], *Yongxian Hu*[1]
[1]*Bone Marrow Transplantation Center of the First Affiliated Hospital & Liangzhu Laboratory, Zhejiang University School of Medicine, Hangzhou, China*

Background: The CD7 antigen, emerging as a novel target for chimeric antigen receptor (CAR) T-cell therapy, particularly as a novel strategy to bridge to allogeneic hematopoietic stem-cell transplantation (HSCT). However, antigen loss-mediated relapse remains a major challenge. Recent clinical data indicate that 30%-51.7% of relapses result from CD7 protein loss [Tan Y et al., J Hematol Oncol. 2023] [Pan J et al., J Hematol Oncol 2021]. The mechanisms underlying the antigen loss remain to be further explored.

Methods: Herein, we analyzed paired specimens collected at screening (pre-treatment) and clinical relapse from 10 patients with T-cell hematologic malignancies (5 T-ALL, 3 T-LBL, 2 HSTL) who experienced CD7-negative relapse ($CD7^-$/relapse). $CD7^+$ tumor cells (pre-treatment) and $CD7^-$ tumor cells (relapse) were prospectively isolated by flow cytometry sorting. Whole-exome sequencing (WES) was conducted to identify acquired somatic mutations, while bisulfite sequencing PCR (BSP) was used to evaluate the methylation status of the *CD7* promoter region spanning from −300 to +200 bp. (ClinicalTrials.gov identifiers: NCT04599556, NCT04538599, and NCT05716113).In addition, we focused on two patients with sufficient samples to further explore alternatively spliced CD7 transcripts and protein sequencing analysis.

Results: In two patients (Pt4 and Pt7), acquired truncating mutations in *CD7* exon 2 were identified as the dominant resistance mechanism. These mutations (frameshift insertion exon2:c.164dupG:p.R55fs in Pt4 and deletion exon2:c.122delG:p.G41Efs*19 in Pt7) were predicted to yield nonfunctional, truncated CD7 proteins lacking the transmembrane domain,

considering either biallelic mutations or upregulation of the mutation copy. Additionally, Pt4 harbored subclonal missense single nucleotide variants (exon2:c.C380A:p.T127N, 28.1%; exon2:c.G341T:p.C114F, 18.3%), indicating clonal heterogeneity.
Notably, non-truncating mutations and mild CD7 (-300 to +200 bp) methylation were concurrently observed in Pt2. A missense mutation (exon2:c.G124C:p.A42P [24.2% VAF]) and an in-frame deletion (c.271_273del:p.91_91del [26.7% VAF]) within the extracellular domain were detected, potentially impairing epitope recognition. These findings suggest a combination of deleterious mutations and ensuing epigenetic silencing.
No genetic alterations were detected in the remaining seven patients. However, analysis of these relapsed samples revealed hypermethylation within a moderate CpG island located in the *CD7* promoter region (-300 to +200 bp). In vitro, azacitidine treatment restored *CD7* mRNA and intracellular protein expression in hypermethylated CD7-negative T-ALL cell lines (Hut78 and H9), supporting methylation-driven transcriptional silencing as a resistance mechanism. Western blot analysis of $CD7^{-}$ tumor cells from Pt3 and Pt4 revealed the presence of low-molecular-weight CD7 isoforms, which were confirmed by protein sequencing to identify N-terminally truncated CD7. Additionally, there has been no discovery of alternative splicing that forms a dominant advantage.



(A) Flow cytometric analysis of CD7 surface expression at pretreatment and relapse in Pt4 and Pt7.
(B) Acquired mutations in CD7 were detected in relapsed samples from Pt4 and Pt7.
These mutations are predicted to result in a truncated protein lacking the transmembrane domain.
(C) Methylation status of the CD7 promoter region. Filled circles represent methylated CpG sites.
(D) Methylation levels were significantly elevated in relapsed samples (10 clones) compared to pretreatment samples (10 clones).(E) Proportion of different splice variants of CD7 transcripts
(F) Western blot analysis reveals a lower molecular weight band in the relapsed sample from Pt2 and Pt3.

Conclusions: Our study elucidates that the dominant mechanism underlying $CD7^-$ relapse is methylation-driven epigenetic silencing under immune pressure. Some patients may develop truncating mutations and rapidly gain clonal advantage and progress.

BU/CY/FLU-ATG VERSUS BU/CY-ATG CONDITIONING REGIMEN IN HAPLOIDENTICAL CELL TRANSPLANTATION FOR SEVERE ACQUIRED APLASTIC ANEMIA

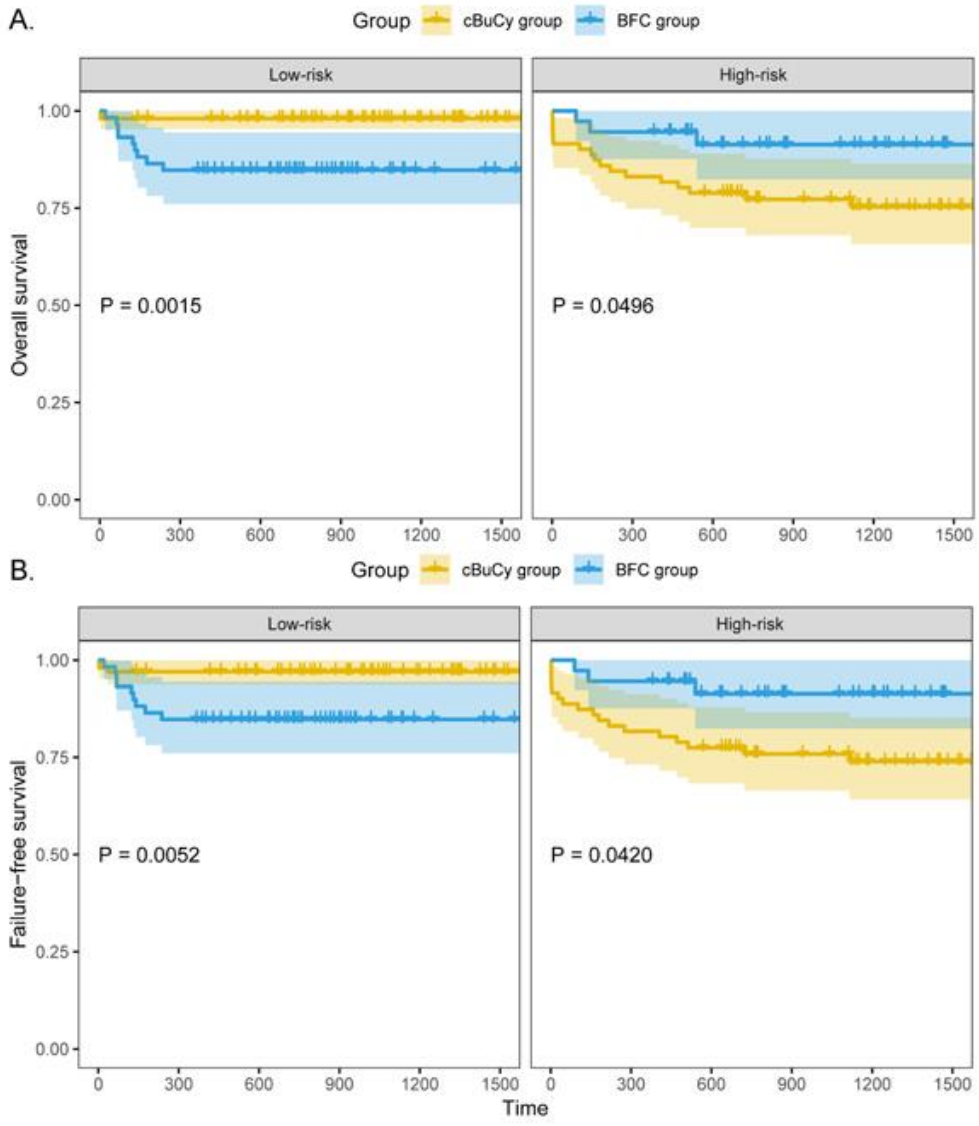
*Fan Lin[1], **Zhengli Xu**[1], Tingting Han[1], Yun He[1], Yuanyuan Zhang[1], Yifei Cheng[1], Xiaodong Mo[1], Jingzhi Wang[1], Yu Wang[1], Xiaohui Zhang[1], Xiaojun Huang[1], Lanping Xu[1]*
[1]Peking University People's Hospital, Beijing, China

Background: The optimal conditioning regimen for haploidentical hematopoietic cell transplantation (haplo-HCT) in patients with severe acquired aplastic anemia (SAA) remains undefined. In G-CSF/ATG-based haplo-HCT, the conventional busulfan 6.4 mg/kg and cyclophosphamide 200 mg/kg (cBuCy) conditioning regimen and fludarabine (Flu)-based regimens are widely adopted. Scattered reports have showed promising outcomes using the two regimens. However, comparisons between cBuCy and Flu-based conditioning regimens are limited.

Methods: In this study, we tried to comprehensively compare transplant outcomes following haplo-HCT with cBuCy regimen and a Flu-based regimen, comprising busulfan 6.4 mg/kg, Flu 150 mg/m^2, and cyclophosphamide 100 mg/kg (BFC regimen). Patients undergoing haplo-HCT with the cBuCy regimen and the reduced-toxicity BFC regimen between 2012 and 2021 at PKUPH were reviewed. To minimize the impact of selection bias and confounding factors, we performed a propensity score matching (PSM) analysis. Patient age, sex, the interval between SAA diagnosis and HCT, and donor-recipient ABO matching group were included in the propensity score model. Finally, this study retrospectively compared two conditioning regimens (cBuCy cohort, n = 172; and BFC cohort, n = 96] in SAA patients who underwent haplo-HCT for SAA.

Results: The BFC and cBuCy regimens achieved comparable 4-year overall survival (OS; 87.3% vs. 88.5%, P = 0.634) and failure-free survival (FFS; 87.3% vs. 87.4%, P = 0.834). However, BFC regimen led to increased Epstein-Barr virus reactivation (P < 0.001) and post-transplant severe pneumonia (P = 0.004 at 1 year). Multivariable analysis identified poorer performance status and a higher Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI) as adverse factors for survival following haplo-HCT. Compared to those without any risk factor, patients with 1 factor (P = 0.016 for OS, and 0.014 for FFS) or 2 factors (P < 0.001 for OS and FFS) had increased risk of worse survival. Patients were then divided into

low-risk (no risk factor) and high-risk (1-2 factors) groups. Compared to cBuCy regimen, BFC regimen achieved better OS (P = 0.0496) and FFS (P = 0.042) in high-risk patients, while survival rates in the low-risk subgroup were relatively lower (P = 0.0015 for OS and 0.0052 for FFS).



Conclusions: Conclusively, we found both the BFC and cBuCy regimens were feasible for conditioning SAA patients undergoing haplo-HCT. Patients with poorer performance status and higher HCT-CI may benefit from the Flu-based conditioning, while cBuCy conditioning regimen can result in favorable outcomes in low-risk patients.

Disclosure: Nothing to declare.

THE CAST STRATEGY (CAR-T/ASCT/SEQUENTIAL CAR-T) WITH LOW-DOSE FRACTIONATED RT BRIDGING IN HEAVILY PRE-TREATED R/R CNSL ：A PROOF-OF-CONCEPT STUDY

Yue Wu[1], Guoai Su[1], Peihao Zheng[1], Fangfang Cheng[1], Huihui Zhao[1], Ruijiao Zhang[1], Ruijie He[1], Chen Zheng[1], Xuelin Han[1], ***Yajing Zhang***[1]
[1]*Beijing Gobroad Boren Hospital, Beijing, China*

Background: The prognosis for patients with ultra-refractory Central Nervous System Lymphoma (CNSL), particularly those with high-risk features like TP53 mutations, is dismal. These patients exhibit profound resistance to multiple lines of therapy, including BTK inhibitors, presenting a critical unmet medical need. We hypothesized that a multi-modal, synergistic platform was required to overcome this therapeutic resistance. We therefore designed and evaluated a novel protocol: CAR-T, Autologous Stem Cell Transplant, and Sequential CAR-T (CAST), bridged by low-dose radiotherapy.

Methods: Between March 2024 and June 2025, five heavily pretreated adults (median age 46; median 4 prior lines) with rapidly progressive, chemorefractory R/R CNSL (4 PCNSL, 1 SCNSL; 3/5 TP53-mutated) were enrolled. The CAST protocol comprised four distinct phases: 1) Low-dose radiotherapy bridge (7.5-10.5 Gy WBRT/CSI) for cytoreduction and to potentially enhance CAR-T trafficking. 2) A first infusion of CD19 CAR-T cells (2×10^6/kg). 3) 1-3 months later, high-dose chemotherapy (BEAM or TBC) followed by autologous stem cell transplant (ASCT; median 2.8×10^6 CD34+/kg). 4) A second, non-overlapping CAR-T infusion (CD22 or CD20; 2×10^6/kg) administered at day +3 to +5 post-ASCT to target potential antigen escape. Primary endpoints included overall response (PET/MRI), minimal residual disease in CSF (MRD, by flow cytometry), safety (CRS/ICANS), and survival.

Figure 1. Schematic of the CAST "Sandwich" Strategy (CAR-T/ASCT/Sequential CAR–T) with Low–Dose WBRT/CSI Bridging for Ultra-Refractory R/R CNSL

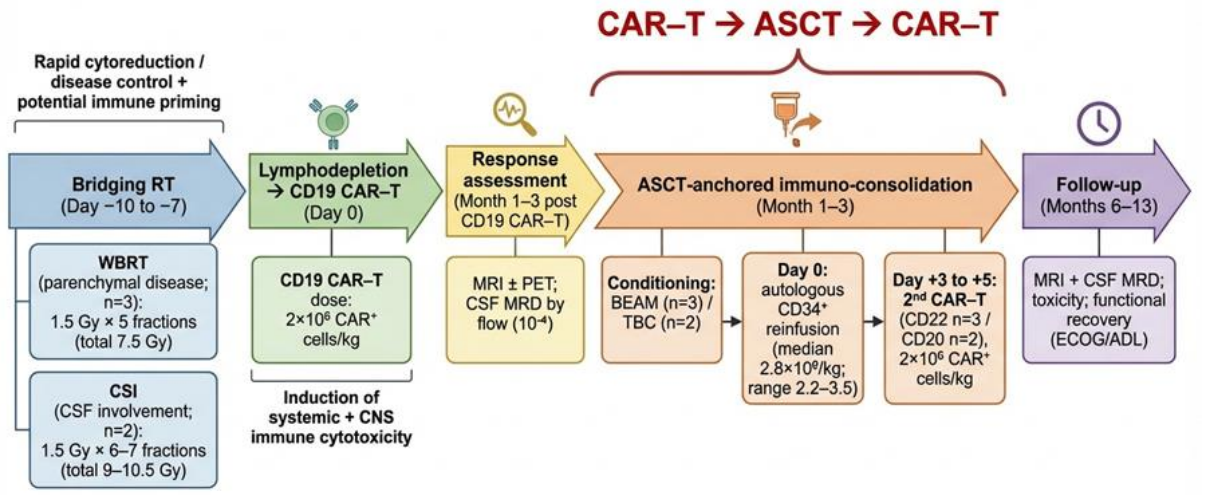

Figure 1. Schematic of the CAST "Sandwich" Strategy (CAR-T/ASCT/Sequential CAR-T) with Low-Dose WBRT/CSI Bridging for Ultra-Refractory R/R CNSL

Results: All five patients successfully completed the entire CAST protocol. Following the initial CD19 CAR-T, 3 patients achieved CR and 2 achieved PR. Significantly, after completion of the full protocol, all 5 patients (100%) converted to and maintained a deep complete remission, confirmed by both imaging and sustained CSF MRD negativity. With a median follow-up of 8 months (range 6-13), all patients remain in continuous remission with no disease progression or deaths observed. The intensive regimen was notably well-tolerated. All cytokine release syndrome (CRS) events were Grade 1-2; no Grade ≥3 CRS or ICANS occurred, and there was no treatment-related mortality. Delayed thrombocytopenia, observed in 3 patients, was effectively managed without clinical sequelae. At last follow-up, all patients maintained an excellent performance status (ECOG 0-1).

Conclusions: This initial study demonstrates that the "CAST" strategy is a feasible, safe, and highly effective approach, inducing 100% deep and durable molecular remissions in an ultra-high-risk CNSL population with no other viable options. By integrating radiation biology, transplant medicine, and dual-target cellular immunotherapy into a unified, mechanistically rational platform, this strategy offers a potential curative pathway for these patients. These promising results provide a strong rationale for an expanded, multicenter Phase II trial to validate these findings.

L-IPM: A NOVEL SCORE SYSTEM FOR PREDICTING LATE IMMUNE EFFECTOR CELL-ASSOCIATED HEMATOTOXICITY (ICAHT) AFTER CAR-T THERAPY AND COMPARISON WITH CAR-HEMATOTOX, ALL-HEMATOTOX, AND E-IPM

Ao-Ran Zhang[1,2,3], Xin-Le Wang[1], Tong Su[1], Yi-Han Yang[1], Ya Luo[1], Xiao-Han Su[1], Su-Xuan Liu[1], Ming-Kun Wang[1], Xu-Ying Pei[1], Xiao-Jun Huang[1], Xiang-Yu Zhao[1], ***Meng Lv***[1]
[1]*Peking University People's Hospital, Beijing, China,* [2]*Peking University Institute of Hematology, Beijing, China,* [3]*National Clinical Research Center for Hematologic Disease, Beijing, China*

Background: Immune effector cell–associated hematotoxicity (ICAHT) profoundly affects long-term outcomes after CAR-T therapy. According to the EHA/EBMT consensus (Blood, 2023), ICAHT is classified as early (day 0–30) or late (≥day 30) neutropenia-associated ICAHT (N-ICAHT). Although CAR-HEMATOTOX, ALL-HEMATOTOX, and eIPM were developed primarily to predict early ICAHT, predictive tools for late N-ICAHT remain limited. This study aimed to develop an effective model to predict late N-ICAHT using routinely available variables.

Methods: A consecutive cohort of 135 patients with hematologic malignancies who received either commercial CAR-T products, including Brexu-cel or investigational CD19, BCMA or CD7 targeted CAR-T between 2022 and 2025 was enrolled. Multivariable logistic regression was used to develop a point-based risk score (Late Inflammatory Prognostic Model Score, L-IPM_{score}), and LASSO regression was applied for machine learning–based model construction (L-IPM_{index}) to predict late N-ICAHT. Model discrimination was assessed using ROC and the DeLong test.
Candidate variables included age, sex, diagnosis, prior HSCT, CRS grade, ICANS grade, IEC-HS, early N-ICAHT grade, and log-transformed peak ferritin, IL-6, and D-dimer levels within 0–30 days. Grade 3–4 late N-ICAHT was used as the dependent variable. Univariate logistic regression was performed, and variables with $p<0.10$ were entered into LASSO regression. The optimal lambda was selected at $\lambda=0.033$ by cross-validation.

Results: The **L-IPM_{score}** was based on four variables assessed within day 0–30 after CAR-T infusion—peak D-dimer, IL-6, ferritin, and early N-ICAHT grade. One point was assigned for each variable exceeding the cutoff (D-dimer ≥5,000 ng/mL, IL-6 ≥168 pg/mL, ferritin ≥2,000 ng/mL, or early N-ICAHT grade 3–4), yielding a total score of 0–4. Patients were categorized as low risk (0–1) or high risk (≥2) for late N-ICAHT by **L-IPM_{score}**. The fitted LASSO model was defined as: 0.427 × (early N-ICAHT Grade) + 0.155 × ln(peak IL-6) + 0.001 × ln(peak ferritin) − 2.330, and was designated as the **L-IPM_{index}**.
Low **L-IPM_{score}** patients (0–1, n=58) were predominantly grade 0–2 late N-ICAHT(91.5%) with only 8.5% grade 3-4 events, whereas high **L-IPM_{score}** patients (≥2, n=77) were enriched for severe toxicity, with grade 3–4 late N-ICAHT in 64.9%. Using the median **L-IPM_{index}** of 0.4185 as the cut-off, low-risk patients (n=67) were predominantly distributed in lower toxicity grades, with 77.7% experiencing grade 0–2 late N-ICAHT. In contrast, high **L-IPM_{index}** patients (n=68) showed a clear shift toward severe toxicity, with 58.8% developing

grade 3–4 late N-ICAHT.
ROC analyses for grade 3–4 late N-ICAHT demonstrated incremental improvement in predictive performance across models. CAR-HEMATOTOX showed modest discrimination (AUC = 0.673, 95% CI 0.583–0.764), comparable to eIPMpre (AUC = 0.689, 95% CI 0.597–0.781). The **L-IPM$_{index}$** exhibited improved accuracy (AUC = 0.728, 95% CI 0.643–0.814). Notably, the **L-IPM$_{score}$** achieved the highest discriminatory ability (AUC = 0.887, 95% CI 0.835–0.938); DeLong's test confirmed significant differences between the **L-IPM$_{score}$** and all other scoring systems (all $p < 0.001$), indicating superior performance in identifying late N-ICAHT.

Characteristics	**Whole Cohort (n=135)**	**Late N-ICAHT 0-2(n=80)**	**Late N-ICAHT 3-4(n=55)**	***P value***	**Characteristics**	**Whole Cohort (n=135)**	**Late N-ICAHT 0-2(n=80)**	**Late N-ICAHT 3-4(n=55)**	***P value***

IMPACT OF TREATMENT SEQUENCE OF GLOFITAMAB AND CAR-T THERAPY ON EFFICACY, SURVIVAL, AND TARGET ANTIGEN EXPRESSION IN RELAPSED/REFRACTORY B-NHL

Yan Gao[1], *Rui Liu*[1], *Zhonghua Fu*[1], *Xuenan Zhang*[1], *Miaomiao Cao*[1], *Yuelu Guo*[1], *Lixia Ma*[1], *Fan Yang*[1], *Biping Deng*[1], *Alex H. Chang*[3], *Xiaoyan Ke*[1], *Kai Hu*[1]
[1]*Beijing GoBroad Hospital, Beijing, China,* [2]*Engineering Research Center of Gene Technology, Ministry of Education, Institute of Genetics, School of Life Sciences, Fudan University, Shanghai, China*

Background: Both CAR-T cell therapy and CD20×CD3 bispecific antibodies (bsAbs) have demonstrated efficacy in relapsed/refractory (R/R) B-cell non-Hodgkin lymphoma (B-NHL). As these immunotherapies are increasingly used in parallel, some patients with suboptimal response or relapse after one therapy may still benefit from the alternative modality. This study investigates how the sequence of CAR-T and bsAb administration influences treatment response, survival, and antigen expression in R/R B-NHL.

Methods: We retrospectively analyzed R/R B-NHL patients treated at Beijing Gaobo Hospital from October 2023 to October 2025. Patients who received bsAb either before CAR-T as bridging/first-line therapy or after CAR-T progression were included. According to treatment sequence, patients were divided into two groups: **Group A (n=19)** received CAR-T first, then bsAb; **Group B (n=11)** received bsAb first, then CAR-T. Outcomes analyzed included objective response rate (ORR), complete response rate (CRR), progression-free survival (PFS), overall survival (OS), and target antigen expression post-treatment.

Results: Among 30 patients, 86.6% were male; median age was 44 years (range 24–75), and 93.3% were stage III–IV. Histologies included DLBCL (n=21), Burkitt lymphoma (n=5), CNSL (n=2), and others (n=2).
Group A (CAR-T → bsAb) had a median follow-up of 18.1 months, with ORR 68.4% (13/19), CRR 42.1% (8/19), median PFS 19.4 months, and median OS 32.8 months.
Group B (bsAb → CAR-T) had a median follow-up of 4.1 months, with ORR 54.5% (6/11), CRR 27.3% (3/11), median PFS 4.4 months, and median OS 8.5 months.
Among patients with paired biopsies, CD19 loss after CAR-T occurred in 20% (2/10), while CD20 loss after bsAb occurred in 100% (5/5).
Prior response to the first immunotherapy significantly affected ORR ($p<0.05$). Patients who responded to the initial therapy achieved an ORR of 86.7% (13/15) after sequential treatment, compared with 40.0% (6/15) in non-responders. Similarly, prior responders showed longer PFS and OS (median PFS 31.1 vs 5.4 months, $p=0.029$; median OS 32.9 vs 7.4 months, $p=0.027$).

Description of CD19/CD20 (immunohistochemistry) status in the two patient sets according to the timing of the biopsy

Characteristic	Group A (CAR-T → bsAb)		Group B (bsAb → CAR-T)	
CD19 status before CAR T-cell Negative Positive	0 17 0 2	0.0% 89.5% 0.0% 10.5%	0 6 5 0	0.0% 54.5% 45.5% 0.0%

Description of CD19/CD20 (immunohistochemistry) status in the two patient sets according to the timing of the biopsy

Not tested Missing				
CD19 status after CAR T-cell Negative Positive Not tested Missing	 1 8 8 2	 5.3% 42.1% 42.1% 10.5%	 1 0 10 0	 9.1% 0.0% 90.9% 0.0%
CD20 status before CD3/CD20 BsAb Negative Positive Not tested Missing	 1 15 1 2	 5.3% 78.9% 5.3% 10.5%	 1 10 0 0	 9.1% 90.9% 0.0% 0.0%
CD20 status after CD3/CD20 BsAb Negative Positive Not tested Missing	 3 0 14 2	 15.8% 0.0% 73.7% 10.5%	 2 0 9 0	 18.2% 0.0% 81.8% 0.0%

Conclusions: The sequence of immunotherapy may influence survival, with CAR-T followed by bsAb potentially providing longer PFS. Bispecific antibody therapy is associated with higher rates of CD20 antigen loss compared to CAR-T–induced CD19 loss, which may contribute to resistance. Patients who initially respond to one immunotherapy may still benefit from the alternative modality upon relapse, supporting sequential treatment strategies in R/R B-NHL.

CD19 CAR-T THERAPY IN TRANSFORMED FOLLICULAR LYMPHOMA: A REAL-WORLD COHORT OF 43 PATIENTS

Rui Liu[1], Zhonghua Fu[1], Miaomiao Cao[1], Lixia Ma[1], Yuelu Guo[1], Fan Yang[1], Biping Deng[2], Alex H. Chang[3], Xiaoyan Ke[1], Kai Hu[1], ***Yan Gao***[1]

Background: Transformed follicular lymphoma (tFL) carries a poor prognosis, particularly after multiple lines of therapy. Although CD19-directed CAR-T therapy has improved outcomes in relapsed/refractory (r/r) large B-cell lymphoma, real-world evidence in tFL—especially data incorporating detailed molecular features—remains limited.

Methods: We retrospectively analyzed 43 pathologically confirmed tFL patients treated with CD19 CAR-T therapy at our center between 2019 and 2025. Baseline characteristics, prior therapies, bridging regimens, safety, treatment response, and molecular findings (IHC/FISH/NGS) were collected. Overall survival (OS) and progression-free survival (PFS) were estimated using the Kaplan–Meier method.

Results: **Baseline characteristics:** The median age was 50 years (range, 26–68), and 53% (23/43) were male. ECOG ≥2 was observed in 30% (13/43). Fourteen patients (33%) were primary refractory, and the median number of prior therapy lines was 3 (range, 2–7).
Bridging therapy: Forty-one patients (41/43) required bridging treatment prior to infusion, with a median of 1 cycle (range, 1–4). Venetoclax-based multidrug regimens were commonly applied; 30/43 received BCL-2 inhibitors and 18/43 received BTK inhibitors.
Molecular features: After transformation, 12/43 showed double-expressor phenotype by IHC. Among 26 patients with FISH testing, 3 had double/triple-hit abnormalities; excluding these, BCL2 rearrangements were present in 8/23. NGS was available for 36/43 patients, with TP53 mutations detected in 19/36.
Median time from FL diagnosis to histologic transformation was 1.83 years (range, 0–13.58). Median MYC expression after transformation was 30% (range, negative–80%), and median Ki-67 was 70% (10%–90%).
Safety: Incidence of CRS of any grade and ≥grade 3 was 34/43 and 5/43, respectively. ICANS occurred in 5/43 patients, with grade ≥3 in 4/43.
Efficacy: At 3 months, ORR and CRR were 56% (24/43) and 47% (20/43), respectively. With a median follow-up of 37.87 months (95% CI, −16.37 to 59.37), 1-year PFS and OS were 45.4% and 66.9%, and 3-year PFS and OS were 41.7% and 63.2%.
Subgroup analyses: When survival was calculated from the date of histologic transformation, 3-year and 5-year OS rates were both 64.7%.
One-year OS for patients with versus without TP53 mutations was 56.4% vs. 76.5% (p=0.433).
One-year OS for patients with versus without BCL2 rearrangement was 45.5% vs. 73.3% (p=0.235).

Conclusions: Despite modest early ORR/CRR, CD19 CAR-T therapy yielded durable long-term survival in this real-world tFL cohort, with a 3-year OS of 63.2%, comparable to—if not exceeding—large international datasets such as CIBMTR. CD19 CAR-T remains an important therapeutic option for heavily pretreated tFL.

Background: Patients undergoing chimeric antigen receptor T-cell (CAR-T) therapy are often treated with antibiotics in the post CAR-T period due to fevers in the setting of cytokine release syndrome. Prior work has suggested that broad spectrum antibiotics in post- and pre-CAR-T period may be deleterious to efficacy and overall survival (OS) in patients with B-cell malignancies. Particularly, PIM (piperacillin-tazobactam, imipenem, meropenem) are implicated with poor outcomes. This relates to dysregulation of gut microbiome and possible hematopoietic impairment. We aimed to investigate the effect of pre- and post-CAR-T antibiotics in patients receiving anti-CD19 and anti-BCMA CAR-T therapy.

Methods: This is a single-center retrospective study of adults with multiple myeloma, B-cell lymphoma, and acute lymphoblastic leukemia treated with CD19 and BCMA targeting CAR-T therapy at our center between April 2017 and August 2024. CD19 products included lisocabtagene maraleucel, tisagenlecleucel, brexucabtagene autoleucel, and axicabtagene ciloleucel. BCMA products included idecabtagene vicleucel and ciltacabtagene autoleucel. Recipients of experimental CAR-T products included as "other". We collected data on pre-CAR-T therapy antibiotic exposure (defined as antibiotics received 30 days pre-CAR-T infusion), post-CAR-T therapy exposure (antibiotics received on day of infusion up to 30 days after). Primary outcomes were progression free survival (PFS) and OS. Secondary outcome was progression at first PET-CT scan. We constructed Cox regression models to model survival outcomes adjusted for age, prior lines of therapy, and infection rate.

Results: Of 329 patients, 96 received anti-CD19 CAR-T, 198 received anti-BCMA CAR-T and 35 were enrolled in trials for experimental products. The median age was 61 with 60% male. Patients receiving anti-CD19 CAR-T were more likely to receive pre-CAR-T antibiotics than patients receiving anti-BCMA CAR-T (17.7% vs. 7.5%, p-value 0.016). Median duration of pre-CAR-T antibiotic was 7 days for CD19 and 8 days for BCMA CAR-T. Majority of patients

received antibiotics post-CAR-T, 83% CD19 patients, 57% BCMA patients, and 66% other products. Patients receiving CD19 were on longer duration of post-CAR-T antibiotics (defined as >5 days versus ≤5 days) than BCMA patients (62.5% vs 42.4%, p-value 0.0026). Median duration of post-CAR-T antibiotics was 7 days for CD19 and 6 days for BCMA. Post CAR-T antibiotics were largely fourth generation cephalosporins such as cefepime, with vancomycin. Few patients received PIM. Median OS with no pre-CAR-T antibiotics was 559 days [IQR 212,973], and 216 days [IQR 91,727] with pre-CAR-T antibiotics. After multivariable adjustment, pre-CAR-T antibiotic exposure was still associated with worse OS (HR 2.52 [1.03,6.16]). Also true for subset analyses: BCMA patients with pre-CAR-T antibiotics had worse OS (HR 2.6 [1.1, 6.3]) as did CD19 (HR 2.45 [1.01,5.9]) than without pre-CAR-T antibiotics. Post-CAR-T antibiotics had no effect on OS. Neither pre nor post-CAR-T antibiotics had statistically significant effect on PFS nor progression at first PET-CT scan.

Conclusions: Exposure to antibiotics in 30 days pre-CAR-T is associated with worse OS, even when adjusted for age, prior lines of therapy, and infection rate. Post-CAR-T antibiotics did not have an effect on PFS, OS or progression at first PET-CT scan. Clinicians should be judicious with antibiotic exposure in the 30 days prior to CAR-T therapy.

Background: Cytokine release syndrome (CRS) is recognized as an early inflammatory complication after haploidentical hematopoietic stem cell transplantation (haplo-HSCT). However, the determinants of CRS, its severity patterns, and the potential contribution of immunogenetic factors remain incompletely defined.
The aim was to evaluate the incidence and risk factors for CRS after haplo-HSCT, focusing on CRS occurrence and its severity. We explored the potential role of PIRCHE score in the graft-versus-host (GvH) and host-versus-graft (HvG) directions and HLA-B leader peptide mismatches, in the development of CRS. We also assessed the impact of CRS on post-transplant outcomes.

Methods: We conducted a retrospective single-center study including 198 consecutive patients undergoing haplo-HSCT. CRS was graded according to ASTCT criteria. Immunogenetic evaluation included calculation of PIRCHE scores in GvH and HvG directions and classification of donor–recipient HLA-B leader peptide genotype and match/mismatch. Logistic regression analyses were performed to identify factors associated with CRS occurrence, grade ≥2 CRS, and early (within 24 hours) grade ≥2 CRS. Post-transplant outcomes were analyzed using competing-risks methodology (Fine–Gray models), with relapse or death treated as competing events. Multivariable models included clinically relevant variables and factors with $p<0.10$ in univariate analyses.

Results: CRS occurred in 76.4% of patients; grade ≥2 CRS and early grade ≥2 CRS were observed in 14.9% and 12.6% of cases, respectively.
In multivariable analysis, reduced-intensity conditioning (RIC) was independently associated with CRS occurrence (OR 3.15, 95% CI 1.46–6.77; p=0.003), whereas recipient CMV seropositivity showed a protective trend.
Grade ≥2 CRS was also independently associated with RIC transplantation (OR 3.51, 95% CI 1.01–12.26; p=0.049), while a TMM donor–recipient HLA-B leader genotype showed a trend toward increased risk (OR 3.84, 95% CI 0.83–17.76; p=0.085).
In the analysis of early grade ≥2 CRS, increasing donor age was independently associated with higher risk (OR 1.04 per year, 95% CI 1.003–1.071; p=0.030), together with specific donor–recipient HLA-B leader mismatches (TMM or MTM pairs; OR 4.49, 95% CI 1.33–15.24; p=0.016). Total PIRCHE score in the GvH (OR 1.01, 95% CI 1.00–1.03; p=0.048) and HvG (OR 1.01, 95% CI 0.99–1.03; p=0.064) directions showed associations in univariate analysis but did not retain statistical significance after multivariable adjustment.
CRS occurrence or severity was not associated with NRM, chronic GVHD, relapse, GRFS, or OS; however, CRS (any grade) was associated with severe acute GVHD (grade 3–4). In a multivariable competing-risks analysis focused on grade 3–4 aGVHD, transplantation from a

sibling donor (vs parent or offspring) independently increased the risk (HR 3.90, 95% CI 1.86–8.18; p=0.0003), whereas CRS occurrence was associated with a significantly reduced risk of severe aGVHD (sHR 0.32, 95% CI 0.16–0.63; p=0.001), and higher PIRCHE-B GvH scores showed a consistent trend toward a lower incidence of severe aGVHD (HR 0.85, 95% CI 0.71–1.00; p=0.051).

Conclusions: CRS is a frequent early complication after haplo-HSCT and is influenced by conditioning intensity, donor age, and immunogenetic factors. The incorporation of PIRCHE scores and HLA-B leader matching suggests that CRS may reflect donor–recipient immunogenicity.

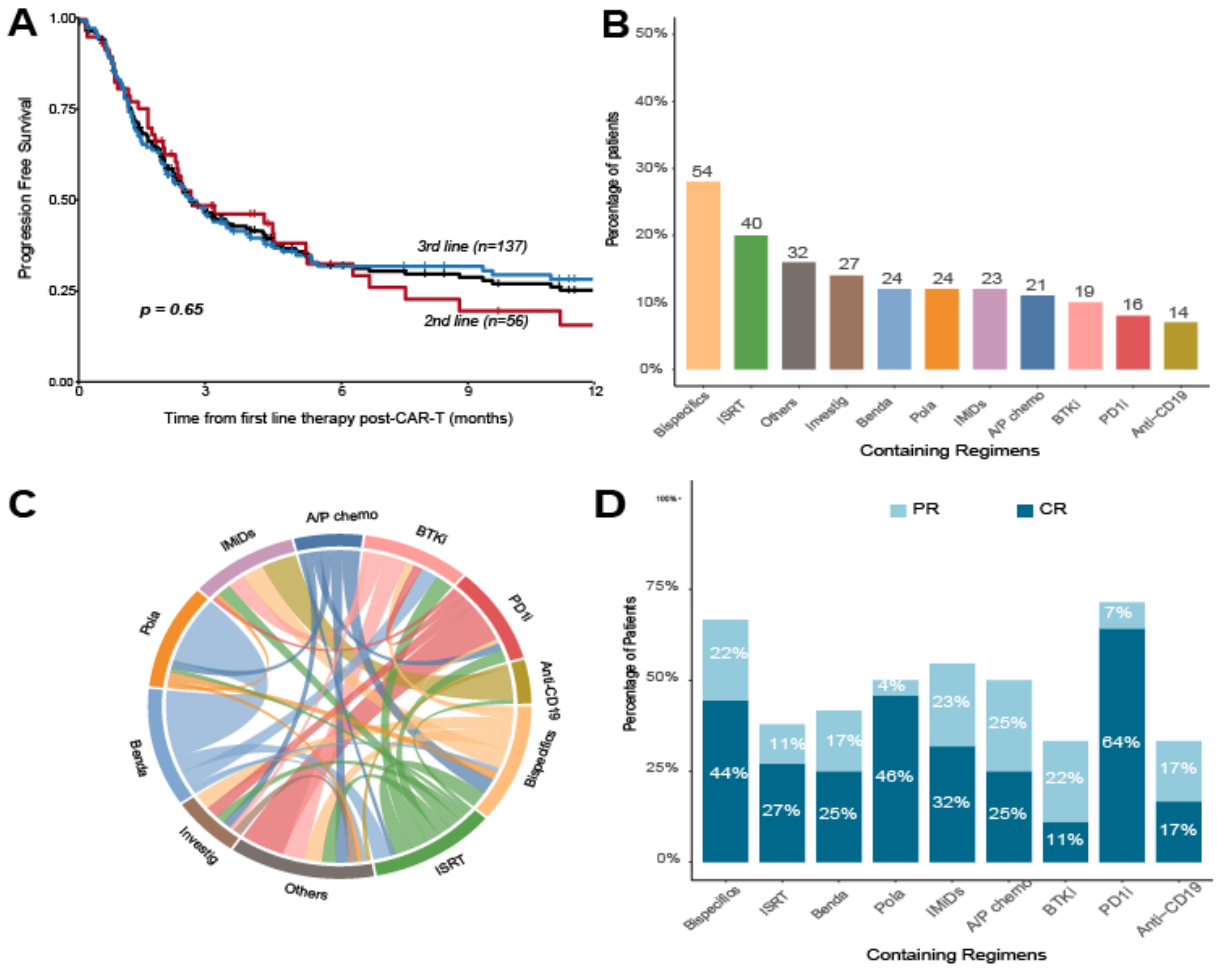
Background: The approval of CD19 chimeric antigen receptor (CAR) T-cell therapy in the second-line setting for large B-cell lymphoma (LBCL) has altered treatment sequencing and

expanded the population at risk for post–CAR-T relapse. However, evidence guiding management after CAR-T failure is largely derived from later-line cohorts. We therefore evaluated outcomes and first salvage strategies in a large international cohort of patients relapsing after early-line CD19 CAR-T therapy.

Methods: We conducted an international, retrospective, multicenter cohort study across five institutions, including adults with LBCL treated with commercial or point-of-care CD19 CAR-T therapy in the second or third-line. Outcomes were assessed from initiation of first salvage therapy. Progression-free survival (PFS) and overall survival (OS) were estimated using Kaplan–Meier methods. Associations between clinical variables and outcomes were evaluated using univariable and multivariable Cox proportional hazards models.

Results: Among 562 LBCL patients treated with CD19 CAR-T therapy, the cumulative incidence of relapse or progression was 41% (95% CI, 37–45). Of the 243 patients who relapsed or progressed, 198 (81%) received salvage therapy. In the salvage-treated cohort, median age was 65 years (IQR, 54–73). Prior CAR-T exposure included axicabtagene ciloleucel (51%), isoantigenic maraleucel (24%), tisagenlecleucel (22%), and point-of-care products (4%); 70% had received CAR-T therapy in the third-line setting.
The overall response rate (ORR) to first salvage therapy was 50%, including 34% complete and 16% partial responses. With a median follow-up of 25 months (IQR, 10–43), 1-year OS and PFS after salvage were similar between patients who received CAR-T therapy in the second versus third-line (OS, 42% vs 44%, p=0.93; PFS, 18% vs 28%, p=0.80; **Fig. 1A**). In multivariable analyses adjusting for age, CAR-T product, time from CAR-T to relapse or progression, and pre-salvage LDH, CAR-T treatment line was not associated with OS, PFS, or response. In contrast, relapse or progression within 3 months of CAR-T therapy was strongly associated with inferior PFS (HR, 3.03; 95% CI, 1.7–5.2).
Post–CAR-T salvage strategies were heterogeneous (**Fig. 1B–C**), most commonly including bispecific antibodies (n=54), involved-site radiotherapy (n=40), bendamustine-based therapy (n=24), and polatuzumab-containing therapy (n=24); treatment categories were not mutually exclusive. Response rates varied by treatment component, with the highest ORR observed among patients receiving checkpoint inhibitor–based therapy (71%) and bispecific antibody–containing therapy (66%) (**Fig. 1D**). One-year OS, analyzed by treatment component exposure, was highest in patients treated with checkpoint inhibitors (67%), followed by bispecific antibodies (57%), and lowest among those receiving anthracycline- or platinum-based therapy (21%). Despite these differences, EFS remained modest across approaches, ranging from 42% with bispecific antibody–containing therapy to 5% with bendamustine- or anthracycline/platinum-based therapy.



Conclusions: In this large multicenter cohort of LBCL patients relapsing after early-line CD19 CAR-T therapy, salvage treatment achieved clinically meaningful responses regardless of prior CAR-T treatment line. Early post–CAR-T relapse identified a high-risk subgroup with poor outcomes. Immunotherapy-based salvage strategies showed the most favorable activity, supporting their preferential consideration and underscoring the need for prospective studies to optimize post–CAR-T treatment sequencing.

INCIDENCE OF SINUSOIDAL OBSTRUCTION SYNDROME (VOD/SOS) DIAGNOSED BY DOPPLER ULTRASOUND/LIVER ELASTOGRAPHY IN PATIENTS AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Anne-Béatrice Notarantonio[1], Emilie Darche[1], Arnaud Campidelli[1], Stephane Morisset[2], Camille Malbrun[1], Adèle Dhuyser[1], Michaël Peres[1], Laura Boulange[3], Céline Kicki[1], Gabrielle Roth-Guepin[1], Caroline Bonmati[1], Simona Pagliuca[1], Nathalie Hottier[1], Caroline Garnier[1], Pierre Feugier[1], Alice Aarnink[1], Caroline Laroye[1], Véronique Decot[1], Alix Martin-Berteaux[1], Marie Detrait[1], Marie-Thérèse Rubio[1], ***Maud D'Aveni-Piney***[1]
[1]*CHRU Nancy, Vandoeuvre-Les-Nancy, France,* [2]*., Perouges, France,* [3]*IMOPA, Vandoeuvre-Les-Nancy, France*

Background: Sinusoidal Obstruction Syndrome (SOS) is a rare but potentially life-threatening complication following allogeneic hematopoietic stem cell transplantation (allo-HSCT). While ultrasound and liver elastography contribute to the early diagnosis of SOS, their predictive value in the pre-transplant setting remains unclear.

Methods: We conducted a real-world, single-center study between January 2017 and December 2024 in patients undergoing allo-HSCT at the University Hospital of Nancy. The primary objective was to assess the association of pre-transplant ultrasound and color Doppler (US-Doppler) according to Lassau criteria, as well as Liver Stiffness Measurement (LSM), with the subsequent development of SOS. Secondary objectives included evaluating the incidence and severity of SOS and its impact on patient outcomes.

Results: A total of 431 patients were included, and pre-transplant US-Doppler with LSM was performed in 347. The cumulative incidence of SOS at day 120 was 8.35% (n = 36; 95% CI, 5.74–10.97), with a median time to onset of 12 days (range, 1–119). According to the 2023 European Society for Blood and Marrow Transplantation (EBMT) diagnostic criteria, 21 patients developed severe SOS and 7 developed very severe SOS. Twenty-nine patients received defibrotide, with a median treatment duration of 21 days (range, 3–60). The median duration of intensive care unit stay among patients with very severe SOS was 13 days (range, 3–34). In univariate analysis, beyond the classical clinical parameters associated to a higher risk of SOS, pre-transplant US-Doppler and LSM were also associated with an increased risk of SOS. In multivariate analysis, the main pre-transplant risk factors significantly associated with SOS were the presence of ≥3 US-Doppler criteria (HR, 4.06; 95% CI,1.14–14.48; p = 0.031) and mean pre-transplant liver stiffness ≥7.5 kPa (HR, 2.74; 95% CI, 1.20–5.92; p = 0.012). SOS incidence was 8.81 fold increased in patients with both LSM≥ 7.5 kPa and ≥3 US-doppler SOS criteria at baseline (n=8) compared to patients with LSM <7.5 kPa and less than 3 US-doppler criteria.

Conclusions: Pre-transplant liver assessment using US-Doppler and LSM is significantly associated with subsequent SOS development, suggesting that these non-invasive approaches may serve as valuable predictive biomarkers. Prospective validation in larger multicenter studies is warranted.

[1]*Fred Hutch Cancer Center, Seattle, United States of America (the),* [2]*University of Washington, Seattle, United States of America (the),* [3]*Mayo Clinic Rochester, Rochester, United States of America (the),* [4]*Karmanos Cancer Center, Michigan, United States of America (the),* [5]*Stanford Medicine, Stanford, United States of America (the),* [6]*Oregon Health & Science University, Portland, United States of America (the),* [7]*University of California San Francisco, San Francisco, United States of America (the),* [8]*Cleveland Clinic, Cleveland, United States of America (the),* [9]*University of Minnesota, Minneapolis, United States of America (the),* [10]*Baylor College of Medicine, Houston, United States of America (the),* [11]*Vanderbilt University Medical Center, Nashville, United States of America (the),* [12]*Northwell School of Medicine, Hyde Park, United States of America (the)*

Background: Patients (pts) with hematopoietic cell transplantation comorbidity index (HCT-CI) scores of ≥3), older age (≥65 years), and/or who are frail per gait speed (<0.8 meters/second) have increased morbidity and mortality after allo-HCT compared to younger and healthier counterparts. We report results of a seamless phase II/III prospective, randomized clinical trial conducted at 11 transplant centers to test new approaches to improve quality of life (QOL) in this pt population.

Methods: Phase II compared peri-transplant specialist-administered supportive and palliative care (SPC), peri-transplant patient-administered management of comorbidities (MC, e.g. physical exercise, stress reduction, education, and as needed cardio-pulmonary rehabilitation as needed), both (SPC+MC), and usual care (UC) for change in Functional Assessment of Cancer Therapy – Bone Marrow Transplantation (FACT-BMT) scores from baseline to day 90 (D90). Pts deceased prior to D90 were assigned FACT-BMT score=0. The winning phase II arm (the experimental arm with the best change in FACT-BMT from baseline to day 90) moved forward versus UC in phase III. Interventions started within 2 weeks before day 0 and continued for a total of 10 weeks each. Patients received weekly reminders for the MC arm. We calculated FACT-BMT Trial Outcome Index (TOI) for all patients and total scores for a subset of patients with available data for all 5 subscales. Clinicaltrials.gov #: NCT03870750

Results: Phase-II was completed after enrolling 35 pts to each of the 4 study arms. Calculating the difference between FACT-BMT scores on D90 minus baseline, excluding missing data, indicated that SPC resulted in a small improvement in QOL compared to either MC or SPC+MC (Table 1); hence SPC was deemed the winning phase II arm and moved forward to Phase III.
Phase-III planned interim analysis was conducted after enrolling 158 SPC pts and 153 UC pts. The SPC and UC arms were well balanced with median age (both 68 years), HCT-CI ≥3 (49% vs 55%), frailty per gait speed (13% vs 12%), female sex (41% vs 34%), non-white race (9.5% vs 11.5%), and Hispanic or unreported ethnicity (7.7% vs 5.7%), respectively. After median follow-up of 362 days, 45 pts had died in each arm.
The mean QOL difference between baseline and D90 FACT-BMT TOI scores was 2.83 for SPC and 4.27 for UC (difference of differences, -1.44, 95% CI of difference, -5.03 to 2.14, p=0.43). Similar findings (p=0.92) were seen when using total scores in a subset (n=204) of pts. Fitting a generalized linear model that included baseline, D30, and D90 values, without assigning a value of 0 to those who died before D90, and testing the null hypothesis that the slope of scores differed between SPC and UC resulted in p=0.85 for TOI scores and p=0.98 for total scores. Comparison of mortality yielded a hazard ratio of 1.13 [0.75-1.73] for SPC vs. UC (Figure).

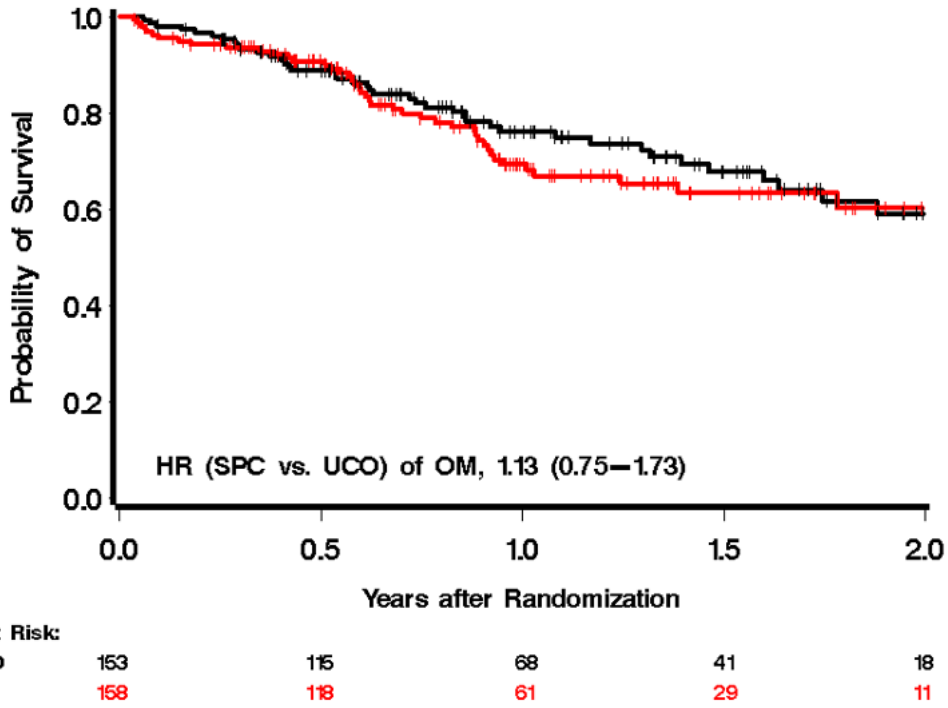
Table 1: Change in FACT-BMT (baseline value minus D90 value) comparing the 4 arms of phase II.

Group	Mean difference (SD)	Median difference (range)
SPC (n=28)	2.93 (28.52)	-0.25 (-38.22 to 100)

CM (n=18)	18.37 (33.80)	9.50 (-11 to 98.33)
SPC+CM (n=27)	15.76 (32.69)	7.67 (-32 to 90)

SPC – Supportive and Palliative Care
CM – Comorbidity management
SD – standard deviation

Figure. Kaplan Meier survival curve comparing Supportive and Palliative Care (SPC) and Usual Care Outcome (UCO).



Conclusions: Specialist-administered SPC showed no meaningful improvement in D90 QOL, nor a survival advantage, compared to UC in older, comorbid, and/or frail allo-HCT recipients, resulting in the cessation of this Phase II/III trial. Different approaches to use SPC for patient support during allo-HCT are needed.

POST-TRANSPLANT CYCLOPHOSPHAMIDE DOSE REDUCTION ENABLES FASTER GRANULOCYTE ENGRAFTMENT WHILE MAINTAINING EFFICACY IN PREVENTING GVHD

Václav Heřman[1,2], *Veronika Válková*[1,2], *Barbora Čemusová*[1], *Ludmila Nováková*[1], *Jan Vydra*[1,2]
[1]*Institute of Hematology and Blood Transfusion, Prague, Czechia,* [2]*Charles University, First Faculty of Medicine, Prague, Czechia*

Background: Post-transplant cyclophosphamide (PTCy) is an established strategy for the prophylaxis of graft-versus-host disease (GVHD) following allogeneic hematopoietic stem cell transplantation (allo-HSCT). While the standard high-dose regimen (100mg/kg) is widely used, non-negligible toxicity prompts evaluation of reduced-dose regimens.

Methods: We retrospectively analysed data from 367 consecutive adult recipients of first allo-HSCT at the Institute of Hematology and Blood Transfusion in Prague between 1/2018 and 6/2025, who received post-transplant cyclophosphamide (together with cyclosporin and mycophenolate-mofetil) as GVHD prophylaxis. Based on previous reports and preliminary data, we have reduced PTCy dose in all patients undergoing HSCT from 2x50mg/kg to 2x35mg/kg since 6/2024 with the aim of decreasing toxicity while maintaining efficacy. Endpoints included cumulative incidence of neutrophil and platelet engraftment, acute and chronic GVHD, relapse, non-relapse mortality (NRM), overall (OS) and disease-free survival (DFS). Comparisons used appropriate statistical tests, including competing-risk methods for cumulative incidence (CI) analyses; survival was evaluated by the Kaplan-Meier method. Multivariate analysis was performed to adjust for baseline differences.

Results: Baseline characteristics differed between the 70 mg/kg group (n = 60) and the 100mg/kg group (n = 307)—the 70mg/kg group was older (mean age 53 vs 48 years, p = 0.005), had a higher comorbidity burden (HCT-CI > 2 in 38% vs 24%, p= 0.04), and a different donor composition (more matched related donors—12% vs 0.3%, fewer haploidentical donors—18% vs 32%; p < 0.001). The 70 mg/kg cohort achieved a significantly shorter time to neutrophil engraftment (median 18.5 vs 21 days), confirmed with competing-risk cumulative incidence analysis (p < 0.001). Median time to platelet engraftment was also shorter in the 70mg/kg cohort (18 vs 20 days), however, competing risks analysis did not show significant difference (60-day CI of 95% vs 93.2%; p = 0.128). We did not find any significant differences between the 70mg/kg and 100mg/kg cohorts in cumulative incidence of acute GVHD (120-day CI of 48,3% vs 44,6%; p = 0.426) or chronic GVHD (1-year CI of 34,5% vs 28%; p = 0.61). Cumulative incidence of relapse was numerically lower with PTCy 70mg/kg but did not reach statistical significance (1-year CI of 11% vs 22%; p = 0.071). NRM was similar between groups (p = 0.802). OS and DFS curves were comparable between both groups (1-year OS of 87% vs 80%; p = 0.2; 1-year DFS of

78% vs 69%; p = 0.16). In multivariate analysis, no variable—including age, HCT-CI, or donor type—was significantly associated with an increased risk of death.

Conclusions: In this retrospective analysis, reduced-dose PTCy (70mg/kg) for GVHD prophylaxis demonstrated comparable efficacy to standard-dose PTCy (100mg/kg) in terms of GVHD prevention, relapse incidence, NRM, and survival outcomes, despite being administered to an older and higher-risk patient population. Reduced-dose PTCy (70mg/kg) was associated with faster neutrophil engraftment. These findings support the feasibility of PTCy dose reduction to 70mg/kg without compromising key clinical outcomes and suggest potential benefits for early hematologic recovery. Prospective studies are warranted to validate these results and to clarify the optimal PTCy dosing.

Garrahan", Buenos Aires, Argentina,* [13]*University Hospital Motol, Department of Pediatric Hematology and Oncology, Prague, Czechia,* [14]*Agia Sofia Children's Hospital, Stem Cell Transplant Unit, Athens, Greece,* [15]*Oslo University Hospital, Department of Pediatric Hematology and Oncology, Oslo, Norway*

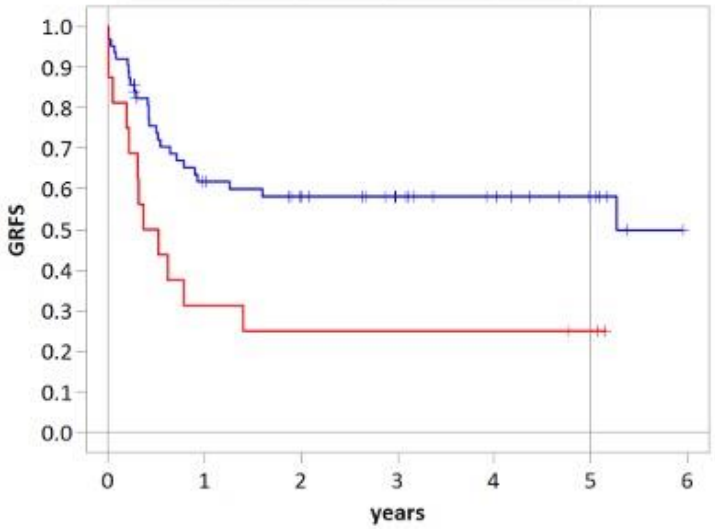
Background: The prognosis of relapsed T-acute lymphoblastic leukemia (T-ALL) remains poor. Few innovative targeted therapies or immunotherapies are available in this setting in contrast to B-ALL. The indication for allogeneic hematopoietic stem cell transplantation (HSCT) is broader in T-ALL : high-risk patients in first complete remission (CR) and almost all patients in CR2. Evaluating the toxicity and efficacy of this procedure is crucial for defining the best standard of care for these patients.

Methods: We report results of the prospective international FORUM-1 study (NCT01949129) of T-ALL patients treated with TBI-etoposide or myeloablative Busulfan or Treosulfan based

regimens according to age (≤ or > 4 years) or remission status before HSCT (CR1 or CR2 or later).

Results:

conditioning	Patients	3-yrs EFS	3-yrs GRFS	3-yrs OS
TBI	63	0.67±0.06	0.58±0.06	0.72±0.06
CHEMO	16	0.31±0.12	0.25±0.11	0.38±0.12
p-value		0.010	0.014	0.005



Between 2013 and October 2025, 392 T-ALL patients received HSCT from an HLA-identical sibling donor (MSD) or 9-10/10 HLA-compatible matched unrelated donor (MD).
Among 38 patients ≤4 years old, 5 (13%) received TBI-etoposide (all >2 years old) and 87% were in CR1. At 3 years, the EFS and OS were 66% and 73% respectively with a CI-NRM of 5% and a CIR of 29%.
Among the 231 patients > 4 years old in CR1, at a median age of 10.2 years (4.1-18.6), 157 (68%) received TBI-etoposide. At 3 years, the EFS and OS were 76% and 78% respectively with a CI NRM of 7% and CIR of 16%. There was no difference in EFS, OS, GRFS, CI-NRM or CIR according to type of donor nor conditioning (3y EFS 76% vs 74% and OS 77% vs 77% respectively in TBI-etoposide vs chemo-conditioning group).
Among the 84 patients > 4 years old in CR2 or later, at a median age of 10.3 years (4-19.5), 67 (80%) received TBI-etoposide. The timing of relapse was distributed as follows: very early 38%, early 27%, late 30%. At 3 years, the EFS and OS were 60% and 65% respectively with a GRFS of 52%, a CI-NRM of 13% and CIR of 26%. There was no significant difference in EFS, OS, GRFS, CI NRM or CIR according to donor type or site or timing of the previous relapse. In contrast, there was a significant superiority of TBI-etoposide over chemo-conditioning for 3 year-EFS (67% vs 31%, p-value=0.01), OS (72% vs 38%, p-value=0.005), GRFS (58% vs 25%, p-value=0.014) and CIR (19% vs 56%, p-value=0.002) but no difference in CI NRM (14% vs 13%).
Of note, no significant difference in the number of patients with viral infection, SOS incidence or acute GvHD was identified between patients receiving HSCT in CR1 or CR2.

Conclusions: Allo HSCT allows cure of many patients with T-ALL, especially when transplanted in CR1. Use of TBI in combination with etoposide must be preferred in patients with ≥CR2. In patients transplanted in CR1, chemo-based conditioning achieved similar survival outcome as TBI-etoposide.

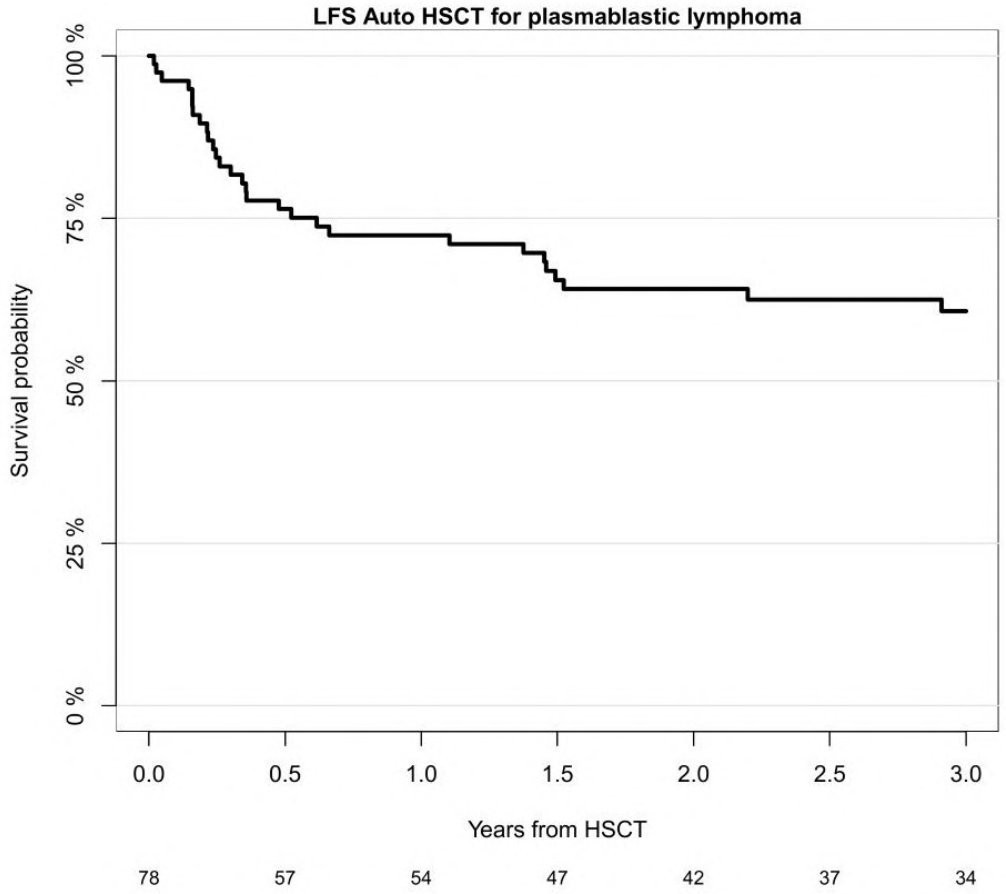
Program, Department of Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon

Background: PBL is a rare form of aggressive B-cell lymphoma. PBL lacks classic B-cell markers but expresses plasmacytic markers. It is commonly associated with HIV infection. The first-line therapy most commonly consists of CHOP chemotherapy, although long-term remission can only be achieved in a minority of patients. Due to its aggressive clinical course, autoHCT is often performed as consolidation therapy after first-line or salvage therapy. However, this practice is currently supported only by small retrospective analyses which, however, show encouraging outcomes. We therefore aimed to study the outcome of PBL after autoHCT for the first time on a reasonable sample size.

Methods: This EBMT registry analysis included adult patients who underwent a first autoHCT for PBL between 2016 and 2022. Diagnostic reports were collected for all patients and were grouped by an expert pathologist according to diagnostic certainty: high, moderate or low. Criteria for high certainty were (1) PBL diagnosis explicitly indicated in the report, (2) site of biopsy compatible with PBL, and (3) absence of CD20 and/or the presence of EBV. Statistical analysis was descriptive, employing univariate and multivariate comparisons to assess the impact of baseline characteristics on survival endpoints.

Results: A total of 78 patients with diagnostic reports meeting high/moderate/low certainty were included. Eighty-three per cent were male, and 32% were HIV-positive. Median age was 51 years (range 23 - 74). AutoHCT was performed after first-line therapy in 56% of patients and after second-line therapy in 32% of patients. The majority of patients were in partial (40%) or complete (55%) remission prior to autoHCT. Conditioning was performed according to BEAM or similar protocols in 73% of the patients. Diagnostic certainty was high in 45% and moderate in 23% of patients. After a median follow-up of 4.5 years, 2-year rates of OS, lymphoma-free survival (LFS), relapse incidence (RI), and non-relapse mortality (NRM) were 79%, 64%, 31%, and 5%, respectively (Figure 1).



Notably, on multivariate analysis, relapse incidence tended to be lower in HIV-positive patients (hazard ratio (HR) 0.35; 95% CI 0.1–1.25). Age, sex, and lines of treatment did not correlate with disease-related outcomes. Neither baseline characteristic correlated with NRM. 2-year LFS and RI in patients with high, moderate, and low diagnostic certainty were 68%, 55%, and 42% (p=0.151); and 20%,34%, and 50% (p=0.105), respectively.

Conclusions: This first large analysis on autologous transplantation in patients with PBL suggests markedly favorable disease control of consolidative autoHCT, contrasting the often limited potential of standard lymphoma-type induction in this entity. This notion is supported by the observation that autoHCT efficacy seems to correlate with diagnostic certainty. In line with previous very preliminary reports, our analysis supports the use of autoHCT in eligible patients with PBL.

EXCELLENT OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR PEDIATRIC AND ADULT NUP98-REARRANGED ACUTE MYELOID LEUKEMIA: A SINGLE-CENTER REAL-WORLD STUDY

Baiqing Sun[1], *Xing-yu Cao*[1,2], *Zhi-jie Wei Wei*[1,2], *Jia-rui Zhou*[1,2], *De-yan Liu*[1,2], *Min Xiong*[1,2], *Yan-li Zhao*[1,2], *Rui-juan Sun*[1,2], *Jian-ping Zhang*[1,2], *Yue Lu*[1,2]
[1]*Hebei Yanda Lu Daopei Hospital, Langfang, China,* [2]*Beijing Lu Daopei Hospital, Beijing, China*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is an effective and curative treatment for NUP98-rearranged acute myeloid leukemia (NUP98-r AML). However, prognostic factors following allo-HSCT remain poorly defined.

Methods: We retrospectively analyzed pediatric and adult patients with NUP98-r AML confirmed by RT-PCR who underwent allo-HSCT between January 2021 and December 2024. Minimal residual disease (MRD) was monitored pre- and post-HSCT using multiparameter flow cytometry (MFC) and RT-PCR.

Results: Among 86 included patients (4.61% of all AML transplants during the period), 44 (51.16%) were pediatric. Median age was 15 years (range 0.83–59). At diagnosis, 23 patients (26.74%) had white blood cell counts ≥100×10⁹/L. Nine fusion partners were identified, most commonly NSD1 (61.63%), followed by HOXA9 (18.60%), with HOXA9 more frequent in adults than children (28.5% vs. 9.0%, P=0.005). Co-mutations included FLT3-ITD (56.98%) and WT1 (52.33%). According to cytogenetic risk stratification, 70.93% were high-risk. Pre-HSCT, 67.44% were in complete remission (CR); among these, 75.86% were MRD-positive by both MFC and NUP98-r. HCT-CI score was ≥1 in 54.65%. Donors were haploidentical donor in 83.72%. BU-based Myeloablative conditioning (MAC) was used in 88.37% the remaining was TBI-based MAC. Post-transplant NUP98-r positivity rates were 40.70%, 9.30%, and 3.49% at 1, 2, and 3 months, respectively. After a median follow-up of 29.2 months, 2-year overall survival (OS), leukemia-free survival (LFS), cumulative incidence of relapse (CIR), and non-relapse mortality (NRM) were 85.12%, 84.80%, 8.08%, and 8.95%, respectively, with no significant differences between adults and children. Multivariate analysis identified non-remission (NR) pre-HSCT as an independent predictor of inferior OS (HR 3.31, P=0.023) and LFS (HR 2.73, P=0.031). NUP98-r positivity at 1 month post-HSCT was associated with worse OS (HR 5.54, P=0.03) and LFS (HR 4.82, P=0.017); positivity at 2 months with inferior LFS (HR 3.91, P=0.039); and positivity at 3 months with poorer LFS (HR 7.59, P=0.009) and higher CIR (HR 19.45, P<0.001). In the CR subgroup, dual-positive MRD (MFC and NUP98-r) pre-HSCT predicted worse OS (HR 6.11, P=0.037), LFS (HR 10.10, P=0.005), and CIR (HR 13.02, P=0.016). Among pediatric patients, NR pre-HSCT correlated with inferior OS (HR 5.62, P=0.047). In adults, TBI-based versus BU-based MAC was associated with poorer OS (HR 17.05, P<0.001), LFS (HR 9.21, P=0.002), and higher NRM (HR 30.62, P<0.001).

Conclusions: Allo-HSCT yields encouraging outcomes in NUP98-r AML, with no survival difference between pediatric and adult patients. Pre-HSCT NR status and early post-HSCT detection of NUP98-r are strongly associated with poorer prognosis. Among CR patients, dual MRD positivity before transplant further identifies a high-risk subgroup. In adults, TBI-based MAC may confer inferior survival outcomes compared to BU-based regimens.

Clinical Trial Registry: NO

Disclosure: Nothing to declare.

Background: Acute myeloid leukemia (AML) featuring NUP98 gene fusions resulting from chromosomal rearrangements at 11p15 is recognized as a high-risk subtype. Given the low incidence of these genetic abnormalities in AML, the therapeutic value of allogeneic hematopoietic cell transplantation (allo-HCT) in this population has not been clearly established.

Methods:

We retrospectively analyzed 147 AML patients with NUP98 fusions or 11p15 rearrangements undergoing first allo-HCT. Data were contributed by 87 EBMT-affiliated centers between 2010 and 2022.

Results:

The cohort included 109 adult patients (median age at transplantation: 46.3 years, range 18.1–73.5) and 38 pediatric patients (median age: 9.4 years, range 0.4–18). In adults, the most common fusions were NUP98-NSD1 (24.8%) and NUP98-HOXA9 (19.3%); in children, NUP98-NSD1 predominated (68.4%), followed by NUP98-KDM5A (13.2%). At transplantation, 112 patients were in CR1, 14 in ≥CR2, and 21 had active disease. CR1 rates were 72.5% in adults vs. 86.8% in children (P=0.04), with active leukemia in 18.3% of adults vs. 2.6% of children. Myeloablative conditioning was used in 67.1% overall, more frequently in children (89.5%) than adults (59.3%; P<0.001).

Donors comprised haploidentical relatives (n=30), HLA-matched siblings (n=34), unrelated donors (n=68; 44 fully matched 10/10, 15 mismatched 9/10, 1 mismatched 8/10, 8 incomplete typing), cord blood (n=12), other matched relatives (n=2), and one-locus mismatched relatives (n=1). Peripheral blood stem cells were the primary source in adults (n=88), whereas bone marrow predominated in children (n=22), followed by peripheral blood (n=8) and cord blood (n=8).

Median follow-up was 2.9 years (95% CI, 2–3.5). Day-30 neutrophil engraftment rate was 93.0% (95% CI, 87.2–96.2; 95.2% adults, 86.5% children). Two-year overall survival (OS) was 69.9% (95% CI, 60.3–77.6), leukemia-free survival (LFS) 52.0% (95% CI, 42.6–60.7), and GVHD-free/relapse-free survival (GRFS) 40.6% (95% CI, 31.4–49.6). Two-year relapse incidence (RI) was 39.1% (95% CI, 30.1–48.0) and non-relapse mortality (NRM) 8.9% (95% CI, 4.8–14.4). Day-100 cumulative incidence of grade II–IV acute GVHD was 22.6% (95% CI, 16.1–29.7; grade III–IV, 9.9% [95% CI, 5.7–15.5]). Two-year chronic GVHD incidence was 23.2% (95% CI, 16.0–31.3), including extensive disease in 8.2% (95% CI, 3.9–14.3).

Univariate analysis revealed trends favoring pediatric patients: 2-year OS 78.7% (95% CI, 60.2–89.3) versus 66.4% (95% CI, 54.5–75.8) in adults (P=0.16); LFS 55.8% versus 50.6% (P=0.65); RI 41.6% versus 38.2% (P=0.58); NRM 2.6% versus 11.1% (P=0.10). Grade II–IV acute GVHD occurred in 13.2% of children versus 26.0% of adults (P=0.11; grade III–IV, 7.9% vs. 10.6%; P=0.63). Chronic GVHD was significantly lower in children (9.6% vs. 28.3%; P=0.045), with no extensive cases versus 11.3% in adults (P=0.14). GRFS was 52.1% in children versus 36.1% in adults (P=0.28). Transplantation with active disease was associated with inferior LFS, higher RI, and worse GRFS, whereas myeloablative conditioning correlated with superior 2-year OS.

Conclusions: This represents the most extensive series to date examining allo-HCT outcomes in NUP98-rearranged AML, encompassing both adult and pediatric cases from this uncommon subgroup. Allo-HCT appears to offer a valuable curative approach for individuals with NUP98-rearranged AML.

Disclosure: Nothing to declare.

IMPORTANCE OF GRAFT COMPOSITION ON EBV REACTIVATION RISK FOLLOWING MODERN GVHD PROPHYLAXIS

Stéphanie Thiant[1], Simon Dufresne[1,2], Imran Ahmad[1,2], Sandra Cohen[1,2], Jean-Sébastien Delisle[1,2], Omar Eduardo Fernandez-Vargas[1,2], Thomas Kiss[1,2], Silvy Lachance[1,2], Denis-Claude Roy[1,2], Olivier Veilleux[1,2], Léa Bernard[1,2], Daiana Gisela Rodriguez[1,2], Guy Sauvageau[1,2], ***Jean Roy***[1,2]
[1]Institut Universitaire d'Hémato-Oncologie et de Thérapie Cellulaire, Hôpital Maisonneuve-Rosemont, Montréal, Canada, [2]Faculty of Medicine, Université de Montréal, Montréal, Canada*

Background: Epstein-Barr virus (EBV) reactivation is a frequent complication after allogeneic (allo) hematopoietic cell transplantation (HCT) and can lead to post-transplant lymphoproliferative disorder (PTLD). While anti-thymocyte globulin (ATG) and post-transplant cyclophosphamide (PTCy) are well-established prophylactic strategies to prevent graft-versus-host disease (GVHD), their comparative impact on EBV reactivation remains insufficiently characterized.

Methods: We conducted a retrospective single-center study in consecutive recipients of allo HCT from a matched related/unrelated, mismatched unrelated or haploidentical donor between January 1, 2019, and December 31, 2024. Patients received either rabbit ATG or

post-transplant cyclophosphamide for GVHD prophylaxis. Primary endpoints were cumulative incidences of positive EBV DNAemia and high level EBV DNAemia (≥ 10^4 copies/mL) by month +6, measured using a whole blood quantitative PCR weekly from D+14 to D+100 then every 2 weeks. Secondary endpoints were incidence of probable/proven PTLD at 2 years, acute GVHD at 6 months, chronic GVHD and non-relapse mortality, as well as overall (OS), and progression-free survival (PFS). We also assessed risk factors for EBV DNAemia. Data on graft cellular content, engraftment, immune reconstitution, CMV reactivation and humoral response to post-transplant hepatitis B revaccination were also analysed.

Results: A total of 286 adults patients were included (Table 1). Of these, 215 patients received ATG and 71 PTCy. High-level EBV DNAemia occurred more frequently in the ATG group (74.9% vs. 49.3%, $p < 0.0001$), particularly at higher doses (4.5 vs. 2.5 mg/kg). In ATG recipients, high CD19+ B-cell doses (≥ 3.88 x 10^7/kg) and an elevated CD19+/CD8+ ratio (≥ 0.84) in grafts were independently associated with the cumulative incidence of high EBV DNAemia, a relationship not observed with PTCy (Figure 1). We observed no PTLD in the PTCy group while, 5 cases occurred in ATG recipients, 4 of whom had received a graft with a high CD19+/CD8+ ratio. In multivariable analysis, use of ATG (HR 3.0; 95%CI 1.6-5.7; p = 0.00084) and an elevated CD19+/CD8+ ratio in the graft (HR = 2.08; 95%CI: 1.4-3.1; p = 0.00025) emerged as the strongest independent predictors of high EBV DNAemia. ATG-treated patients exhibited delayed $CD4^+$ T-cell reconstitution and prolonged $CD4^+/CD8^+$ ratio inversion. Rituximab (RTX) had no impact on OS or PFS but was associated with sustained B-cell depletion, hypogammaglobulinemia, impaired hepatitis B immunity after vaccination with less patients achieving protective anti-HBsAg antibody levels (≥ 10 IU/mL) (p = 0.0176) and reduced anti-HBsAg antibody titers (p = 0.0064).

Table 1. Epstein-Barr virus related outcomes

		ATG N=215 (%)	PTCy N=71 (%)	p-v
EBV DNAemia at +6 months (copies/mL)	Any	161 (74.9)	35 (49.3)	0.00
	< 10 000	86 (40.0)	16 (22.5)	
	10 000 - 50 000	57 (35.4)	12 (16.9)	
	50 001 - 100 000	11 (6.8)	2 (2.8)	
	> 100 000	18 (11.2)	2 (2.8)	
Onset of EBV ≥10^4 copies/mL	Median time, days post HCT (range)	36 (17-165)	86 (39-109)	<0.00
EBV treatment	None	83 (38.6)	18 (51.4)	0
	RTX 1-4 doses	78 (36.4)	17 (48.6)	
	Median time of RTX in months (range)	1.7 (1.1-5.9)	3.6 (1.6-5.3)	<0.00

EBV outcome (among those with EBV reactivation)	Spontaneous resolution	82 (50.9)	15 (42.9)	
	Resolved following RTX[1]	76 (47.2)	16 (45.7)	0.00
	Stable[2]	0	4 (11.4)	
	Progression or death prior evaluation	3 (1.8)	0	
PTLD	Any (polymorphic/monomorphic)	5 (2.2)	0	0
	Median time of response, days (range)	40 (27-55)	NA	N
6 years survival post RTX	OS with RTX (95%CI)	64.2 (43.7-78.9)	80.7 (51.1-93.4)	0
	OS with no RTX (95%CI)	73.9 (63.4-81.9)	69.0 (48.5-82.7)	0
	PFS with RTX (95%CI)	58.3 (41.2-71.9)	63.9 (53.9-72.3)	0
	PFS with no RTX (95%CI)	75.6 (47.3-90.1)	66.6 (47.9-79.9)	0

p-values calculated using Fisher's exact test (categorical variables) and the Mann–Whitney U test (continuous variables).

[1] # of viral copies = 0 is considered as resolved.[2] # of viral copies remained the same ±

15%.

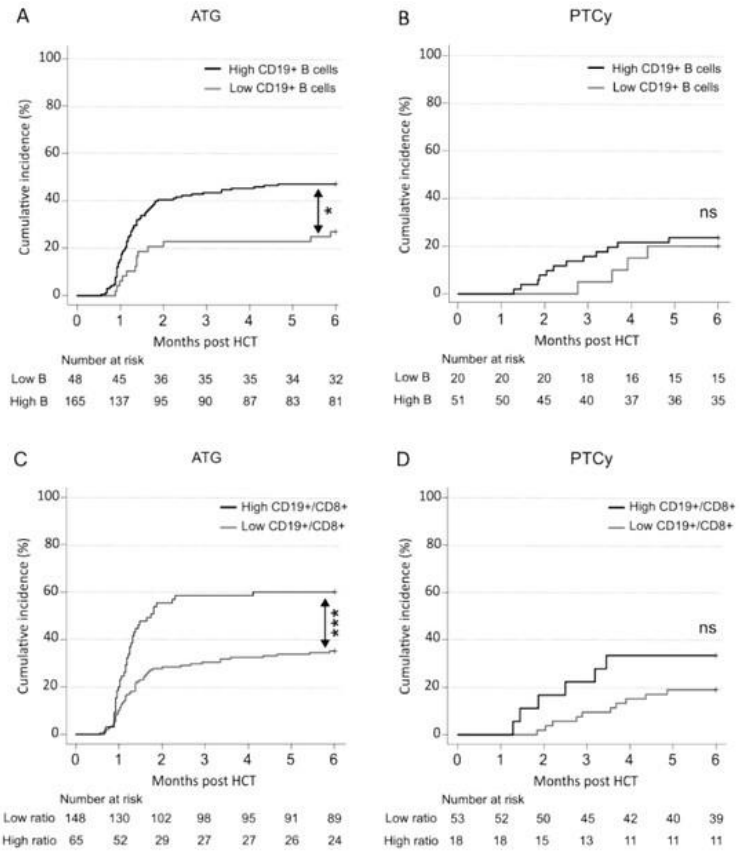

Figure 1. Association between graft B-cell content and cumulative incidence of EBV DNAemia ≥ 10^4 copies/mL post allogeneic transplant. (A) Cumulative incidence of high EBV DNAemia according to a threshold of 3.88 x 10^7 CD19+/kg in the ATG group. (B) Same analysis in the PTCy group (threshold: 4.78 x 10^7 CD19+ cells/kg). Cumulative incidence of high EBV DNAemia based on the CD19+/CD8+ ratio (threshold: 0.84) in the ATG group (C) and in the PTCy group (D). *$p < 0.05$; ***$p < 0.001$.

Conclusions: A high CD19+/CD8+ ratio in infused grafts was associated with a higher risk of high-level EBV reactivation in ATG-based GVHD prophylaxis but not after PTCy, highlighting distinct immune regulation and depletion patterns, as well as divergent early T-cell reconstitution dynamics. This new predictive factor may help identify patients who might

benefit from more aggressive management such as increased monitoring frequency, lower treatment threshold, or even primary prophylaxis.

PATIENTS WITH RELAPSED/REFRACTORY SYSTEMIC LIGHT CHAIN AMYLOIDOSIS ACHIEVE DEEP HEMATOLOGIC AND ORGAN RESPONSES WITH THE NOVEL MDC-CAR-BCMA001

Kiavasch Mohammad Nejad Farid[1], *Ute Hegenbart*[1], *Stefan Schönland*[1], *Brigitte Neuber*[1], *Angela Hückelhoven-Krauss*[1], *Carsten Müller-Tidow*[1], *Peter Dreger*[1], *Anita Schmitt*[1], *Uta Elisabeth Höpken*[2], *Armin Rehm*[2], *Michael Schmitt*[1]
[1]*Heidelberg University Hospital, Heidelberg, Germany,* [2]*Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany*

Background: B-cell maturation antigen (BCMA) has emerged as an attractive immunotherapeutic target in plasma cell disorders, however no commercial BCMA-directed chimeric antigen receptor (CAR) T-cell therapy is available for systemic light chain (AL) amyloidosis. We pursued compassionate use of the in-house manufactured 2nd-generation BCMA-directed MDC-CAR-BCMA001 in patients with relapsed/refractory AL amyloidosis and report on our updated findings in this challenging patient group.

Methods: Seven patients were treated with a fixed dose of 800 x 10^6 BCMA-directed CAR T-cells after lymphodepleting chemotherapy with fludarabine/cyclophosphamide (4/7) or bendamustine (3/7 – in cases of neuropathy or severe nephropathy). Leukapheresis, manufacturing and administration of CAR T-cells were performed in-house.

Results: Median age of the patients was 62 years (range: 57-70 years); underlying plasma cell disorder was monoclonal gammopathy in one case, smoldering myeloma in four and concurrent symptomatic multiple myeloma in the two remaining cases. Six out of seven patients had at least triple-class refractory disease and were not in remission prior to CAR T-cell infusion remission (4/7 progressive disease). Overall response was observed in 6/7 patients (86%, 3 complete remissions and 3 very good partial remissions) with a median time to best response of only 13 days. All evaluable patients (3/3) achieved measurable residual disease negativity. In responders, near-total suppression of amyloidogenic serum free light chain levels was achieved. Organ responses including near-complete cardiac and near-complete renal responses as well as improvements in neuropathy and myopathy were

observed in 4/7 patients at a median of 140 days. Six out of seven patients are alive and 3/6 responders are in sustained remission after a median follow-up of 327 days (including deep remissions over two years with long-lasting CAR T-cell persistence). All patients experienced manageable cytokine release syndrome (max. grade 3), rapidly resolving after tocilizumab and/or dexamethasone. Reversible deterioration of amyloid-involved organ function was observed in one patient. Neither immune effector cell-associated neurotoxicity nor higher-grade late hematotoxicity were observed.

Conclusions: MDC-CAR-BCMA001 shows a manageable toxicity profile with high efficacy even in heavily pretreated patients, making it a suitable construct for treating the vulnerable cohort of AL amyloidosis patients. Long-lasting, deep hematologic responses translate into excellent organ responses even in patients with advanced organ disease. These findings warrant further prospective evaluation, as planned in the phase I *CLEAR AL* trial (EU CT No. 2025-520790-39-00).

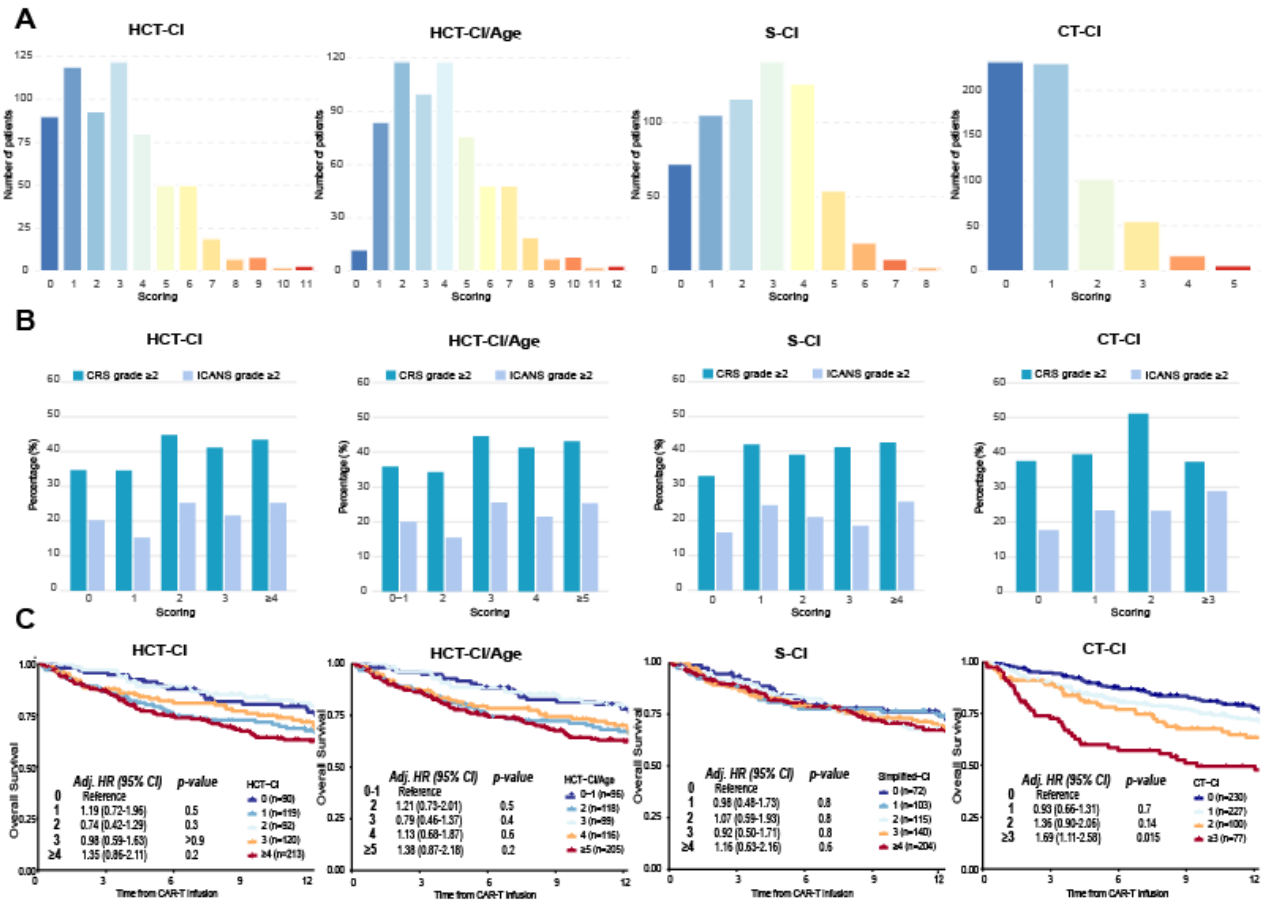
Background: Comorbidity indices are central to fitness assessment and risk stratification before hematopoietic cell transplantation, yet their utility in the CAR-T setting remains uncertain. Given the distinct clinical profile and toxicity spectrum of CAR-T recipients, it is unclear whether transplant-derived tools meaningfully inform outcomes. We therefore evaluated the clinical utility of four comorbidity indices in large B-cell lymphoma (LBCL) patients treated with commercial CAR-T across multiple centers.

Methods: We conducted an international, multi-center retrospective study across five centers, including adults with LBCL treated with commercial CAR-T products between 2016-2025. Comorbidities were assessed using: the Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI), the Comorbidity-Age Index (HCT-CI/Age), the Simplified-Comorbidity Index (S-CI), and the Cellular Therapy-Comorbidity Index (CT-CI). Primary endpoints were 1-year overall survival (OS) and progression-free survival (PFS); non-relapse mortality (NRM) was evaluated as a secondary endpoint. Correlations between indices were quantified using Spearman's rank coefficient. Discriminative ability for OS/PFS was evaluated with Harrell's C-index. Cox models for OS/PFS and Fine–Gray competing risk regression for NRM. Multivariable models included clinically relevant covariates and were stratified by center.

Results: Among 642 patients (median age 65 years; IQR 56–72), 57% received axi-cel, 19% liso-cel, and 23% tisa-cel; 79% received bridging therapy, and 68% received ≤2 lines of pre-apheresis treatments. Grade ≥2 CRS and grade ≥2 ICANS occurred in 40% and 22% of patients, respectively. With a median follow-up of 26.1 months (IQR 12.3–43.2), 1-year OS was 70% (95% CI 66–74) and 1-year PFS was 49% (95% CI 45–53), while 1-year NRM was 4.4% (95% CI 2.9–6.2).Overall, patients receiving CAR-T were highly comorbid (Fig.1A). Correlation between indices varied substantially, with the strongest correlation observed between HCT-CI and HCT-CI/Age (ρ=0.99) and the weakest between CT-CI and S-CI (ρ=0.18). Rates of grade ≥2 ICANS increased with higher comorbidity burden, ranging from

17-20% in the lowest category to 25-29% in the highest categories (Fig.1B). Similar pattern was observed for grade ≥2 CRS, which were as high as 43% in the highest categories (Fig.1B).
Higher comorbidity scores were associated with shorter OS for all indices except the S-CI (Fig.1C). In multivariable analysis adjusting for age, performance status, LDH pre-lymphodepletion, CAR-T product, and bridging therapy, only CT-CI≥3 remained significantly associated with inferior OS (Adj.HR 1.69, 95% CI 1.11–2.58; p=0.015). Two-year OS estimates were 32% for CT-CI≥3 versus 67% for CT-CI=0. A high CT-CI was also the only index associated with inferior PFS (Adj.HR 1.48, 95% CI 1.02–2.16; p=0.038). None of the indices discriminated NRM risk.
Discrimination across indices was limited: C-indices for OS ranged from 0.53 with S-CI to 0.60 with CT-CI, and for PFS from 0.52-0.58. Calibration was similarly poor across all models.



Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI; Sorror, *Blood* 2025); Comorbidity-Age Index (HCT-CIAge; Sorror, *JCO* 2014); Simplified-Comorbidity Index (S-CI; Shouval, *Blood Adv* 2022); Cellular Therapy-Comorbidity Index (CT-CI; Greenbaum, *Blood Adv* 2025)

Conclusions: In this large international study established comorbidity indices showed limited prognostic value in LBCL patients undergoing CAR-T therapy. Among all indices evaluated, only the CT-CI meaningfully stratified OS and PFS, and none predicted NRM.

These findings suggest that transplant-derived comorbidity tools may not adequately capture risk in CAR-T recipients, highlighting the need for CAR-T–specific fitness assessments.

Background: Primary graft failure (PGF) remains a severe, life-threatening complication of allogeneic hematopoietic stem cell transplantation (allo-HSCT) with limited data on the incidence and predictors in heterogeneous cohorts.

Methods: We conducted a retrospective analysis of 2423 consecutive adult (n= 1621) and pediatric (n=802) patients who underwent allo-HSCT between 2002 and 2023 with a median follow-up of 629 days (range: 1 day-21ye⁹ars). PGF was defined as failure to achieve neutrophil engraftment (ANC >0.5×10⁹/L) by day +28 post-HSCT without relapse of underlying malignant disease. Secondary graft failure (sGF) was defined as loss of donor hematopoiesis of underlying malignant disease. Gray's method was used to estimate cumulative incidence (CI) of PGF and sGF with competing risks (relapse, death without PGF). Risk factors for PGF were analyzed using Cox regression.

Results:

Characteristics of the cohort	N=2423
Period	
2002_2012	191 (7.88%)
2013_2023	2232 (92.1%)
Age

Female_to_male	Female_to_female	421	Reference	
	Female_to_male	482	1.44 (0.83, 2.48)	0.194
	Male_to_female	617	0.92 (0.52, 1.63)	0.778
	Male_to_male	881	0.88 (0.52, 1.50)	0.648

The overall incidence of PGF was 5.6% (n=135) and the 2 year CI of sGF was 2.2%. In multivariate analysis, independent factors significantly associated with a reduced risk of PGF were: diagnosis of leukemia (HR=0.37, 95%CI 0.19-0.70, p=0.002), lymphoprolipherative diseases/multiple myeloma (HR=0.27, CI 0.09-0.77, p=0.015), and solid tumor (HR=0.17, CI 0.04-0.80, p=0.025) compared to aplastic anemia (AA); use of matched related donor (MRD, HR=0.06, CI 0.03-0.14, p<0.001), matched unrelated (MUD, HR=0.24, CI 0.14-0.39, p<0.001), or mismatched unrelated (MMUD, HR=0.45, CI 0.25-0.81, p=0.008) donor compared to haploidentical donor; and peripheral blood stem cells (PBSC) vs. bone marrow (BM) (HR=0.35, CI 0.22-0.57, p<0.001). PGF patients were younger (median 17 vs. 26 years, p<0.001). Two year OS was 37% in PGF patients vs. 78% in patients with engraftment.

Conclusions: PGF is a rare but devastating complication of allo-HSCT. The highest risk is associated with haploidentical transplantation and use of bone marrow as a source. These

findings underscore the critical need for developing preventive strategies for high-risk patients and an aggressive salvage approach once PGF occurs.

Background: Allogeneic hematopoietic stem cell transplantation (alloHSCT) is the only potentially curative intervention for myelodysplastic syndrome (MDS), but novel strategies are needed to reduce relapse and improve survival. Orca-T is an investigational precision cell therapy for treatment of hematological malignancies. In a Phase 1b clinical trial (NCT04013685), Orca-T exhibited an excellent safety profile and low rates of severe Graft-versus-Host disease (GVHD). In a Phase 3 prospectively randomized trial (NCT05316701), Orca-T met the primary endpoint of improving moderate-to-severe chronic GVHD-free survival in comparison to calcineurin inhibitor/methotrexate prophylaxis. The goal of the present study was to compare the clinical outcomes of myelodysplastic syndrome (MDS) patients who received either Orca-T or post-transplant cyclophosphamide (PTCy) for the control of GVHD.

Methods: The Orca-T patients in this study included all MDS patients in the Ph3 trial who received Orca-T and all MDS patients in the Ph1b trial who met the Ph3 eligibility criteria. For comparison to PTCy patients, a dataset was acquired from CIBMTR-NMDP. The PTCy patients in this study included those in the CIBMTR registry who had a diagnosis of MDS, received PTCy + tacrolimus ± mycophenolate, and had pre-transplant demographic and clinical profiles that were similar to the Orca-T patients. Additional inclusion criteria were ages 18-65, myeloablative conditioning regimen, and an 8/8 HLA-matched donor. We studied the following endpoints: overall survival (OS), relapse-free survival (RFS), GVHD and relapse-free survival (GRFS), moderate-severe chronic GVHD-free survival (cGFS), and the cumulative incidences of non-relapse mortality (NRM), relapse, grades 3-4 acute GVHD and moderate-severe chronic GVHD. Standard survival and competing risk methods were used; $p<.05$ defined significance.

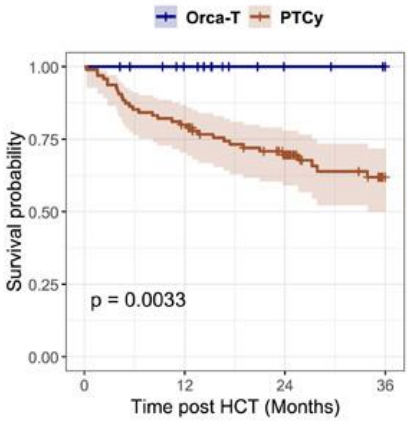
Results: Orca-T MDS patients (n=25), in comparison to PTCy MDS patients (n=95), exhibited increased OS (p=.003), increased RFS (p=.005), and decreased relapse (p=.026) (Table 1 and Fig. 1). The 1-year estimates for NRM, GRFS and gr. 3-4 aGVHD favored Orca-T, but did not reach statistical significance. The cumulative incidence of moderate-to-severe cGVHD was lower in the PTCy group, but cGFS was similar. The analysis consistently showed lower overall survival estimates for PTCy patients across various subgroups, defined by recipient age, sex, HCT-CI, KPS, and donor type. Thus, differences in demographic and clinical characteristics between the treatment groups are unlikely to explain the overall observed difference in OS.

Table 1. Clinical Outcomes.

Outcome[1]	Orca-T (N=25)	PTCy (N=95)	P-value[2]
Overall survival			**0.003**
1-year	100% (—%)	80% (70-87%)	
2-year	100% (—%)	70% (59-78%)	
3-year	100% (—%)	62% (50-72%)	
RFS	95% (69-99%)	64% (53-73%)	**0.005**
GRFS	67% (43-83%)	51% (40-61%)	0.11
NRM	0% (—%)	9.9% (4.8-17%)	0.11
Relapse	5.0% (0.31-21%)	26% (18-36%)	**0.026**

[1] 1-year estimate (95% CI)
[2] Log-rank test (survival) or Gray's test (cumulative incidence)

Figure 1. Overall Survival.



Conclusions: In conclusion, MDS patients treated with Orca-T, in comparison to PTCy, exhibited increased OS, increased RFS, decreased relapse, and decreased NRM. These observations provide evidence supporting the use of Orca-T for improved clinical outcomes.

MACROPHAGE ACTIVATION BEFORE LYMPHODEPLETION CAN PREDICT CRS, ICANS, AND LATE CYTOPENIA AFTER CD19 CAR-T CELL THERAPY FOR HEMATOLOGICAL CANCER

Monica Da-My Tran[1], *Marianne Ifversen*[1], *Henning Grønbæk*[2], *Holger J. Møller*[2], *Sørine T. Neumann*[1], *Eva Kannik Haastrup*[1], *Inge Marie Svane*[3,4], *Özcan Met*[3], *Søren L. Petersen*[1], *Klaus Müller*[1,4], *Katrine Kielsen*[1,4]
[1]*Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark,* [2]*Aarhus University Hospital, Aarhus, Denmark,* [3]*Herlev Hospital, Herlev, Denmark,* [4]*University of Copenhagen, Copenhagen, Denmark*

Background: CAR-T cell therapy is challenged by immune-related toxicities, including cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity (ICANS), and late cytopenia. Growing evidence suggests that macrophage activation plays a key role in the pathophysiology of these toxicities. We investigated whether circulating markers of macrophage activation (soluble mannose receptor, sMR and sCD163) could predict the severity of CRS, ICANS, and late cytopenia after CD19 CAR-T therapy.

Methods: We included 35 patients treated with CD19 CAR-T therapy for B-ALL (*n*=14) or B-NHL (*n*=21) at Rigshospitalet in Denmark from 2019-2025 (Table). Patients received tisagenlecleucel (*n*=13), axicabtagene ciloleucel (*n*=10), or an academic CAR-T product (DK-CLIC-1901, *n*=12). sMR and sCD163 levels were measured using in-house ELISA assays in plasma collected before lymphodepleting chemotherapy (pre-LD), on day of CAR-T infusion, daily from day +1 to +8, and on days +10, +12, +14, and +90 post-infusion. 156 healthy controls with a median age of 27 years (range: 7.7-69) were included for comparison.

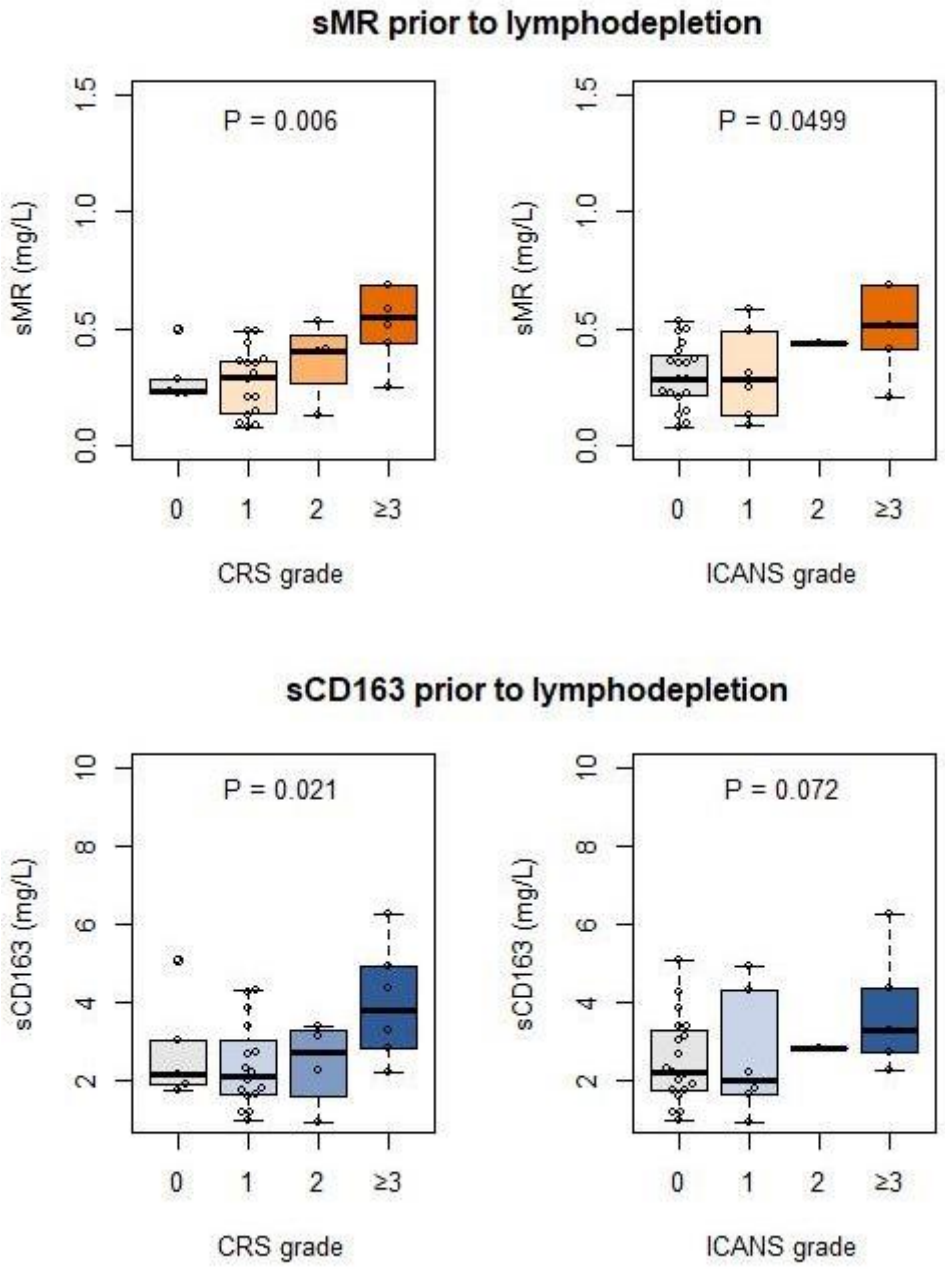
Patient and treatment characteristics	**N=35**
Age at infusion (years), median (range)	40 (1.7-71.8)
Male sex, n (%)	29 (82.9%)
Diagnosis, n (%) B-ALL B-NHL	14 (40.0%) 21 (60.0%)

No. of prior lines of therapy, median (range)	2 (1-5)
Prior HSCT, n (%) Allogeneic HSCT Autologous HSCT	7 (20.0%) 2 (5.7%)
Refractory to previous treatment line, n (%)	20 (57.1%)
Pre-LD LDH (U/L), median (range)	228 (142-2230)
Elevated pre-LD LDH, n (%)	19 (54.3%)
Bridging therapy, n (%) Chemotherapy-based regimens IT therapy only Radiotherapy ± steroids Targeted therapy Steroids only None	9 (25.7%) 5 (14.3%) 3 (8.6%) 4 (11.4%) 5 (14.3%) 9 (25.7%)
CAR-T product, n (%) Tisa-cel (Kymriah®) Axi-cel (Yescarta®) DK-CLIC-1901	13 (37.1%) 10 (28.6%) 12 (34.3%)
CAR-T dose (cells × 10^6/kg), median (range)	2.0 (0.23-4.8)

Days from leukapheresis to infusion, median (range)	33 (13-58)

Results: Pre-LD levels of sMR and sCD163 were significantly elevated in patients compared with healthy controls (median 0.35 vs. 0.18 mg/L, P<0.0001, and 2.32 vs. 1.45 mg/L, P<0.0001, respectively). After CAR-T infusion, both markers rose and peaked at day +6 for sMR (0.50 mg/L) and day +12 for sCD163 (4.1 mg/L). Pre-LD levels of sMR and sCD163 were not associated with diagnosis, prior lines of therapy, bridging therapy, or same-day CRP, IL-6 or LDH levels (all P≥0.05).
Grade ≥3 CRS and ICANS occurred in 17% and 14% of patients. sMR and sCD163 levels were significantly higher pre-LD in patients developing grade ≥3 CRS compared with grade 0-2 and tended to be higher in patients with grade ≥3 ICANS (Figure). In Cox regression analyses, the pre-LD levels of both markers were associated with increased risk of severe CRS (sMR: HR=2.7 per doubling, P=0.008; sCD163: HR=4.5 per doubling, P=0.034). Similarly, pre-LD sMR levels were associated with a higher risk of severe ICANS (HR=2.7 per doubling, P=0.027). Furthermore, high pre-LD LDH levels were associated with increased risk of severe CRS (HR=2.09 per doubling, P=0.011), while age, diagnosis, CAR-T product, and CAR-T cell dose were not associated with CRS or ICANS in our cohort.
Patients with grade ≥3 neutropenia (52% by ICAHT), thrombocytopenia (38%), and anemia (21%) between day +30 and +90 had higher pre-LD sMR levels compared with grade 0-2 (P=0.0008, P=0.002, and P=0.02, respectively), and higher pre-LD sCD163 levels were observed in patients with late grade ≥3 thrombocytopenia (P=0.04). In a logistic regression, higher sMR levels pre-LD were associated with increased risk of late grade ≥3 ICAHT (OR=7.2 per doubling, P=0.012) and prolonged grade ≥3 thrombocytopenia (OR=13.6 per

doubling, P=0.016).



Conclusions: Elevated levels of sMR and sCD163 before the start of lymphodepletion were associated with the development of severe CRS, ICANS, and late cytopenia in patients treated with CD19 CAR-T therapy, indicating a potential role as risk biomarkers. Our findings further support the emerging evidence of a role of activated macrophages in the

pathogenesis of CAR-T-related toxicities and point to macrophage-targeted interventions as a possible therapeutic strategy.

CAR-T BRIDGING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHILDREN WITH REFRACTORY/RELAPSED ACUTE LYMPHOBLASTIC LEUKEMIA

Xiaoxi Lu[1], *Hongye Cai*[1], *Yiping Zhu*[1], *Yuan Ai*[1], *Shuwen Sun*[1], *Dongjun Li*[1], *Ju Gao*[1], *Ziting Xia*[1], *Shengnan Su*[1]
[1]*West China Second University Hospital, Sichuan University, Chengdu, China*

Background: Acute lymphoblastic leukemia (ALL) is the most common malignant tumor in children, accounting for 75%-80% of pediatric acute leukemia. Among these, 15%-20% of patients experience refractory or relapsed disease, resulting in extremely poor long-term prognosis. In recent years, the clinical application of CAR-T has improved prognosis for children with refractory or relapsed ALL. Furthermore,bridging hematopoietic stem cell transplantation (HSCT) following combination chemotherapy or CAR-T has significantly enhanced the long-term survival rates for these patients.Herein,we investigate the efficacy and safety of sequential allogeneic hematopoietic stem cell transplantation for pediatric patients with refractory/relapsed acute lymphoblastic leukemia (R/R ALL) who achieved CAR-T cell therapy.

Methods: A retrospective study was conducted on 40 pediatric R/R ALL patients who accepted allogeneic hematopoietic stem cell transplantation following CAR-T between January 2017 and October 2025 In West China Second University of Sichuan University.

Results: A total of 40 patients were enrolled, comprising 19 males and 21 females, with 38 cases of B-cell ALL and 2 cases of T-cell ALL.The median age of the enrolled patients was 4.5 (0.5-14.0) years.Among 40 patients,fifteen patients(38%) received CD7,CD19 or CD22 mono-target CAR-T, fourteen patients(35%) received CD19/CD22 dual-target CAR-T, and twelve patients(27%) received multi-target CAR-T, such as CD19/CD22/CD72 or CD19/CD22/CD133. Patient and transplant characteristics are shown in Table 1. All the patients received MRD remission after CAR-T therapy by flow cytometry except 3 patients still had positive fusion genes. In the transplantation group, donors included Haploidentical (n=25), Cord Blood (n=7), Matched Unrelated Donor (n=4), Matched Sibling Donor (n=3), and Mismatched Unrelated Donor (n=1). All patients achieved hematopoietic reconstitution. Neutrophil engraftment (defined as ANC≥0.5 *10^9/L for three consecutive days) was achieved at a median of 12(10-34) days post-transplant.The median time to platelet engraftment (defined as PLT≥20*10^9/L for 7 consecutive days without transfusion support) was 18(7-43)days.With a median follow-up of 20(1-92) months, the Overall Survival(OS) was 67%,and the Leukemia-Free Survival(LFS) rate was 61%.The OS was 49% for mono-target CAR-T group, 78% for dual-target CAR-T group, and 100% for multi-target CAR-T

group respectively. The OS was 68% for patients with negative fusion genes prior to transplantation, compared to 33% for those with positive fusion genes (p=0.04).The incidence of grade II-IV acute GVHD was 15%, and the incidence of chronic GVHD was 40%. Engraftment syndrome was observed in 27 patients.Ten patients experienced relapse, resulting in a cumulative incidence of relapse (CIR) of 33%. Among these, Two patients received donor-derived CAR-T therapy upon relapse and achieved remission again, with sustained monitoring showing negative MRD,while eight died after relapse. Among the eight deceased cases, six were from the mono-target CAR-T group and two from the dual-target CAR-T group.

Conclusions: CAR-T Bridging allo-HSCT can improve long-term survival in pediatric patients with R/R ALL. Among them, children who received dual-target or multi-target CAR-T therapy prior to transplantation appeared to have better outcomes than those who received mono-target CAR-T.Furthermore,whether the fusion gene is negative before transplantation is a key factor affecting the prognosis of pediatric patients.

Disclosure: Nothing to declare from all authors in relation to this study.

OUTCOMES OF DONOR LYMPHOCYTE INFUSION FOR MEASURABLE RESIDUAL DISEASE AND RELAPSE AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: A SINGLE-CENTRE RETROSPECTIVE ANALYSIS

Safia Belbachir[1], *James Dungate*[1], *Julian Cooney*[1], *Matthew Wright*[1], *Usha Chandra Sekaran*[1], *Paul Cannell*[1], *Duncan Purtill*[1]
[1]*Fiona Stanley Hospital, Murdoch, Australia*

Background: Donor lymphocyte infusion (DLI) is a key intervention for relapse after allogeneic stem cell transplantation (alloSCT). Identifying predictors of response and optimal timing remains critical to improving outcomes.

Methods:

We analysed 43 consecutive patients who received donor lymphocyte infusions (DLI) following allogeneic stem cell transplantation (alloSCT) for haematological malignancies between 2015 and 2025. Indications for DLI were categorised as frank relapse (n=30), measurable residual disease (MRD) relapse or persistence (n=7), or mixed chimerism (n=6). MRD relapse was defined by molecular disease detection in the absence of morphological relapse. Frank relapse was defined by ≥5% bone marrow blasts and/or the presence of extramedullary disease. Complete response (CR) was defined as morphological remission with <5% bone marrow blasts; CR with incomplete count recovery (CRi) and morphologic leukaemia-free state (MLFS) were included as CR. For MRD-directed DLI, response was defined as molecular MRD clearance, for mixed chimerism, response was defined as reversion to full donor chimerism. Survival analyses were landmarked from the date of first DLI . Primary endpoints were CR, overall survival (OS), and progression-free survival (PFS). Multivariable Cox regression was used to identify independent predictors of outcome.

Results: Baseline patient, disease, and transplant characteristics are summarised in Table 1. Median time from alloSCT to first DLI was 14.5 months(range 1.2–41.3), and median time from relapse to DLI was 1.6 months(range 0.2–16.9). The CR rate was 51.2%, significantly higher in MRD compared with frank-relapse indications (85.7% vs. 40.0%; p=0.042). Acute and chronic GVHD post-DLI occurred more frequently in responders (31.8% vs. 4.8%, p=0.046; 54.5% vs. 23.8%, p=0.062). Adjunct therapies were administered to 28 patients (65%), with a median of one agent (range 1–3); complete response rates were similar between adjunct-therapy and DLI-only groups (46.4% vs. 60.0%; p=0.53).

With a median follow-up of 25.0 months, median OS for the cohort was 10.4 months, with a 1-year OS of 43.2%. Patients receiving DLI pre-emptively for MRD relapse showed superior 1-year OS compared with frank relapse (85.7% vs. 33.5%; p=0.033). Median OS was 8 months in the frank-relapse group and was not reached in the MRD-relapse group (HR 0.14; 95% CI 0.02–1.04; p=0.05).

Patients receiving pre-emptive DLI for MRD relapse also demonstrated numerically superior disease control (median PFS 25 vs 8 months; 1-year PFS 62.5% vs. 31.6%; p=0.01).

In multivariable analysis, the development of chronic GVHD post-DLI independently predicted improved OS (HR 0.27; 95% CI 0.09–0.80; p=0.018) and PFS (HR 0.33; 95% CI 0.14–0.81; p=0.015). Age, number of DLI cycles, cumulative CD3+ dose, adjunct therapy, and acute GVHD did not independently impact survival.

Characteristic	N	Percentage
Total Patients (N)	43	100%

MLFS	1	2.3%
Active Disease	6	14.0%
Conditioning Regimen		
Myeloablative (MAC)	23	53.5%
Reduced Intensity (RIC)	20	46.5%
Donor Type		
Matched Related Donor (MRD)	20	46.5%
Matched Unrelated Donor (MUD)	18	41.9%
Mismatched Unrelated Donor (MMUD)	2	4.7%
Haploidentical Donor	3	7.0%

Conclusions: In our experience, DLI was associated with clinically significant response both when given alone or in combination with chemotherapy. Efficacy appears enhanced when administered preemptively for MRD relapse compared with frank relapse. The development of chronic GVHD post-DLI is a strong independent prognostic factor, highlighting a potent graft-versus-leukemia effect. These findings support the continued use of DLI for disease relapse after transplantation, as well as further investigation of the use of DLI to MRD relapse.

SECONDARY MALIGNANCY RISK AFTER ALLOGENEIC HSCT WITH PTCY OR ATG PROPHYLAXIS: A RETROSPECTIVE STUDY

*Davide Chizzoniti[1,2], Barbara Sarina[2], Laura Giordano[2], Raffaele Scorza[3], Chiara De Philippis[2], **Daniele Mannina**[2], Jacopo Mariotti[2], Daniela Taurino[2], Flavio Pistolese[2], Arianna Giacomel[2], Armando Santoro[2,1], Stefania Bramanti[2]*
[1]Humanitas University, Pieve Emanuele, Italy, [2]IRCCS Humanitas Research Hospital, Rozzano, Italy, [3]Politecnico di Milano, Milano, Italy

Background: Long-term survival after allogeneic stem cell transplantation has improved, but secondary malignancies have emerged as a major cause of late non-relapse mortality, underscoring the need for tailored lifelong surveillance.

Methods: We retrospectively analyzed 223 adults who underwent allo-HSCT between 2009 and 2019 and received either PTCy- or ATG-based GvHD prophylaxis. Only long-term survivors, defined as patients alive ≥2 years post-transplant, were included. The cumulative incidence of secondary malignancies, excluding basal cell carcinomas, was estimated using competing-risk methods (CIF), with death as the competing event. Group comparisons used Gray's test, and risk factors were evaluated through Fine–Gray subdistribution hazard models, with covariates reported with 95% confidence intervals.

Results: GvHD prophylaxis consisted of PTCy-based regimens in 144 patients (65%) or ATG-based in 79 patients (35%). Median age at transplant was 47 (31–72), and 59% of patients were male. Underlying diagnoses included acute myeloid leukemia (18%), acute lymphoblastic leukemia (8%), myelodysplastic syndromes (10%), non-Hodgkin lymphoma (31%), Hodgkin lymphoma (29%), aplastic anemia (1%), and myeloproliferative neoplasms (3%). At the time of allo-HSCT, 72% of patients were in complete remission, 14% were in partial response and 14% had stable or progressive disease. Conditioning included myeloablative (19%), non-myeloablative (27%), and reduced-intensity regimens (54%). Peripheral blood stem cells were used in 69% and bone marrow in 31%, with matched related (26%), matched unrelated (16%), and haploidentical donors (58%).
In total, 42 out of 223 patients (18,8%) developed a secondary cancer, 30 out of 144 (20,8%) in the PTCy group and 12 out of 79 (15,2%) in the ATG group. [Tab1]
With a median follow-up of 101 months, The 5-year cumulative incidence of secondary malignancies was significantly higher in the PTCy cohort than in the ATG group (9.8% vs 3.9%, respectively; p = 0.022) [Fig.1]. In multivariable Fine–Gray analysis, PTCy remained independently associated with increased risk (HR 2.16), while other clinical and transplant-related variables did not emerge as significant predictors. No predominant tumor subtype emerged.
The divergence in cumulative incidence curves became more pronounced after 50 months from transplant, and by 150 months the estimated cumulative risk reached 38.5% in the PTCy group versus 26.1% in the ATG cohort. Importantly, no significant differences were observed in the incidence of solid tumors of viral etiology between the two groups, suggesting that the excess risk is not driven by infection-related cancers.
Despite the higher incidence, survival outcomes were comparable: 5-year OS was 91% with PTCy versus 95% with ATG, and 5-year PFS was 86% and 89%, respectively. Subgroup

analyses showed no significant OS differences across disease status, donor type, stem cell source, or conditioning intensity. Age at transplant was not associated with secondary malignancy risk.

	PTCy	ATG
Patients in cohort, n	144	79
Secondary malignancies included in main analysis, n (%)	30 (20.8%)	12 (15.2%)
5-year cumulative incidence of secondary malignancies	9.8%	3.9%
p value	*	0.022
Estimated cumulative incidence at 150 months	38.5%	26.1%
Tumor subtype, n		
Melanoma	9	0
Squamous cell carcinoma (all sites)	9	5
Other solid tumors†	8	5
Hematologic malignancies‡	4	2
† *Other solid tumors* include: colon adenocarcinoma, breast carcinoma, prostate carcinoma, endometrial carcinoma, lung cancer (including adenocarcinoma), pancreatic cancer, GIST, malignant peripheral nerve sheath tumor, carcinoma of unknown primary		

‡ *Hematologic malignancies* include: myelodysplastic syndrome, acute myeloid leukemia, primary myelofibrosis, Hodgkin lymphoma, Burkitt lymphoma, marginal zone lymphoma

Conclusions: In this cohort of long-term allo-HSCT survivors, PTCy-based GvHD prophylaxis was associated with a significantly higher cumulative incidence of secondary malignancies compared with ATG. Furthermore, these findings underscore the need for enhanced, long-term cancer surveillance strategies, especially in patients receiving PTCy. This surveillance strategy as well as adherence to screening programs should be stressed also beyond the fifth post-transplant year.

Disclosure: No disclosure to declare.

NOVEL PRECISION ALEMTUZUMAB DOSING RESULTS IN BETTER DAY 0 TARGET RANGE ACHIEVEMENT AND IMPROVED HSCT OUTCOMES IN IEI PATIENTS

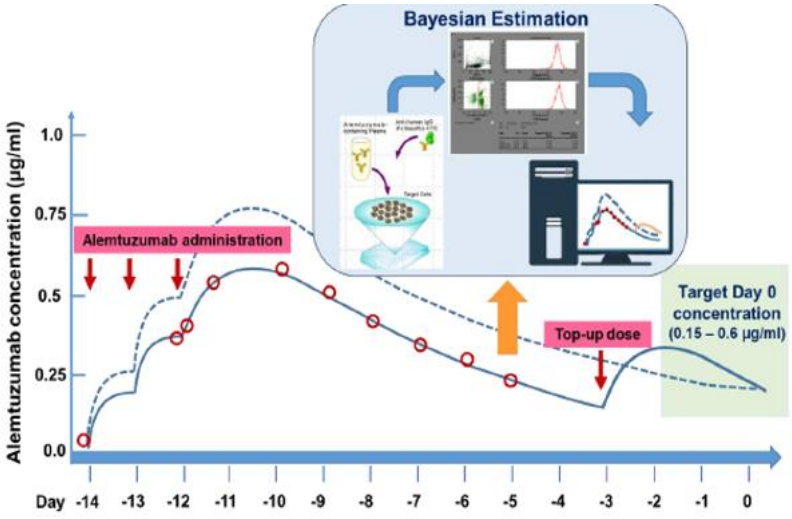
Ruby Khoury[1], Kana Mizuno[1], Anhar Hosawi[1], Lance Kuo-Esser[1], Caitlin Cottrell[1], Evelyn Nguyen[1], Brady Landon[1], Jessica Anderson[1], Sharat Chandra[1], Michael B. Jordan[1], Ashish Kumar[1], Jack Bleesing[1], Blachy Davila Saldana[1], Stella M. Davies[1], Carol Moore[1], Rebecca A. Marsh[1], Parinda A. Mehta[1], ***Pooja Khandelwal***[1]
[1]*Cincinnati Children's Hospital Medical Center, Cincinnati, United States of America (the)*

Background: Reduced intensity and reduced toxicity conditioning regimens offer low rates of toxicities and superior survival for patients with inborn errors of immunity undergoing allogeneic hematopoietic stem cell transplant (HCST). However, these approaches can be associated with increased rates of mixed chimerism and secondary graft loss. Peri-transplant alemtuzumab levels impact HCST outcomes; with low levels increasing the risk of acute graft versus host disease (GVHD) and high levels delaying immune reconstitution and increasing the risk of clinically significant mixed chimerism and secondary graft failure. We hypothesized that model-informed precision dosing of alemtuzumab with therapeutic concentration intervention (Precision Alemtuzumab Dosing) could achieve target Day 0 alemtuzumab levels of 0.15-0.9ug/mL in most patients, and minimize the risks of acute GVHD, clinically significant mixed chimerism, and secondary graft failure.

Methods: Prospectively enrolled patients were given model-informed initial alemtuzumab dosing of 10 mg/m2 divided over days -14 to -12. Alemtuzumab levels were measured through Day -5 or -4. Individual PK profiles were estimated using MW\Pharm software (version 2.4) based on our previously reported population PK model. Patients who were projected to clear alemtuzumab by Day 0 to <0.15ug/mL were given additional model-informed individualized "top-up" alemtuzumab dosing on Day -3 or -2 (Figure 1). Mixed chimerism was defined as a whole blood chimerism < 95% on two consecutive measurements within a 2-week period. Clinically significant mixed chimerism was defined as whole blood myeloid chimerism <50%. Secondary interventions evaluated included a CD34+ stem cell boost or a second transplant.

Results: Thirty-three patients of median age 3y2m years (range 3 months-32 years 9m) were treated. The underlying diagnoses and demographic information are presented in Table 1. Sixteen patients (49%) needed a top up dose, and twenty-four patients (73%) achieved Day 0 alemtuzumab levels within the optimal therapeutic range of 0.15-0.9ug/mL. Twenty-nine (88%) were evaluable for Day +100 outcomes. Two patients (7%) developed acute grade I GVHD. Ten patients (35%) experienced mixed chimerism and only one patient who had reactivated HLH during conditioning experienced clinically significant mixed chimerism in all lineages and subsequent secondary graft failure. Thirteen patients (40%) were evaluable for 1-year outcomes. Two patients (15%) had chronic limited skin GVHD. Six patients (46%) had mixed chimerism and only one (8%) had clinically significant mixed chimerism at one year. Five out of thirty-three patients (15%) received a CD34+ selected boost at a median of 6.5 months post-transplant at the discretion of the treating physician. The median myeloid chimerism was 47.8% (range 33%-78%) at the time of the boost.

Median age at transplant (range)	3y2m (43m-32y9m)
Gender Male Female	 16 (48%) 17 (52%)
Diagnosis HLH sJIA CGD WAS SAA XMEN SCID HyperIgE	 12 (36%) 10 (30%) 3 (9%) 3 (9%) 2 (6%) 1 (3%) 1 (3%) 1 (3%)
Preparative Regimen Alemtuzumab/Fludarabine/Melphalan/Thiotepa Alemtuzumab/Busulfan/Fludarabine	 27 (82%) 6 (18%)



Conclusions: Our novel precision alemtuzumab dosing is feasible and results in target range achievement in >70% of patients (compared to historic experience of approximately 25% of patients treated with standard-of-care alemtuzumab dosing regimens). It appears to result in low rates of acute GVHD, clinically significant mixed chimerism, and secondary graft failure at day +100.

Clinical Trial Registry: ClinicalTrials.gov ID NCT03302754.

PRELIMINARY BASIS FOR A PREDICTIVE ALGORITHM OF REHABILITATION REQUIREMENTS IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT PATIENTS

Gabriele Magliano[1], Alessia Arcangeli[2], Silvia Silvestri[2], Giulia Brambilla[1], Mirko Farina[1], Vera Radici[1], Daniele Avenoso[1], Alessandro Leoni[1,3], Simona Bernardi[1,3], Federica Re[1,3], Maria Anna Dossena[2], Daniele Corbo[4], Marialaura Calonghi[2], ***Riccardo Marnoni***[1]*, Silvia Zanon[1], Domenico Russo[1], Michele Malagola[1], Enrico Morello[1]*

Civili, Brescia, Italy, [2]Unit of Physiotherapy, University of Brescia, ASST Spedali Civili, Brescia, Italy, [3]Centro di Ricerca Emato-Oncologica AIL, Brescia, Italy, [4]Unit of Neuroradiology, University of Brescia, ASST Spedali Civili, Brescia, Italy

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is among the most effective strategies for treating hematologic malignancies, and although the benefits of physical activity and rehabilitation are acknowledged across transplant phases, comprehensive and individualized rehabilitative care is still lacking.

Methods: We therefore aimed to determine whether significant correlations exist among currently available clinical variables to identify the most informative predictors of rehabilitative needs in HSCT patients, with the long-term goal of using such predictors to develop an algorithm capable of early detecting rehabilitation requirements.
Clinical data from the hospitalization period of all patients undergoing allo-HSCT for any diagnosis at the ASST Spedali Civili di Brescia between November 2018 and February 2025 were retrospectively collected. The potential predictors analyzed included sex, age, Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI), Patient-Generated Subjective Global Assessment (PG-SGA), 4-Meter Gait Speed, 30-Second Chair Stand Test, Handgrip strength, Activities of Daily Living (ADL), Instrumental Activities of Daily Living (IADL), need for non-invasive ventilation (NIV), onset of neurological complications, use of high-dose steroid therapy, length of hospital stay, and ICU admission. Surrogate endpoints considered indicative of rehabilitative need were relapse occurrence and post-transplant hospital readmission.

Results: Of the 190 patients evaluated, 181 were included in analyses for relapse and 141 for rehospitalization. In relapse comparison tests, relapsed patients showed higher median age (68.4 vs 65.5 years; p=0.032), greater proportion of individuals >60 years (92.1% vs 69.9%; p=0.005), and lower mean handgrip strength (27.9 vs 34.1 kg; p=0.005). In multivariate logistic regression with average marginal effects (AME), age >60 years emerged as the strongest predictor of relapse risk (OR: 17.76; CI: 2.83–362.30; p=0.011; AME: +0.243; p<0.001). Conversely, handgrip strength (OR: 0.86; CI: 0.78–0.93; p<0.001; AME: –0.019 per kg; p<0.001), female sex (OR: 0.23; CI: 0.05–0.90; p=0.042; AME: –0.166; p=0.015), and NIV use (AME: –0.164; p=0.040) were significantly associated with reduced relapse probability (Table and Image 1). Regarding readmission, prolonged hospitalization was the strongest predictor of increased risk (OR: 3.43; CI: 1.30–9.83; p=0.016; AME: +0.251; p=0.010), whereas NIV use (OR: 0.15; CI: 0.03–0.61; p=0.013; AME: –0.323; p=0.001) and gait speed (OR: 0.11; CI: 0.01–1.04; p=0.063; AME: –0.431; p=0.050) were associated with lower rehospitalization likelihood (Table and Image 1)**.**

Predictors	**Relapse**				**Rehospitalization**		
	OR	**95% CI**	**p-value**		**OR**	**95% CI**	**p-value**
Sex (female vs male)	0.23	0.05-0.90	0.042		0.38	0.08-1.75	0.219

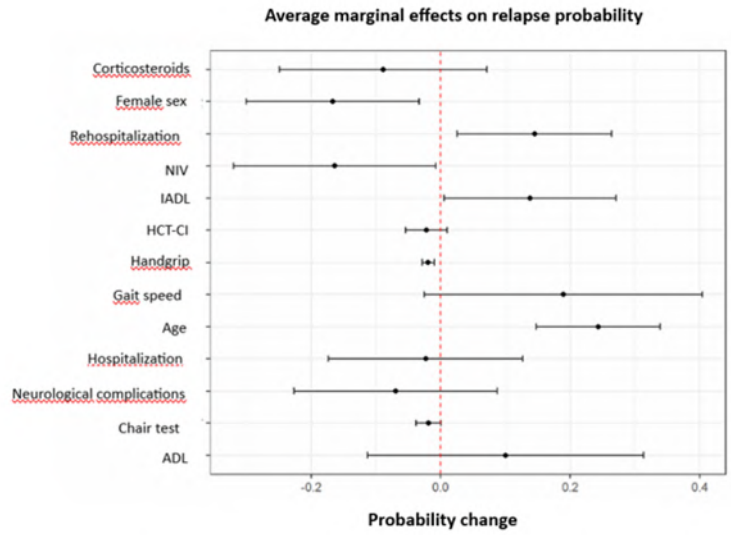
PGS-GA day 28	-	-	-		2.27	0.67-8.55	0.202
Gait speed	4.48	0.91-37.94	0.095		0.11	0.01-1.43	0.105
Chair stand test	0.86	0.73-1.01	0.073		0.98	0.85-1.13	0.771
Handgrip	0.86	0.78-0.93	<0.001		1.03	0.97-1.10	0.350
ADL	2.48	0.29-35.22	0.440		0.55	0.04-7.27	0.641
IADL	3.77	0.81-23.39	0.116		0.38	0.07-2.07	0.263
NIV	0.20	0.01-1.29	0.152		0.14	0.02-0.68	0.022
Neurological complications	0.56	0.12-2.2	0.424		3.83	0.95-17.77	0.068
Days of hospitalization	-	-	-		3.81	1.12-14.86	0.039
High dose corticosteroids	0.47	0.09-1.94	0.325		0.47	0.09-1.94	0.325

Table 1



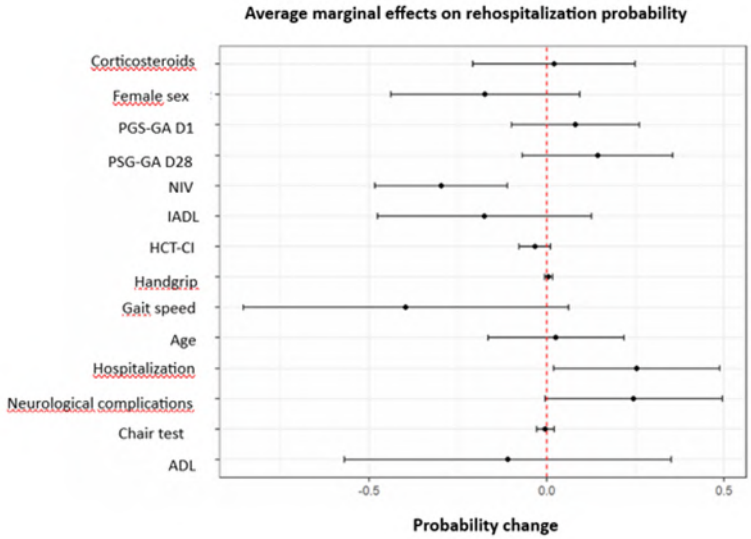


Image 1

Conclusions: Age, sex, handgrip strength, gait speed, NIV use, and hospital-stay duration emerge as significant predictors of rehabilitative needs in HSCT patients. Future prospective studies, focusing on longitudinal assessment of post-transplant evolution are required to

refine predictor selection based on current findings and literature evidence, validate the clinical and rehabilitative impact of identified predictors, and develop a predictive algorithm suitable for practical clinical implementation.

Background: Emapalumab, a fully human anti-interferon-γ (IFNγ) monoclonal antibody, is FDA-approved for adult and children with primary hemaphagocitic lymphohistiocytosis (pHLH) with refractory, recurrent or progressive disease or intolerance with conventional HLH therapy. We present an expanded analysis of emapalumab treatment in pHLH, focusing on responses in previously untreated patients and in those with central nervous system (CNS) involvement.

Methods: We conducted a pooled analysis of 3 prospective studies (NI-0501-04 [2013 to 2019; n=45], NI-0501-05 [2021; n=37 of 45 in NI-0501-04], NI-0501-09 [2019 to 2022; n=35] for a total of 80 emapalumab-treated patients. Patients who received ≥3 emapalumab doses and had a recorded investigator assessment comprised the response-evaluable set at week 8/EOT (n=68) and the best response-evaluable set (n=74); those with ≥3-month follow-up formed the bridging-success survival set (n=70). Responses were based on treating investigator global assessments, classified as CR (complete response or non-active disease), PR (partial response or HLH improvement) or no response (NR; progressive disease, reactivation, worsening or death). Absolute risk differences (RD) were reported with 95% confidence intervals (CI) calculated with the Exact method and Fisher exact p values (α=0.05). Safety was not evaluated in this pooled analysis. Analyses were descriptive.

Results: Median patient age was 0.8 years (0.01–16.67); 54% were male. CNS involvement was present in 25/77 patients (32%); 27/80 (34%) were previously untreated.
CNS subgroup: At Week 8/EOT, 16/19 evaluable CNS-positive patients (84%) achieved OR (CR 16%, PR 68%), whereas 39/43 evaluable CNS-negative patients (91%) achieved OR (CR 26%, PR 65%). Best OR up to Week 8/EOT were 91% (CNS+) and 96% (CNS-). Median time

to first OR was 16 days in both groups. Bridging-success survival occurred in 15/23 CNS+ patients (65%) and 42/50 CNS- patients (84%), RD −18.8% (95% CI −42.5% to 2.7%; Fisher exact *p*=0.125).
Prior-treatment subgroup: Previously untreated patients (PUP) had an OR of 19/22 (86%) at Week 8/EOT (CR 23%, PR 64%) and 96% best OR up to Week 8/EOT (CR 29%, PR 67%); previously treated patients (PTP) had an OR of 36/40 (90%) at week 8/EOT(CR 22%, PR 68%) and 94% best OR (CR 34%, PR 60%). Median time to first OR was similar across both cohorts (15 days [PUP] and 16 days [PTP], respectively). Bridging-success survival for both cohorts was comparable (76% [PUP] vs 79% [PTP], RD −3.2% (95% CI −26% to 16.4%; Fisher exact *p*=0.772).

Conclusions: Emapalumab shows strong efficacy across pHLH subgroups. OR kinetics were similar across both CNS+ and CNS-, with many CNS+ patients responding and bridging to HSCT or sustaining control. Similar outcomes were observed between both PUP and PTP cohorts with pHLH.

MAAT033 FOR GUT MICROBIOTA OPTIMIZATION TO IMPROVE SURVIVAL AFTER ALLOGENEIC HCT: THE PHOEBUS TRIAL

Florent Malard[1], Myriam Labopin[2], Ernst Holler[3], Joël Doré[4], ***Natalia Gemperle Ortiz***[5]*, Emilie Plantamura[5], Mohamad Mohty[6]*
[1]Sorbonne University, Saint Antoine Hospital, Assistance Publique - Hôpitaux de Paris, Paris, France, [2]EBMT Paris Office, Hôpital Saint Antoine, Paris, France, [3]University Medical Center Franz Josef, Regensburg, Germany, [4]INRAE Metagenopolis, Université Paris- Saclay, Jouy-en-

Josas, France, [5]MaaT Pharma, Lyon, France, [6]Sorbonne University, Clinical Hematology and Cellular Therapy Department, Saint Antoine Hospital, Paris, France

Background: Allogeneic hematopoietic transplantation (alloHCT) is a well-established therapy for high-risk hematologic malignancies, with nearly 20,000 procedures reported annually to the European Society for Blood and Marrow Transplantation. Despite its effectiveness, outcomes are often limited by relapse, infections, graft-*versus*-host disease (GvHD) and conditioning-related toxicity. Emerging evidence suggests that gut microbiota diversity plays a critical role in reducing these complications and may even lower relapse risk. Fecal microbiota transplantation offers a promising strategy to restore microbial balance and improve clinical outcomes after alloHCT.

Methods: The PHOEBUS trial is a multi-center randomized, double blinded phase IIb trial evaluating the efficacy of MaaT033 in improving survival of adult alloHCT subjects (Clinicaltrials.gov identifier: NCT05762211).
MaaT033 is a freeze-dried, full-ecosystem, high-richness and diversity, fecal microbiota medicinal product, formulated as delayed-release capsules and derived from healthy pooled allogeneic human fecal material.
388 subjects aged ≥ 50 years with hematologic malignancies for which an alloHCT is indicated will be randomized 1:1 to receive either MaaT033 or placebo, before initiation of the conditioning regimen and after hematopoietic recovery following alloHCT. Stratification is based on the Disease Risk Index and donor-host compatibility.
Inclusion criteria comprise age ≥ 50 years, reduced-toxicity or intensity conditioning regimen, neutrophils >0.5 G/L, and administration of broad-spectrum antibiotics within the last 90 days prior to inclusion. Exclusion criteria comprise non-myeloablative and conventional myeloablative conditioning regimen, *in vitro* T-cell depletion, alloHCT with cord blood cells, use of alemtuzumab, vedolizumab or abatacept for GvHD prophylaxis, and history of chronic digestive disease.
Study recruitment is ongoing in France, Germany, Spain, Belgium, The Netherlands and the UK.

Results: The primary endpoint is evaluation of overall survival at 12 months after alloHCT. Key secondary endpoints include evaluation of GvHD-free survival, and GvHD-free/relapse-free survival at 12 months after alloHCT. Additional endpoints are assessment of the safety of MaaT033, cumulative incidence of acute and chronic GvHD, non-relapse mortality, incidence of severe infections, and quality of life. Exploratory endpoints are the evaluation of the effects of MaaT033 on immune recovery, nutritional status, and healthcare resource utilization.
Subjects receive MaaT033 or placebo (3 capsules/day) for 1 week before the start of the conditioning regimen. Experimental treatment is resumed at neutrophil recovery and pursued for up to 90 days after alloHCT. Subjects are followed for study assessments up to 12 months post-alloHCT, and thereafter every 6 months to monitor survival, relapse, and chronic GvHD. The study will conclude once all participants have at least 24 months of follow-up, unless death or early termination occurs.
Two interim safety analyses, conducted after the first 60 and 120 randomized subjects, were favorable, with no safety signals or excess 90-day post-alloHCT mortality attributable to MaaT033. Additionally, during its third meeting (July 2025), the Data and Safety Monitoring

Board, which meets every 6 months, reviewed the safety data and confirmed that MaaT033 has an acceptable safety profile, recommending that the trial continue as planned.

Conclusions: The PHOEBUS trial explores for the first time the potential of a full microbiota ecosystem therapy to enhance survival in alloHCT recipients. Recruitment is ongoing and preliminary safety assessments are favorable.

DYNAMIC MONITORING OF THE PROGNOSTIC NUTRITIONAL INDEX (PNI) IN CAR-T THERAPY FOR RELAPSED/REFRACTORY LYMPHOMA: A RETROSPECTIVE STUDY

*Na Zhang[1], Rui Liu[1], Zhonghua Fu[1], Shilin Gan[1], Menglu Pei[1], **Jing Liu**[1], Yanhong Zhang[1], Miaomiao Cao[1], Lixia Ma[1], Yuelu Guo[1], Fan Yang[1], Biping Deng[2], Alex H. Chang[3], Xiaoyan Ke[1], Kai Hu[1]*
[1]Beijing GoBroad Hospital, Beijing, China, [2]Beijing GoBroad Boren Hospital, Beijing, China, [3]Engineering Research Center of Gene Technology, Ministry of Education, Institute of Genetics, School of Life Sciences, Fudan University, Shanghai, China

Background: The prognostic nutritional index (PNI) is a well-established marker that reflects both nutritional status and systemic inflammation, and serves as a powerful predictor of survival and treatment response across various malignancies. However, evidence regarding the relationship between dynamic PNI changes and clinical outcomes in chimeric antigen receptor T-cell (CAR-T) therapy remains limited. This study investigated temporal changes in PNI during CAR-T treatment and evaluated its association with treatment-related toxicities and survival outcomes in patients with relapsed/refractory (R/R) lymphoma.

Methods: We retrospectively analyzed 372 patients who received CAR-T therapy in our department between December 2018 and January 2024. PNI was calculated using:
PNI = Serum albumin (g/L) + 5 × Lymphocyte count ($\times 10^9$/L).
PNI was measured at four time points: baseline before infusion (D0), and days 7, 14, and 21 after CAR-T infusion. Spearman correlations and logistic regression analyses were performed to assess associations between PNI, cytokine levels, and toxicities. Cox regression models were applied to evaluate the relationship between PNI and survival outcomes.

Results: A total of 372 patients were included (53.0% male; median age 51). Subtypes included DLBCL (n=223), FL (33), PCNSL (23), HGBL (24), PMBL (17), BL (14), and others (51). Median BMI was 22.6 kg/m². ECOG ≥2, IPI ≥3, and stage III–IV were observed in 32.3%, 38.7%, and 91.1% of patients.

After CAR-T infusion, CRS occurred in 76.9% (grade ≥3: 7.0%), and ICANS in 3.0% (grade ≥3: 1.3%). Grade ≥3 cytopenias included neutropenia (43.3%), anemia (33.1%), and thrombocytopenia (11.6%).

PNI dynamics

PNI was stable at baseline, declined sharply to nadir by day 7, and partially recovered by day 21.

PNI and CRS

Lower PNI correlated with more severe CRS, with day-7 PNI showing the strongest association ($P<0.0001$). Baseline, day-14, and day-21 PNI were also significant.

PNI and cytopenias

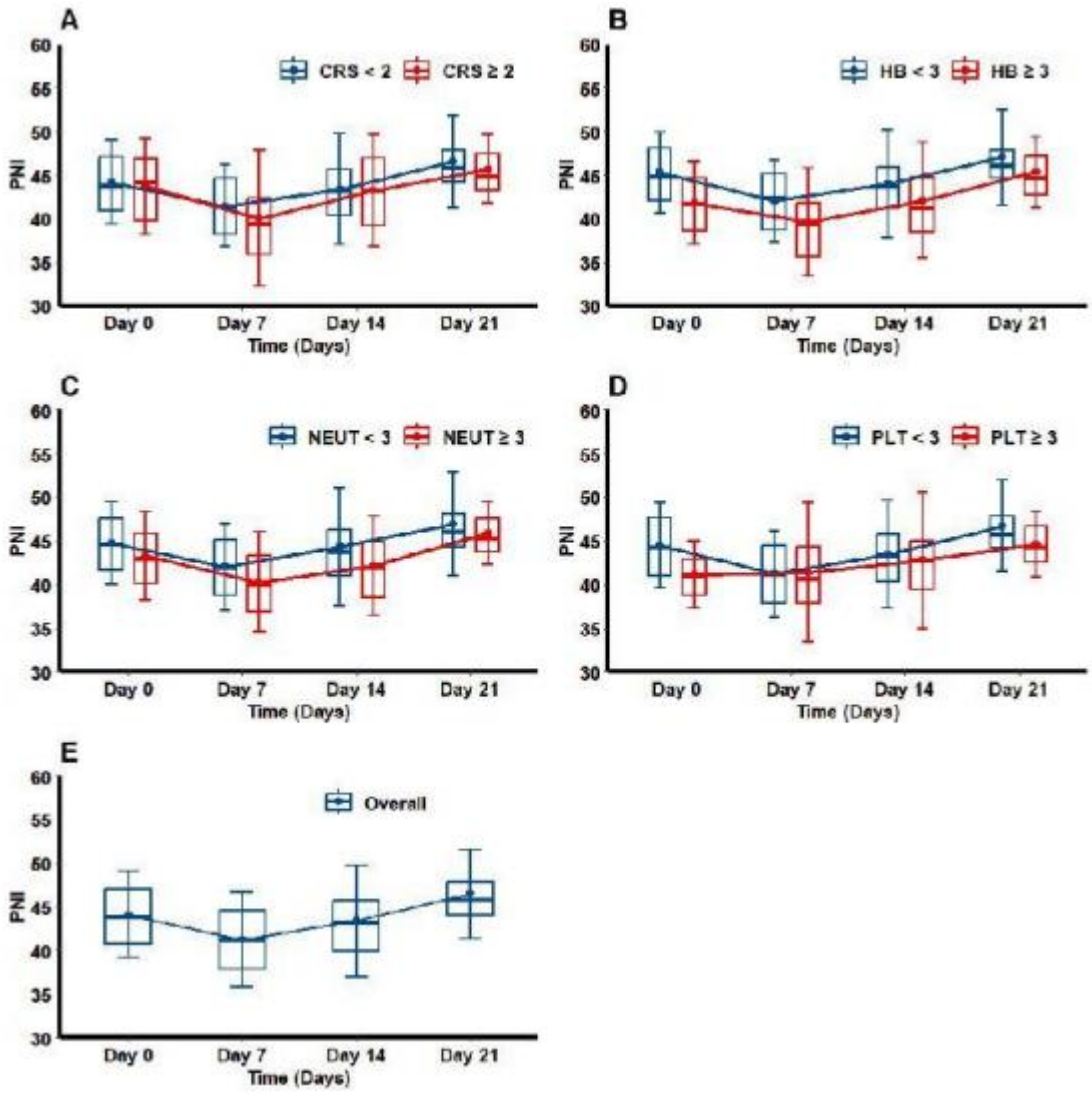
Patients with grade ≥3 neutropenia, anemia, or thrombocytopenia had consistently lower PNI at all timepoints (all $P<0.01$). Baseline PNI independently predicted hematologic toxicity:

- Anemia: OR=0.871, $P<0.001$
- Neutropenia: OR=0.955, $P=0.048$
- Thrombocytopenia: OR=0.867, $P<0.001$

Survival outcomes

At 30.84 months of follow-up, median PFS was 11.11 months; median OS was not reached. Five-year PFS and OS were 40.87% and 53.25%.

PNI at D0, D7, and D14 significantly predicted PFS and OS in univariate analyses. In multivariate models, PNI at D0, D7, and D14 independently predicted OS, while only baseline PNI predicted PFS.



Conclusions: This study demonstrates that PNI undergoes distinct dynamic changes during CAR-T therapy in patients with R/R lymphoma. Lower PNI levels—both at baseline and during treatment—are strongly associated with more severe CRS, higher rates of hematologic toxicities, and poorer long-term survival. A rapid decline in PNI during the early treatment period may serve as an early warning indicator for high-risk patients. Integrating PNI into routine monitoring may improve risk stratification and support individualized clinical management during CAR-T therapy.

CIRCULATING TUMOR DNA (CTDNA) AND IL-10 OR IL-10/IL-6 RATIO DYNAMIC MONITORING FOR PREDICTING RELAPSE IN RELAPSED/REFRACTORY CNS LYMPHOMA: A RETROSPECTIVE COHORT STUDY

*Xuenan Zhang[1], Rui Liu[1], Zhonghua Fu[1], **Yan Gao**[1], Fan Yang[1], Lixia Ma[1], Miaomiao Cao[1], Yuelu Guo[1], Biping Deng[2], Alex H. Chang[3], Xiaoyan Ke[1], Kai Hu[1]*
[1]Beijing GoBroad Hospital, Beijing, China, [2]Beijing GoBroad Boren Hospital, Beijing, China, [3]Engineering Research Center of Gene Technology, Ministry of Education, Institute of Genetics, School of Life Sciences, Fudan University, Shanghai, China

Background: Central nervous system lymphoma (CNSL) carries a high risk of relapse in the relapsed/refractory setting. Early identification of impending relapse may offer a crucial window for timely clinical intervention. This study evaluated the predictive value of serial cerebrospinal fluid (CSF) circulating tumor DNA (ctDNA), interleukin-10 (IL-10), and the IL-10/IL-6 ratio for relapse in patients with CNSL undergoing CAR-T cell therapy or other treatment modalities.

Methods: We retrospectively analyzed 46 patients with CNSL (primary CNS lymphoma [PCNSL], n = 33; secondary CNS lymphoma [SCNSL], n = 13) treated at Beijing GoBroad Hospital between August 1, 2023, and August 1, 2025. CSF samples were collected at baseline and at multiple time points for ctDNA assessment, flow cytometry, and cytokine profiling. Tumor-specific immunoglobulin gene rearrangements were used to track ctDNA and were compared with imaging and clinical relapse. The median age was 56 years (range, 35–75), and 50% were male. Treatments included autologous stem-cell transplantation (ASCT; n = 13), CAR-T therapy (n = 16), ASCT combined with CAR-T therapy (n = 14), and chemotherapy (n = 3). The median number of ctDNA tests per patient was 1.5 (range, 1–9), and cytokine tests 1 (range, 0–9).

Results: Among the 46 patients, 12 (26.1%) experienced relapse, with 11 detected radiographically and 1 detected by flow cytometry. Of the 12 relapsed patients, 5 (42%) were ctDNA-positive, including 2 patients in whom ctDNA positivity preceded radiographic relapse by an average of 109 days (91–127 days). Seven relapsed patients were ctDNA-negative, and two patients had ctDNA positivity without subsequent relapse.
The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and overall accuracy of ctDNA for relapse prediction were 41.7% (5/12), 94.1% (32/34), 71.4% (5/7), 82.1% (32/39), and 80.4% (37/46), respectively. Fisher's exact test showed a highly significant association between ctDNA status and relapse ($P = 0.009$).ROC curve analysis demonstrated predictive value for CSF IL-10 and IL-10/IL-6 ratio, with AUCs of 0.850 and 0.791, respectively (both $P < 0.05$). The optimal cutoffs for relapse prediction were 1.765 pg/mL for IL-10 and 0.275 for the IL-10/IL-6 ratio. Among the 43 patients with cytokine measurements, the sensitivity, specificity, PPV, NPV, and accuracy for IL-10 and IL-10/IL-6 ratio were 70.0% (7/10), 69.7% (23/33), 41.2% (7/17), 88.5% (23/26), and 69.8% (30/43), respectively. Elevated IL-10 or IL-10/IL-6 ratio was significantly associated with relapse ($P = 0.034$).

Conclusions: CSF ctDNA, IL-10, and the IL-10/IL-6 ratio are significant biomarkers for predicting relapse in CNSL. ctDNA demonstrated the highest specificity and PPV, and ctDNA positivity—particularly when preceding radiographic progression—may serve as an early warning indicator of relapse. In contrast, IL-10 and the IL-10/IL-6 ratio exhibited higher sensitivity and complement the predictive limitations of ctDNA. Both biomarkers showed strong NPVs, underscoring their utility in identifying patients at low risk of relapse. While ctDNA displayed superior overall performance, integrating both ctDNA and cytokine-based markers may enhance relapse prediction in clinical practice for CNSL patients.

A FIRST-IN-HUMAN STUDY OF HLA-PARTIALLY TO FULLY MATCHED ALLOGENEIC CRYOPRESERVED DECEASED DONOR BONE MARROW TRANSPLANTATION FOR PATIENTS WITH HEMATOLOGIC MALIGNANCIES

Sagar Munjal[1], *Sagar Patel*[2], *Shahbaz Malik*[3], *Uttam Rao*[3], *Taiga Nishihori*[4], *Preethi Prasad*[1], *Vicki Graves*[1], *Scott Goebel*[5], *Erik Woods*[1]
[1]*Ossium Health, San Fransisco, United States of America (the),* [2]*Transplant and Cellular Therapy Program, Huntsman Cancer Institute, University of Utah, Salt Lake City, United States of America (the),* [3]*St. David's South Austin Medical Center, Austin, United States of America (the),* [4]*Moffit Cancer Center, Tampa, United States of America (the),* [5]*Indiana University of Indiana, Indianapolis, United States of America (the)*

Background: Cryopreserved bone marrow hematopoietic progenitor cells (HPCs) can serve as valuable option to address unmet needs in allogeneic hematopoietic cell transplants (HCT). PRESERVEI (NCT05589896) evaluates cryopreserved, minimally manipulated allogeneic HPCs from deceased donor vertebral body bone marrow (BM) across 4/8–8/8 HLA-matched grafts. These cells are processed using minimal manipulation. This report provides prespecified interim data for Cohort 1 (n=4).

Methods: Four hematologic malignancy patients received donor HPC, marrow. Transplants were performed using 4/8 HLA-matched grafts for patient 1, 3 & 4, and 5/8 HLA-matched for patient 2. CD34+ cell doses were 5.72, 6.11, 5.22, and 7.53 X 10^6 cells/kg, respectively. Graft-versus-host disease (GVHD) prophylaxis included tacrolimus, mycophenolate mofetil (MMF), and post-transplant cyclophosphamide (50 mg/kg on Days +3 and +4). Neutrophil and platelet engraftment times were recorded; safety and GVHD were monitored; relapse and death were tracked.

Results: Patient 1 (age 52, T cell ALL) and patient 2 (age 62, AML) received myeloablative conditioning (MAC) while patient 3 (age 47, HTLV- ATLL) received reduced-intensity conditioning (RIC). Patient 4 (age 58, MDS) received RIC regimen.
Neutrophil engraftment was observed on Days +15, +17, +17 and +17; platelet engraftment observed on Days +18, +28, +20, and +27, respectively for the four patients. No clinically

significant local toxicity reported on day of infusion Grade 1 skin acute GVHD manageable with steroids was reported for patient 4 on day 49 and resolved on day 52. No grade III-IV acute GVHD, or severe chronic GVHD relapse, or death have been reported at the time of initial analysis. Mild chronic GVHD reported in patient 2 manifested by thrombocytopenia, peripheral edema and dysphagia, the patient was managed by methyl prednisone with resolution of symptoms. Secondary graft failure was reported for patient 3 after viral reactivation which was considered not related to the HPC marrow graft. No patient in cohort 1 met prespecified stopping rules.

Table 1: Patient demographics and characteristics for Cohort 1 patients

Patient	Age (years)	Gender (M/F)	Race	Disease	Conditioning Regimen (MAC vs. RIC)	CD34+ Dose (x10^6/kg)
Patient 1	52	Male	Asian	T-cell ALL (CR1)	MAC	5.72
Patient 2	62	Female	White	AML (CR1)	MAC	6.11
Patient 3	47	Female	White	HTLV-ATLL (CR1)	RIC	5.22
Patient 4	58	Male	African American	AML (CR1)	RIC	7.53

CR: Complete Remission, **RIC:** Reduced-Intensity Conditioning), **MAC:** Myeloblative Conditioning

Fig 1: PRESERVE I Cohort 1 patient journey
* Bone Marrow Chimerism

Conclusions: These preliminary encouraging data from cohort 1 demonstrate that transplantation of the cryopreserved off the shelf HPC, marrow cells from deceased donors is feasible and safe for infusion. The interim cohort 1 data highlights the potential of this novel graft source for patients with unmet medical needs. Cohort 2 will proceed per the protocol to further evaluate safety and early efficacy.

UPFRONT TRANSPLANTATION VS. INTENSIVE REMISSION INDUCTION IN MDS/AML, MDS-EB AND OLIGOBLASTIC AML - LIMITED PREDICTIVE VALUE OF BLAST COUNT AT DIAGNOSIS

Lisa-Marie Necke[1], *Lucas Mix*[1], *Wolfgang A. Bethge*[1], *Claudia Lengerke*[1], *Jan C. Schroeder*[1]
[1]*University Hospital Tuebingen, Tübingen, Germany*

Background: Patients with myelodysplastic neoplasms/acute myeloid leukemia (MDS/AML, ICC2022), MDS with Excess Blasts (MDS-EB) and oligoblastic AML with myelodysplasia-related changes (AML-MR, ICC2022) respond poorly to induction chemotherapy. Furthermore, complications of induction chemotherapy may cause early mortality or morbidity with only 50-60% of patients reaching potentially curative allogeneic hematopoietic stem cell transplantation (alloHSCT). Recent prospective evidence from the ETAL3-ASAP trial supports upfront alloHSCT in relapsed or refractory AML, but there is a lack of evidence to guide this decision at first diagnosis.

Methods: We retrospectively analyzed 232 patients with MDS/AML, MDS-EB and AML-MR with diagnostic bone marrow (BM) blast counts >5% who underwent alloHSCT at our center between 2007 and 2023. Cox regression models were fitted for overall survival (OS), and propensity score matching was used to further adjust for differences in baseline characteristics.

Results: 176 of 232 (75.9%) patients received intensive induction (induction group), while 56 of 232 (24.3 %) underwent upfront alloHSCT (upfront group). There were no differences between groups in age at alloHSCT, sex, HCT-CI score, conditioning intensity and donor matching. Patients in the upfront vs. the induction group more often had favorable ELN risk (18.9% vs. 8.1%, p = 0.058), BM blast counts <20% at diagnosis (81.8% vs. 7.5%, p<0.001), and more frequently showed a Karnofsky performance index (KPI) of 100% (31.5% vs. 17.3%, p = 0.042).Five-year OS was comparable in the upfront group vs. the induction group (57.2% vs. 45.7%, p=0.1). While blast counts at initial diagnosis were not associated with OS (HR 1.39 [0.66-2.94], p=0.389), there was a significant association of blast counts >5% at alloHSCT with inferior OS (HR 1.68, [1.14-2.46], p = 0.008).Interestingly, within the upfront group 5y-OS was not associated with blast counts at alloHSCT <5% vs. 5-9% vs. 10-20% vs. >20% (58.2% vs. 53.5% vs. 50% vs. 68.2%, p =

0.6). Multivariate analysis confirmed ELN risk as a good predictor of OS (HR 2.23 [1.02-5.23], p = 0.045), while application of induction therapy was not associated to outcome (HR 1.12, [0.69-1.81], p=0.637). Furthermore, there was no difference in 5-year OS between patients in remission after induction and patients in the upfront group (59.6% vs 57.2%, p =0.95).

To adjust for potential selection bias in the upfront group, we matched 21 patients in the upfront group to 131 patients in the induction group based on ELN risk, diagnostic BM blast count, and KPI. There were no significant differences between matched patients from the upfront vs. induction group in 5-year OS (38.1% vs. 47.2%, p = 0.98), RFS (47.1% vs. 48.2%, p = 0.89), relapse incidence (32.9% vs 23.4%, p = 0.5), and NRM (32.3% vs 34.3%, p = 0.58), respectively.

Table 1	Variable	Category	n	Overall	Induction	Upfront	p value

IMPACT OF POST-TRANSPLANT INTRATHECAL THERAPY ON CENTRAL NERVOUS SYSTEM RELAPSE IN ACUTE LYMPHOBLASTIC LEUKEMIA

Julia Bannatyne Undabeitia[1], *Alejandro Lada Colunga*[2], *María Huguet Mas*[3], *Edson Iván Quispe Cuba*[4], *José Juan Rifón Roca*[5], *Sara Villar Fernández*[5], *Juan Manuel Cerezo Martin*[1], *Ana Tobalina García*[1], *Maria Oviedo Madrid*[1], *Jose Antonio Flores García*[1], *Elba Vélez Blanco*[1], *Ana Pilar González Rodríguez*[2], *M Mercedes Colorado Araújo*[1], *Miriam Sánchez Escamilla*[1], *Mónica López Duarte*[1], *Enrique María Ocio San Miguel*[1], *Arancha Bermúdez Rodríguez*[1]
[1]*Hospital Universitario Marqués de Valdecilla, Santander, Spain,* [2]*Hospital Universitario Central de Asturias, Oviedo, Spain,* [3]*Institut Català d'Oncologia, Hospital Germans Trias i Pujol, Badalona, Spain,* [4]*Hospital Universitario de Navarra, Navarra, Spain,* [5]*Clínica Universidad de Navarra (CUN), Pamplona, Spain*

Background: It is well established that central nervous system (CNS) relapse after allogeneic hematopoietic stem cell transplantation (HSCT) carries a very poor prognosis in adults with acute lymphoblastic leukemia (ALL), but isolated CNS relapses remain uncommon. There is no clear consensus regarding the benefit of administering post-transplant IT prophylaxis.

Methods: Multicenter retrospective study that reviewed across 5 Spanish centers, 126 patients aged ≥18 years with ALL who underwent allogeneic HSCT from 2014 to 2025. All patients had received pre-HSCT IT therapy as part of standard treatment protocols and part of the cohort routinely received post-transplant CNS prophylaxis.
The objective was to evaluate the association between post-HSCT IT prophylaxis and CNS relapse, and to identify additional associated factors.

Results: Baseline characteristics are described in Table 1. Seventy-eight patients were male (38%). The median age at diagnosis was 40 years (IQR, 26–51).
The most frequent ALL subtype was Ph-negative, followed by Ph-positive ALL and T-ALL (62 (49.2%), 33 (26.2%), and 23 (18.3%) patients respectively).
Thirty patients (23%) received immunotherapy prior to transplantation.
The median number of pre-HSCT treatment lines was 1 (1–2), and most patients were treated according to PETHEMA protocols.
The median time from diagnosis to transplant was 6 months (IQR 5–11).
At transplant, 75% of patients were in first complete remission, achieving MRD negativity 70%.
Most patients received myeloablative conditioning (103 (82%)), predominantly TBI-based (63%). The median number of pre-HSCT IT was 4 (3–7), and 59 (47%) of the patients received >4 doses.
Seventeen patients (13.5%) received peri-transplant IT during conditioning, and 35 (28%) received post-HSCT prophylactic IT with a median of 4 doses (2–5).
With a median follow-up of 56 months (21–81), OS was 50%. Thirty-four patients (27%) relapsed (30 medullary relapses, and 4 combined relapses) with a median time to combined relapse of 7.5 months (4–13.25). No patient presented with isolated CNS relapse.
Among the 4 patients who experienced combined relapse, two had T-ALL, one Ph-negative ALL with a KMT2Ar, and one MPAL. None had CNS involvement at initial diagnosis.
Two patients underwent HSCT in first complete remission, and three were MRD-negative at transplant.
Overall survival, relapse-free survival, and non-relapse mortality at 2 years were 68% (95% CI, 58–75), 69% (59–77) and 21% (14–29) respectively, Figure 1. The cumulative incidence of relapse at 2 years was 31% (23–41), and the incidence of combined relapse 4% (2–11).
Post-HSCT IT prophylaxis was not associated with a reduced risk of CNS relapse (CI of CNS relapse at 2 years 0% vs 6% (95% CI, 2–16, p=0.20) and no isolated CNS relapses were observed in either group.
Regarding toxicity related to IT, one patient experienced cognitive impairment, other developed a cerebrospinal fluid fistula, and a third patient developed subcortical leukoencephalopathy in the context of TBI and IT.

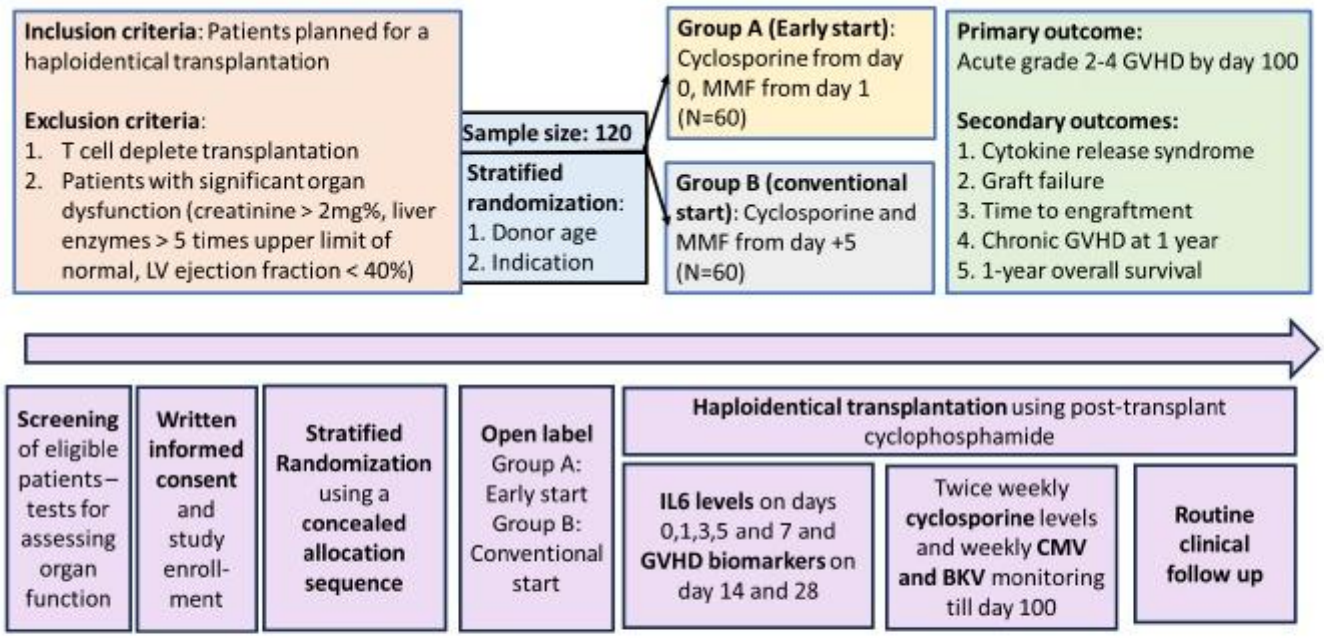
TIMING OF CALCINEURIN INHIBITOR–MMF AFTER HAPLOIDENTICAL TRANSPLANTATION WITH PTCY: RESULTS OF A PHASE II RANDOMIZED STUDY

Mithun Abraham Prakash[1], *Uday Kulkarni*[1], *Nutan Joshi*[1], *Sujith Karumuthul*[1], *Sushil Selvarajan*[1], *Sharon Lionel*[1], *Kavitha M Lakshmi*[1], *Sangeetha T*[1], *Selvakumar N*[1], *Madhan Kumar*[1], *Christopher Benjamin*[1], *Devakirubai Mohan*[1], *Anu Korula*[1], *Aby Abraham*[1], *Biju George*[1], *Poonkuzhali Balasubramanian*[1], *Vikram Mathews*[1]
[1]*Christian Medical College, Ranipet, India*

Background: Haploidentical hematopoietic stem cell transplantation (haplo-HSCT) using post-transplant cyclophosphamide (PTCy) has broken immunological barriers and expanded access to transplantation but remains associated with a high incidence of cytokine release syndrome (CRS) and acute graft-versus-host disease (aGVHD). Conventionally, calcineurin inhibitors (CNI) and mycophenolate mofetil (MMF) are initiated on day +5. However, emerging retrospective data suggest that earlier initiation of immunosuppression may reduce CRS without increasing graft failure or GVHD. Prospective randomized data addressing this question are limited. We report a pre-planned interim analysis of an ongoing randomized phase II trial evaluating early versus conventional initiation of CNI/MMF following T-cell replete haplo-HSCT.

Methods: This is an open-label, randomized phase II study (IRB Min No. 16035 dated 24.01.2024) with a planned total sample size of 120 patients undergoing T-cell replete haplo-HSCT for malignant and non-malignant hematologic disorders. Patients were randomized to receive either early immunosuppression (cyclosporine from day 0 and MMF from day 1; intervention arm) or conventional immunosuppression (cyclosporine and MMF from day +5; comparator arm). Randomization was stratified by donor age. Conditioning regimens included myeloablative (MAC), reduced-intensity (RIC), and non-myeloablative (NMA) approaches. Outcomes assessed included CRS, acute GVHD, graft failure, CMV reactivation, relapse, treatment-related mortality (TRM), and overall survival (OS). Categorical variables were compared using chi-square or Fisher's exact tests. The study has been funded by Indian Council of Medical Research (ICMR) Small Extramural Grants – 2024.



MMF = mycophenolate mofetil; GVHD = graft versus host disease; IL6 = interleukin-6; CMV =cytomegalovirus; BKV = Human p

Twice a week monitoring of cyclosporine levels and weekly monitoring for CMV and BK virus constitute the current standard-
management for patients undergoing haploidentical transplantation. There are no additional study-related visits.

Figure: Study schema and study-related procedures

Results: At interim analysis, 64 patients had completed at least 100 days of follow-up (comparator n=34; intervention n=30). Median follow-up was 195 days (range 3–492). Baseline characteristics, including age, disease type, HCT-CI score, conditioning intensity and $CD34^+$ cell dose, were well balanced between arms.
CRS occurred less frequently in the intervention arm compared with the comparator arm (63.3% vs 82.4%, p=0.059). However there was no decrease in the incidence of grade ≥2 CRS between the two arms. Rates of engraftment were comparable, with graft failure observed in one patient in the comparator arm and none in the intervention arm. Median time to platelet recovery was similar between groups, while neutrophil recovery occurred earlier in the intervention arm (15 [13–25] vs 17 [12–35] days, one-sided p=0.026).
The incidence of aGVHD among engrafted patients did not differ significantly (38.2% vs 30%, p=0.80). CMV reactivation was numerically higher in the intervention arm, but not statistically significant (46.7% vs 23.5%, p=0.067). Day-100 NRM (20.0% vs 20.6%) and

overall survival at last follow-up (73.3% vs 79.4%, p=0.768) were similar between both groups.

Transplant characteristics and outcomes	**Comparator (n=34) Median (Range) or N (%)**	**Intervention (n=30) Median (Range) or N (%)**	**p value**
Median age	18(1-50)	23(1-54)	0.850
Male sex	26 (76.5%)	18 (60.0%)	0.185
Pediatric	14 (41.2%)	11 (36.7%)	0.800
Patient CMV IgG Positive	34 (100%)	26 (86.7%)	0.043
Disease type Malignant Non-malignant	 26 (76.5%) 8 (23.5%)	 21 (70.0%) 9 (30.0%)	0.584
Donor sex (Male)	19 (55.9%)	18 (60.0%)	0.803
Donor Age	31 (2-55)	29 (5–53)	0.622
HCT-CI score 0 1 ≥2	 26 (76.5%) 5 (14.7%) 3 (8.8%)	 23 (76.7%) 4 (13.3%) 3 (10.0%)	0.978
Conditioning MAC RIC NMA	 20 (58.8%) 13 (38.2%) 1 (2.9%)	 19 (63.3%) 11 (36.7%) 0 (0%)	0.623
CD34 dose infused (x 10^6/kg)	8.49 (6.24–12.0)	8.8 (6.2–14.3)	0.331
Cytokine release syndrome Grade 1 Grade 2	28 (82.4%) 24 4	19 (63.3%) 18 1	 0.059 0.36
Day of Neutrophil Engraftment	17 (12–35)	15 (13–25)	0.026
Day of platelet engraftment	26 (17–48)	20 (15–39)	0.531
CMV reactivation	8 (23.5%)	14 (46.7%)	0.067

Graft failure	1 (2.9%)	0 (0%)	1.000
Acute GVHD Grade II- IV	13 (38.2%)	10 (30%)	0.802
Overall survival	27 (79.4%)	22 (73.3%)	0.768
TRM Day 30	4 (11.8%)	5 (16.7%)	0.723
TRM Day 100	7 (20.6%)	6 (20.0%)	1.000

Conclusions: In this interim analysis of a randomized phase II trial, early initiation of CNI and MMF following T-cell replete haplo-HSCT with PTCy was associated with a trend towards reduction in CRS and earlier neutrophil recovery, without an increase in aGVHD, graft failure or early mortality. These findings support the safety of early immunosuppression and suggest a potential strategy to mitigate CRS in haploidentical transplantation.

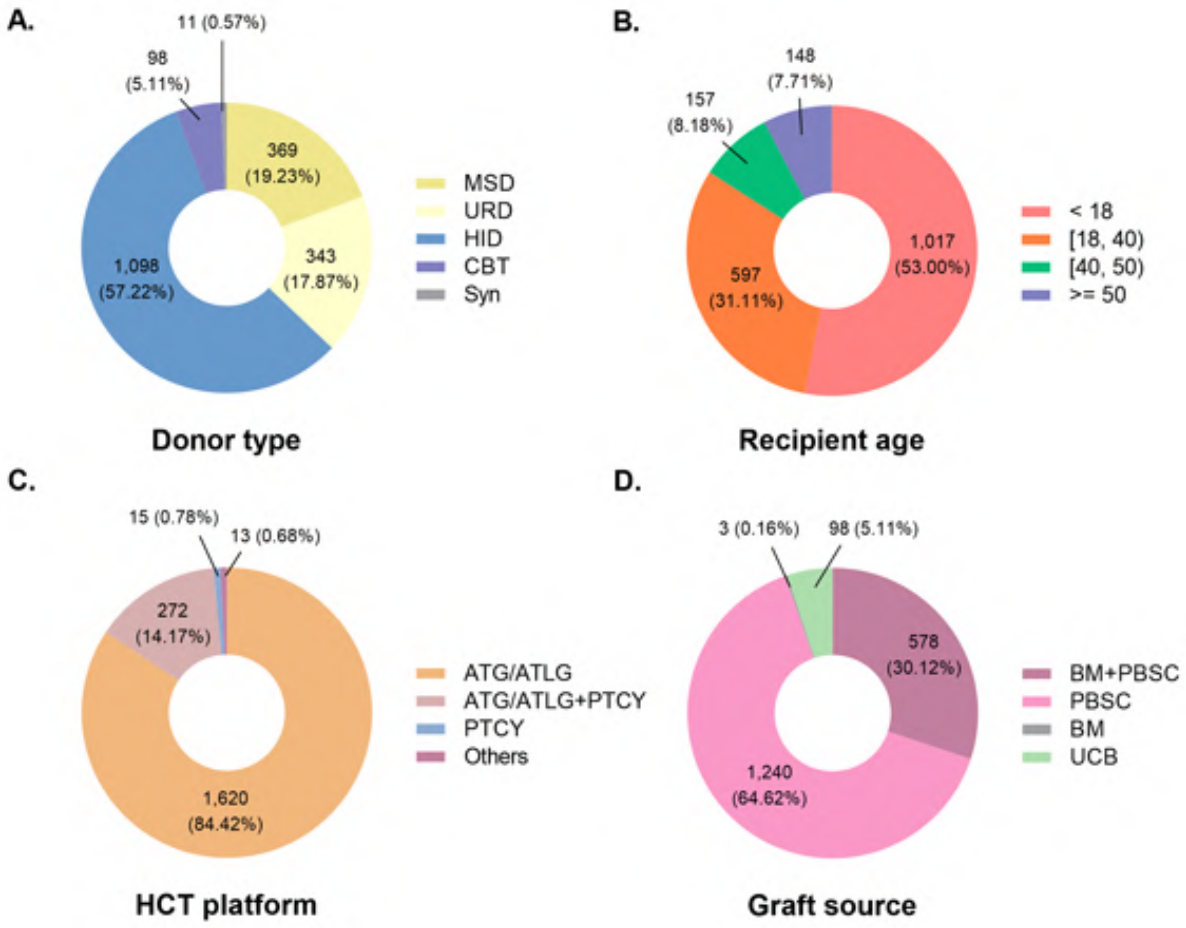
Background: Allogeneic hematopoietic stem cell transplantation (HCT) is well established as curative treatment for aplastic anemia (AA). China holds the largest number of allogeneic HCT cases worldwide, reaching 14,947 cases in 2023. Over the past decades, there have been continuous efforts to augment transplant protocols by improving conditioning regimens, graft-versus-host disease (GVHD) prophylaxis, and donor selection. Hence, HCT has been increasingly considered in individuals with AA in China. And the upper limit of age for HCT among AA recipients has continuously been broken. More than 1,000 cases of transplants for AA have been conducted annually in China since 2018. Compared to Europe and the US, HCT for AA in China can feature distinct characteristics, which stem from the practical experience of transplant centers, donor availability, drug accessibility, etc..

Methods: A nationwide registration of HCT has been organized by the Stem Cell Application Section of the Hematology Branch of the Chinese Medical Association since 2008. Every 6 months, data including transplant numbers, patient gender and age, disease, donor type, stem cell source, conditioning regimen, and GVHD prophylaxis was reported to the CMBTRG via Excel form. This cross-sectional study focused on transplant activity data for AA in China in 2024.

Results: In 2024, 1,919 transplants were reported in 1,893 patients (53.00% pediatrics, 31.11% young adults aged < 40 years, and 15.89% older adults) with AA by 158 actively transplanting centers in China. Haploidentical donor (HID) was the leading donor source of HCT (n = 1,098, 57.22%) for AA in China, which was observed across all age groups. Matched sibling donor (MSD, n = 369) and unrelated donor (URD, n = 343) were used in 19.23% and 17.87% of transplants, respectively. Flu+Cy (35.23%) was the most commonly used regimen for MSD HCT. In the haploidentical and unrelated setting, Bu+Flu+Cy (36.07% and 39.94%, respectively) and Bu+Cy (23.32% and 31.78%, respectively) were the two leading conditioning regimens. The anti-thymocyte globulin/anti-T-lymphocyte globulin (ATG/ATLG)-based platform (n = 1,620, 84.42%) was the predominant transplant modality in China, followed by the ATG/ATLG plus PTCY platform (n = 272, 14.17%). PBSC (n =1,240, 64.62%) and BM plus PBSC (n = 578, 30.12%) were the two leading graft sources. Apart from its use in all URD transplants, PBSC also accounted for 71.54% of MSD (71.54%) and HID (57.01%) transplants. Co-infusions have been employed in 26.35% (n = 506) of transplants to prevent GVHD, which were more likely to be used in pediatrics, PBSC transplants, and alternative HCT with HID and URD. The three-dugs regimen comprising calcineurin inhibitors (CNI), mycophenolate mofetil (MMF), and methotrexate (MTX) was the most commonly used GVHD prophylaxis in the ATG/ATLG-based setting (1258/1620, 77.65%). In the ATG/ATLG+PTCY-based setting, the regimen utilizing CNI±MMF/MTX ranked first (162/272, 59.56%). The prevalence of CNI+MMF+MTX regimen was also observed across MSD (57.45%), URD (70.85%), and HID (78.32%) transplants. Novel GVHD prophylaxis regimens have incorporated aniti-CD25 monoclonal antibody and ruxolitinib.



Conclusions: This survey offers a comprehensive overview of the current HCT landscape in China and serves as a valuable resource for clinical practice.

IRON OVERLOAD (IO) IS ASSOCIATED WITH AN INCREASED RISK OF INFECTIOUS COMPLICATIONS AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION (HCT) WITH POST TRANSPLANT CYCLOPHOSPHAMIDE (PTCY) BASED PROPHYLAXIS

Jose Tinajero[1], Winston Lee[1], Dat Ngo[1], Dongyun Yang[1], Salman Otoukesh[1], Amanda Blackmon[1], Idoroenyi Amanam[1], Shukaib Arslan[1], Brian Ball[1], Paul Koller[1], Amandeep Salhotra[1], Karamjeet Sandhu[1], Ahmed Aribi[1], Ibrahim Aldoss[1], Haris Ali[1], Vinod Pullarkat[1], Andrew Artz[1], Anthony Stein[1], Guido Marcucci[1], Steven Forman[1], Ryotaro Nakamura[1], Joo Song[1], ***Monzr Al Malki***[1]
[1]*City of Hope, Duarte, United States of America (the)*

Background: The adverse effect of iron overload (IO) on outcomes of allogeneic hematopoietic cell transplantation (HCT) has been previously described as delayed engraftment and increased non-relapsed mortality (Al Malki et al. BBMT 2020). Additionally, iron is a nutrient for microorganisms and high pre-HCT serum ferritin (SF) levels have been previously associated with an increased risk of invasive fungal infections after HCT (Dadwal et al. BBMT 2011). However, its impact on patients receiving post-transplant cyclophosphamide (PTCy) as GvHD prophylaxis is unknown.

Methods: In this study, we included patients who underwent HCT and received PTCy at the City of Hope National Medical Center between June 2013 and December 2023 for a hematologic disease. We retrospectively analyzed infectious (documented viral, fungal, and bacterial infections) outcomes up to D+100 and stratified patients by pre-HCT SF level of 2000 ng/mL. The study was approved by the institutional review board at City of Hope.

Results: There were 584 consecutive patients who met criteria for analysis and were included in our study. There were 142 and 442 patients who had SF >2000 and $\leq$ 2000 ng/mL, respectively. The median age was similar between the cohorts (52 vs 52.5, p=0.82). The median SF value was 3107 versus 763.6 ng/mL between cohorts, respectively. Iron stain (IS) was done in 194 patients with available pre HCT bone marrow samples with median ISS (IS score) of 3 (range; 0-4). Fifty-nine patients had ISS of 0-2, and 135 patients with ISS of 3-4, with patients in the higher ISS (3-4) group having a higher baseline median SF (1118.2 vs 202.6 ng/mL, p<0.001). The total incidence of any infection up to D+100 post HCT between SF>2000 and $\leq$2000 ng/mL was 77.5% and 64.3% (p=0.003) respectively. There was a higher incidence of fungal (18.3% vs 8.8%, p=0.001) and viral (55.6% vs 43.7%, p=0.01) infections in the SF > 2000 cohort, however bacterial infections were not significantly different (36.5% vs 29.4%, p=0.11).

Conclusions: In conclusion, IO defined by SF of 2000 ng/mL correlated with higher ISS in pre-HCT bone marrow. IO was a strong adverse prognostic factor for infections post-HCT. Better viral and fungal prophylaxis and pre-emptive therapies approach might be necessary for patients with IO undergoing HCT with PTCy-based GvHD prophylaxis platform.

OPTIMIZING ALTERNATIVE DONOR SELECTION IN ALLOGENEIC HSCT: DISEASE- AND CONDITIONING-SPECIFIC ADVANTAGES OF UMBILICAL CORD BLOOD TRANSPLANTS

Eun-Jeong Jeong[1], *Ye Sul Jeung*[2], *Sin Young Park*[2], *Hyunsoo Cho*[2], *Ja Min Byun*[2], *Youngil Koh*[2], *Junshik Hong*[2], *Sue Shin*[3], *Jong Hyun Yoon*[3], *Inho Kim*[2], *Sung-Soo Yoon*[2], *Dong-Yeop Shin*[2]
[1]*Seoul National University Bundang Hospital, Seongnam-si, Korea (the Republic of),* [2]*Seoul National University Hospital, Seoul, Korea (the Republic of),* [3]*Seoul Metropolitan Government-Seoul National University Boramae Medical Center, Seoul, Korea (the Republic of)*

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) offers curative potential for various hematologic malignancies; however, many patients lack suitable HLA-matched donors. Advances in HLA typing and T-cell depletion have enabled the use of alternative graft sources, but the optimal donor choice in specific clinical settings remains uncertain.

Methods: We retrospectively analyzed 223 consecutive patients who underwent first allogeneic HSCT between January 2015 and December 2023 at Seoul National University Hospital. After excluding recipients of HLA-identical sibling or fully matched unrelated transplants, the final cohort included 146 haploidentical, 39 mismatched unrelated donor (MMUD), and 38 umbilical cord blood (UCB) transplants. Overall survival (OS) and relapse-free survival (RFS) were estimated using the Kaplan–Meier method, and prognostic factors were evaluated using Cox proportional hazards regression.

Results: The 5-year OS rates were 41.9% (95% CI, 34.4–51.0%) for haploidentical, 52.8% (95% CI, 39.0–71.5%) for MMUD, and 59.4% (95% CI, 45.4–77.9%) for UCB transplants ($p = 0.067$). The corresponding RFS rates were 36.8% (95% CI, 29.5–45.8%), 40.7% (95% CI, 27.8–59.6%), and 59.4% (95% CI, 45.4–77.9%), showing significantly inferior outcomes for haploidentical transplants ($p = 0.034$). Conditioning intensity influenced survival differently by donor type. Among UCB recipients, MAC resulted in significantly superior 5-year OS and RFS compared with RIC (OS: 66.5% vs. 28.6%, $p = 0.012$; RFS: 66.5% vs. 28.6%, $p = 0.0085$), whereas no significant difference was observed in haploidentical or MMUD transplants. In lymphoid malignancies, UCB transplantation achieved markedly higher survival compared with other donor sources, with a 5-year OS of 77.8% (95% CI, 60.8–99.6%; $p = 0.028$) and a 5-year RFS of 77.8% (95% CI, 60.8–99.6%; $p = 0.0061$). Among patients in complete remission (CR) at transplantation, UCB again demonstrated superior outcomes, with a 5-year OS of 77.8% compared with 48.5% for haploidentical and 57.2% for MMUD transplants ($p = 0.034$), and a 5-year RFS of 77.8% compared with 40.7% and 37.5%, respectively ($p = 0.0095$). In multivariate analysis, CR at day 100 post-transplantation was the strongest independent predictor of OS (HR = 11.19, $p < 0.001$) and RFS (HR = 12.16, $p < 0.001$), while UCB transplantation was independently associated with improved RFS (HR = 0.22, $p = 0.017$). Acute and chronic graft-versus-host disease incidences were comparable among groups.

Conclusions: UCB transplantation provided favorable long-term outcomes, particularly in lymphoid malignancies when myeloablative conditioning was feasible and disease remission was achieved early. Conditioning intensity and post-transplant remission status were key determinants of long-term survival. These findings support a risk-adapted donor selection strategy incorporating disease type, conditioning intensity, and early remission status to optimize outcomes in alternative donor HSCT.

Disclosure: The authors declare no conflicts of interest. This study was supported by the Seoul National University Hospital (grant number 0320220060).

[1]Division of Hematology, Department of Oncology, Geneva University Hospitals, Geneva, Switzerland, [2]Translational Research Center for Oncohematology, Department of Medicine, Faculty of Medicine, University of Geneva, Geneva, Switzerland, [3]Department of Pathology and Immunology, Faculty of Medicine, University of Geneva, Geneva, Switzerland, [4]Transplantation Immunology Unit and National Reference Laboratory for Histocompatibility, Department of Diagnostic, Geneva University Hospitals, Geneva, Switzerland, [5]Geneva Centre for Inflammation Research (GCIR), Geneva, Switzerland

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a curative therapy for hematologic diseases but remains limited by graft-versus-host disease (GvHD) and non-relapse mortality (NRM). Emerging evidence suggests circadian rhythms influence immune function and transplant outcomes. Hou et al. reported that afternoon PBSC infusions were associated with higher acute GvHD and worse survival, highlighting a potential role for graft timing.

Methods: We retrospectively analyzed 368 adult patients undergoing first allo-HSCT with PBSC at Geneva University Hospitals between 2015 and 2024. Bone marrow and ex vivo manipulated grafts were excluded. Patients were stratified into early versus late infusion groups based on the results of a receiver operating characteristic (ROC) analysis. Clinical and graft characteristics, and outcomes including OS, progression-free survival (PFS), cumulative incidence of relapse, NRM, and acute GvHD were analyzed. Multivariable regression, accounting for covariates significantly different among the two groups, was performed.

Results: The ROC analysis for overall survival (OS), identified 11:17 a.m. as the optimal cutoff for infusion timing in our cohort (AUC = 0.53; sensitivity = 0.90; specificity = 0.23). Early infusion (<11 a.m.) was associated with improved 2-year OS (83% vs 65%, p=0.0078)

and reduced NRM (3.2% vs 13%, p=0.02) compared to late infusion. No differences were observed in relapse rates, PFS, or time to neutrophil engraftment. Acute GvHD incidence showed a non-significant trend towards reduction in the early group. To note, a higher proportion of patients in the early infusion groups received frozen grafts (n=42, 67%) compared to patients in the late infusion group (n=95, 31%; p<0.001). Multivariable analysis including the graft congelation status as covariate confirmed that later infusion remained independently associated with poorer OS (HR 2.29; p=0.015).

Conclusions: Timing of PBSC infusion appears to influence allo-HSCT outcomes, with early morning graft administration improving OS and reducing NRM. Two currently phase 3 randomised clinical trials are ongoing comparing patients undergoing transplantation between 11:30 a.m. and 12:30 p.m. or between 5:30 p.m. and 6:30 p.m. in the context of allo-HSCT for malignant (NCT06294678) or non-malignant (NCT06294691) haematological diseases. Our data support the potential of circadian-informed transplant strategies and underscore the need for prospective trials to validate timing as a simple, low-cost intervention to optimize allo-HSCT outcomes across centers.

CLINICAL CHARACTERISTICS, PROGNOSTIC FACTORS, AND TRANSPLANT OUTCOMES IN HEMATOLOGICAL MALIGNANCIES WITH BEHÇET'S DISEASE: A RETROSPECTIVE STUDY OF 114 PATIENTS

Xiaoyu Cao[1], *Hui Fu*[1,2], *Mengzhu Zhao*[3], *Wenjun Wu*[1,4], *Ji-nuo Wang*[1,4], *Jian Yu*[1,4]
[1]*Bone Marrow Transplantation Center of The First Affiliated Hospital & Liangzhu Laboratory, Zhejiang University School of Medicine, Hangzhou, China,* [2]*Department of Hematology, Taizhou Hospital of Zhejiang Province, Affiliated to Wenzhou Medical University, Linhai, China,* [3]*Department of Rheumatology, The First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China,* [4]*Institute of Hematology, Zhejiang University, Hangzhou, China*

Background: Approximately 10–20% of patients with hematological malignancies (HMs), particularly myelodysplastic syndromes (MDS) and acute leukemia (AL), are reported to have coexisting autoimmune diseases, among which systemic vasculitis represents a common

manifestation. Behçet's disease (BD), a distinct form of systemic vasculitis characterized by pan-vasculitis and recurrent mucocutaneous and systemic inflammatory lesions, has been increasingly recognized in association with HMs. Notably, trisomy 8 (+8), one of the most frequent cytogenetic abnormalities in MDS and AL, has been implicated in the pathogenesis of BD or BD-like syndromes in this context, with a reported prevalence exceeding 70% in MDS patients exhibiting BD-like features.This study aimed to analyze the clinical features, long-term outcomes, and prognostic factors in patients with HMs coexisting with BD, focusing on the efficacy of hematopoietic stem cell transplantation (HSCT).

Methods: We conducted a retrospective analysis, including 29 patients with HMs and BD from the First Affiliated Hospital, Zhejiang University School of Medicine between Jan 2016 and Dec 2024, and 85 cases with complete data identified through a systematic literature review up to May 2025. Statistical analyses, performed using SPSS software, encompassed descriptive statistics, survival analysis (Kaplan-Meier method, log-rank test), and multivariate Cox proportional hazards regression to identify prognostic factors.

Results: The cohort comprised 114 patients (50 male, 64 female) with a median age of 49 years (range: 7-81). Primary HM diagnoses were BD-MDS (n=88, 77.2%), BD-AML (n=24, 21.1%), and BD-ALL (n=2, 1.8%). BD onset preceded HM diagnosis in 57 patients (50.0%). Trisomy 8 (+8) was present in 80 patients (70.2%), and 33 patients (28.9%) underwent allogeneic HSCT (allo-HSCT). Multivariate Cox analysis identified male sex (HR=1.82, 95% CI 1.01-3.29, P=0.048), age ≥60 years (HR=3.15, 95% CI 1.83-5.42, P<0.001), and BD onset preceding HM (HR=2.12, 95% CI 1.19-3.78, P=0.011) as independent adverse prognostic factors for overall survival (OS). Patients with BD-MDS had significantly superior OS compared to those with BD-AL (P<0.001). Allo-HSCT significantly improved OS in the overall cohort (P=0.013). Among all patients, trisomy 8 had no significant impact on OS (P=0.831). However, allo-HSCT recipients with +8 had significantly better OS than non-transplanted +8 patients (P=0.029). Moreover, all 6 surviving patients who underwent HSCT at our center maintained sustained remission of both hematologic malignancies and Behçet's disease through serial follow-up evaluations.

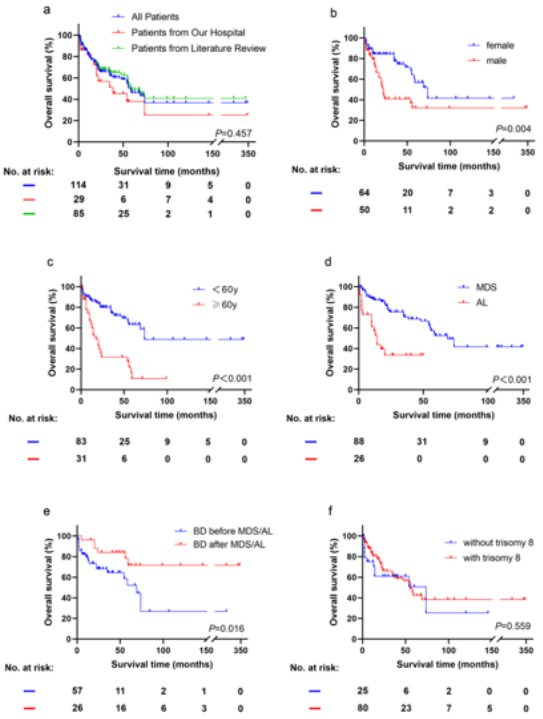

Figure 1. Survival of patients with MDS/AL-BD: (a) Overall survival of patients with MDS/AL-BD. (b) Overall survival of male and female patients. (c) Overall survival of elderly patients(≥ 60y) and young patients(＜60y). (d) Overall survival of MDS and AL patients.(e) Overall survival of patients with BD onset before MDS/AL and patients with MDS/AL onset before BD. (f) Overall survival of patients with and without trisomy 8. The survival time was defined as the period from diagnosis with MDS/AL to death.

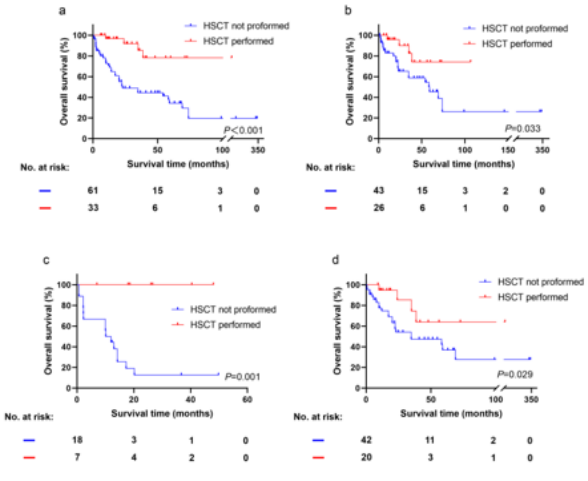

Figure 2. Patients treated with HSCT have better prognosis. (a) Overall survival of patients who received HSCT and those who did not. (b) Overall survival of patients with MDS who received HSCT and those who did not. (c) Overall survival of patients with AL who received HSCT and those who did not. (d) Overall survival of patients with trisomy 8 who received HSCT and those who did not.

Conclusions: BD–HM, particularly with trisomy 8, represents a distinct clinical and biological entity characterized by prominent GI involvement, systemic inflammation, and unique therapeutic challenges. In patients with HMs and BD, male sex, advanced age (≥60 years), and BD onset prior to HM diagnosis are independent adverse prognostic factors. Patients with BD-MDS exhibit significantly better survival than those with BD-AL. These data support early recognition and aggressive management of BD and HM overlap syndrome, with allo-HSCT as

the cornerstone for fit patients, and highlight the potential of targeted immunomodulation as an adjunct or alternative in the future.

CUMULATIVE CYCLOSPORINE A EXPOSURE AND LONG-TERM OUTCOMES IN ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKAEMIA

Hauke Wilcken[1], *Jörg Sahlmann*[2], *Alexandra Kutilina*[1], *Miriam Mozaffari Jovein*[1], *Laura Gengenbach*[1], *Francesca Biavasco*[1], *Jesús Duque-Afonso*[1,3], *Ralph Wäsch*[1], *Robert Zeiser*[1], *Jürgen Finke*[1], *Kristina Maas-Bauer*[1], *Claudia Wehr*[1], *Thomas Meyer*[1,3]
[1]*Medical Center – University of Freiburg, Freiburg, Germany,* [2]*Institute of Medical Biometry and Statistics University of Freiburg, Freiburg, Germany,* [3]*Collaborative Research Institute Intelligent Oncology (CRIION), Freiburg, Germany*

Background: Early Cyclosporine A (CsA) exposure influences both graft-versus-host disease (GvHD) control and antileukemic immunity after allogeneic stem cell transplantation (alloHCT). Prior studies relying on median CsA trough concentrations report inconsistent associations with relapse and survival. This may partially be due to the fact that median trough levels incompletely reflect cumulative immunosuppressive burden. We addressed this methodological limitation by reconstructing continuous daily concentration curves to quantify cumulative exposure in a homogeneous cohort of patients suffering from acute myeloid leukaemia (AML).

Methods: All adults receiving first alloHCT with a CsA/ATLG-based GvHD prophylaxis regimen for AML between 2009-2025 at the University Medical Centre Freiburg were included (N=320, Table 1). Daily CsA concentration curves were reconstructed using a unified LOWESS-based smoothing framework. After outlier filtering, LOWESS-smoothing was applied to individual patient measurements and interpolated onto a one-day grid. Daily and cumulative AUC values were derived via trapezoidal integration. Patient-level cumulative exposures for days 0-20 and 0-100 were normalised to a pooled reference curve and dichotomised at the median. To avoid reverse causality, exposure measurement was truncated before day 100 in the event of death, relapse, or the start of systemic immunosuppression for GvHD. Survival outcomes were analysed using Kaplan-Meier, Cox regression, and Fine-Gray competing risk models, adjusted for established clinical covariates including donor type, conditioning intensity, GvHD prophylaxis and risk-adapted dosing by disease risk index (DRI).

Results: High cumulative CsA exposure during days 0-100 was associated with markedly improved overall survival (OS) (Figure 1) and relapse-free survival (RFS). Five-year OS was 66.1% in the high-exposure group versus 43.4% in the low-exposure group (log-rank $p<0.001$), and this advantage remained highly significant in the adjusted Cox model (HR 0.55; 95% CI 0.38-0.79; $p=0.001$). Relapse-free survival similarly favoured high exposure

(HR 0.66; 95% CI 0.47-0.92; p=0.015). Despite numerical differences at five years in non-relapse mortality and relapse, the adjusted Fine–Gray model provided no evidence of a difference (NRM: SHR 0.68, 95% CI 0.41–1.15, p=0.16; relapse: SHR 0.70, 95% CI 0.46–1.12, p=0.11). High early (day 0-20) exposure was additionally associated with a significantly lower risk of chronic GvHD in a landmark analysis (SHR 0.54; 95% CI 0.33-0.90; p=0.015).

		low CsA exposure (N=160)	**high CsA exposure (N=160)**	**Total (N=320)**	**p-value**
Mean CsA level day 0–100 (ng/ml)		199 (185-212)	238 (226-255)	223 (199-242)	<0.001
Patient age at transplantation		62 (51-68)	60(50-69)	62(51-69)	0.91
Donor age at apheresis		29 (23-37)	30 (23-38)	29 (23-37)	0.98

	Other	1 (0.6%)	1 (0.6%)	2 (0.6%)	

Table 1. Baseline characteristics by Cyclosporine A exposure group. Patients were dichotomised into low and high exposure groups based on the median cumulative CsA exposure index for days 0–100. Continuous variables are reported as median (interquartile range) and were compared using the Wilcoxon rank-sum test. Categorical variables are shown as number and were compared using χ^2 tests or Fisher's exact test.

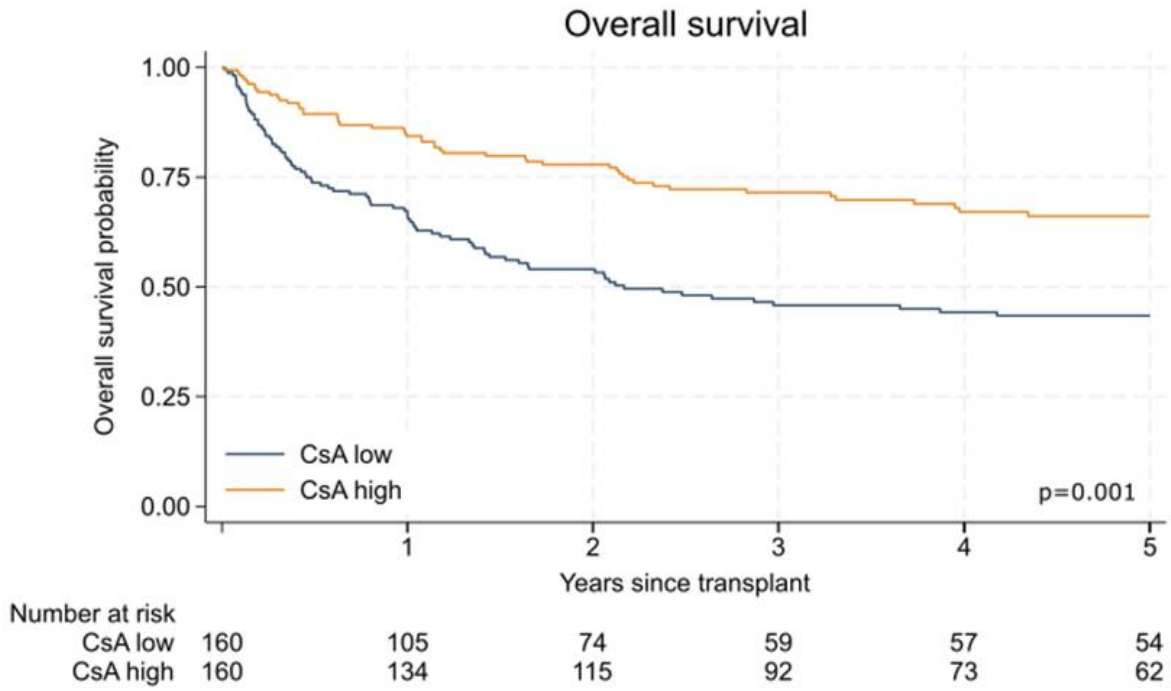

Figure 1. Kaplan–Meier overall survival by CsA exposure (day 0–100). Patients in the high-exposure group showed significantly improved survival over 5 years compared with those in the low-exposure group (log-rank p=0.001).

Conclusions: Higher cumulative CsA exposure in the first 100 days after alloHCT, was associated with markedly improved OS and RFS and less cGvHD, independent of disease risk. These findings suggest that, in contrast to concerns derived from solely trough-based monitoring, greater cumulative exposure within standard therapeutic ranges was not associated with less GvL activity.

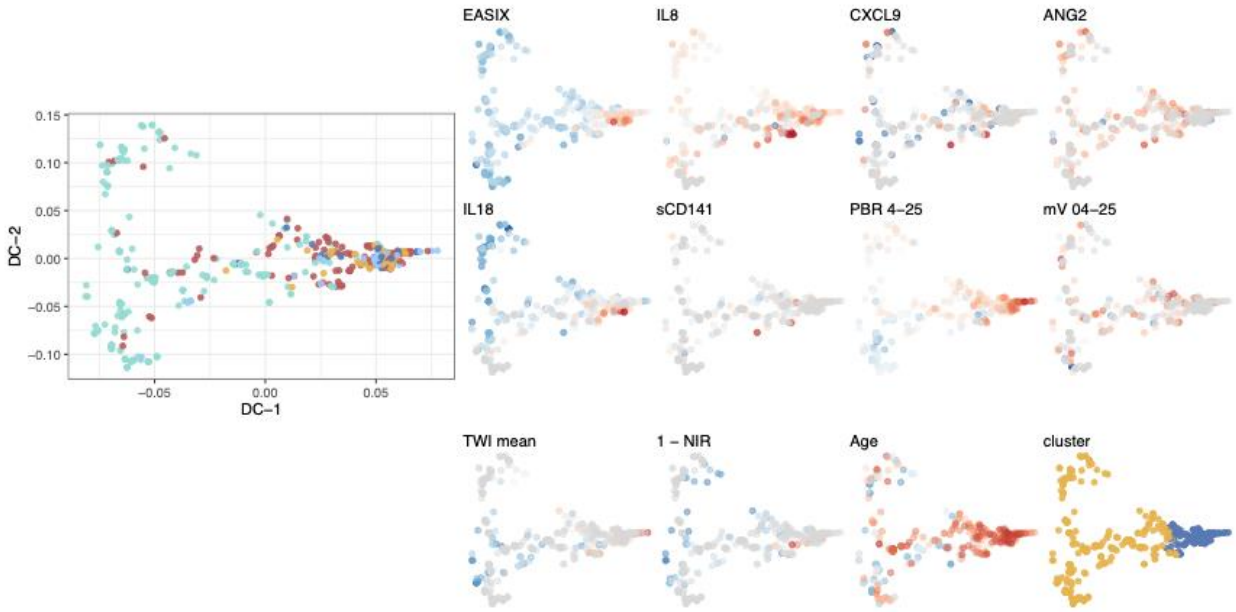
ENDOTHELIAL DYSFUNCTION IN PATIENTS WITH ACUTE LEUKEMIA: LESSONS TO LEARN FROM MULTIMODAL CLUSTERING

Lina Alasfar[1,2], Jule Buhl[2], Laura Simons[2], Tim Sauer[2], Franziska Sunderer[2], Lena Maier-Hein[3], Silvia Seidlitz[3], Carsten Müller-Tidow[2], Peter Dreger[2], ***Thomas Luft***[2]
[1]Charité – Universitätsmedizin Berlin, Berlin, Germany, [2]Universitätsklinikum Heidelberg, Heidelberg, Germany, [3]Deutschen Krebsforschungszentrum (DKFZ), Heidelberg, Germany*

Background: Early mortality after allogeneic hematopoietic stem cell transplantation (alloHSCT) is associated with endothelial cell dysfunction that can be demonstrated already before conditioning therapy. We set out to study whether the reported pre-transplant endothelial alterations may be triggered by cytotoxic therapy and/or neutropenia-associated infections during induction therapy for acute leukemia.

Methods: In the context of a prospective observational study (NCT05502887) we included 152 patients before alloHSCT as well as 102 healthy individuals (controls). We performed longitudinal, comprehensive endothelial assessments on a subset of them diagnosed with acute leukemia, before first induction chemotherapy (n= 30), on day 7-9 after first induction therapy (peripheral blast clearance) (n= 31), directly before second induction chemotherapy (n= 18), and before alloHSCT (n=22).
Sublingual microscopy (Glycocheck®), digital hyperspectral imaging (Tivita®), and serum endothelial markers (endothelial activation and stress index (EASIX), Angiopoietin (ANG)2, CXCL8, CXCL9, interleukin (IL)-18, and soluble thrombomodulin) were measured before alloHSCT and at each time point for the longitudinal sub-cohort. To integrate these diverse measurements into a single interpretable pattern, we used a multimodal clustering approach: the data from all tests were first simplified using UMAP, a dimensionality-reduction method that groups related measurements closer together, and then patients were assigned to clusters using k-medoids, a robust clustering algorithm that identifies representative profiles. This approach allowed us to classify patients into clinically meaningful groups based on shared endothelial characteristics.

Results: The clustering and dimensionality reduction showed a clear difference between patients and controls. Most of the patients were in a single cluster that had significantly elevated endothelial distress markers and was associated with adverse transplantation outcomes, particularly non-relapse mortality. In the longitudinal acute leukemia subcohort, we found a remarkable stability of altered endothelial measures (IL18, Glycocheck®, Tivita®), in patients irrespective of age, from initial diagnosis until the pre-conditioning landmark, whereas EASIX at initial diagnosis reflected tumor load. In contrast, markers of acute endothelial distress (ANG2, CXCL8, sCD141) increased during induction chemotherapy and normalized until transplantation. This could also be seen in the UMAP coordinates and diffusion maps where most of these patients differed from controls for all time points.
The diffusion map analysis clearly separated the two clusters and showed regions of high EASIX, IL18, reduced glycocalyx thickness and low digital perfusion that were highly spatially correlated with the endothelial risk cluster. Most of the acute leukemia patients with high values of endothelial dysfunction markers at initial diagnosis clustered in this region, and their diffusion map positions remained relatively unchanged across time.



Conclusions: In patients with acute leukemia undergoing alloHSCT, multimodal clustering show unique pretransplant patterns driven by endothelial dysfunction-associated markers. Altered sublingual and digital endothelial and perfusion markers together with increased IL18 were present already at initial diagnosis and remained stable during the pretransplant course. Collectively, these results suggest that pre-transplant endothelial integrity alterations in patients with AML are caused by disease related factors rather than by treatment toxicity.

Valenciana, Valencia, Spain, [8]Banco de Cordón de Galicia, Axencia de Doazón de Órganos e Sangue, Santiago de Compostela, Spain, [9]Banco de Cordón del País Vasco, Centro Vasco de Transfusiones y Tejidos Humanos - Osakidetza, Galdacano, Spain, [10]IRCCS San Raffaele Scientific Institute, Milan, Italy, [11]Hospital das Clínicas HCFMUSP, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [12]Monacord, Centre Scientifique de Monaco, Monaco, Monaco, [13]Organización Nacional de Trasplantes, Madrid, Spain

Background: During the past decades, Spanish cord blood (CB) banks have delivered a large number of cord blood units (CBU) used by EBMT centres. This study addressed whether outcomes of cord blood transplantations (CBTs) using Spanish CBUs have improved over time.

Methods: We retrospectively analysed 1629 CBTs, performed between 2005 and 2023 in 200 EBMT centres, reported to Eurocord registry, which used at least one CBU coming from any of the 7 public Spanish CB banks linked to REDMO (located in Barcelona, n=966; Malaga, n=462; Madrid, n=140; Valencia, n=93; Santiago de Compostela, n=57; Pais Vasco n=28; Tenerife, n=4). Using an intention-to-treat approach (no censoring if a subsequent transplant is performed), the primary endpoint was 5-year overall survival (OS) from the day of CBT. Based on the analysis of continuous risk of death after transplantation, 3 time periods were considered: 2005-2010 (P1, n= 558), 2011-2013 (P2, n= 480) and 2014-2023 (P3, n= 591).

Results: Comparing P3 with P1 period, we observed: (1) lower percentage of patients with acute leukaemia in advanced stage at CBT; (2) more AMLs than ALLs; (3) lower percentage of patients transplanted for lymphoid diseases (lymphomas, myelomas, other chronic lymphoproliferative disorders); (4) higher nucleated and $CD34^+$ cell doses infused; (5) increased use of busulfan for myeloablative conditioning regimens (MACs); (6) less ATG use. Overall, the 5-year OS significantly improved with time, whether considering all, single or double CBTs (**Figure**). The most striking improvements reflected by a statistically significant 5-year OS increase $\geq$ 20%, were observed (1) in males; (2) when recipient age at CBT was $\geq$ 10 and < 40 years; (3) if a MAC including either TBI or a 2-drug busulfan-based TBI-free regimen was used; (4) for single CBTs, when there was a donor/recipient HLA incompatibility restricted to HLA-A and/or HLA-B loci (low-resolution typing for HLA-A and -B, high-resolution for HLA-DRB1) (**Table**). We did not observe any significant improvement over time with RIC. Disease-specific analyses showed a statistically significant 5-year OS improvement $\geq$ 20% in patients with: (1) acute myeloid leukaemias who received either a double CBT after a MAC or a single CBTs after a 2-drug busulfan-based TBI-free MAC (**Table**); (2) acute lymphoblastic leukaemias who received a single CBT with no more than 2 donor/recipient HLA mismatches or with HLA mismatch(es) restricted to the HLA-A locus; (3) myelodysplastic syndromes (Table). No such improvement was observed for non-malignant diseases (**Table**). Notably, all results described above remained significant when adjusted on total nucleated or $CD34^+$ cell dose infused or on recipient age at CBT.

Figure: 5-year overall survival according 3 times periods: P1 (2005-2010), P2 (2011-2013) and P3 (2014-2023)

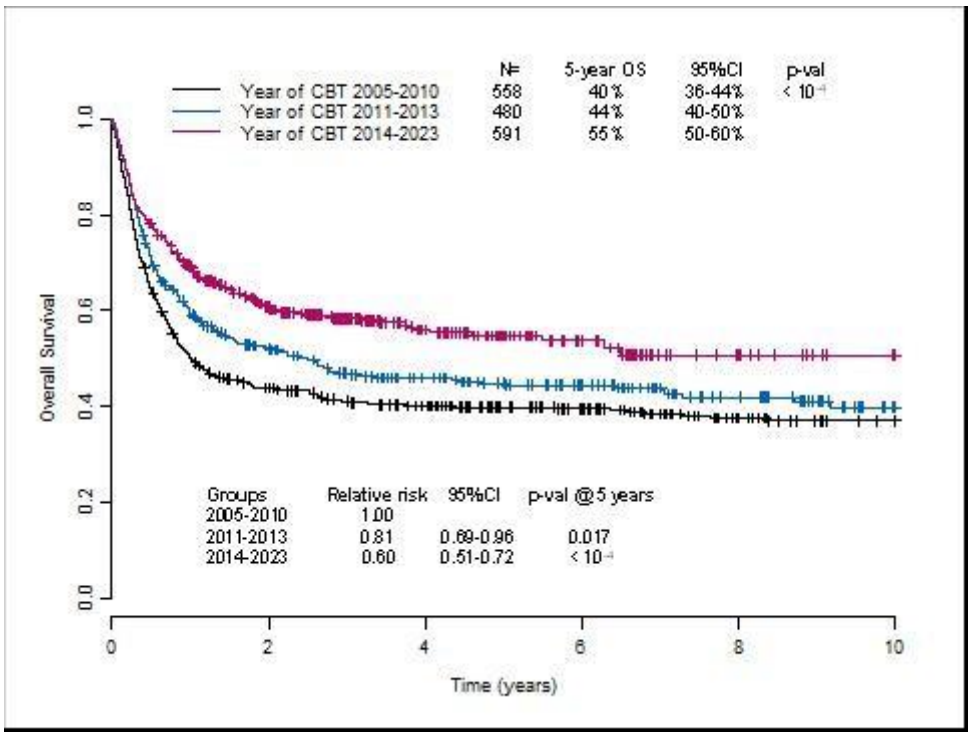

Table: Covariates improving over time

Table	Type of CBT	N=	Kaplan-Meier Estimates			Log-Rank test	Maximum difference
Covariates			P1	P2	P3	p-values	between P1, P2 & P3
All CBTs	single + double CBTs	1629	40%	45%	55%	< 10^{-4}	15%
Single CBTs	single CBTs	1041	44%	47%	58%	< 10^{-4}	14%
Double CBTs	double CBTs	588	33%	42%	49%	0.0016	16%
Overall analyses							

Recipient age at CBT > 10 to < 40 years	single + double CBTs	522	36%	47%	57%	0.0001	21%
Male recipients	single + double CBTs	921	36%	44%	56%	$< 10^{-4}$	20%
TBI-based MACs	single + double CBTs	285	39%	56%	61%	0.0004	22%
Two-drug busulfan-based TBI-free MACs	single + double CBTs	205	49%	53%	72%	0.028	23%
Donor/recipient HLA mismatch restricted to HLA-A and/or -B loci	single CBTs	464	46%	41%	61%	0.0004	20%
Disease-specific analyses							
AMLs with MACs	double CBTs	92	22%	32%	64%	0.0022	42%
AMLs with 2-drug busulfan-based TBI-free MACs	single CBTs	51	36%	43%	81%	0.027	45%
ALLs with 0 to 2 donor/recipient HLA mismatches	single CBTs	249	43%	46%	66%	0.0071	23%
ALLs donor/recipient mismatch restricted to the HLA-A locus	single CBTs	44	29%	58%	71%	0.046	42%

Myelodysplastic syndromes	single + double CBTs	95	20%	52%	55%	0.01	35%
Non-malignant diseases	single + double CBTs	246	59%	68%	73%	0.13	14%

Conclusions: Survival after CBTs using Spanish CBUs has significantly improved during the past decades, especially since 2014. The striking outcome improvements likely resulted from the experience gained through long-term use of classic MAC regimen, such as the busulfan/cyclophosphamide combination, and from a better selection of the CBUs, aiming for higher cell doses and improved donor/recipient HLA matching.

EFFICACY OF THE TRIPLET THERAPY WITH VENETOCLAX, AZACITIDINE AND GILTERITINIB FOR THE TREATMENT OF FLT3-ITD MUTATED R/R AML PATIENTS BRIDGING TO ALLOGENEIC STEM CELL TRANSPLANTATION

Chen Liang[1], *Aiming Pang*[1], *Yi He*[1], *Rongli Zhang*[1], *Mingzhe Han*[1], *Sizhou Feng*[1], *Donglin Yang*[1], *Erlie Jiang*[1]
[1]*State Key Laboratory of Experimental Hematology, National Clinical Research Center for Blood Diseases, Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China*

Background: Patients with relapsed or refractory (R/R) acute myeloid leukemia (AML) with FLT3-Internal Tandem Duplication (ITD) mutation have a poor prognosis and high risk of relapse.Triplet therapy with venetoclax[VEN], azacitidine[AZA] and gilteritinib is effective and significantly improves response rates and survival outcomes in this high-risk patient population.

Methods: We analyzed 48 FLT3-ITD mutated AML patients in a retrospective cohort study. Patients with R/R disease or persistent MRD received triplet therapy (VEN, AZA and gilteritinib) and bridged to allo-HSCT between August 2021 and June 2024. Bone marrow aspirates were obtained, cytogenetic and molecular characteristics were collected at the time of diagnosis. HLA-haploidentical donor transplants were performed if no HLA matched sibling or unrelated donor was available. Patients received myeloablative conditioning regimens followed by post-transplant gilteritinib maintenance therapy. The therapeutic process and clinical outcomes were retrospectively analyzed.

Results: 48 adult patients were enrolled in this study, 27 (56.2%) were female and 21 (43.8%) were male. The median age was 41 (range 15-61). Based on prognostic stratification defined by the 2022 European LeukemiaNet (ELN) guidelines, 38 (79.2%) patients were categorized in the Intermediate-risk group and 10 (20.8%) were categorized in the adverse-risk group at diagnosis. At the time of enrollment, 38 (79.2%) patients had R/R disease, of whom 36 cases failed to achieve remission with prior chemotherapy and two cases attained complete remission with MRD positivity. The remaining 10 patients (20.8%) were in CR1 but were detected with persistent positive MRD during chemotherapy.
After one cycle of triplet therapy (VEN, AZA and gilteritinib), 39 (81.3%) patients reached CR/CRi (16 were MRD negative and 23 were MRD positive). The remaining 9 (18.7%) patients showed no treatment response and proceeded to transplantation with active disease. No treatment-related mortality (TRM) was observed. Patients received myeloablative conditioning with a modified Bu/Cy/Cla/Ara-c (busulfan/cyclophosphamide/cladribine/cytarabine) or MCBC (melphalan/cladribine/busulfan/cyclophosphamide) preparative regimen. All patients engrafted successfully, with hematopoietic recovery within 60 days of transplantation. Gilteritinib maintenance therapy started between day +30 to latest day +90 after allo-HSCT. At the time of this analysis, 40 (83.3%) patients remained alive, while disease relapse had occurred in 9 patients (18.8%). The median follow-up of alive patients was 16.6 months (11-43.2). The 1-year overall survival (OS) and relapse-free survival (RFS) were 83.3% (95% CI 72.7-93.9%) and 75.0% (95% CI 62.7-87.3%), respectively. The leading causes of death were leukemia relapse (n=4), followed by grade IV aGVHD (n=3) and severe infection (n=1). The 1-year incidences of relapse and non-relapse mortality (NRM) were 14.6% (95% CI 6.3-26.1%) and 10.4% (95% CI 3.8-21.0%) , respectively. 19 (39.6%) patients experienced aGVHD and 15 (31.3%) experienced cGVHD.

Conclusions: The triplet therapy of VEN, AZA and gilteritinib resulted in high rates of CR/CRi and enhanced the feasibility of HSCT in FLT3-ITD mutated AML patients with R/R disease or persistent MRD. Sequential allo-HSCT followed by gilteritinib maintenance therapy may significantly improve the long-term prognosis in this high-risk group of patients.

A113

THE EFFICACY OF MEMORY T CELL DONOR LYMPHOCYTE INFUSION IN AUGMENTING IMMUNE FUNCTION FOLLOWING ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

Jiayu Huang[1], *Chuanhe Jiang*[1], *Chengwei Jin*[2], *Luxiang Wang*[1], *Zilu Zhang*[1], *Haiyang Lu*[1], *Su Li*[2], *Xiaoxia Hu*[1]
[1]*Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China,*
[2]*GoBroad Medical Institute of Hematology (Shanghai Center), Liquan Hospital, Shanghai, China*

Background: Prolonged immune reconstitution associated with allogeneic hematopoietic cell transplantation (allo-HCT) increases the risk of severe infection, a significant cause of mortality in these patients. Despite the improvements in the use of prophylactic strategies and the establishment of first-line treatment, there remains a necessity to formulate a novel therapy for these patients. Memory T cells, defined by expression of CD45RO and absence of CD45RA isoform, has been reported as an effective method to rapidly recover T cell immunity post allo-HCT, which contributed to the enhanced capacity for anti-infection. In this study, we analyzed the efficacy and safety of CD45RA-depleted memory T-cell infusion in treating refractory or persistent viral or fungal infection following allo-HCT.

Methods: In this retrospective study, we screened those allo-HCT receipts who received at least once CD45RA-depleted memory T-cell adoptive cell therapy (ACT) and obtained the required information by using institutional electronic medical records. Between March 2024 and November 2025, 20 adult patients were enrolled.

Results: Baseline characteristics and transplant procedure are described in Table 1. The pathogens treated include viruses (90%), including epstein-barr virus (EBV, 35.0%), Cytomegalovirus (CMV, 10.0%), human parvovirus B19 (10.0%), adenovirus (ADV, 10.0%), herpes simplex virus-1 (HSV1, 15.0%), herpes simplex virus-2 (HSV2, 5.0%), BK virus (BKV, 10.0%), john cunningham virus (5.0%), human herpesvirus 6B (HHV6B, 5.0%), human parainfluenza viruses (HPIVs, 5.0%), and fungi (15.0%), including fusarium (10.0%) and aspergillus (5.0%). 48 infusions of CD45RA-depleted memory T-cell ACT were administrated to the 20 patients with a cumulative dose of 23.2 (range: 4.3–47.7) $\times 10^6$ cells/kg across a median of two cycles (range: 1–4). Memory T cells were obtained from original transplant donor (n=15, 75.0%) and third-party donor (n=5, 25.0%). The first ACT infusion was administered at a median of 98 days (range: 23-774) after allo-HCT, with half of patients (n=10) receiving ACT within 100 days. During the treatment period, 14 (70.0%) patients continued concomitant use of immunosuppressants. After a median follow-up of 52 (range: 16-636) days, 18 patients (90.0%) are alive at time of analysis (December 2025), and 12 patients (60.0%) attained complete remission from the infection. In three patients with fungi infection (including fusarium and aspergillus), a marked improvement in clinical symptoms was observed in these patients. Of 18 patients with viruses infection, the cumulative incidence of negative viral polymerase chain reaction after first ACT was 72.2% (13/18 patients). The median duration to achieve negative test for each virus are 15 days (EBV, one patient continues to test positive), 5 days (CMV), 38 days (B19), 10 days (ADV, one patient continues to test positive), 35 days (HSV1, one patient continues to test positive), 9 days (HSV2), 36 days (BKV, one patient continues to test positive), 33 days (HHV6B) and 36 days (HPIVs). Treatment was well tolerated; adverse events included acute graft versus host disease (GvHD) in 1 patient (5.0%), chronic GvHD in 3 (15.0%) and primary disease relapse in 1 (5.0%).

Characteristics	All
Age at allo-HCT (years), median (range)	46 (25-66)
Sex, *n* (%)	

Male	14 (70.0%)
Female	6 (30.0%)
Conditioning intensity, *n* (%)	
MAC	13 (65.0%)
RIC	7 (35.0%)
Donor type, *n* (%)	
HID	18 (90.0%)
MUD/MMUD	1 (5.0%)
MSD	1 (5.0%)
T-cell depleted, *n* (%)	
Ex vivo	1 (5.0%)
In vivo	
rATG-based	16 (80.0%)
PTCY-based	3 (15.0%)

Tabel 1. Patients'characteristics. Abbreviation: allo-HCT, allogeneic hematopoietic cell transplantation; HID, haploidentical donor; MUD/MMUD, matched/mismatched unrelated donor; MSD, matched sibling donor; MAC, myeloablative conditioning; PTCy, post-transplant cyclophosphamide; rATG, rabbit anti-thymocyte globulin; RIC, reduced-intensity conditioning.

Conclusions: CD45RA-depleted donor memory T cell infusion provides clinical benefit in allo-HCT receipt with refractory and persistent infection, without evidence of the safety concerns reported.

Disclosure: Nothing to declare.

A114

LONG-TERM SURVIVAL AND HIGH-RISK DETERMINANTS FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANT IN MANTLE CELL LYMPHOMA

Muhammad Azeem Khan[1], *Patrick B. Johnston*[1], *Stephen M. Ansell*[1], *Jonas Paludo*[1], *Luis F. Porrata*[1], *Jose Villasboas Bisneto*[1], *Yucai Wang*[1], *Urshila Durani*[1], *Nora N. Bennani*[1], *Ivana N. Micallef*[1]
[1]*Mayo Clinic, Rochester, United States of America (the)*

Background: High-dose chemotherapy followed by autologous stem cell transplantation (ASCT) has been a cornerstone of treatment for mantle cell lymphoma (MCL). However, the therapeutic landscape has shifted away from ASCT in favor of Bruton tyrosine kinase inhibitor (BTKi) containing regimens. Despite this shift, patients with high-risk morphologic features and TP53 aberrations continue to experience inferior outcomes with BTKi-based approaches. In this context, the role of ASCT remains uncertain. The goal of this study was to evaluate outcomes in MCL following ASCT in the setting of these adverse prognostic features.

Methods: We conducted a single center retrospective study of all patients with MCL who underwent ASCT between August 1996 and January 2021 at Mayo Clinic, Rochester, MN. Categorical variables were compared using the Chi-square test and/or Fisher's exact test. Overall survival (OS) and progression free survival (PFS) were evaluated using the Kaplan–Meier method with group comparisons by log-rank test. Patients were stratified by high-risk features including blastoid or pleomorphic morphology, a proliferation index (Ki67) ≥ 30%, TP53 mutations and high mantle cell lymphoma international prognostic index (MIPI) scores.

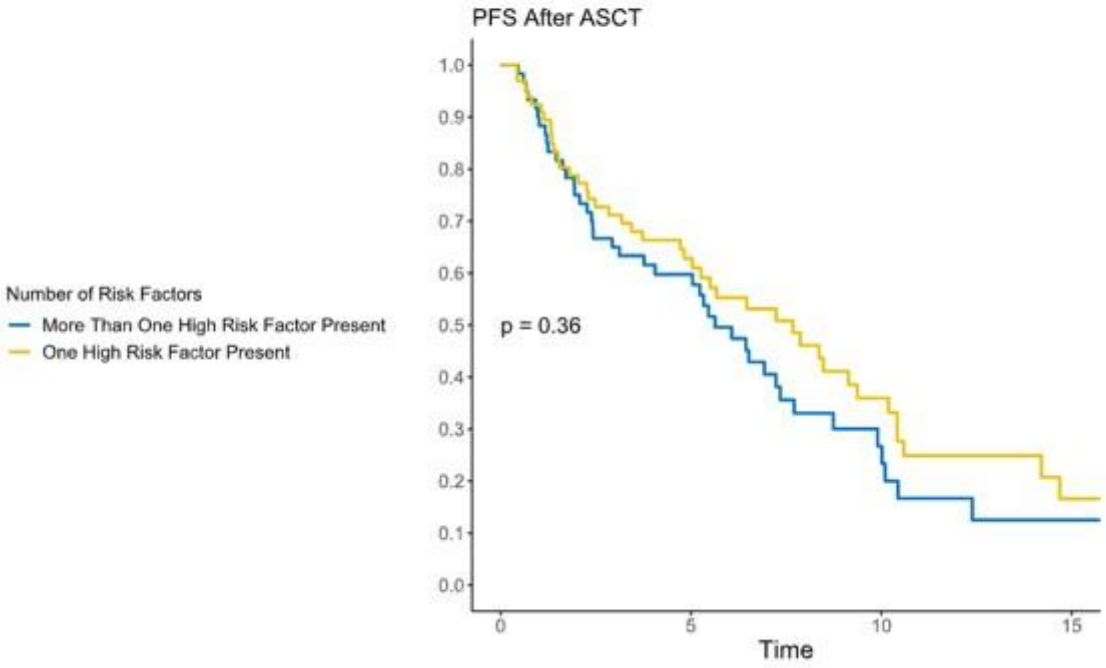
Results: A total of 303 patients were included in the study. The median age at the time of ASCT was 59.9 years and the cohort was predominantly male (78.5%), Caucasian (91.4%) and diagnosed with advanced-stage disease (95%). The median follow-up after ASCT was 11.2 years. The median PFS for the entire cohort was 8.4 years (95% CI, 7.3-10.2) and the median OS was 10.9 years (95% CI 9.5-15.4 years).
Blastoid or pleomorphic morphology, a high proliferation index, and elevated MIPI scores were each significantly associated with shorter PFS and OS, as shown in Table 1. Patients with a single high-risk feature had a trend toward longer PFS compared with those harboring multiple high-risk factors (7.7 vs 5.6 years), although this difference was not statistically significant (p = 0.36), as demonstrated in Figure 1.
The entire cohort was further stratified by PFS (< 5 vs ≥ 5 years) and OS (< 5 vs ≥ 5 years and (< 10 vs ≥ 10 years). Patients with PFS < 5 years were more likely to have aggressive morphology (p=0.007) and high MIPI scores (p=0.05) than those with PFS > 5 years. Conversely, patients with OS ≥ 10 years were less likely to have aggressive morphology (p=0.07) or high risk MIPI scores (p=0.001).
Ninety-two of 303 patients received rituximab maintenance after ASCT, and 149 of 303 ultimately relapsed. Post-ASCT therapies included BTKi in 59 of 303 patients and CAR-T in 11 individuals.

Table1:

		PFS (y)	p-value	OS (y)	p-value
All patients (n=303)		8.4		10.9	
Morphology (n=303)	Aggressive (n=65)	5.3	**< 0.001**	7.6	**0.004**
	Not-aggressive (n=238)	9.9		12. 5	
Proliferation index (n=161)	Ki-67 ≥ 30 % (n=88)	7.7	**0.006**	10.6	**0.004**
	Ki-67 < 30 % (n=73)	10.9		NR	
TP-53 status (n=39)	Mutated (n=12)	5	0.27	NR	0.21
	Wild type (n=27)	6.5		NR	
MIPI (n=164)	High risk (n=52)	5.6	**< 0.001**	7.7	**< 0.001**
	Not high risk (n=112)	10.3		15.8	

Abbreviations: y=years, n=number, NR=not reached.

Figure1:



Conclusions: Our study demonstrates that ASCT can provide durable benefit in MCL, with median PFS exceeding five years across all high-risk categories. These findings support a continued role for ASCT in the management of MCL, including high-risk patients who experience inferior outcomes with BTKi based therapy and in those who are unable to tolerate or have contraindications to BTKi.

Background: The role of non-donor-specific anti-HLA antibodies in allogeneic HSCT remains unclear, despite the well-recognized adverse impact of donor-specific antibodies on post-transplant outcomes.

Methods: We conducted a retrospective multicenter study including 401 allogeneic HSCT patients from five Italian transplant centers. Patients were categorized into three groups based on pre-transplant anti-HLA antibody status: no detectable antibodies (No Anti-HLA), non–donor-specific antibodies (AntiHLA-NoDSA), and donor-specific antibodies (DSA). Descriptive statistics were generated for the overall cohort and stratified by antibody group. The association between antibody status and overall survival was evaluated using Kaplan–Meier estimates and Cox proportional hazard models, performed first in univariate analyses and subsequently adjusted for clinically relevant covariates in multivariate models.

Results: Among 401 allogeneic HSCT recipients, No Anti-HLA, AntiHLA-NoDSA and DSA patients were 278 (69%), 78 (19%) and 45 (11%), respectively. The cohort had a median age of 59 years (IQR 47–66), and females represented 44%. Female sex was more frequent in the AntiHLA-NoDSA group (54/78, 69%) compared with the No Anti-HLA group (101/278, 36%). Donor types included HLA-identical siblings, matched unrelated donors (MUD), mismatched unrelated donors (mMUD), and haploidentical donors.
Disease characteristics were comparable across groups: 306/401 (76%) of patients had myeloid malignancies, and 251/385(65%) underwent transplantation in first complete remission or full remission with similar proportions in each subgroup. Pre-transplant transfusion burden was higher in the AntiHLA-NoDSA subgroup, with >20 RBC units in 30/78 (38%) and >20 platelet units in 31/78 (40%), compared with 82/278 (30%) and 73/278 (26%) in the No Anti-HLA group and 16/45 (36%) and 13/45 (29%) in the AntiHLA-DSA group. In the Cox model, >20 pre-transplant transfusions of RBCs (HR 1.81, 95% CI 1.24–2.64, p=0.01) and platelets (HR 1.65, 95% CI 1.13–2.42, p=0.01) were both independently associated with inferior overall survival. Platelet refractoriness was infrequent overall (3%) but more common in the AntiHLA-NoDSA subgroup (9%).[tab. 1]
Among AntiHLA-NoDSA patients, median maximal MFI was 5,649, with a cumulative MFI of 12,650. The median PRA was 21% for class I and 1% for class II.
At two years, overall survival was 69% in the No Anti-HLA group and 55% in the AntiHLA-NoDSA group (log-rank p = 0.14). [Fig. 1] In the Cox model, the presence of non–donor-specific antibodies was associated with a higher mortality risk, though without statistical significance (HR 1.36, 95% CI 0.90–2.05, p = 0.14). This association remained directionally consistent after adjustment for clinical covariates in the multivariate analysis (HR 1.44, 95%

CI 0.93–2.24, p = 0.11). No significant associations were observed between survival and antibody characteristics (maximum MFI, cumulative MFI, or PRA for class I and II).

Patients Characteristic	**Overall** N = 401[1]	**No anti-HLA antibodies** N = 278[1]	**AntiHLA-NoDSA** N = 78[1]	**DSA** N = 45[1]

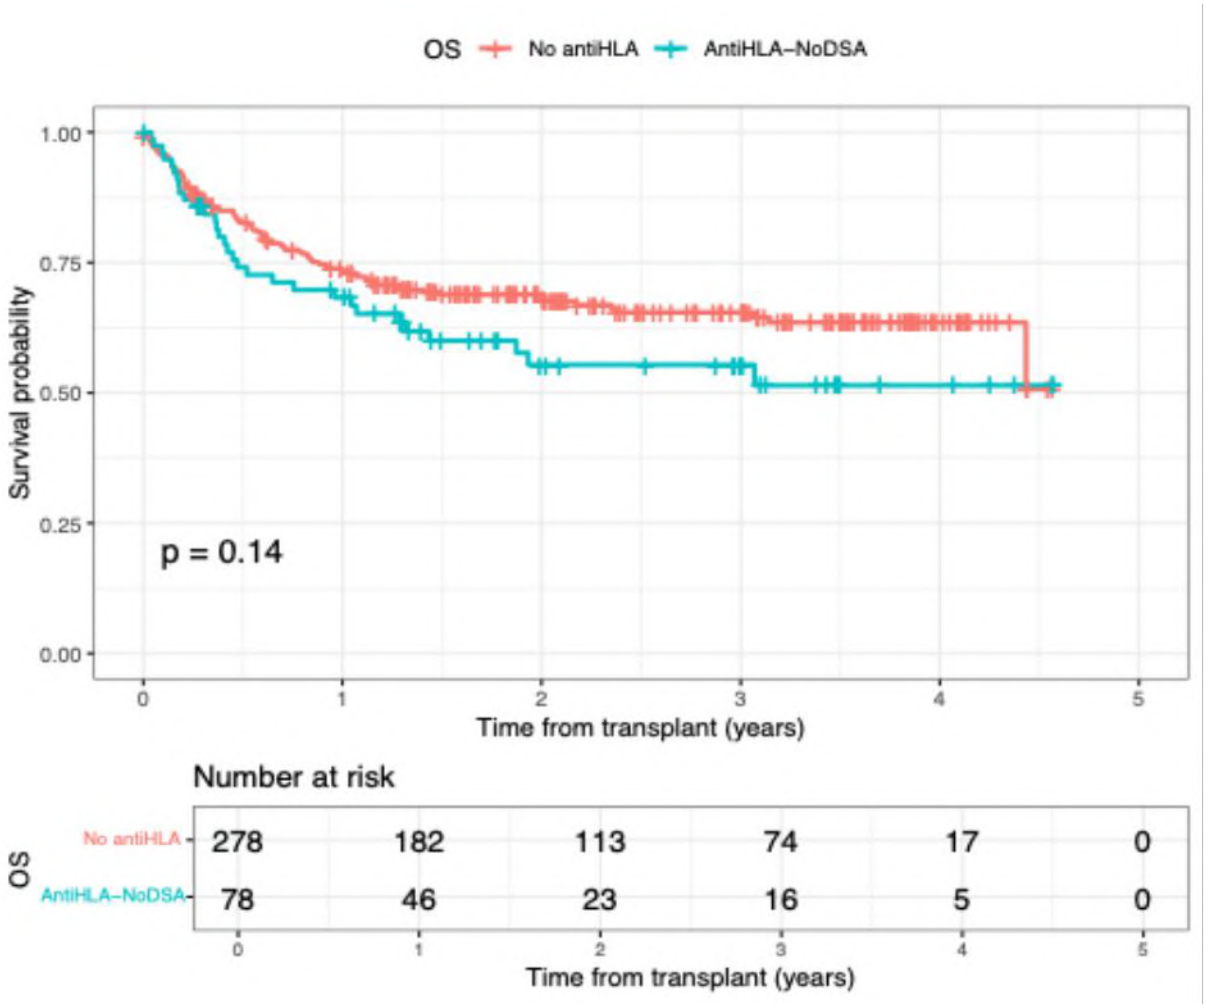
[1]n (%); Mean (SD), Median (Q1-Q3), Min, Max, Complete remission (CR)



Conclusions: The alignment between survival curves and hazard ratio patterns reveals a consistent and clinically relevant signal implicating non–donor-specific anti-HLA antibodies as an unfavorable predictive factor in allogeneic HSCT in our multicenter cohort of 401 patients. These findings challenge the current paradigm that only donor-specific antibodies are clinically meaningful and position non-DSA as an overlooked immunologic variable warranting systematic and in-depth evaluation in future prospective studies.

Background: The DKMS (Germany) and the NMDP (USA) have embarked on a large collaborative project to characterize more than 2000 donor peripheral blood stem cell (PBSC) grafts in unprecedented detail. Here, we present an exploratory analysis focusing on microbiome-dependent mucosal-associated invariant T (MAIT) and Vδ2 populations, which have both been associated with favorable HCT outcomes in prior studies. We hypothesized that receiving a graft bearing higher 'doses' of these cell populations would be associated with favorable clinical outcomes.

Methods: PBSC graft samples were collected, processed, freshly stained (34-color panel for immunophenotyping of lymphocytes and hematopoietic stem cells), and analyzed using high dimensional full spectrum flow cytometry at the NMDP contract laboratory (n = 457; Roswell Park, Buffalo, NY) or the DKMS laboratory in Dresden, Germany (n = 270). Clinical data were collected via CIBMTR. We included patients who were transplanted for AML or MDS, with at least 1 year of follow-up data available. A Cox proportional hazard model was fitted to assess the relationship of MAIT and Vδ2 populations (dose/kg recipient weight in the graft) with transplant outcome and identify significant risk factors, including GVHD prophylaxis, cryopreservation status, patient and donor age, refined disease risk index, HCT-CI, conditioning intensity, and HLA matching.

Results: Patients with AML or MDS, receiving unrelated donor PBSC allografts were studied (n = 727). The median recipient age was 64.2 years. 404 (55.57%) received post-transplant cyclophosphamide (PT-Cy) as GVHD prophylaxis.
In multivariable analyses, recipients of grafts bearing a below-median number of Vδ2 cells was associated with significantly worse overall survival compared with equal to or below-median (HR=1.337, 95% CI 1.032-1.733, p = 0.0281; **Figure 1**). Additional clinical factors associated with worse overall survival are high/very high disease risk index (HR=1.637, 95% CI 1.234-2.172, p = 0.0006) compared to low/intermediate group and HCT-CI 3+ (HR=1.597, 95% CI 1.252-2.037, p = 0.0002) compared with the HCT-CI 0-2 group. There were no statistically significant differences in acute or chronic GVHD in patients who received above-median Vδ2 doses in our multivariable models. Multivariable analyses found no

associations between MAIT cell graft content and outcome (OS shown in **Figure 1**).
Given the OS finding among patients who received higher numbers of Vδ2 cells in their graft product, we next characterized the causes of death in the cohort. Notably, infection was reported as the cause of death in 3.9% in the above-median Vδ2 setting and 7.9% in the recipients of grafts containing below-median numbers of Vδ2 cells (p = 0.034; Fisher's exact test).

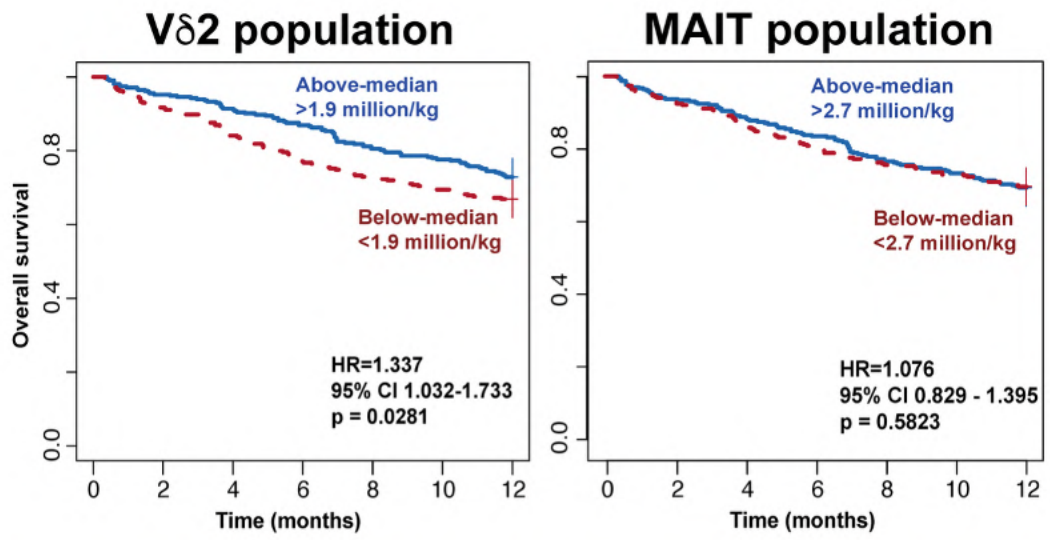

Figure 1: Kaplan-Meier curves comparing overall survival (OS) in the recipients of above- and below-median Vδ2 and MAIT cell-containing grafts. Data shown derived from 627 patients (a portion of participants had missing TNC data, thus absolute numbers could not be calculated). Statistics shown are derived from MV Cox proportional hazard model accounting for: GVHD prophylaxis (PT Cy vs others); Graft cryopreservation status (fresh vs frozen); patient age, donor age, disease risk, HCT-CI, conditioning intensity, HLA matching.

Conclusions: We report a novel association between the Vδ2 content of the donor graft and 1 year overall survival in the allo-HCT recipient. Vδ2 cells have previously been associated with lower rates of GVHD and improved OS when measured after HCT, however their number in the donor graft has not previously been correlated with outcome. Intriguingly, little is known regarding the functional capacity of these T cells after HCT, and further studies will focus on uncovering the mechanism by which they may contribute to improved overall survival.

Background: Treatment with chimeric antigen receptor T-cells (CAR T) has demonstrated efficacy in patients with CD19-positive hematological malignancies and lower toxicity than other treatment options. We established an academic CAR-T cell program to broaden access for patients without other curative treatment options and to enable faster, more flexible local production.
We report preliminary results from the initial phase 1b/2 trial using the academic autologous 4-1BB anti-CD19 CAR-T product DK-CLIC-1901 (CTIS # 2024-515174-27-00). The primary objective was to evaluate the safety of DK-CLIC-1901. The secondary objectives were to assess feasibility, clinical efficacy, and immunological response after DK-CLIC-1901 infusion.

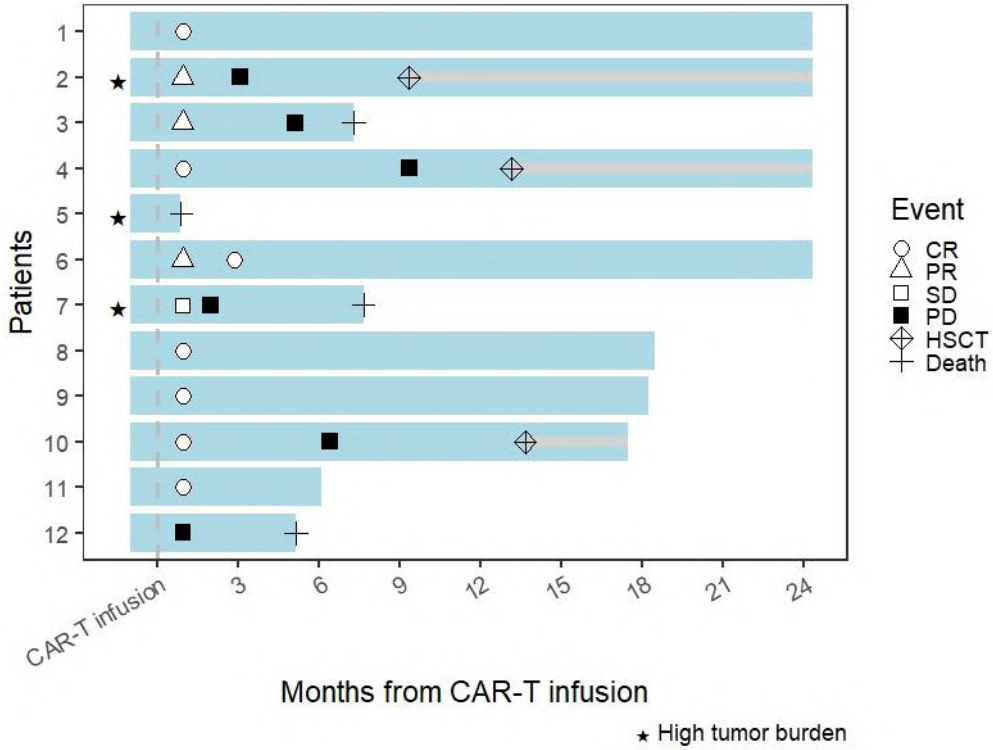
Methods: The main inclusion criteria were relapsed or refractory B-cell ALL or NHL, age between 1-70 years, adequate performance status and organ function (lung, heart, liver, and kidney), life expectancy ≥ 12 weeks, and written informed consent.
Patients received a single infusion of fresh-to-fresh autologous, *in vitro*-expanded DK-CLIC-1901 CAR T-cells at a minimum dose of $1x10^6$ CAR T-cells/kg, with a dose reduction to $2x10^7$CAR T-cells in total in case of high tumor burden. The DK-CLIC-1901 product was manufactured on the CliniMACS Prodigy platform (Miltenyi) using a lentiviral vector carrying a 4-1BB anti-CD19 CAR transgene [N. Kekre et al, Front Immunol 2022].

Results: Thirteen patients passed the initial screening for participation. One patient was excluded before apheresis due to rapid progression of hematological malignancy; 12 patients underwent apheresis and received CAR-T infusion (Table).

Clinical characteristics	**N=12**
Age (years), median (range)	54 (16-67)
Male sex, *n*. (%)	11 (92%)
Diagnosis, *n*. (%) B-ALL B-NHL DLBCL Transformed FL HGBL	 2 (17%) 10 (83%) 3 (25%) 4 (33%) 1 (8%)

Burkitt lymphoma Mantle cell lymphoma	1 (8%) 1 (8%)
High tumor load, *n*. (%) ALL: >20% blasts in BM NHL: ≥10 cm tumor mass or BM involvement	 0 (0%) 3 (25%)
LDH at the start of LDT (U/L), median (range)	229 (130-2200)
Prior lines of treatment, median (range)	3 (1-4)
CAR-T indication, *n*. (%) Primary refractory ≥2 relapse Relapse after autologous/allogeneic HSCT	 5 (42%) 4 (33%) 3 (25%)
LDT with FLU (30 mg/m^2 x4) and CY (500 mg/m^2 x2), *n*. (%)	12 (100%)
Time from enrollment to apheresis (days), median (range)	6 (2-16)
DK-CLIC-1901 production time (days from apheresis to CAR-T infusion), median (range)	13 (13-19)
Cellular composition of DK-CLIC-1901 product, median (range) CAR-T cell count (x10^6 CAR T-cells / kg bodyweight) CAR-T cell count (x10^8 CAR T-cells in total) CD4/CD8 T cell ratio	 2 (0.23-3.1) 200 (20-200) 0.63 (0.29-3.69)

CRS occurred in 9 patients (grade ≥3: n=3) and ICANS in 3 patients (grade ≥3: n=2), with a higher frequency in patients with high tumor burden (CRS grade ≥3: 67% vs. 11%; ICANS: 67% vs. 11%). One patient with a high tumor load died at day +26 from intracerebral hemorrhage following severe CRS/ICANS. Another patient developed HHV-6 encephalitis after CAR-T infusion with persistent neurological sequelae [NM Birk et al, Front Hematol 2025]. Late cytopenia was manageable, with grade ≥3 neutropenia (ICAHT), thrombocytopenia, and anemia occurring in 11%, 33%, and 0% of 9 evaluable patients at day 90 following CAR-T infusion.
Median follow-up time was 12 months (26 days to 2.0 years). Nine of 11 evaluable patients (82%) responded to CAR-T infusion, of which 5 remain in CR more than 6 months from CAR-T infusion (Figure). Two patients had loss of B-cell aplasia within the first year after CAR-T infusion (day +83 and +125), which was followed by a CD19-positive relapse in one patient. The estimated 1-year overall and progression-free survival were 65% (95%CI: 42-100) and 39% (95%CI: 19-82), and the 1-year cumulative incidence of non-relapse mortality was 8%. Three of the 6 patients with relapse or progressive disease were confirmed CD19 positive, and three patients (25%) were subsequently rescued with allogeneic HSCT.



Conclusions: This is the first trial of point-of-care manufactured CAR-T cells in Denmark and demonstrates that administering fresh CLIC-1901 product is safe, feasible and efficacious, especially in patients with low tumor burden. Our platform provides a feasible and rapid manufacturing procedure for future CAR-T products, which may also include targets outside commercial interests.

OUTCOMES OF CRYOPRESERVED VERSUS NON-CRYOPRESERVED STEM CELL ALLOGRAFTS: A COMPARATIVE ANALYSIS

*Saskia C. Vandahl[1,2], Georg-Nikolaus Franke[3,2], Thomas Lehmann[1,2], **Jenny Miethke**[1,2], Ulf Schnetzke[1,2], Madlen Jentzsch[3,2], Carmen D. Herling[3,2], Judith Seemann[3,2], Vladan Vučinić[3,2,4], Klaus H. Metzeler[3,2], Andreas Hochhaus[1,2], Inken Hilgendorf[1,2], Karin G. Schrenk[1,2]*
[1]Universitätsklinikum Jena, Jena, Germany, [2]Mitteldeutsches Krebszentrum, Jena/Leipzig,

Germany, [3]Universitätsklinikum Leipzig, Leipzig, Germany, [4]Fraunhofer Institut für Zelltherapie und Immunologie, Leipzig, Germany

Background: The use of fresh allogeneic stem cell grafts is traditionally preferred, to ensure optimal cell viability and functionality. However, the COVID-19 pandemic increased the use of cryopreserved stem cells due to logistical challenges in donor availability and allogeneic hematopoietic stem cell transplantation (alloSCT) scheduling. Cryopreservation offers greater flexibility but may impair cell viability, potentially delaying engraftment and reducing overall survival.

Methods: In this retrospective study, 394 consecutive alloSCT patients (170 females and 224 males, median age 58 years, (range 21-75) transplanted at the University Hospitals of Jena and Leipzig between January 2019 and December 2023 were analyzed. Of these, 97 patients received cryopreserved peripheral blood stem cell grafts, while 297 were transplanted with fresh allografts. The primary endpoints were time to neutrophil and platelet engraftment, defined according to EBMT-guidelines. Secondary endpoints included overall survival, relapse rate, non-relapse mortality, and incidence of acute and chronic graft-versus-host disease (GvHD).

Results: The majority of patients (n = 237, 60%) was diagnosed with acute myeloid leukemia (AML) with balanced disease risk index in both groups. The proportion of myeloablative (n = 37, 38.1% versus n = 100, 33.7%) and reduced intensity conditioning (n = 60, 61.9% versus 197, 66.3%) was similar between both cohorts. HLA-match, donor status, CMV-status of donor and recipient, age of donor, CMV-reactivation, and immunosuppression demonstrated no significant disparities.
No significant differences were observed between recipients of fresh or cryopreserved grafts in terms of neutrophil or platelet engraftment times, indicating comparable hematopoietic recovery kinetics. The median time to neutrophile engraftment was 17.5 days (range 8-32, IQR 8) in patients receiving cryopreserved grafts versus 18 days (range 8-139, IQR 6) in patients with fresh grafts ($p = 0.615$). Similarly, the median time to platelet recovery was 19 days (range 10-223, IQR 12) and 18 days (range 6-331, IQR 10), $p = 0.146$ in the two groups, respectively. Overall survival, number of patients with relapse, and time to relapse revealed no significant difference in patients with cryopreserved grafts versus fresh grafts. Acute GvHD and chronic GvHD did not differ significantly between groups. The only significant differences were found in infusion related adverse events (39.2% versus 17.2%, $p < 0.001$) and infections (75.3% versus 64%, $p = 0.047$).

Conclusions: The use of cryopreserved hematopoietic stem cells is safe in the alloSCT-setting without compromising neutrophil or platelet recovery, survival rate and risk of relapse, respectively. These data support the increased use of cryopreserved stem cells during logistical constraints such as those seen during the COVID-19 pandemic, expanding donor availability and transplant timing options without adverse effects on key clinical endpoints.

Background: Autologous and allogeneic stem cell transplantation (auto-; allo-SCT) represent potentially curative approaches for patients (pts) with T-cell lymphoma. Large-scale outcome data on SCT in anaplastic large cell lymphoma (ALCL), particularly, a recent comparison of ALCL anaplastic lymphoma kinase (ALK)-positive vs. ALCL ALK-negative have not been reported. Several studies suggest younger age is the predominant factor for better outcomes of ALK-pos. pts. We aimed to compare the results of auto- and allo SCT in patients with ALK-pos. and ALK-neg. ALCL.

Methods: Pts registered with the EBMT registry between 2010 and 2022 and the following inclusion criteria were analyzed: age ≥18 years (yrs), diagnosis of ALK-pos. or neg. ALCL, auto-SCT as first/or salvage SCT or allo-SCT either as first SCT or after auto-SCT.

Results: 497 pts with ALK-neg. and 81 pts with ALK-pos. ALCL (median age 58 and 46 yrs, respectively) received up-front auto-SCT. At diagnosis, IPI ≥ 3 was 38% and 70%, respectively.
3-yr PFS and 3-yr OS rates after up-front auto-SCT were 68.5% and 75.1%, and 84.1% and 83.5 in ALK-neg. and ALK-pos. ALCLs, respectively. The 3-yr RI and NRM were 27.7% and 22.3%, and 3.9% and 2.6%. ALK-neg. and ALK-pos. pts transplanted in first CR (CR1) showed comparable outcomes [3-yr PFS 74.9% vs. 74.1%; 3-yr OS: 85.4% vs 83.5%] while

PR1 patients survived significantly better if having ALK-positivity [3-yr PFS 55.3% vs. 78.6%; 3-yr OS 68.4% vs 92.3%].
In r/r situation, 328 pts with ALK-neg. and 201 pts with ALK-pos. ALCL received salvage auto-SCT with a median age of 54 and 38 years. After a median of two therapies, 3-yr PFS and 3-yr OS after salvage auto-SCT were 62.4% and 57.1%, and 73.8% and 85.1% in ALK-neg. and ALK-pos. ALCLs, respectively. The 3-yr RI and NRM were 31.3% and 39.2%, and 6.3% and 3.6%, accordingly. Auto-SCT ALK-pos. and ALK-neg. pts transplanted in later CR (CR2+) showed comparable outcomes [3-yr PFS 65.5% vs. 55.7%; 3-yr OS: 78.8% vs 86.3%] while PR2+ pts with ALK-neg. status worse survival [3-yr PFS 55.1% vs. 61.5%; 3-yr OS: 73.3% vs 80.8%].
247 pts with ALK-neg and 100 pts with ALK-pos ALCL received salvage allo-SCT with a median age of 52 and 33 years. In the allo-SCT group (median of 3 therapies prior) with 49% and 23% undergoing prior auto-SCT in ALK-neg. and ALK-pos. pts, 3-yr outcomes were as follows: PFS: 49.5% vs. 62%; OS: 59.7% vs. 79%, RI 30.9% vs. 28%; and NRM 19.6% vs. 10%. In CR pts at allo-SCT, 3-yr outcomes were: PFS 63.1% vs. 67%; OS 72% vs. 85%. In PR pts at allo-SCT, 3-yr PFS and OS were 31% vs. 77%, and 51% vs. 77%, respectively.

Conclusions: In both, ALK-pos. and ALK-neg. ALCL, transplantation resulted in excellent survival after auto- or allo-SCT. Outcomes of auto-SCT performed in CR1/CR2+ were comparable between both entities while PR pts survived better if being ALK-positive. Outcomes post-allo-SCT were significantly better in the group of ALK-pos. pts probably reflecting a significantly younger age of these pts. A matched-pair analysis of ALK-pos. and ALK-neg. pts is ongoing.

Background: Out-of-specification (OOS) CAR-T products and manufacturing failure (MF) remains a major barrier for delivery of this treatment modality in aggressive B-cell non-Hodgkin lymphomas (B-NHL). Understanding MF patterns and OOS CAR-T outcomes, together with the rate of remanufacturing success is essential to improve access and clinical performance in real-world practice.

Methods: We conducted a multicentre, retrospective study of patients with aggressive B-NHL undergoing leukapheresis for commercial CAR-T therapy in Spain from 2019 to 2025. Manufacturing outcomes were categorised as first-attempt result (in-spec, OOS, or MF), remanufacturing attempt, and final product (OOS-infused, delayed-infused after in-spec remanufacturing, or non-infused), following previously published UK experience (Dulobdas et al., Blood Cancer J 2025). Survival was estimated using Kaplan-Meier curves. All CAR-T apheresis procedures performed at participating centres during the study period were

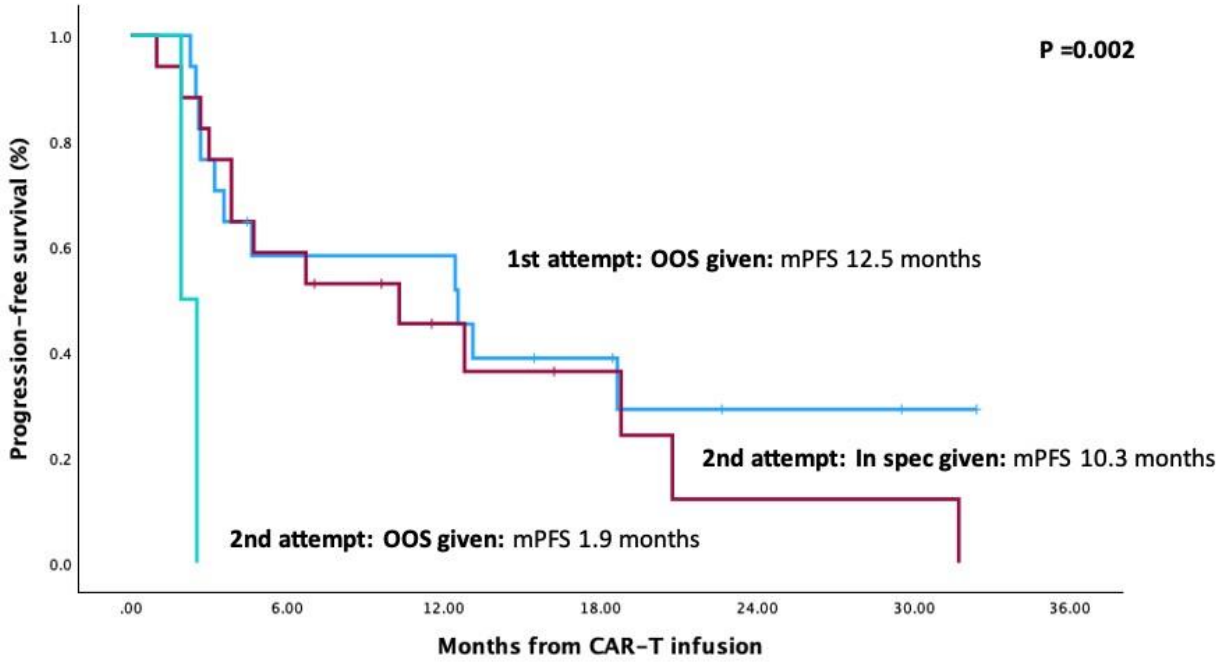
included. Manufacturing failure incidence was calculated overall and adjusted for product mix, accounting for the relative distribution of CAR-T products.

Results: A total of 1,210 apheresis procedures were analyzed, 79% corresponding to axicabtagene ciloleucel and 21% to tisagenlecleucel; 50 patients (4.13%) experienced manufacturing failure or out-of-specification products. Median age was 63 years (range: 41–78) and 60% were male. Subtypes included diffuse large B-cell lymphoma not otherwise specified (56%), transformed follicular lymphoma (18%), high-grade B-cell lymphoma (12%) and T-cell/histiocyte-rich large B-cell lymphoma (6%). Most patients (76%) underwent CAR-T in ≥3rd line and 78% were primary refractory. Based on product distribution, estimated MF incidence was 4.18% for axi-cel (40/956) and 3.94% for tisa-cel (10/254). Among MF cases, 56% had an OOS product available after the first attempt, of which 17 were infused, 3 proceeded to remanufacturing and 8 were not infused. When no OOS product was available, remanufacturing was attempted in 18 patients. Overall, 21 remanufacturing attempts yielded 17 in-spec products infused, 2 in-spec products not infused, and 2 OOS products infused. Final outcomes were OOS-infused (n=19), delayed-infused after remanufacturing (n=17) and non-infused (n=14).Among infused patients (n=36; axicabtagene ciloleucel 81%, tisagenlecleucel 19%), cytokine release syndrome occurred in 81% (grade ≥3: 3%) and ICANS in 55% (grade 3–4: 13%). The best overall response rate was 50% (CR 37%, PR 13%). Median OS was 12.5 months for infused versus 1.2 months for non-infused patients ($p<0.001$). Median PFS was 10.3 versus 0.7 months, respectively ($p<0.001$). Post-infusion PFS was comparable after first-attempt OOS infusion and second-attempt in-spec infusion, while inferior PFS was observed after second-attempt OOS infusion (Figure 1). Age >60 years ($p=0.04$), double-hit lymphoma ($p=0.028$), shorter time from diagnosis to apheresis ($p=0.014$), primary refractory disease ($p=0.008$) and prior bendamustine exposure (9/50; $p=0.049$) were associated with inferior PFS. Autoimmune disorders were present in 10% of patients.

IMPACT OF OOS STATUS AT INFUSION:

PFS from infusion:

Infusion group	Median PFS (95%CI)	p
1st attempt: OOS product given	12.5 (1.9-23.1)	0.002
2nd attempt. In spec product given	10.3 (1.5-19.1)	
2nd attempt. OOS product given	1.9 (NA)	



Conclusions: Manufacturing failure occurred in 4.13% of apheresis procedures, with nearly half of patients receiving CAR-T through OOS infusion or remanufacturing. Post-infusion outcomes were similar between OOS-infused and delayed-infused patients, while failure to reach infusion was associated with poor survival. These findings underscore the importance of optimized manufacturing pathways. Further analyses of OOS and manufacturing failure causes will be presented at the Congress.

INCIDENCE AND RISK FACTORS FOR POOR GRAFT FUNCTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE IN A MULTICENTER COHORT

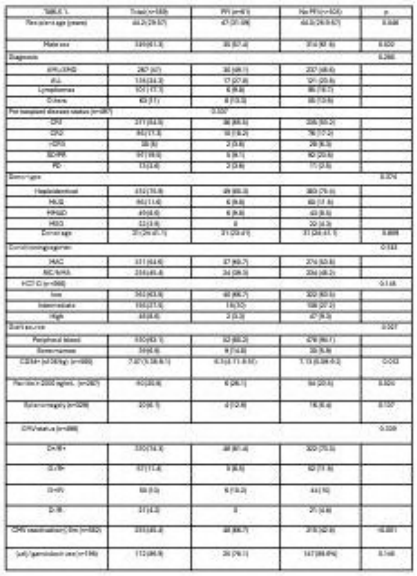
*Josefina Troccoli Moretti[1], Adriana Vitriu[1], Leandro Castellanos[2], Mariano Berro[3], Jorge Arbelbide[4], **Olivia Gelo**[1], Ana Gabriela Sturich[2], Maria Marta Rivas[3], Gonzalo Ferini[4], Ana Lisa Basquiera[2], Maximiliano Cattaneo[5], Karla Oliveros[6], Cecilia Sernaque[7], Priscila Wernicke[8], Georgina Bendek[4], Martin Saslavsky[5], Gustavo Kusminsky[3], Martin Castro[6], Silvina Palmer[7], Sofia Pelayes[8], Maria Cecilia Foncuberta[1]*
[1]Instituto Alexander Fleming, Buenos Aires, Argentina, [2]Hospital Privado Universitario de Córdoba, Córdoba, Argentina, [3]Hospital Universitario Austral, Buenos Aires, Argentina, [4]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [5]CETRAMOR, Rosario, Argentina, [6]Sanatorio Anchorena, Buenos Aires, Argentina, [7]Hospital Britanico, Buenos Aires, Argentina, [8]Sanatorio Sagrado Corazon, Buenos Aires, Argentina

Background: Poor graft function (PGF) is a clinically relevant complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT) associated with substantial morbidity. Post-transplant cyclophosphamide (PTCy) has been proposed as a potential contributor to PGF development; however, data regarding its incidence and risk factors in this specific setting remain limited.
Objectives: To estimate the cumulative incidence of PGF within the first 6 months after allo-HSCT with PTCy, identify clinical factors associated with PGF development, and describe therapeutic strategies used for its management.

Methods: We conducted a multicenter retrospective study including ≥18-year patients with hematologic diseases undergoing allo-HSCT between 2016 and 2024 at 8 centers of the GATMO-TC. Donors included haploidentical, matched or mismatched unrelated, and HLA-identical related donors. GVHD prophylaxis consisted of PTCy plus mycophenolate mofetil and a calcineurin inhibitor, using peripheral blood or bone marrow as the graft source. PGF was defined as neutrophils <500/µL and/or platelets <20,000/µL from day +28 with donor chimerism >95%, without relapse or active GVHD. Six-month PGF cumulative incidence was estimated using cumulative incidence functions considering competing events: early

mortality (≤30 days), primary graft failure, and early relapse (≤180 days). Risk factors were assessed using Fine–Gray competing risks regression.

Results: A total of 569 patients were included (median age 44.2 years; 61.3% male). Diagnoses included AML/MDS (47%), ALL (24.3%), lymphomas (17.7%) and others. The 6-month cumulative incidence of PGF was 10.4% (95% CI 7.9–12.9), early mortality 4.7%, primary graft failure 2.0%, and early relapse 6.0%. Among patients with PGF (n=61), 84% had secondary PGF. Management included thrombopoietin receptor agonists (TPO-Ras) (n=21), TPO-Ras plus filgrastim and erythropoietin (n=7), filgrastim alone (n=13), or transfusional support; seven patients required second-line therapy ($CD34^+$ boost n=3, change of TPO-Ras n=3, second transplant n=1). Median time to response was 1.10 months (IQR 1–3), with no difference according to treatment strategy(p=0.388). Letermovir prophylaxis was used in 56/427 seropositive receptors. 44.8% had ≥1 CMV reactivation within 6 months. In univariate analysis, higher infused $CD34^+$ cell dose was associated with a reduced risk of PGF (HR 0.54 per 5×10^6/kg increase; 95% CI 0.32–0.90; p=0.017), while bone marrow graft source (HR 2.69; 95% CI 1.31–5.54; p=0.007) and CMV reactivation within 6 months (HR 2.42; 95% CI 1.41–4.14; p=0.001) were associated with increased PGF risk. The presence DSA showed a trend toward increased risk but did not reach statistical significance (HR 2.57; 95% CI 0.80–8.32; p=0.110). In multivariate analysis, bone marrow graft source (HR 2.46; 95% CI 1.10–5.49; p=0.028), CMV reactivation ≤6 months (HR 2.44; 95% CI 1.41–4.22; p=0.001), and presence of DSA (HR 2.93; 95% CI 1.05–8.20; p=0.040) remained independently associated with PGF.



Conclusions: In this multicenter cohort of allo-HSCT recipients receiving PTCy-based GVHD prophylaxis, the incidence of PGF was not higher than that reported in non-PTCy platforms. Bone marrow graft source, CMV reactivation within 6 months, and donor-specific anti-HLA

antibodies were the main independent risk factors for PGF. These findings support optimization of graft quality and intensified CMV monitoring and prophylaxis strategies in patients receiving PTCy.

ALLOGENEIC STEM CELL TRANSPLANTATION WITH 3-DAYS BUSULFAN PLUS FLUDARABINE AS CONDITIONING REGIMEN FOR PATIENTS WITH RELAPSED OR REFRACTORY T- AND NK/T-CELL LYMPHOMAS

Ji Hyun Lee[1], *Deok-Hwan Yang*[2], *Jae-Cheol Jo*[3], *Yoo Jin Lee*[3], *Won-Sik Lee*[4], *Yoon Seok Choi*[5], *Joon Ho Moon*[6], *Young Rok Do*[7]
[1]*Dong-A University College of Medicine, Busan, Korea (the Republic of),* [2]*Chonnam National University Hwasun Hospital, Hwasun, Korea (the Republic of),* [3]*Ulsan University Hospital, Ulsan, Korea (the Republic of),* [4]*Inje University College of Medicine, Busan, Korea (the Republic of),* [5]*Korea University College of Medicine, Seoul, Korea (the Republic of),* [6]*Kyungpook National University, Daegu, Korea (the Republic of),* [7]*Keimyung University School of Medicine, Daegu, Korea (the Republic of)*

Background: Peripheral T-cell lymphomas (PTCL) and NK/T-cell lymphoma (NKTCL) are characterized by chemo-resistance, frequent relapses, and rapid progression. Allo-SCT can provide durable disease control, but optimal conditioning intensity/regimen remains uncertain. The objectives of this study is to prove the feasibility in terms of efficacy and safety of 3-days intravenous busulfan (Bu) in combination with fludarabine (Flu) in relapsed and refractory T- and NK/T-cell lymphomas.

Methods: This is a prospective phase II trial which plans to enroll 34 patients. Histologically confirmed relapsed and refractory T- and NK/T-cell lymphomas who relapsed after or were refractory to one or more of previous chemotherapy including auto-SCT and had achieved partial response (PR) or complete response (CR) after salvage chemotherapy were enrolled. Patients who had HLA full-match (8/8 in HLA-A, B, C, DR by DNA high-resolution technique) or one-locus mismatch (7/8) sibling, or unrelated bone marrow (BM) or peripheral blood (PB) or cord blood (CB) stem cell donors were enrolled. Conditioning therapy was started on day -8. Busulfan (Busulfex®; Patheon Manufacturing Services LLC, Greenville, NC 27834) was given 3.2 mg/kg intravenously once daily for 3 days (days -7 to -5) and fludarabine 30 mg/m^2 was infused once daily for 6 days (days -8 to -3) (Bu3Flu6). Primary endpoint of this study is 2-year progression-free survival (PFS). This is the preliminary result of 15 patients enrolled to the study.

Results: Twenty-three patients received Allo-SCT with Bu3Flu6 conditioning regimen for relapsed or refractory T- and NK/T-cell lymphomas. Median age was 55 years (range, 33–66 years), and the median number of prior lines of therapy was 2 (range, 1–4). Eleven patients (47.8%) had previously undergone autologous stem cell transplantation. Peripheral blood stem cells were used in 22 patients and cord blood in 1 patient; donor types included

matched sibling donors in 47.8%, matched unrelated donors in 43.5%, and one-locus mismatched donors in 8.7% of patients. After a median of 3 cycles of salvage chemotherapy, 15 patients (65.2%) achieved complete remission (CR) and 8 patients (34.8%) partial remission (PR) prior to Allo-SCT. Among the 8 patients in PR before transplantation, 5 patients achieved CR after Allo-SCT with Bu3Flu6 conditioning. With a median follow-up duration of 17.8 months (range, 0.67–96.30 months), the 2-year progression-free survival and overall survival rates were 58.3% (95% CI, 35.0–75.8%) and 53.6% (95% CI, 30.7–72.0%), respectively. All patients achieved neutrophil and platelet engraftment, with median times of 12 and 12 days, respectively. No unexpected regimen-related toxicities, including sinusoidal obstruction syndrome or hemorrhagic cystitis, were observed. Grade 3–4 acute graft-versus-host disease (GVHD) and moderate-to-severe chronic GVHD occurred in 39.1% and 56.5% of patients, respectively, and chronic GVHD complicated by severe infection led to death in two patients.

Conclusions: 3-days Bu and 6-days Flu combination as a conditioning regimen is effective with tolerable safety profile for relapsed or refractory T- and NK/T-cell lymphoma patients who are undergoing Allo-SCT after achieving CR or PR to salvage regimen.

Clinical Trial Registry: NCT02859402

Disclosure: Nothing to disclose.

THE IMPACT OF HLA-DPB1 PERMISSIVE AND NON-PERMISSIVE MISMATCH ON OUTCOMES IN MATCHED RELATED DONOR HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR THALASSEMIA

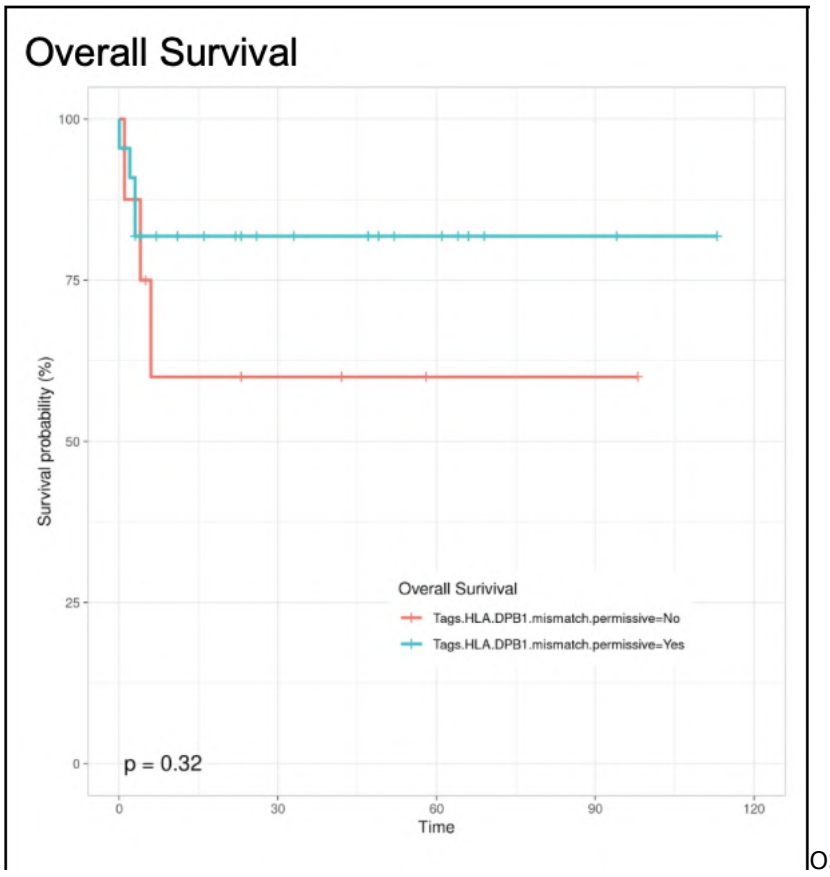
Mohana Reddy D M[1], *Rajat Kumar Agarwal*[1], *Tejashree Sridhar*[1], *Ankita Kumari*[1], *Vidhi Mayur*[1], *Deepa Trivedi*[2], *Vaibhav Shah*[2], *Priya Marwah*[3], *Kim Hoa*[4], *Sadaf Khalid*[5], *Aliya Batool*[5], *Nithya R*[1], *Lawrence Faulkner*[6]
[1]*Sankalp India Foundation, Bengaluru, India,* [2]*Sanlap India Foundation, Ahemadabad, India,* [3]*Mahatma Gandhi Medical College, Jaipur, India,* [4]*Hue Central Hospital, Hue, Viet Nam,* [5]*Akbar Niazi Teaching Hospital, Islamabad, Pakistan,* [6]*Cure2children Foundation, Florence, Italy*

Background: Allogeneic HSCT remains the only definitive cure for transfusion-dependent thalassemia. While the permissive versus non-permissive HLA-DPB1 mismatch framework is well established as a determinant of GVHD and survival in unrelated donor transplantation, its significance in matched related donor HSCT-where DPB1 disparity is uncommon-has never been clearly defined. In this study, we systematically evaluate the clinical impact of DPB1 permissiveness in the matched related donor setting, addressing a long-standing evidence gap in thalassemia transplantation.

Methods: We conducted a retrospective analysis of 786 consecutive matched related donor HSCTs for transfusion-dependent thalassemia performed between 2017 and 2025 across

centres in Jaipur, Bangalore, Ahmedabad, Islamabad, and Vietnam. High-resolution DPB1 typing was available for 771 recipients. All transplants used a uniform platform consisting of Flu-ATG-Bu-Cy conditioning, cyclosporine–methotrexate–based GVHD prophylaxis, and G-CSF–primed bone marrow grafts, following our previously published protocol. The median patient age at transplant was 7.09 (IQR:4.11 - 11.03, Range: 1.01 - 21.07) years, with a median follow-up of 2.2 (IQR:0.8 - 4.4, Range: 0 - 9.4) years. DPB1 mismatches were assessed using the IPD-IMGT/HLA T-cell-epitope (TCE) algorithm and categorised as permissive or non-permissive. Clinical endpoints included overall survival (OS), disease-free survival (DFS), graft failure or rejection, GVHD-relapse-free survival (GRFS), transplant-related mortality (TRM), and grade 3–4 acute or moderate–severe chronic GVHD.

Results: Among 786 typed matched related donor transplants, 30 (3.8%) showed DPB1 mismatches - 22 permissive and 8 non-permissive-occurring across 15 sibling donors, 8 father, 6 mothers, and 1 cousin. Baseline characteristics, including age, sex, conditioning, and GVHD prophylaxis, were comparable between groups. There were no significant differences in overall survival (p=0.32), transplant-related mortality (p=0.75), disease-free survival (p=0.075), graft rejection (p=0.078), or GVHD-relapse-free survival (p=0.83). Grade 3 acute and moderate chronic GVHD occurred in one patient with a permissive mismatch, while no ≥ grade 3 GVHD events were observed in the non-permissive group. Across all variables assessed, DPB1 permissiveness showed no significant impact on outcomes.



OS

Conclusions: This large multi-centre series shows that DPB1 permissiveness is associated with meaningful differences in outcomes among matched related donor transplants for thalassemia. While acknowledging the limitations of the small number of mismatched cases, DPB1 disparities-permissive or non-permissive-do appear to influence prognosis in this setting.

CLINICAL OUTCOMES OF FULLY HLA-MATCHED SIBLING VERSUS PARENTAL HSCT IN CHILDREN WITH HEMOGLOBINOPATHIES

Mohana Reddy D M[1], *Vidhi Mayur*[1], *Tejashree Sridhar*[1], *Rajat kumar Agarwal*[1], *Geetha Lathe*[1], *Deepa Trivedi*[2], *Vaibhav Shah*[2], *Priya Marwah*[3], *Amit Seadi*[1], *Ankita Kumari*[1], *Lawrence Faulkner*[4]
[1]*Sankalp India Foundation, Bengaluru, India,* [2]*Sanlap India Foundation, Ahemadabad, India,* [3]*Mahatma Gandhi Medical College, Jaipur, India,* [4]*Cure2children Foundation, Florence, Italy*

Background: Hematopoietic cell transplantation (HCT) is the only well-established long-term curative treatment. The highest success rates are achieved with HLA-matched sibling donors. However, in the absence of a matched sibling particularly in younger patients or those from smaller families, closely related family members, such as biological parents, are increasingly considered as potential donors. This study aims to evaluate the donor type, age, bone marrow cellularity, and donor–recipient sex mismatch on outcomes of fully HLA-matched pediatric HSCT.

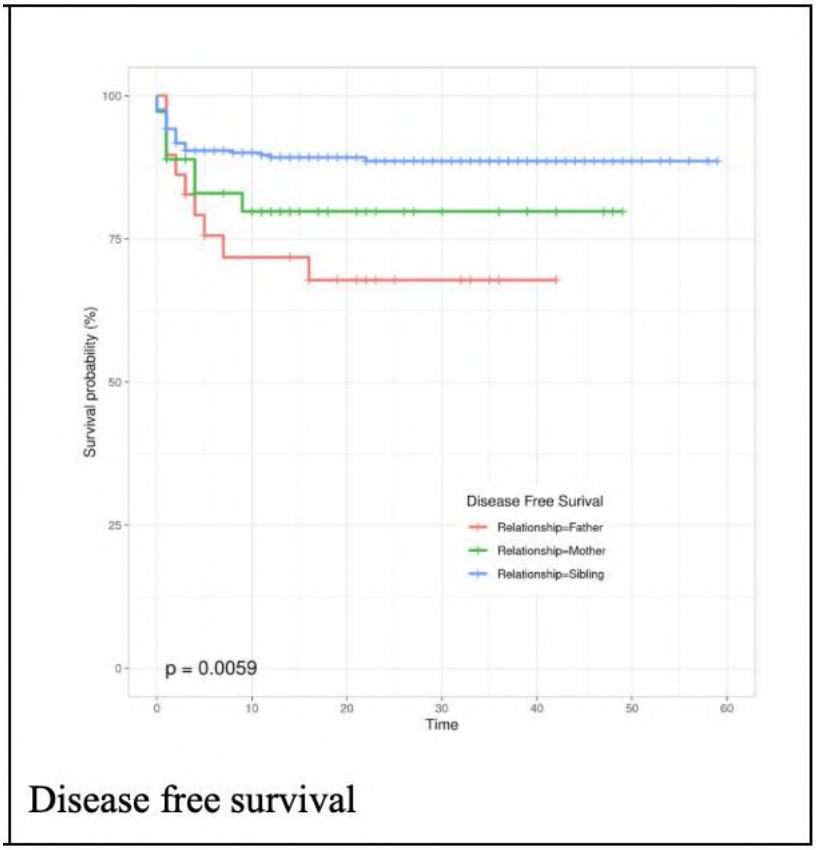
Methods: This is a multicenter study including pediatric patients with severe hemoglobinopathies who underwent hematopoietic stem cell transplantation (HSCT) from fully HLA-matched related donors between October 2020 and November 2025. All patients received granulocyte-colony stimulating factor (G-CSF)-primed unmanipulated bone marrow and myeloablative conditioning (fludarabine, busulfan, cyclophosphamide, and anti-thymocyte globulin (ATG), while ATG-free conditioning was used in the sibling cohort from May 2023. Graft-versus-host disease (GVHD) prophylaxis included cyclosporine and methotrexate, with supportive care administered according to individual institutional protocols.

Results:

A total of 404 paediatric patients underwent fully HLA-matched HSCT using matched siblings (n = 339) and matched parental donors (father, n = 30; mother, n = 35). The median follow-up was 15.8 months (IQR, 6.5–26.2 months). Overall survival (OS) was 92.9%, 91.7%, and 86.2% following sibling, maternal, and paternal donor transplants, respectively (p = 0.53). Disease-free survival (DFS) was 89.6 % in sibling donors, 80.6% maternal and 70% paternal donors (p = 0.0059).

The engraftment rate was 97.6% in sibling donor transplants (2.3% primary and 1.1% secondary graft failures), 93.3% in paternal donor transplants (6.6% primary and 10% secondary graft failures), and 91.4% in maternal donor transplants (8.5% primary and 2.8% secondary graft failure). Graft rejection was the highest in paternal donors (20.6%) and maternal donors (11.1%), and the lowest in sibling donors (3.9%) at p = 0.0041. Acute graft-versus-host disease (GVHD) grade ≥3 was observed in 2.4% siblings, 6.6% paternal, and 14.3% (5) maternal donor recipients (p < 0.0001).

The median donor age was 8.06 years (IQR, 5.05 -11 years) for sibling donors, 36.02 years (IQR, 32-40.7 years) for paternal donors, and 33.04 years (IQR, 28.7 - 36.2 years) for maternal donors. Donor recipient sex matching was observed in 44% (n = 177) of transplants, including male-to-male (24.2%) and female-to-female (19.5%) pairs. Sex mismatch was present in 56.1% (n = 227) of transplants, including male-to-female (20.7%) and female-to-male (35.4%) pairs. Overall survival did not differ between sex-matched and sex-mismatched transplants (92.1% vs 92.5%; p = 0.85). Disease-free survival was also comparable (88.1% vs 86.7%; p = 0.73). Similarly, graft rejection (5.1% vs 6.1%; p = 0.50) and GVHD (16.3% vs 17.1%; p = 0.81) did not differ by sex-matching status. Grade ≥3 acute GVHD occurred in approximately 4.5% of sex-matched and 5.7% of sex-mismatched transplants.



Disease free survival

Conclusions: In pediatric HSCT for severe hemoglobinopathies, fully HLA-matched sibling and parental donors achieve excellent overall survival, with disease-free survival and graft outcomes slightly higher with sibling donors, and donor–recipient sex mismatch does not significantly affect survival, graft rejection, or GVHD incidence

Disclosure: The authors declare no competing financial interests.

PATIENTS WITH HIGH GRADE TRANSFORMATION OF WALDENSTRÖM'S MACROGLOBULINEMIA CAN BE RESCUED WITH TRANSPLANTATION. REPORT FROM THE LYMPHOMA WORKING PARTY OF THE EBMT

Charalampia Kyriakou[1], *Maud Ngoya*[2], *Nour Moukalled*[3], *Irma Khvedelidze*[2], *Ali Bazarbachi*[4]
[1]*University College London Hospitals NHS Foundation Trust, London, United Kingdom of Great Britain and Northern Ireland (the),* [2]*European Bone Marrow Transplantation Lymphoma Working Party, Paris, France,* [3]*Bone Marrow Transplantation Program, Department of Internal*

Medicine, American University of Beirut Medical Center, Beirut, Lebanon, [4]Chair of the European Bone Marrow Transplantation Lymphoma Working Party, Paris, France

Background: High Grade Transformation of Waldenstrom's Macroglobulinemia (tWM) although rare, is a serious complication. This retrospective EBMT registry study aimed to analyse the results of autologous (ASCT), allogeneic (Allo-SCT) stem cell transplantation and CAR T Cell therapy for patients with tWM.

Methods: EBMT centers submitted data for 310 tWM patients. ASCT was used in 217, Allo-SCT in 49 patients between 2010-2023, CAR T Cell therapy in 44 between 2023 -2024.

Results: Of the 217 ASCT patients, 122 were male with a median age of 53.9 years and Karnofsky performance status (KFS) ≥90 in 67%. Median time from diagnosis to ASCT was 8.1 (2.4-202) months. ASCT was performed post 1st treatment line in 37%, post 2nd line in 43%,following 3rd line in 20%. Disease status was CR in 118 patients (57%), Very Good Partial Response (VGPR) /Partial Response (PR) in 57 (27%), Primary Refractory (PRD) / Progressive Disease (PD) in 30 (14%) and in 12 (2%) it was not available (NA). 63% received BEAM based conditioning. The estimated Overall Survival (OS) was 68.9%, Progression Free Survival (PFS) 59.5%, Relapse Incidence (RI) 36.3%, Non-Relapse Mortality (NRM) 4.2% at 2 years respectively.
Of the 49 Allo-SCT patients, 33 were male with a median age of 47.6 years and KFS ≥90 in 60%. Median time from diagnosis to Allo-SCT was 13.6 (3.1-167) months. 43% had the Allo-SCT following 1st line, 33% post 2nd line, 24% following ≥3rd treatment lines. 39% had failed previous ASCT. Disease status was CR in 23 patients (47%), VGPR / PR in 14 (29%), PRD / PD in 9 (18%) and in 3 (6%) it was not available. Myeloablative conditioning (MAC) was used in 30 patients (61%), reduced intensity conditioning (RIC) in 19 (39%) and TBI was used for 14 (29%). Stem cell donor was sibling in 18 (37%), unrelated in 24 (49%) haploidentical in 7 (14%). 29 (63%) patients had in vivo T cell depletion. Median follow up was 7.8 years (3.1-8.2). The estimated OS was 43%, PFS 29%, RI 55%, NRM 17%, graft versus host disease (GVHD)-free/relapse-free survival (GRFS) 21% at 2 years respectively. The incidence of acute GVHD grade III/IV was 12% and chronic extended GVHD was 9%.
From the 44 CAR T Cell treated patients, 29 were male, median age was 61years, KFS ≥90 in 50%. Median time from diagnosis to CAR T Cell therapy was 12.8 (3.3- 198.2) months. 37% had CART following 1st treatment line, 43% after 2nd and 20% after ≥3rd prior treatment lines. The disease status was CR in 3 patients (7%), VGPR / PR in 6 (13.5%), PRD / PD in 33 (75%) and in 2 (4.5%) it was not available. Median follow up was 3 (0-6) months, OS 68.5%, PFS 35.8%, RI 59.7%, NRM 4.5% at 1 year respectively.

Conclusions: This EBMT analysis is the largest cohort of tWM patients to date, reporting satisfactory rescue survival outcomes of ASCT and CAR T cell therapy although longer follow up is required for this approach. Allo-SCT survival outcomes were low.

Disclosure: No conflict of interest to declare

Background: Patients with relapsed or refractory large B-cell lymphoma (LBCL) often require disease control while awaiting leukapheresis for CD19 CAR T-cell therapy. While bridging therapy administered between apheresis and lymphodepletion is well described, the clinical impact of therapy given after the CAR-T decision but before apheresis ("holding therapy") remains limited. We evaluated the association between pre-apheresis holding and outcomes after CD19-directed CAR T-cell therapy.

Methods: We performed a retrospective study of adults with LBCL who underwent leukapheresis for CD19 CAR-T (2022–2025) at our center. Holding therapy was defined as any systemic therapy or radiotherapy given after the decision to proceed with CAR-T therapy and before apheresis. Patients receiving holding plus bridging were compared with those receiving bridging alone. Primary endpoints were disease status at apheresis and day-28 response following CAR-T infusion. Secondary endpoints included best response within 1 year, progression-free survival (PFS), overall survival (OS), cumulative incidence of relapse and non-relapse mortality (NRM), and early and late hematologic toxicity (grade ≥3 neutropenia, anemia, thrombocytopenia, and N-ICAHT). Multivariable logistic, Cox, and competing-risk regression models were used.

Results: We included 147 adults with LBCL undergoing leukapheresis for CD19 CAR-T (59% lisocabtagene maraleucel, 37% axicabtagene ciloleucel and 5% tisagenlecleucel). Among these, 89 patients received holding plus bridging and 58 bridging alone. Median time from relapse to apheresis was longer with holding (54 vs 36 days), whereas apheresis-to-infusion intervals were similar between groups (**Table 1**).
Among patients who received holding plus bridging, 40 (45%) continued the same regimen

for bridging and 49 (55%) switched. Pre-apheresis CR/PR was more frequent after holding (40% vs 19%). However, day-28 response after CAR-T did not differ across holding strategies (p=0.80) (**Fig 1A-1B**); best 1-year response was also similar among groups (p=0.59). In multivariable models adjusting for KPS, primary refractory disease, pre-apheresis LDH and SUVmax, the hazard ratio for PFS for holding was 0.34 (95% CI 0.14–0.81; p=0.014) and for OS was 0.63 (95% CI 0.19–2.14; p=0.50). One-year cumulative incidence of relapse was 31% with holding versus 42% without (p=0.11), and 1-year CI of NRM was 4.8% versus 6.2% (p=0.50).
Early grade ≥3 cytopenias were common regardless of holding exposure (day-30 neutropenia 83% vs 82%; thrombocytopenia 32% vs 26%). Grade ≥3 anemia was more frequent with holding (40% vs 26%, p=0.074). Early N-ICAHT grade distribution differed, with more grade 4 events among patients receiving holding (9.2% vs 0%) (**Fig 1C**). In the day-30 landmark analysis, late grade ≥3 cytopenias and late N-ICAHT did not differ between groups.

Characteristic [1] n (%); Mean (SD)	**Received Holding** N = 89[1]	**Did Not Receive Holding** N = 58[1]	**Overall** N = 147[1]
CAR-T Product Received			
Lisocabtagene maraleucel	52 (58%)	34 (59%)	86 (59%)
Axicabtagene ciloleuce	31 (35%)	23 (40%)	54 (37%)
Tisagenlecleucel	6 (6.7%)	1 (1.7%)	7 (4.8%)
Karnofsky Performance Status pre-CAR-T			
< 90	65 (76%)	33 (57%)	98 (69%)
LBCL Subtype			
DLBCL NOS	68 (76%)	46 (79%)	114 (78%)
High-grade B-cell Ly.	13 (15%)	7 (12%)	20 (14%)
Disease stage at apheresis			

III-IV	60 (69%)	39 (67%)	99 (68%)
LDH range pre-lymphodepletion			
Elevated	29 (34%)	20 (37%)	49 (35%)
Primary refractory pre-apheresis	36 (41%)	35 (60%)	71 (49%)
Bulky disease pre-apheresis	9 (10%)	5 (8.6%)	14 (9.7%)
Pre-apheresis SUVmax	11 (14)	16 (11)	13 (13)
CAR-T Treatment Line ≤ 2	70 (79%)	51 (88%)	121 (82%)
Time(days) from apheresis to infusion			
Median (IQR), Range	39 (12), 35-47	40 (13), 33-46	39 (12), 34-46

Conclusions: In this real-world cohort, pre-apheresis holding therapy was associated with favorable PFS, without excess relapse or NRM, and did not worsen late hematologic toxicity. Early hematotoxicity was modestly higher with holding, but late cytopenias and N-ICAHT were not increased. Overall, these findings support the feasibility of pre-apheresis holding strategies to maintain disease control while patients await leukapheresis for CD19 CAR T-cell therapy.

Background: In allo-HSCT setting, some studies have shown that iron overload was associated with lower overall survival (OS), and that deferasirox, an oral iron-chelating agent, may have possible antileukemia effect. On behalf of the SFGM-TC, we conducted a prospective, interventional study on iron chelation, matched with retrospective data of non-chelated patients from the SFGM-TC registry. The study aimed to evaluate the impact of iron chelation therapy on OS and progression free survival (PFS) from 6 months after allo-HSCT for AML and MDS.

Methods: Patients at inclusion were: (1) in CR at 6 months after allo-HSCT for AML or < 10% of blasts for MDS (2) with a ferritin level above 1,000 µg/L. All patients received deferasirox starting 6 months after allo-HSCT until a target ferritin level of 500 µg/L, unless intolerance. In parallel, we created a control group of allo-HSCT patients from the SFGM-TC registry and who did not receive iron chelation therapy. The control group was built using a propensity score matching (PSM) method, which balances between the two groups of patients potential confounding factors. A 1:2 ratio (chelated vs non-chelated) with a calliper <= 0.18 was set. The analysis period began 6 months after allo-HSCT and continued until the end of the data availability period or until death. Analyses employed exact matching, inverse probability of treatment weighting (IPTW), and multivariable Cox models, with adjustment for chronic GVHD and sensitivity analyses using E-values.

Results: A total of 41 AML/MDS patients treated by iron chelation were included between April 2015 and February 2022 from 7 allo-HSCT centres. The median age was 58 years (20-70), 66% were male, 85% had an AML, a majority of ELN 2010 intermediate-II score (76%), and a median ferritin level before and after allo-HSCT of 1529 (14-4157) and 1781 (1000-10 041) µg/L respectively. A control group of 82 patients from 950 AML/MDS allo-HSCT patients from SFGM-TC registry who did not receive iron chelation was built from PSM with a standard mean difference < 0.1 for each potential confounding factors. Across analytic methods, deferasirox was associated with improved PFS (HR 0.41–0.44) and favorable OS (HR 0.28–0.43). TRM was significantly reduced in PSM and Cox models (HR 0.21), with a trend in

IPTW. CIR did not differ significantly. The adverse events (AE) associated with iron chelation therapy were acceptable. Ferritin decreased under deferasirox, from 1,700 µg/L at baseline to <1,000 µg/L by 18 months.The median duration of iron chelation was 12.5 (0.8-24.3) months. A reduction in dosage occurred in 9.5% of cases. The permanent discontinuation in 33% of patients was predominantly related to acute renal failure (n=4) and altered of renal biomarkers (n=4).

Conclusions: In our study we evaluated the use of deferasirox after allo-HSCT for AML/MDS. We demonstrated a doubtful effect of iron chelation on OS but a clear benefit on PFS. The tolerance profile was acceptable, but special attention to renal function should be considered to modulate potentially the dose of desferasirox. This study reinforces the place of iron chelation in the therapeutic arsenal after-HSCT in AML/SMD patients.

Immunoematologia e Medicina Trasfusionale, ASST Mantova, Mantova, Italy,* [7]*S.S Ematologia, U.O. Oncologia ASST del Garda, Desenzano del Garda, Italy,* [8]*Unit of Blood Diseases and Bone Marrow Transplantation, Department of Clinical and Experimental Science, University of Brescia, ASST Spedali Civili di Brescia; Centro di Ricerca Emato-Oncologica AIL (CREA), ASST Spedali Civili di Brescia, Brescia, Italy*

Background: CAR-T cell therapy has revolutionized the treatment of Large B-Cell Lymphoma (LBCL); however, relapse remains frequent. Metabolic inflammation may modulate CAR-T expansion and relapse risk. The influence of body mass index (BMI) and metabolic status on CAR-T efficacy remains unclear. In this study, we evaluated the association between BMI, metabolic factors, and outcomes after CAR-T therapy in a bicentric real-world cohort.

Methods: We retrospectively analyzed patients with LBCL treated with commercial CAR-T products (axi-cel or tisa-cel) at the Bone Marrow Transplantation Units of Brescia and Verona,

Italy. Baseline BMI, lipid profile, glycemic status, and cardiovascular/metabolic comorbidities were collected prior to CAR-T. Patients were classified as BMI <25 kg/m² (Cohort 1) or BMI ≥25 kg/m² (Cohort 2).
A metabolic syndrome–like profile was defined by the presence of ≥3 factors among BMI >30 kg/m², diabetes or fasting glucose >100 mg/dL, hypertriglyceridemia, and hypertension. Event-free survival (EFS), cumulative incidence of relapse, and non-relapse mortality (NRM) were analyzed using univariate and multivariate Cox regression models and the Gray test, as appropriate.

Results: Sixty-five patients were analyzed (Brescia n=37, Verona n=28): 36 (55%) had BMI <25 (Cohort1), while 29 (45%) had BMI ≥25 (Cohort2). Baseline characteristics were comparable between cohorts, except for a higher prevalence of hypertension in Cohort 2 (58% vs 22%, p=0.01). Eight patients (12%) met criteria for a metabolic syndrome–like profile. Median follow-up was 17.4 months (IQR 11.7–26.5).
Patients with BMI ≥25 showed significantly superior EFS, with a 12-months EFS of 55% (95%CI 35–72) compared with 22% (95%CI 9–38) in patients with BMI <25 (p=0.04) (Figure 1). Median EFS was 18.1 months versus 3.8 months, respectively. The association between BMI and EFS remained consistent across CAR-T products and age groups (≥65 vs <65 years).
By contrast, patients with a metabolic syndrome–like profile had markedly inferior outcomes, with a median EFS of 1.4 months compared with 8.7 months in those without this profile (p=0.005). Bulky disease at leukapheresis showed a trend toward reduced EFS (p=0.07). In multivariate analysis, BMI ≥25 remained independently associated with improved EFS (HR 0.44, 95% CI 0.20–0.95; p=0.036), while a metabolic syndrome–like profile predicted inferior EFS (HR 7.66, p=0.01).
Patients with BMI ≥25 also exhibited a significantly lower cumulative incidence of relapse, with a 12-months incidence of 37.7% (95%CI 19.3-56.1) compared with 70.8% (95%CI 50.5-84.0) in Cohort 1 (p=0.02). No significant differences in NRM were observed between cohorts (24-month NRM: 6.5% vs 8.4%, p=0.90) (Figure 1). Conversely, patients with metabolic syndrome–like profile showed trend toward higher NRM (p 0.09).

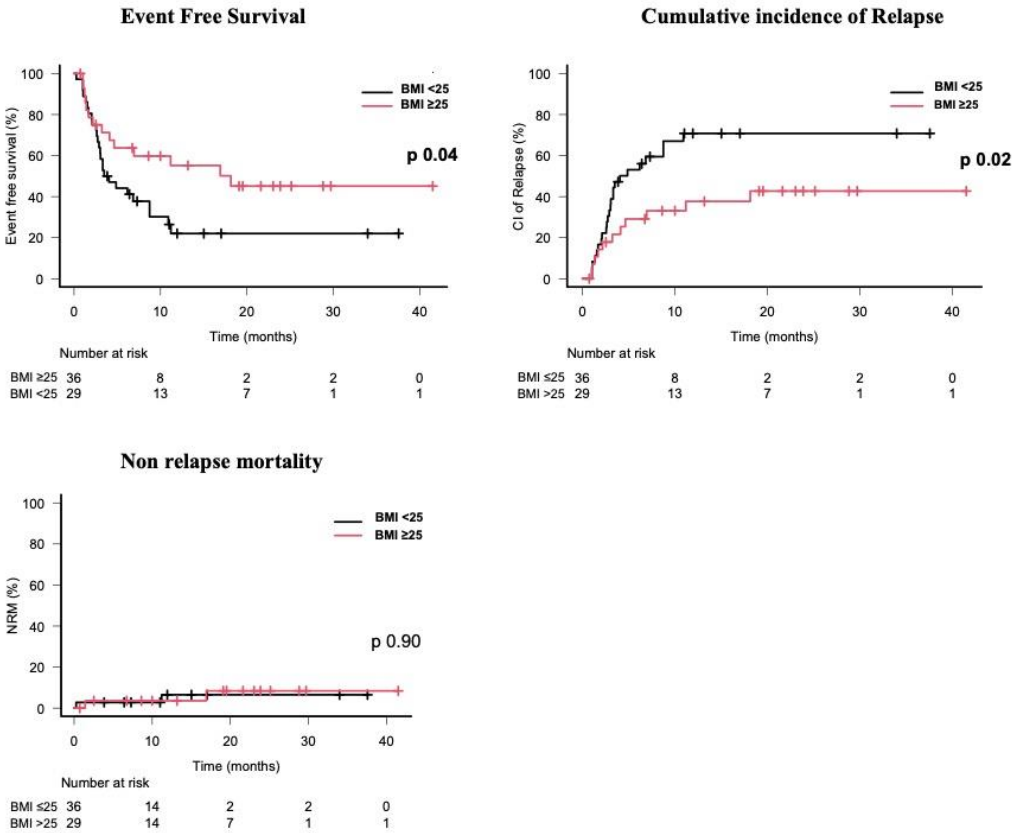

Figure 1: Impact of baseline body mass index (BMI) on outcomes after CAR-T cell therapy.

Conclusions: In this bicentric real-world cohort, elevated BMI (≥25) was independently associated with superior EFS after CAR-T cell therapy, driven by a significantly lower relapse risk and without increased NRM. This effect may be partially explained by the body weight–based dosing of CAR-T cells in LBCL. Conversely, the presence of a metabolic syndrome–like profile identified patients with inferior outcomes. Overall, these findings suggest that BMI and metabolic status are important modulators of CAR-T efficacy and warrant prospective validation.

Clinical Trial Registry: Not applicable.

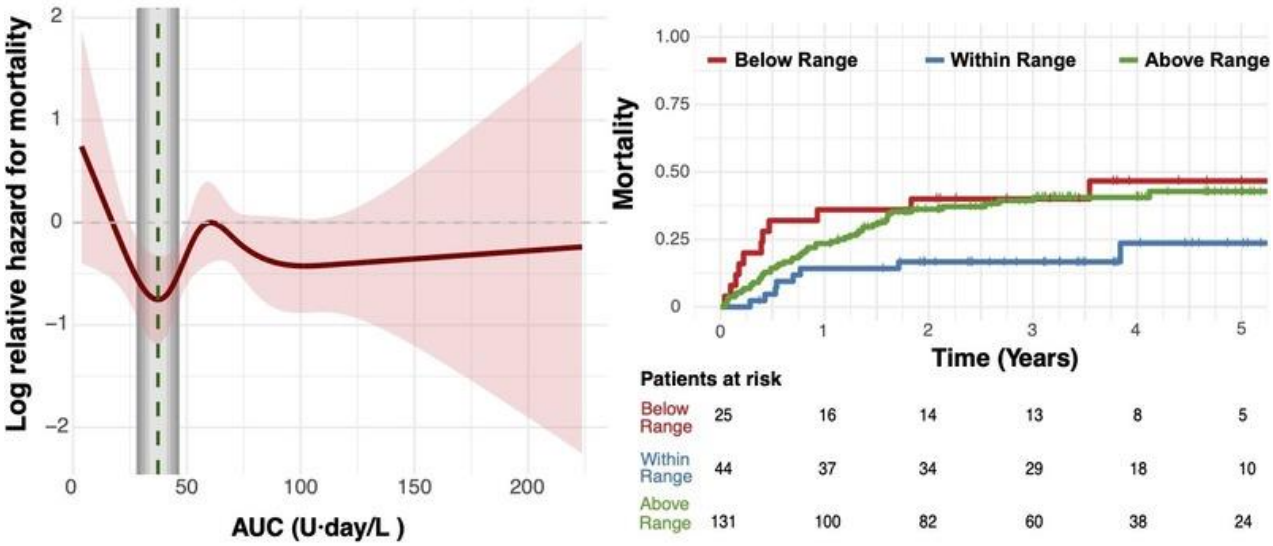
POPULATION PHARMACOKINETICS AND OPTIMAL EXPOSURE OF ANTI-THYMOCYTE GLOBULIN IN MYELOABLATIVE HEMATOPOIETIC CELL TRANSPLANTATION

Hamid Ghazal[1], *Riley Ngo*[1], *Sofia Leuchter*[2], *Megan Kinzel*[1], *Rosy Dabas*[1], *Poonam Dharmani-Khan*[1], *Faisal Khan*[1], *Kareem Jamani*[1], *Na Li*[1], *Tony Kl Kiang*[3], *Jan Storek*[1]
[1]*University of Calgary, Calgary, Canada,* [2]*Queen's University, Kingston, Canada,* [3]*University of Alberta, Edmonton, Canada*

Background: Anti-thymocyte globulin (ATG) prevents graft-versus-host disease (GVHD) in allogeneic hematopoietic cell transplantation (HCT). However, variable ATG exposure impacts transplant outcomes. We aimed to develop a population pharmacokinetic (popPK) model for ATG in myeloablative HCT and evaluate the relationship between area under the time-concentration curve (AUC) and mortality to identify the optimal ATG AUC.

Methods: We studied 200 adult HCT recipients who received myeloablative conditioning (MAC) and a peripheral blood stem cell graft from 7/8 or 8/8 HLA-matched related or unrelated donors. ATG was given on days -2, -1, and 0. All patients received additional GVHD prophylaxis with methotrexate and cyclosporine. Serum concentration of lymphocyte-binding ATG was determined by flow cytometry in 2,140 samples. For the popPK modeling, the cohort was split into a model development cohort (n = 134) and a validation cohort (n = 66). The modeling was performed using Monolix Suite 2024R1. The relationship between model estimated AUCs and mortality was evaluated in all 200 patients (combined development and validation subcohorts) using a Cox proportional hazards model. The relationship between model estimated AUCs and cause-specific outcomes (e.g., relapse or acute graft-versus-host disease [aGVHD]) was evaluated using a competing risk analysis.

Results: A two-compartment model with parallel linear and target-mediated elimination best described ATG disposition (Abstract Figure 1). Population means and residual standard errors (RSE%) were 11.78 L (2.05%) for the central volume of distribution (V1), 0.20 L/h (4.36%) for linear clearance (CL), and 2.20 U/L (7.08%) for the initial ATG-binding capacity of lymphocytes in the central compartment (R0_initial). Lean body weight (LBW) positively correlated with V1, CL, and intercompartmental clearance, while pre-ATG absolute lymphocyte count (ALC) positively correlated with R0_initial. Internal and external validation (using the development and validation subcohorts, respectively) confirmed model stability and robustness. The optimal ATG AUC range was 30–45 U·day/L. In multivariate analysis, patients whose AUC was within this range had lower mortality than those whose AUC was outside this range (hazard ratio=0.46, p=0.03) (Abstract Figure 2). The low mortality of patients with AUC within the range of 30–45 U·day/L appeared to be due to both low incidence of grade III-IV aGVHD, which was high in patients with AUC <30 U·day/L, and low incidence of relapse, which was high in patients with AUC >45 U·day/L.



Conclusions: This novel model described the pharmacokinetics of ATG in adult HCT recipients following MAC. The model identified LBW and ALC as significant covariates for ATG disposition. Furthermore, we identified the optimal ATG AUC (associated with the lowest mortality). These findings provide the foundation for developing an individualized dosing strategy aimed at improving post-HCT survival.

EXPLORING BASELINE COGNITIVE FUNCTION ASSESSMENTS AS A PREDICTOR OF ICANS IN CAR-T CELL THERAPY PATIENTS

Safia Belbachir[1], *Ellen Bashall*[1], *Amy Oliver*[1], *Allison Barraclough*[1]
[1]*Fiona Stanley Hospital, Murdoch, Australia*

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has revolutionized the treatment of several haematological malignancies. However, immune effector cell-associated neurotoxicity syndrome (ICANS) remains a significant and potentially life-threatening complication. While tumour burden surrogate markers have shown some success in predicting ICANS risk, the utility of neurocognitive assessments, such as the Montreal Cognitive Assessment (MoCA), is not well-established.

Methods: We conducted a single-centre retrospective study of consecutive adults treated with commercial CAR-T therapy (May 2020–January 2025). Pre-infusion MoCA was analysed continuously, by standard cut-points (normal 26–30, mild 18–25, moderate 10–17, severe <10), and using validated ≤24 cut-point for low vs normal cognition. ICANS was graded per

ASTCT criteria. Multivariable analyses identified predictors of ICANS incidence/severity, ICANS-directed therapies, hospital/ICU stay. Domain-specific MoCA sub-scores (visuospatial/executive, naming, attention, language, abstraction, delayed recall, orientation) and longitudinal post-infusion assessments explored cognitive associations.

Results: Ninety-two patients were included (median age 63.5 years, range 16–84; 62% male). Median baseline MoCA score was 24 (range 15–30). At baseline, 48.8% of patients had normal cognition, 42.7% had mild cognitive impairment, and 8.5% had moderate or severe impairment.

Patients with low baseline MoCA had a significantly higher incidence of ICANS (any-grade ICANS: 65.5% vs 32%; p=0.005). High-grade ICANS (≥2) was also more frequent in the low MoCA group (41.4% vs 16%; p=0.017). Median ICANS duration was longer in patients with low MoCA (4 days [range 1–24] vs 2 days [1–14]; p=0.001). Rates of ICU admission (27% vs 16%; p=0.25), ICU duration, corticosteroid use, tocilizumab use, and other ICANS-directed therapies were numerically higher **i**n the low MoCA group but did not differ significantly.

On multivariable analysis, low baseline MoCA remained independently associated with ICANS (p=0.018), alongside CD28 costimulatory domain products (p=0.006) and CAR-T target (CD19 vs BCMA; p=0.003). Tocilizumab use showed a borderline association (p=0.059), while age was not significant (p=0.12). For high-grade ICANS, low MoCA (p=0.047) and CD28 costimulatory domain (p=0.016) remained independent predictors. Lower baseline language and naming scores predicted any-grade and high-grade ICANS, respectively (p=0.018 and p=0.033), with no associations for other cognitive domains.

Forty-nine patients underwent post-infusion MoCA assessments; 80% demonstrated stable or improved cognitive performance. Patients with low baseline MoCA showed significant improvement (median ΔMoCA +3 [−1 to +7], p<0.001), while those with normal baseline MoCA remained stable (median ΔMoCA 0 [−3 to +1]). Importantly, ICANS did not adversely affect longitudinal cognition: among patients who developed ICANS (n=20), 90% maintained or improved cognitive function at follow-up, with no difference compared with those without ICANS (median ΔMoCA +1 vs +1; p=0.76).

Conclusions: Baseline MoCA, a simple 10-minute assessment, independently predicts ICANS incidence and severity in CAR-T patients . ICANS appears to be a clinically significant but predominantly transient neuroinflammatory event and was not associated with measurable long-term global cognitive decline in most patients; notably, 90% of patients who developed ICANS maintained or improved cognitive function in this cohort. These findings are hypothesis-generating and warrant validation in larger, prospective, multicentre studies incorporating detailed neurocognitive profiling.

Disclosure: None.

A133

EASIX OUTPERFORMS EBMT AND CIBMTR RISK MODELS IN PREDICTING VOD/SOS DESPITE DEFIBROTIDE USE IN ALLOGENEIC HSCT

Melis Bektaş[1], Ahmet Güngör[1], Uğur Şahin[1], Meltem Kurt Yüksel[1], Selami Koçak Toprak[1], Pervin Topçuoğlu[1], Önder Arslan[1], Muhit Özcan[1], Taner Demirer[1], ***Güldane Cengiz Seval***[1]
[1]*Ankara University Faculty of Medicine, Ankara, Turkey*

Background: Hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) remains a severe and potentially fatal complication after allogeneic hematopoietic stem cell transplantation (allo-HSCT), even in patients receiving defibrotide. Conventional clinical risk models such as EBMT and CIBMTR may inadequately capture early endothelial injury. The Endothelial Activation and Stress Index (EASIX) has emerged as a biomarker of endothelial stress and may improve risk prediction.
Objective: To determine whether EASIX outperforms EBMT and CIBMTR risk models in predicting VOD/SOS in allo-HSCT patients treated with defibrotide.

Methods: Adult patients (≥18 years) undergoing allo-HSCT at a single center between 2015 and 2025 who received defibrotide prophylactically or therapeutically were retrospectively analyzed. Patients with pre-existing liver cirrhosis, active infection, or dialysis dependence were excluded. EBMT, CIBMTR, and EASIX scores were calculated at the start of conditioning and compared between patients with and without VOD/SOS.

Results: Eighty-one patients were included; 19 (23.4%) developed VOD/SOS. Median EASIX scores were significantly higher in patients who developed VOD/SOS compared with those who did not (7.92 vs. 3.23, $p = 0.003$). EBMT risk scores were also higher in the VOD/SOS group ($p < 0.001$), whereas CIBMTR scores were not significantly different ($p = 0.06$). ABO incompatibility ($p = 0.005$) and hepatic steatosis (68.4% vs. 40.8%, $p = 0.02$) were additional factors associated with VOD/SOS. Exposure to busulfan or total body irradiation was not significantly associated with VOD/SOS development.

Conclusions: Despite defibrotide use, VOD/SOS remains a major complication after allo-HSCT. EASIX outperformed CIBMTR and complemented EBMT risk assessment in identifying patients at increased risk. Incorporating EASIX into the pretransplant evaluation may refine risk stratification and support targeted prophylactic strategies.

Disclosure: Nothing to declare.

A134

NON-CRYOPRESERVED HEMATOPOIETIC STEM CELLS FOR AUTOLOGOUS TRANSPLANTATION IN MULTIPLE MYELOMA: REDUCED TOXICITY AND DISTINCT INFLAMMATORY PROFILE AS COMPARED TO CRIOPRESERVED PRODUCTS

Mauricio Sarmiento Maldonado[1], *Patricia Macanas*[1], *Richard Broekhuizen*[1], *Carolina Gavilan*[1], *Javier Diaz Vidal*[1], *Emilio Salinas*[2], *Catherine Gutierrez*[1], *Veronica Jara*[1], *Elizabeth Rivera*[1], *Patricia Alcalde*[3], *Virginia Escamilla*[3], *Jose Antonio Pérez -Simón*[3]
[1]*Pontificia Universidad Católica de Chile/Red de Salud Christus UC, Santiago, Chile,* [2]*Universidad Austral de Chile, Valdivia, Chile,* [3]*Hospital Universitario Virgen del Rocio, Sevilla, Spain*

Background: Autologous transplantation using non-cryopreserved hematopoietic stem cells (non-CRYO) has been proposed as a safe and effective alternative to cryopreservation (CRYO), potentially reducing toxicity and resource demands. However, the biological basis of this approach remain unclear.

Methods: We conducted a study including a retrospective cohort (2018–2023) and a prospective cohort (2023–2024) across two centers (Santiago, Chile; Seville, Spain). The retrospective phase analyzed outcomes in 283 CRYO and 148 non-CRYO recipients. The prospective phase evaluated 13 CRYO and 27 non-CRYO patients for clinical endpoints as well as biomarkers including plasma inflammatory markers (IL-2, IL-6, IL-8, IFN-γ, VEGF-D, MMP-1, IL-18, TNF-α) quantified by ELISA.

Results: Non-CRYO recipients achieved faster neutrophil recovery (11 vs 14–15 days, p=0.006) and had shorter hospital stay (13–14 vs 18–19 days, p=0.005). Platelet engraftment was slightly earlier in CRYO (11–12 vs 13 days). Toxicity profile was favourable to the non-CRYO cohort: febrile neutropenia (19–22% vs 45–50%, p=0.005), severe mucositis (19–20% vs 60–66%, p=0.001), and total parenteral nutrition requirement (4–8% vs 20–25%, p=0.001). Inflammatory profiling showed higher IFN-γ in non-CRYO, while CRYO grafts exhibited higher levels of IL-6, IL-8, and VEGF-D, consistent with endothelial activation and inflammatory stress. No early mortality occurred in either cohort. With a median follow up of 36 months, overall survival 89% and 88% in the non-CRYO vs CRYO (p= 0.92).

Table. Clinical outcomes and inflammatory markers in CRYO vs non-CRYO autografts

Outcome / Marker	CRYO	Non-CRYO	p-value
Neutrophil engraftment (days, median)	14–15	11	0.006
Platelet engraftment (days, median)	11–12	13	0.005

Outcome / Marker	CRYO	Non-CRYO	p-value
Febrile neutropenia (%)	45–50%	19–22%	0.005
Severe mucositis ≥G3 (%)	60–66%	19–20%	0.001
Total parenteral nutrition (%)	20–25%	4–8%	0.001
Hospital stay (days, median)	18–19	13–14	0.005
IFN-γ (Tx)	Lower	Higher	0.044
IL-8 (Tx)	3.60 mg/L	1.25 mg/L	0.017
IL-8 (Post)	Higher	Lower	0.048
VEGF-D (Tx)	5.47 pg/mL	1.22 pg/mL	0.004
VEGF-D (Post)	6.21 pg/mL	3.35 pg/mL	0.044
IL-6 (Tx/Post)	Higher (trend)	Lower (trend)	n.s.[1]
MMP-1 (Tx/Post)	Higher (trend)	Lower (trend)	n.s.[1]
IL-18 (Tx/Post)	Variable	Variable	n.s.[1]

Notes: Tx = transplant day; POST = post-transplant; n.s. = not significant. Values shown as reported medians where available; otherwise direction of difference is indicated. CRYO indicates cryopreserved; Non-CRYO indicates non-cryopreserved.

Conclusions: Non-cryopreserved autologous transplantation reduces early morbidity and favors a distinct, less inflammatory immune milieu compared with cryopreservation. This strategy may represent a safe, effective, and operationally efficient alternative, particularly in high-throughput or resource-limited settings.

Background: Liso-cel is an autologous, CD19-directed, CAR T cell product with favorable efficacy and well-established safety profile across B-cell malignancies. Understanding outcomes of liso-cel treatment in younger patients remains an area of interest. In this study, we evaluated the effectiveness and safety of liso-cel in patients aged <50 years with R/R LBCL.

Methods: Patients in the United States with R/R LBCL who received commercial liso-cel as second-line (2L) or later treatment from 02/2021 to 05/2025 and had ≥1 postinfusion assessment reported to the Center for International Blood and Marrow Transplant Research (CIBMTR) were included. Effectiveness outcomes were ORR, CR rate, duration of response (DOR), PFS, and OS. Safety outcomes were AEs of special interest and nonrelapse mortality rates; results are descriptive.

Results: Of 1144 total patients assessed, 74 (6%) were aged <50 years at infusion (median age, 42 years [range, 21.5–49.5]) and 62% were male. Among patients aged <50 years with data available, 73% had DLBCL, 9% had primary mediastinal B-cell lymphoma (PMBCL), and 9% had high-grade B-cell lymphoma; 83% had refractory disease; and 52% had elevated LDH preinfusion. Most patients had ≥1 comorbidity per Hematopoietic Cell Transplantation-Comorbidity Index criteria (80%) and ECOG PS of 0–1 (90%). Median number of prior lines of therapy (LOT) was 3 (range, 1–13), and 18% received liso-cel as 2L treatment; 61% received bridging therapy and 36% were reported as intended for outpatient infusion. Compared with the overall cohort, patients aged <50 years had higher prevalence of PMBCL, refractory disease, elevated LDH, and comorbidities, but similar ECOG PS, number of prior LOTs, and receipt of bridging therapy. Median follow-up in patients aged <50 years was 14.8 months (95% CI, 12.7–24).
In patients aged <50 years, responses were deep (ORR, 72%; CR rate, 68%) and durable, with median DOR not reached (NR) and 12-month DOR rate of 80%, consistent with outcomes in the overall cohort (**Table 1**). Survival outcomes were also consistent in patients aged <50 years and the overall cohort, with median PFS and OS NR and similar 12-month rates (**Figure 1**; **Table 1**).
Liso-cel safety profile in patients aged <50 years was consistent with the overall cohort and clinical trials. Any-grade cytokine release syndrome and immune effector cell–associated neurotoxicity syndrome were reported in 58% and 28% of patients aged <50 years,

respectively, with low rates of grade ≥3 events (4% and 12%) (**Table 1**). Cytopenia at Day 30 was reported in 11% of patients and clinically significant infections at any time after infusion in 55%. Rates of second primary malignancies (1%), tumor lysis syndrome (3%), and grade 3/4 organ toxicity (7%) were low. In patients aged <50 years, 22 (30%) died, most commonly due to PD (n = 19/22 [86%]).

Conclusions: Consistent with clinical trials, these results reinforce that despite higher incidence of high-risk disease factors, younger patients with R/R LBCL experience clinically meaningful efficacy while the well-established safety profile of liso-cel is maintained, allowing potential outpatient use in the real-world setting.

Table 1. Summary of effectiveness and safety outcomes in patients < 50 years of age and the overall cohort

	Patients <50 years of age (n=74)	**Overall cohort (N=1144)**
ORR, % (95% CI)	72 (60–81.5)	81 (79–84)
CR rate, % (95% CI)	68 (56–78)	72 (69–75)
12-mo DOR rate, % (95% CI)	80 (65–89)	60.5 (57–64)

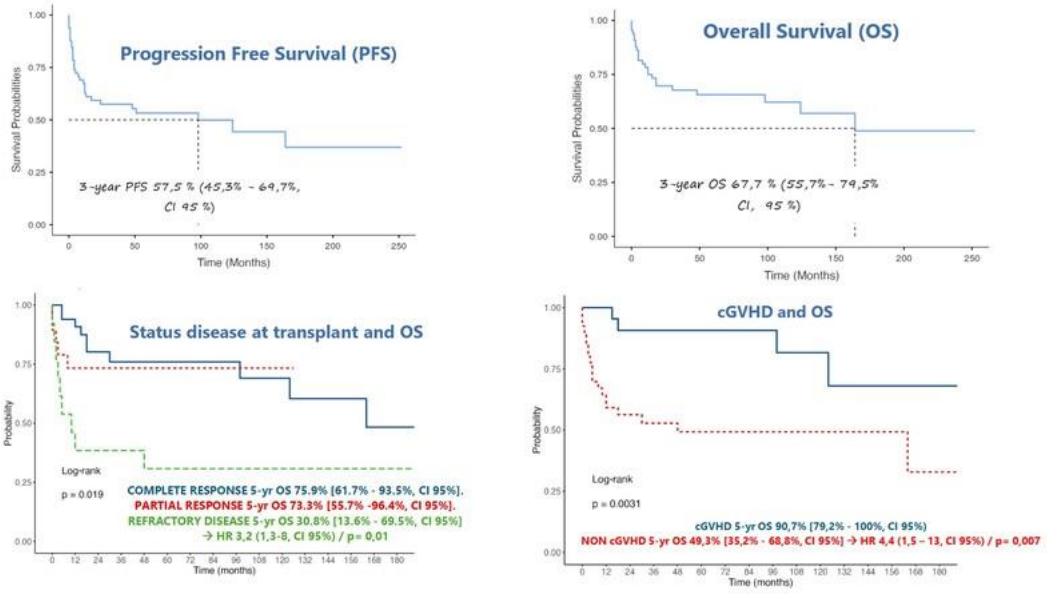
[1]Complejo Asistencial Universitario de Salamanca, Salamanca, Spain

Background: T-cell non-Hodgkin lymphomas (T cell-NHL) are aggressive haematological neoplasms that, in most cases, have an adverse prognosis, with high chemorefractary rates. In these cases, allogeneic hematopoietic stem cell transplantation (Allo-HSCT) is the only potencial curative treatment. The objective of the study is to analyze the efficacy of Allo-HSCT in T cell-NHL.

Methods: Single- center retrospective study of patients with T cell-NHL undergoing Allo-HSCT from 1997 to 2025.

Results:



65 patients undergoing Allo-HSCT. The median age was 51 years (18-70). Most of patients has a nodal T-NHL subtype (67,5%), 31% have previous autologous HSCT and 20% have a refractory disease to allo-HSCT (principal patients and Allo-HSCT characteristics are in Table).

At +100 day, 71% of patients were in complete response (CR). The incidence of relapse/progression was 24.5% (18.5% at one year) with a very low incidence (7%) in patients with nodal subtype and a high incidence in cutaneous subtypes (70%) (OR 42 (5,1-346,1 95% CI); p<0.001). Mortality was 37% and the first cause of death was infection (37.5% of deaths), followed by relapse/progression (25%). Mortality was higher in patients with high-risk HTC-CI (OR 7.6 (1.4-41.89 95% CI); p=0.02) and in patients with refractory disease at transplant (OR 6.5 (1.4-29.6 95% CI); p=0.02). Non relapsed mortality (NRM) was 9% at +100 day and 15.5% at one year. No other factor analyzed had an significant impact on relapse or mortality.

The rate of acute Graft Versus Host Disease (aGVHD) at day +100 was 50.5% (grade 3-4 33.5% (n=9)) and the rate of chronic GVHD at one year was 23% (moderate-severe 46.5% (n=7)); of them, 5 patients had a previous relapse with manipulation of immunosuppresor

treatment or an infusion donor lymphocyte (n=2) treatment.
With a median of follow-up in alive patients of 78 months (4-52), 5-year progression-free survival (PFS) and overall survival (OS) were 53.2% and 65.6%, respectively, with median PFS and OS of 8 and 13,5 years, respectively. T-cell NHL subtype, refractory disease at transplant, and high risk HCT-CI were associated with lower OS and PFS, while the development of cGVHD had a protective effect (Figure). So, median PFS and OS in nodal T-cell NHL was 164 months (5-year PFS and OS of 69%) versus only 7 and 10 months in extranodal T/NK subtype (PFS with HR 5.7 (1.3-25.7, 95% CI)/p=0.02 and OS with HR 5 (1.1-22.3, 95% CI)/p=0.03)); and median PFS of 2 months in Hepatosplenic (HR 5.2 (95% CI (1.5-18.2)/p=0.01)) and 4 months in Cutaneous subtypes (HR 4.6 (1.7-9.89 95% CI)/p<0.001)). In refractory disease at transplant, median PFS and OS were 4 and 10 months; in high-risk HCT-CI, 8 and 30 months; and in non cGVHD patients, 12 and 48 months, respectively. All these factors maintained their independent impact in the multivariate analysis.

		N (%)
Sex	Male	41 / (63)
OMS T-cell NHL subtype	Nodal T-cell lymphomas	44 / (67.5)
	Primary cutaneous T-cell lymphomas	10 / (15.5)
	Hepatosplenic T-cell lymphoma	4 / (6)
	Mature T-cell and NK-cell leukaemias	4 / (6)
	Extranodal NK/T-cell lymphoma	2 / (3)
	Intestinal T-cell lymphoma, NOS	1 / (1.5)
Lymphoma Stage (n=56)	III-IV	45 / (80,5)
DRI Score	High Risk	14 / (21,5)
HCT-CI	Low Risk (0)	43 / (66)
	Intermediate Risk (1-2)	13 / (20)
	High Risk (>3)	9 / (14)
	Identical sibling	29 / (44,5)

Donor	Haploidentical	16 / (24,5)
	Identical unrelated	14 / (21,5)
	Mismatch unrelated	6 / (9,5)
Conditioning	Reduced intensity	52 / (80)
	Myeloablative	13 / (20)

Conclusions: Allo-HSCT is an effective treatment for T-NHL and offers high PFS after long-term follow-up, especially in nodal subtypes. Disease status at transplant, High DRI, and HCT-CI are poor prognostic factors, whereas the beneficial effect of cGVHD demonstrates the curative potential of the graft-versus-lymphoma effect.

Background: Hemophagocytic Lymphohistiocytosis (HLH) is an underestimated but potentially life-threatening CAR-T complication. Among anti-CD19 CAR-T cell recipients, secondary HLH (sHLH) incidence is reported around 3%. Secondary HLH is often misdiagnosed[CP1] , and the treatment is not standardized. This retrospective study aimed to assess the real-world sHLH incidence and characteristics after CAR-T administration.

Methods: We retrieved clinical data from the EBMT registry regarding patients treated with CAR-T cells from 2014 to 2022. We collected additional information about CAR-T cell indication and product, sHLH manifestations, outcome and treatment.

Results: We collected 815 patients (677 B-Lymphoma, 71 B-ALL, 67 Multiple Myeloma), among 21 EBMT centers with a median follow-up time of 2 years. Twenty-seven patients, (20 with B cell lymphoma and 7 with B-ALL), experienced sHLH after CAR-T cells with an incidence of 3.6% (95%CI: 2.5 - 5.1) at 90 days and a median onset time of 11 days (range 5-86). Two-years Overall Survival and Progression Free Survival were 54.3% and 38.6%, respectively. B-ALL patients showed a higher incidence of sHLH than B-Lymphoma ones (10% vs. 3%). No event occurred after 90 days. Secondary HLH frequency was higher in patients treated with tisagenlecleucel (40,7%), followed by axicabtagene ciloleucel (37%), brexucabtagene autoleucel (14.8%), and others (7.4%). Cytokine Release Syndrome was present in 93% of patients (34% grade 3-4), which resolved in 60% of them before sHLH onset.
Fever was the most prominent feature (n=18, 75% of patients), followed by liver (n=13, 54%), kidney (n=8, 32%), and lung toxicity (n=5, 22%). The median ferritin value was 10723 ng/ml (range 1558-50565). Increased liver enzymes, LDH, triglycerides and impaired coagulation test were common. Eleven patients underwent a bone marrow aspirate, with evidence of hemophagocytosis in 45% of cases.
Twenty patients (80%) received treatment, most commonly with a combination of steroids and anakinra. The median follow-up post-sHLH was 2 years. Four patients died in absence of sHLH resolution. Nine additional patients died after sHLH resolution: 7 following relapse (incl. 2 within 30 days post-resolution) and 2 without relapse within 30 days post sHLH resolution. The survival after sHLH was 81.5% at 90 days and 50.1% at 2 years.

Conclusions: This registry study characterizes CAR-related sHLH. Secondary HLH incidence differed between patients B-ALL and B-Lymphoma patients. Our study showed a better sHLH prognosis than what previously reported. These real-world data underscore the need for clinical awareness and provide a base to define standardized diagnostic criteria and treatment algorithms for this complication.

RISK STRATIFICATION FOR HIGHER GRADE ICANS IN ANTI CD19 CAR T-CELL THERAPY TO GUIDE MANAGEMENT OF HIGH RISK PATIENTS

Jonas Wißkirchen[1], *Maria Protopapa*[1], *Julia Winternheimer*[1], *Isabelle Ries*[2], *Beate Hauptrock*[1], *Georg Heß*[1], *Stefan Bittner*[1], *Eva Wagner-Drouet*[1]
[1]*University Medical Center Mainz, Mainz, Germany,* [2]*Centre Hospitalier de Luxembourg, Luxembourg, Luxembourg*

Background: Effectiveness of CD19 CAR-T cell therapy is complicated by its inflammatory side effects: cytokine release syndrome (CRS) and immune effector cell associated neurotoxicity syndrome (ICANS). Some clinical features such as CAR product or high tumor burden are associated with increased incidence and severity of ICANS and CRS, but biomarkers such as glial fibrillary acidic protein (GFAP) or neurofilament light chain (Nfl) showed conflicting results for prediction of high grade ICANS.
A predictive score to identify patients at risk to develop high grade ICANS may guide to a preemptive or prophylactic intervention and improve outcomes.

Methods: We established a clinical score to identify patients at risk for high grade ICANS assessing the following criteria: CAR-T cell product (axi- or brexu-cel), tumor (B-ALL, DLBCL after >3 previous lines of therapy or high tumor burden) and patient factors (age >70y, CNS disease). Serum levels of Nfl and GFAP on d-5 were determined to assess their value in supplementing clinical risk scoring.
Patients that met at least 2 clinical criteria, were considered to be at risk for high grade ICANS. CRS and ICANS were graded using ASBMT consensus criteria.
In 04/23 we adapted the guidelines for the treatment of CRS & ICANS in our institution. Patients at high risk for ICANS received preemptive dexamethasone 1x10mg for CRS II° and dexamethasone 10mg qid already for ICANS I° (TOX 2). Low risk patients received dexamethasone 10 qid only for CRS III° and ICANS II° (TOX 1).

Results: Since 01/22 32 patients receiving CD19 CAR-T cell products met the criteria for high risk ICANS. 10 patients (9 axi-, 1 brexu-cel) treated between 01/22 and 04/23 were treated according to our former routine TOX 1 (Cohort 1). Since 04/23, 22 patients (15 axi-, 7 brexu-cel) followed our TOX 2 guidelines (Cohort 2).
The rate of ICANS was significantly higher in TOX2 patients (p=0.0139) and all ICANS ≥III° cases occurred in this cohort (negative predictive value=1). Rate of CRS did not differ between the two risk groups (p=0.7868).
Nfl levels on d-5 supplemented the clinical risk scoring and improved its predictive accuracy (AUC= 0.835 vs. 0.742 for the clinical score only). GFAP showed no significant correlation with occurrence of ICANS (p=0.62).
Intensified toxicity management significantly reduced the rate of high grade CRS (p=0.0361). Rate of higher grade ICANS also appeared lower.
The preemptive immunosuppressive approach did not have a negative impact on early lymphoma response by d+90 (p=0.1064).

Conclusions: Our risk assessment correctly identified patients at high risk for ICANS: In cohort 1 incidence of CRS (30%) and ICANS ≥III° (40%) was higher than reported for the

overall population within clinical trials. Inclusion of Nfl levels improved its positive predictive value by 10%.
Risk adapted toxicity management with early use of dexamethasone proved feasible in clinical routine and reduced the severity of both CRS and ICANS. This tailored approach may help to spare steroid exposure in contrast to a general prophylactic approach.
No negative impact on early response at day+90 was observed.

Disclosure: Jonas Wißkirchen: Pierre Fabre and Kite Gilead (travel expenses), Takeda (Honorarium).

A141

VENETOCLAX PLUS HIGH-DOSE CYTARABINE AND MITOXANTRONE (HAM-VEN) AS BRIDGE TO OR SALVAGE THERAPY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION IN RELAPSED/REFRACTORY AML

*Christina Rautenberg[1], **Sara Jennrich**[1], Christoph Schliemann[2], Christian Reicherts[2], Judith Metzdorf[1], H. Christian Reinhardt[1], Matthias Stelljes[2], Thomas Schroeder[1]*
[1]University Hospital Essen, Department of Hematology and Stem Cell Transplantation, West German Cancer Center, Essen, Germany, [2]University Hospital Münster, Department of Medicine A, Münster, Germany

Background: High-dose cytarabine-based salvage regimens are commonly used for the treatment of relapsed/refractory acute myeloid leukemia (R/R AML), but response and survival remain suboptimal. Aiming to improve the outcome the BCL2 inhibitor Venetoclax (VEN) was included into chemotherapy-based salvage therapies. In a recent phase I/II trial (RELAX, EudraCT 2018-003025-28) the addition of VEN to high-dose AraC and mitoxantrone (HAM) showed high efficacy with a CR/CRi rate of 75% and a median overall survival (OS) of 25 months. However, pts in clinical trials often represent highly selected cohorts potentially impeding translation into clinical routine. Therefore, our analysis aimed to investigate response to and outcome after HMA-VEN-based salvage therapy with focus on transplant rate and post-transplant outcome in a real-world setting.

Methods: All pts receiving HAM-VEN as salvage therapy for R/R AML at two German centers between 2021 and 2024 were included. Treatment included cytarabine 1000-3000mg/m^2 IV BID (day 3-5), mitoxantrone 10mg/m^2 IV QD (day 5-7) and VEN 400mg PO QD (day 1-14). The study was approved by the local ethics committee (approval number: 22-10708-BO).

Results: Sixty-five pts with a median age of 54 (range, 18 to 72) received salvage therapy with HAM-VEN either for refractory (n=27, 42%) or relapsed disease (n=38, 58%). Pts had received a median of 1 (range, 1-3) therapy lines including 22 (34%) with allo-SCT and 11 (17%) with previous VEN exposure prior to HAM-VEN. ELN 2022 genetic risk was favorable, intermediate and adverse in 9 (14%), 22 (34%) and 34 (52%) pts. Patient-, disease- and treatment-related factors were comparable among those who received HMA-VEN for relapsed or refractory disease. Following HAM-VEN, 44 (68%) pts achieved CR/CRi and 49% of those evaluable for measurable residual disease (MRD) achieved MRD negativity (CR_{MRD-}). CR and

MRD-negativity rate were comparable among those receiving HMA-VEN for relapsed or refractory disease (relapsed, CR 70% vs. refractory, CR 67%, p=0.79; relapsed CR_{MRD-} 54% vs. refractory, CR_{MRD-} 41%, p=0.54). Furthermore, response was comparable among different ELN 2022 disease risk groups (CR favorable 89%, intermediate 68%, adverse 63%). Response rate did also not differ between pts without and with prior allo-SCT (74% vs. 59%, p=0.26). In contrast, those patients without previous VEN exposure showed significantly higher response rate compared to those who had already received VEN (75% vs. 36%, p=0.02). Day+30 mortality was 6% (n=4) and related to infections in all cases. After a median FU of 12 months (range, 1 to 38) the estimated 1-year OS and EFS rates were 56% and 40%, respectively.
Fifty-four (83%) pts proceeded to allo-SCT including 16 (30%), who had received previous allo-SCT. Median follow-up from allo-SCT was 9 months (range, 1 to 35). One-year OS, RFS, relapse incidence and NRM) were 57%, 53%, 36% and 6% respectively Posttransplant OS did not differ among patients receiving 1st or 2nd allo-SCT after HAM-Ven (1-yr OS 57% vs. 56%, p=0.56).

Conclusions: Our real-world analysis confirms HAM/VEN as save and efficient salvage treatment for R/R AML facilitating a bridge to transplant in a high rate of patients with an encouraging posttransplant outcome including patients after second transplantation.

SARCOPENIA ASSESSMENT BY BIOELECTRICAL IMPEDANCE AND FUNCTIONAL TESTS PREDICTS CLINICAL OUTCOMES AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

*Gabriele Magliano[1], Carolina Bresciani[2], Lara Galletta[2], Giulia Brambilla[1], Mirko Farina[1], Vera Radici[1], Daniele Avenoso[1], Alessandro Leoni[1,3], Simona Bernardi[1,3], Federica Re[1,3], Marialaura Calonghi[2], Anna Maria Dossena[2], Daniele Corbo[4], **Silvia Zanon**[1], Riccardo Marnoni[1], Domenico Russo[1], Michele Malagola[1], Enrico Morello[1]*
[1]Unit of Blood Diseases and Bone Marrow Transplant, University of Brescia, ASST Spedali Civili, Brescia, Italy, [2]Unit of Physiotherapy, University of Brescia, ASST Spedali Civili, Brescia, Italy, [3]Centro di Ricerca Emato-Oncologica AIL, Brescia, Italy, [4]Unit of Neuroradiology, University of Brescia, ASST Spedali Civili, Brescia, Italy

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a potentially curative therapy for various hematological diseases, yet its outcomes are strongly influenced by patients' nutritional and functional status, with sarcopenia—defined by reduced muscle mass, strength, and physical performance—being associated with increased treatment toxicity, longer hospitalization, poorer survival, and possibly predicting inferior Overall Survival (OS), lower Progression-Free Survival (PFS), and higher Non-Relapse Mortality (NRM), although its independent prognostic role in allo-HSCT remains insufficiently explored.

Methods: This retrospective study included patients who underwent allo-HSCT for any diagnosis at Spedali Civili di Brescia between November 2018 and February 2025. Data collection included demographics, transplant-related risk scores — Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI), Clinical Frailty Scale (CFS), Disease Risk Index (DRI), and Transplant Conditioning Intensity (TCI) — functional tests (handgrip strength, chair stand test, gait speed), and body composition by Bioelectrical Impedance Analysis (BIA), including Phase Angle (PhA), Fat-Free Mass (FFM), Fat Mass (FM), Body Cell Mass (BCM), Total Muscle Mass (TMM), and Appendicular Skeletal Muscle Mass (ASMM). Sarcopenia was defined using European criteria: muscle mass (ASM, ASM/height²), strength (handgrip), and physical performance (gait speed, chair test), categorized as absent, mild, moderate, or severe. Outcomes included OS, mortality (relapse- or complication-related), and relapse incidence. Associations between sarcopenia indices and outcomes were assessed using descriptive statistics and univariate/multivariate analyses**.**

Results: 182 patients were included: 110 (60.4%) were alive and in complete remission, 38 (20.9%) relapsed, and 34 (18.7%) were deceased. Sarcopenia was absent in the majority of patients (67%), while 33% met at least one criterion. The estimated median overall survival of the studied population was 30 months (16–49). In univariate analysis (log-rank test), overall survival was significantly lower in patients meeting at least one criterion for sarcopenia (p=0.015), with a median estimated survival of 14 months (3–24) in sarcopenic patients compared to 30 months (16–43) in those without any sarcopenia criteria (Image 1). In univariate analyses, lower handgrip strength and ASM/height² were significantly associated with mortality (p=0.008), while relapse correlated with lower handgrip strength (p=0.008), percentage muscle mass (p=0.047), ASMM/height² (p=0.039), and BMI (p=0.043). Multivariate analysis (Table 1) showed that patients who relapsed or died had significantly lower lean, cellular, and muscle mass, with percentage BCM reaching statistical significance (p=0.020). Female sex was a protective factor, reducing risk by 76% (HR=0.21, p=0.013), as well as handgrip strength (HR=0.91, p=0.017), highlighting its role as an early, sensitive, and easily implementable prognostic marker. Overall, muscle strength, more than isolated anthropometric indices, appeared to drive post-transplant outcomes.

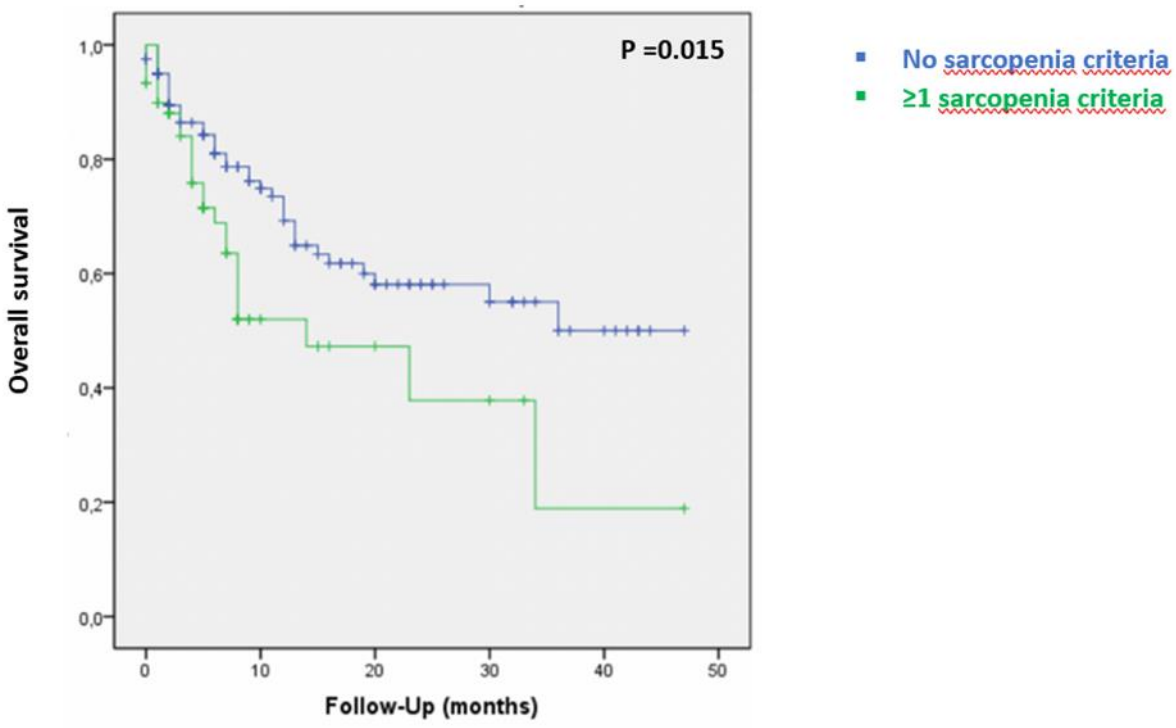

Image 1

Characteristics	HR	95% CI	p-value
Sex (female vs male)	0.24	0.08-0.73	**0.013**
Age	0.98	0.91-1.04	0.5
BMI (overweight vs normal)	0.60	0.21-1.66	0.3
Gait speed	3.04	0.32-29	0.3
Chair test	1.0	0.91-1.11	0.9
Handgrip	0.91	0.84-0.98	**0.017**
Clinical Frailty Scale	1.20	0.72-2.0	0.5
Disease Risk Index	1.09	0.50-2.39	0.8

Transplant Conditioning Intensity	0.66	0.37-1.17	0.2

Table 1

Conclusions: This study confirms the prognostic relevance of sarcopenia in allo-HSCT candidates, highlighting both functional and anatomical components. Handgrip strength is a practical, modifiable marker for routine assessment and risk stratification. Pre-frail and frail patients may benefit from tailored pre-habilitation combining exercise and nutritional support. A multidisciplinary approach with physiotherapists, nutritionists, and physicians enables individualized interventions, while ongoing monitoring with functional tests and BIA guides adaptive rehabilitation. Integrating sarcopenia assessment into pre-transplant protocols may improve survival, reduce complications, and enhance quality of life.

Disclosure: Nothing to declare.

POOR GRAFT FUNCTION AND GRAFT FAILURE AFTER ALLOGENEIC HSCT: FOCUS ON CELLULAR THERAPY. A RETROSPECTIVE SINGLE-CENTER ANALYSIS

Natalia Zubarovskaya[1], *Zoya Kuzmina*[2], *Rosskopf Konrad*[3], *Volker Witt*[1], *Herbert Pichler*[1], *Roswitha Lüftinger*[1], *Elke Zepperer*[2], *Anita Lawitschka*[1,2]
[1]*St. Anna Children's Hospital , Medical University Vienna, Vienna, Austria,* [2]*Children's Cancer Research Institute, Vienna, Austria,* [3]*Medical University Graz, Graz, Austria*

Background: Poor graft function (PGF) and graft failure (GF) are life-threatening complications after allogeneic HSCT, and stem cell boost (SCB) represents a promising alternative to second transplantation. We performed a single-centre retrospective analysis of pediatric patients receiving SCB between 2014 and 2024 to evaluate patient (ptn) and treatment characteristics, SCB indications and responses according to EBMT criteria (Shapiro et al. 2023), overall survival (OS) by disease type, and the incidence of GvHD after SCB.

Methods: Among 328 allo-HSCT recipients, 18/328 pts (5%) developed PGF or primary/secondary GF requiring SCB. The median age was 11.3 years (range, 0.7–23), with a median observation time of 1.4 years (range, 0.1–8.8). Underlying diseases were malignant in 12/18 and non-malignant in 6/18 pts. HSCT/SCB were performed from a matched sibling donor in 5/18 pts, a matched unrelated in 10/18 and a haploidentical donor in 3/18 pts. GVHD prophylaxis post SCB was given in 9/18 pts, mainly those with non-malignant diseases. Response to SCB was classified as complete response (CR), partial response (PR), or no response (NR) according to EBMT consensus criteria. Overall survival (OS) was evaluated from the date of SCB.

Results: SCB was performed at a median of day +128 (range, 12–157) after allo-HSCT. PGF was diagnosed in 12/18 and primary or secondary GF in 6/18 pts. The main indications for SCB were viral infection in 12/18 and pending relapse in 4/18 pts. SCB products included

cryopreserved and non-cryopreserved CD34⁺-selected grafts (7/18 and 1/18 pts, respectively), as well as αβ-TCR–depleted or CD3/CD19–depleted grafts (10/18 pts). CD34⁺-selected grafts contained a median of 3.7 × 10^6 CD34⁺ cells/kg (range, 0.85–4.4) and 4 × 10^3 CD3⁺ cells/kg (range, 1–7); αβ TCR–depleted or CD3/CD19–depleted grafts contained a median of 5.3 × 10^6 CD34⁺ cells/kg (range, 1.9–8.4) and 3 × 10^5 CD3⁺ cells/kg (range, 0.01–5). Prior to SCB, 5/18 pts received plasma exchange and immune adsorption for B-cell dysregulation and antibody-production, with additional rituximab administered in 3 of these pts. After SCB, all patients receiving CD34⁺-selected SCB (8/8) achieved stable hematologic engraftment and became transfusion independent, whereas 70% (7/10) of patients receiving αβ TCR–depleted or CD3/CD19-depleted SCB achieved engraftment. Two-year OS was 100% in non-malignant diseases (6/6 pts) and 58% in malignant diseases (7/12 pts), with deaths in the malignant group primarily attributable to disease progression ($p > 0.05$).
SCB induced GvHD was rare with acute GvHD (I–II) in 2/18 pts, and no cases of severe acute and chronic GvHD, GvHD rates were comparable across different SCB product types.

Conclusions: SCB is a safe and effective treatment for PGF and GF after allo-HSCT, achieving high response rates and favourable survival without significant GvHD. Outcomes were excellent for non-malignant diseases, whereas OS was lower in malignant diseases, likely reflecting underlying disease risk. Despite the small cohort, these data support early consideration of SCB as a first-line cellular therapy for post-transplant graft dysfunction.

SCALABLE MANUFACTURING AND NATIONWIDE DISTRIBUTION OF ORCA-T: A PRECISION-ENGINEERED ALLOGENEIC IMMUNE CELL THERAPY

*Amy Putnam[1], Sandy Tang[1], Katie Chaddock Chaddock[1], Marina Becker[1], Jamie Goldman[1], Lauren Smith[1], Kate Bickett[1], Virginia Sullivan[1], James Scott McClellan[1], **Anna Pavlova**[1], Everett H. Meyer[2], Nathaniel B. Fernhoff[1], Jeroen Bekaert[1]*
[1]Orca Bio, Menlo Park, United States of America (the), [2]Division of BMT and Cellular Therapy, Stanford University School of Medicine, Stanford, United States of America (the)

Background: Orca Bio is a clinical-stage biotechnology company advancing a pipeline of high-precision allogeneic cell therapies to replace diseased blood and immune systems. Our lead investigational candidate, Orca-T, is manufactured from mobilized apheresis collections of 8/8 HLA-matched donors and comprises purified regulatory T cells (Treg), hematopoietic stem and progenitor cells (HSPC), and conventional T cells (Tcon). Donor products are transported to a central GMP facility, where each cellular component is purified and formulated. Treg and HSPC are shipped as fresh infusions, while Tcon is cryopreserved. Final products are couriered under controlled conditions to treatment centers for administration. Logistics across apheresis sites, the central facility, and clinical centers are supported by OrcaPort, a proprietary supply chain platform, in partnership with the National Marrow Donor Program (NMDP).

Methods: We report manufacturing and distribution data from Orca-T in the Phase 1b (NCT4013685) and Phase 3 (NCT05316701) trials. Between December 2019 and September 2024, 243 products were manufactured, 215 from single-day collections and 28 from two-day collections. Time zero was defined as completion of the final collection. Apheresis centers and treatment centers were utilized widely across the US (Figure 1). Overall, 96% of products were delivered within 60 hours and 100% within 70 hours; 99% were infused within the 72-hour release window. Product quality was consistent: adjusted ideal body weight averaged 74 ± 13 kg (46–104); Treg dose was 2.7 ± 0.4 × 10^6/kg (1.3–3.7) with 92% ± 3% purity (78–97%); HSPC dose was 6.2 ± 3.0 × 10^6/kg (1.1–15.2); residual T cells were 17 ± 134 × 10^3/kg (0–1825); Tcon products were dosed at 3 × 10^6/kg.

Results: These results demonstrate that Orca-T can be reliably manufactured at scale, maintaining high purity, and distributed nationwide within a controlled logistics framework.

Conclusions: Collectively, these findings establish the feasibility of precision-engineered cell therapy manufacturing and distribution to enable multicenter clinical studies and lay the foundation for future commercial application.

OUTCOMES AFTER STANDARD- VS. REDUCED-DOSE TREOSULFAN IN ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

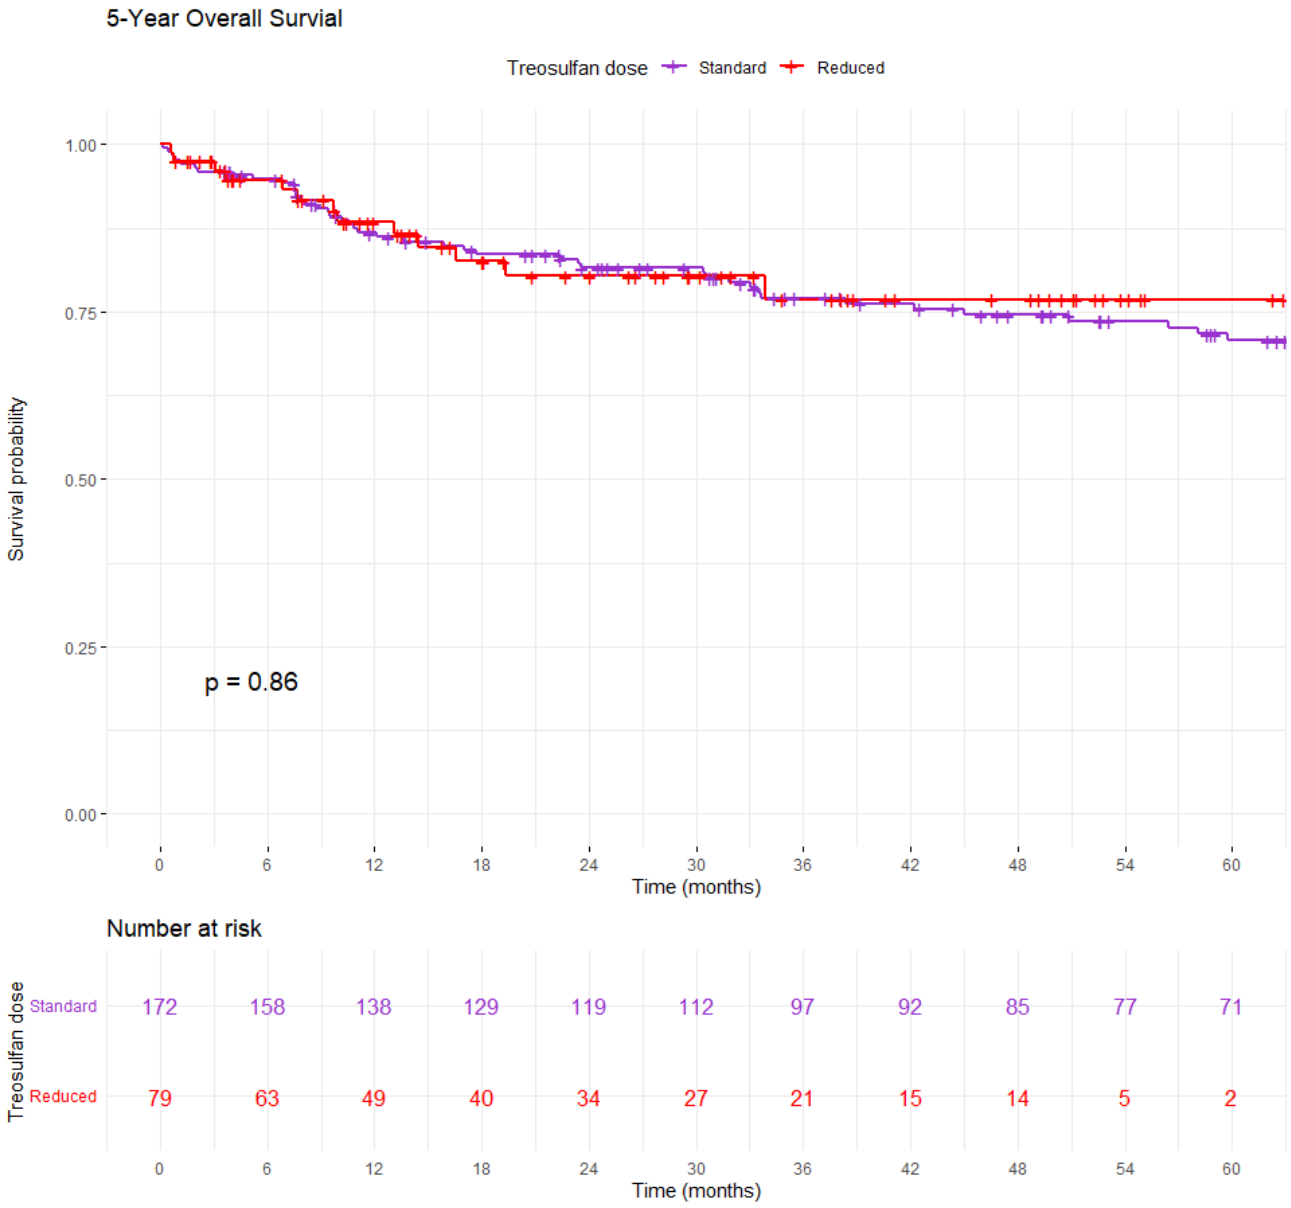
Johanne Schovsbo[1], *Eileen Wedge*[1], *Henrik Sengeløv*[1], *Brian Kornblit*[1], *Bo Mortensen*[1], *Niels Smedegaard Andersen*[1], *Søren Petersen*[1], *Marietta Nygaard*[1], *Ida Schjødt*[1], *Morten Holmström*[2], *Kirsten Grønbæk*[1,3], *Lone Smidstrup Friis*[1,3]
[1]*Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark,* [2]*National Center for Cancer Immune Therapy, Herlev Hospital, Herlev, Denmark,* [3]*Institute of Clinical Medicine, Copenhagen University, Copenhagen, Denmark*

Background: Treosulfan-based conditioning is increasingly used in allogenic hematopoietic cell transplantation (allo-HCT) due to its myeloablative efficacy and reduced toxicity. However, evidence guiding optimal dosing remains limited and its clinical impact remains insufficiently defined. Conditioning with Fludarabine and Treosulfan (FluTreo) was implemented at Copenhagen University Hospital, Rigshospitalet, in 2014 with a standard dose of 42 g/m². In 2020, a dose-adjusted algorithm introduced 30 g/m² treosulfan for older patients or those with higher comorbidity. This study examines the impact of treosulfan dose on clinical outcomes, with the aim of improving understanding of dose optimization in FluTreo conditioning.

Methods: We performed a retrospective cohort study of all adults receiving FluTreo conditioning prior to allo-HCT for malignant disease at Rigshospitalet from 2014–2024. Diagnoses included myelodysplastic syndrome (MDS), high-risk acute myeloid leukemia (AML) and other myeloid malignancies. Patients received either standard-dose or reduced-dose treosulfan based on time of transplantation, age and comorbidity score (HCT-CI). Clinical data were extracted from electronic medical records. Statistical analyses included descriptive statistics, Kaplan–Meier survival analysis, and competing risks models.

Results: A total of 252 patients were included with 173 receiving standard-dose and 79 receiving reduced-dose Treosulfan. Reduced-dose recipients were older (median 64.5 years [inter quartile range (IQR) 52.6–67.8] vs. 57.7 years [IQR 52.1–62.2], p=0.00016), while comorbidity burden was comparable (median HCT-CI 2 [IQR 0–3] vs. 2 [IQR 0.5–3.5], respectively, p=0.27). Diagnostic distribution was similar between groups (around 70% MDS, 15% AML and 15% other diagnoses) (p=0.50), with a median IPSS-R for the MDS patients of 4.5 in both groups (p=0.59). Median follow-up was 5.9 and 2.2 years, in the standard and reduced dose groups respectively. For the entire cohort, overall survival (OS) was 87.2% [83.0–91.6%] at 1 year and 77.0% [71.4–83.0%] at 3 years. OS at 1 and 3 years was 86.7% [81.7–92.1%] and 77.0% [70.6–84.0%] in the standard-dose group, and 88.4% [81.1–96.3%] and 76.8% [65.8–89.7%] in the reduced-dose group (p=0.86). Cumulative incidence of relapse (CIR) for the whole cohort was 15.8% [11.1–20.5%] at 1 year and 21.4% [16.0–26.9%] at 3 years. CIR at 1 and 3 years was 14.0% [8.7–19.2%] and 18.5% [12.5–24.4%] with standard dose, and 19.3% [10.0–28.8%] and 29.3% [16.8–41.8%] with reduced dose (p=0.12). Non-relapse mortality (NRM) for the cohort was 6.8% [3.6–10.0%] at 1 year and 8.4% [4.8–12.1%] at 3 years. NRM at 1 and 3 years was 7.3% [3.4–11.4%] and 9.5% [4.9–14.0%] with standard dose, and 4.6% [0.0–9.4%] at both time points with reduced dose (p=0.35). Analyses of toxicity, chimerism, graft-versus-host disease, and

prognostic factors are ongoing.



Conclusions: Treosulfan dose adjustment was not associated with differences in overall survival, relapse, or non-relapse mortality. Despite significantly older age in the reduced-dose group, outcomes remained comparable, indicating that reduced-dose treosulfan may be a viable option for selected patients. Ongoing analyses of chimerism, graft-versus-host disease, and toxicity will help further define the clinical implications of treosulfan dosing and guide individualized conditioning strategies in allo-HCT.

REAL-WORLD EXPERIENCE WITH TABELECLEUCEL

Kiavasch Mohammad Nejad Farid[1], *Florian Kocher*[2], *Tobias Arnold*[3], *Josia Fauser*[2], *Elisa Henze*[4], *Christian Schultze-Florey*[4], *Carmen Diana Herling*[5], *Vladan Vučinić*[5], *Matthias Stelljes*[6], *Christian Reicherts*[6], *Raphael Stadelmann*[7], *Christof Scheid*[8], *Udo Holtick*[8], *Stavroula Masouridi-Levrat*[9], *Marc Wehrli*[10], *Urban Novak*[10], *Paul Schnitzler*[1], *Chiraz Ben-Salah*[1], *Isabelle Krämer*[1], *Anita Schmitt*[1], *Carsten Müller-Tidow*[1], *Thomas Luft*[1], *Peter Dreger*[1], *Michael Schmitt*[1]
[1]*Heidelberg University Hospital, Heidelberg, Germany,* [2]*Medical University of Innsbruck, Innsbruck, Austria,* [3]*University Hospital of Gießen and Marburg, Gießen, Germany,* [4]*Hannover Medical School, Hannover, Germany,* [5]*University Hospital Leipzig, Leipzig, Germany,* [6]*University Hospital Münster, Münster, Germany,* [7]*Lausanne University Hospital and University of Lausanne, Lausanne, Switzerland,* [8]*University of Cologne, Cologne, Germany,* [9]*Geneva University Hospital and University of Geneva, Geneva, Switzerland,* [10]*Bern University Hospital and University of Bern, Bern, Switzerland*

Background: Tabelecleucel (Tab-cel) is an allogeneic Epstein–Barr virus (EBV)-specific T-cell therapy approved in the European Union for relapsed or refractory (R/R) EBV-associated post-transplant lymphoproliferative disorder (PTLD) after failure of rituximab or immunochemotherapy. Despite its promise as the first approved therapeutic option, real-world evidence remains limited. The aim of this study was to evaluate the scope of use and outcomes of Tab-cel treatment in the real-world setting across Germany, Austria, and Switzerland (DACH countries).

Methods: Eleven patients with EBV-positive PTLD or other EBV-associated lymphoproliferative disorders (LPD) from nine academic centers were included for detailed analysis of their (disease) characteristics and survival parameters. The cohort analyzed includes all known Tab-cel–treated patients in DACH until July 2025.

Results: Eight patients with PTLD (six after solid organ transplantation, two after allogeneic hematopoietic cell transplantation) and three with EBV-associated LPD were treated with a median of two cycles Tab-cel (range 1-3). After a median follow-up of 15.1 months, 6/11 patients (55%) remain alive. Initially, 7/11 patients (64%) achieved an objective response and best response occurred after a median of 37 days after the first Tab-cel infusion (i. e. end of cycle one). Despite a high relapse and progression rate after Tab-cel affecting 7/11 patients (64%), estimated median overall survival was 10.7 months (CI 4.4-14.7) due to successful salvage treatments. Immunotherapy-related adverse events were rare.

Conclusions: Tab-cel demonstrates meaningful efficacy with a favorable safety profile in R/R PTLD/LPD within this highly vulnerable population of immunodeficient or transplanted patients. However, the durability of response depends on re-establishing effective immunosurveillance, and Tab-cel alone was not consistently sufficient to maintain long-term disease control. Future approaches should clarify how best to integrate Tab-cel into the therapeutic pathway for R/R LPD, potentially including optimized HLA matching to enhance antiviral activity and consideration of consolidation strategies following Tab-cel therapy. This study contributes to the early real-world experience with Tab-cel and highlights its potential for achieving remission induction.

MESENCHYMAL STEM CELLS DERIVED FROM DIFFERENT SOURCES AND THEIR SECRETOMES IN MULTIPLE SCLEROSIS THERAPY: A SINGLE CENTER EXPERIENCE

Ahmad Ibrahim[1], *Samar Abbas*[2], *Alain Chebly*[3], *Frederic Harb*[4], *Rawad Salameh*[5], *Wassim Hamadeh*[6], *Albert Azar*[5], *Colette Hanna*[2], *Charbel Khalil*[7]
[1]*Middle East Institute of Health, University of Balamand, Beirut, Lebanon,* [2]*Lebanese American University, Beirut, Lebanon,* [3]*Center Jacques Loiselet for Medical Genetics and Genomics (CGGM), Faculty of Medicine, Saint Joseph University, Beirut, Lebanon,* [4]*University of Balamand, Faculty of Medicine and Medical Sciences, Beirut, Lebanon,* [5]*Reviva Regenerative Medicine Center, Beirut, Lebanon,* [6]*Lebanese University, Beirut, Lebanon,* [7]*Lebanese American University, School of Medicine; Reviva Regenerative Medicine Center, Beirut, Lebanon*

Background: Multiple sclerosis (MS) is a chronic autoimmune, inflammatory, and demyelinating disease of the central nervous system (CNS), affecting young adults. While current treatments can improve symptoms, there remains a need for novel therapeutic approaches. Mesenchymal stem cell (MSC) therapy has emerged as a promising strategy for various neurodegenerative disorders due to its immunomodulatory properties and the therapeutic potential of its secretome. The MSC secretome comprises growth factors, cytokines, and extracellular vesicles that contribute to tissue repair and immune regulation.

Methods: This retrospective, experimental study conducted between 11/2023 and 11/2024, on an outpatient basis, involved 10 pts who were divided in 2 groups (each n = 5): Group A received bone marrow-derived MSCs and their secretome (BM-MSC + Secretome), while Group B received umbilical cord-derived MSCs and their secretome (UC-MSCs+Secretome). Median age was 53 yo (47-60). All pts were were refractory to the usual conventional treatments. Ten collections from BM and UC were made. BM aspirates were obtained by puncturing the iliac crest. UC units were collected from the unborn placenta of full-term deliveries in a multiple bag system containing 17 mL of citrate phosphate dextrose buffer (Cord Blood Collection System; Eltest, Bonn, Germany). Processing was performed within 24 h of collection. All MSCs were cultured with DMEM/F12 supplemented with 5% PSA at subconfluency. After 48h of incubation at 37 °C at a humidified atmosphere containing 5% CO2, the supernatant, containing all released cytokines and chemokines was collected. Two injection sessions were performed per patient on day 0 and 180; the number of cells were 10^8 diluted in 100 ml of secretome and cells were at passage three. The clinical outcome for evaluation was Kurtzke's expanded disability status scale (EDSS) and Symbol Digit Modalities Test (SDMT).

Results: Patients in Group B demonstrated greater improvement in the EDSS and SDMT compared to Group A. Additionally, we observed encouraging trends in cognitive and psychological parameters, as well as moderate improvements in neurological assessments, functional disability, and unaided mobility. Enhanced brain connectivity was also noted, alongside reduced dependency in daily activities such as eating, with patients maintaining clear communication. These findings suggest that UC-MSCs+Secretome may offer superior

therapeutic benefits in the treatment of MS compared to BM-MSCs+Secretome .In our study, we observed a reduction in CD20/CD19 expression on B lymphocytes following cell therapy, indicating a decrease in B cell population. This is noteworthy given the role of B cells in MS pathogenesis.

Conclusions: This trial suggests that BM-MSCs and UC-MSCs, along with their secretomes, may offer neuroprotective and clinical benefits in MS patients refractory to conventional treatments. However, due to the limited sample size and follow-up duration, further studies involving larger cohorts, repeated dosing, and objective biomarkers are essential to confirm these findings.
We propose that the timing of MSC administration is a critical factor in optimizing therapeutic outcomes. Administering high-dose MSCs during the early inflammatory phase of MS may enhance their effectiveness as a novel treatment strategy.

TREOSULFAN-FLUDARABINE AS A REDUCED INTENSITY CONDITIONING ALTERNATIVE TO BUSULFAN-FLUDARABINE FOR ADULT ALLOGENEIC STEM CELL TRANSPLANTATION: SINGLE-CENTER, EARLY REAL-LIFE CLINICAL AND ECONOMICAL COMPARATIVE OUTCOMES

Clémence Delaye[1], *Arnaud Pagès*[1], *Jamila Marghadi*[1], *Bernard Do*[1], *Cristina Castilla-Llorente*[1], *Aurélien Sutra-Del-Galy*[1], *Céline Chauvel*[1], *Jean-Henri Bourhis*[1], *Sylvain Pilorge*[1], *Maxime Annereau*[1], *Tereza Coman*[1]
[1]*Gustave Roussy, Villejuif, France*

Background: Reduced-intensity conditioning (RIC) has substantially extended transplantation (allo-HCT) practices by balancing disease control with treatment-related toxicity. FB2 (Fludarabine 120 mg/m² + Busulfan 6.4 mg/kg) remains one of the most widely used RIC backbones. However, high-quality studies suggest that treosulfan-based regimens may reduce toxicity without compromising disease control. Based on this evidence, our center implemented FT10 (Fludarabine 120 mg/m² + Treosulfan 30 g/m²) in 2023 as an alternative RIC regimen. We report here our real-life comparative experience focusing on early post-transplant outcomes and economic indicators.

Methods: We retrospectively reviewed all allo-HCTs performed between 2021 and 2025 using FT10 or FB2 conditioning, both combined with anti-lymphocyte globulin ((ATG) Thymoglobulin 5 mg/kg or Grafalon 30 mg/kg), for adults with AML or MDS. Transplant practices were identical across the study period: peripheral blood stem cell grafts, ciclosporine + methotrexate for GVHD prophylaxis, letermovir prophylaxis, and unchanged center-level procedures and teams. Clinical variables and outcomes were extracted from electronic medical records. Due to shorter follow-up in the FT10 cohort, survival outcomes

were reported at a fixed 6-month (6m) landmark. Between-group imbalances were included in multivariable models. Fine-Gray competing risks models were used as appropriate. Costs were assessed from the French national health insurance perspective and reflect reimbursement-based hospital charges. The study was approved by the local ethics committee (IRB 2025-655).

Results: A total of 135 adults were included: FB2 (n = 100) and FT10 (n = 35). Baseline characteristics were comparable between FB2 and FT10 regarding age (median 63 vs 60 years), disease type (AML 70% vs 74%), remission status (CR1 69% vs 51%), disease risk, time from diagnosis to allo-HCT, donor type, ABO compatibility, comorbidity score, and subsequent injections of donor lymphocytes (DLI). The FT10 group had more secondary AML/MDS (43% vs 18%, p = 0.0061), second allo-HCT (23% vs 3%, p = 0.0009), and Grafalon use (69% vs 1%, p < 0.0001).
Median follow-up was 29.7 (FB2) and 8.3 months (FT10). The 6m overall survival (OS) and relapse-free survival (RFS) were similar in both groups. In multivariable analysis, CR1 status at allo-HCT significantly improved the RFS (HR=0.35, 95%CI 0.12 – 0.98, p= 0.04) independently of the conditioning group. The 6m incidence of relapse was 18% (FB2) vs 9% (FT10) and did not reach a statistical significance owing to limited power. The 6m TRM was similar (6% (FB2) vs 5% (FT10)). Day 100, grade ≥ II acute GVHD was comparable (11% (FB2) and 14% (FT10)). Engraftment rates, infectious complications and sinusoidal obstruction syndrome were similar between groups. FT10 was associated with higher upfront transplant-related costs (p=0.0036) but significantly lower secondary costs related to post-transplant unplanned care (p=0.0224) consistent with less severe or less resource-intensive complications. Detailed analysis of healthcare burden will be provided including a sensitivity analysis for ATG costs.

Conclusions: Despite being used in a substantially higher-risk population, FT10 achieved early post-transplant outcomes comparable to FB2, with a lower burden of early unplanned healthcare costs. These findings support the feasibility and cost effectiveness of FT10 as a reduced-toxicity RIC option for AML/MDS.

CD72-GATED PRE-CAR-T MRD AS A NOVEL PREDICTOR OF POST-TRANSPLANT OUTCOMES IN R/R B-ALL ACHIEVING MRD-NEGATIVE REMISSION AFTER CD19 CAR-T THERAPY

Man Chen[1], *Min-Jing Fu*[1], *Wei Zhao*[1], *Gai ling Zhang*[2], *Jing Long*[3], *Hui Wang*[2,1]
[1]*Beijing Lu Daopei Hospital, Beijing, China,* [2]*Hebei Yanda Lu Daopei Hospital, Langfang, China,* [3]*Beijing Lu Daopei Institute of Hematology, Beijing, China*

Background: Antigen loss limits MRD monitoring after CD19/CD22 CAR-T in r/r B-ALL. CD72, a B-lineage–restricted marker, offers a reliable alternative. We validated a CD72-gated

MFC strategy and assessed its prognostic value for post–HSCT outcomes in MRD-negative patients after CD19 CAR-T.

Methods: CD72-based MRD gating was validated in 66 B-ALL and assessed for lineage specificity in 129 acute leukemia samples. We retrospectively analyzed 129 r/r B-ALL patients achieving MRD-negative CR by day 28 post–CAR-T who underwent first allo-HSCT. Patients were stratified by CD72-gated pre–CAR-T MRD (≤1% vs. >1%). Outcomes included OS, LFS, CIR, and NRM; targeted sequencing profiled mutations.

Results: ***Validation of CD72-based gating***
CD72-based MRD detection showed near-perfect concordance with CD19-based gating (R^2 = 0.9936 in CR and 0.9993 in NR cases). CD72 was positive in 95.8% of B-ALL cases (vs. 29.3% AML, 23.5% T-ALL; $P < 0.001$), confirming strong B-lineage specificity.
Post–CAR-T and HSCT outcomes (Figure 1)
Among 129 patients (median age 13 years), all achieved MRD-negative CR and underwent allo-HSCT. Baseline characteristics were comparable between MRD groups. Among 114 genetically tested patients, 86.8% harbored mutations, most frequently in *IKZF1* (16.7%), *WT1* (9.6%), *ETV6* (9.6%), and RAS pathway genes (21.9%). Fusion positivity (36.4%) included *KMT2A-r* (8.5%) and *BCR::ABL1* (10.9%), with comparable distribution between MRD groups. After a median follow-up of 38.5 months, the 3-year OS and LFS were 76.6% and 72.3%, respectively. Patients with pre–CAR-T MRD ≤1% had significantly better outcomes (3-year OS 88.1% vs. 69.2%, $P = 0.014$; LFS 88.1% vs. 64.1%, $P = 0.004$) and lower relapse risk (CIR 6.0% vs. 19.2%, $P = 0.034$).
Multivariate Analysis (Table 1)
Patients harboring KMT2A rearrangement had significantly worse OS (HR = 3.57, 95% CI 1.11–11.50, $P = 0.033$). Similarly, IKZF1 mutation was associated with poorer OS (HR = 2.75, 95% CI 1.09–6.96, $P = 0.033$), and TP53 mutation predicted markedly inferior OS (HR = 5.31, 95% CI 1.85–15.28, $P = 0.002$), LFS (HR = 3.64, 95% CI 1.31–10.10, $P = 0.014$), and higher NRM (HR = 5.19, 95% CI 1.29–20.90, $P = 0.021$). Pre-CAR-T MRD > 1% was also an adverse factor for OS (HR = 2.83, 95% CI 1.12–7.15, $P = 0.028$), LFS (HR = 3.39, 95% CI 1.37–8.40, $P = 0.008$), and NRM (HR = 3.63, 95% CI 1.00–13.20, $P = 0.050$). Age, BCR::ABL1, complex cytogenetics, CAR-T cell dose, and the interval between CAR-T infusion and subsequent HSCT did not significantly impact OS, LFS, CIR, or NRM (*all* $P > 0.05$).

Conclusions: CD72-gated MFC enables reliable, lineage-specific MRD monitoring in B-ALL and addresses the limitations of antigen-loss after CD19/CD22 CAR-T therapy. Importantly, CD72-gated pre–CAR-T MRD serves as a novel, independent biomarker predicting post-transplant survival and relapse. Integrating CD72-based MRD with molecular risk profiling (e.g., *KMT2A*, *TP53*, *IKZF1*) provides a powerful stratification tool to optimize transplant timing and post–CAR-T management in r/r B-ALL.

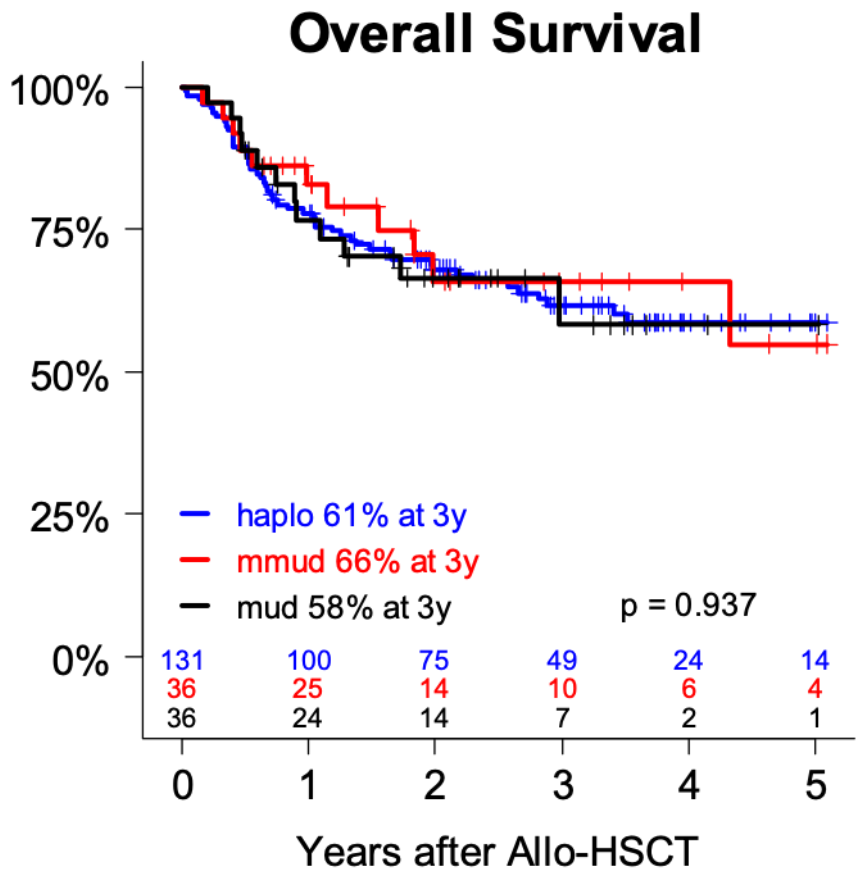
NON-MYELOABLATIVE CONDITIONING FLUCYTBI WITH POST-TRANSPLANTATION CYCLOPHOSPHAMIDE IS SAFE AND EFFECTIVE FOR BOTH HAPLOIDENTICAL AND UNRELATED DONOR ALLOGENEIC TRANSPLANTATION IN OLDER PATIENTS WITH AML OR MDS

Guillaume Berton[1], Sabine Furst[1], Benjamin Bouchacourt[1], Samia Harbi[1], ***Charlotte Nykolyszyn***[1]*, Cassandre Petit-Deharo[1], Federico Pagnussat[1], Camille Rouzaud[1], Sylvain Garciaz[1], Claude Lemarie[1], Pierre Jean Weiller[1], Didier Blaise[1], Raynier Devillier[1]*
[1]Institut Paoli Calmettes, Marseille, France

Background: The non-myeloablative conditioning regimen (NMAC) from Baltimore based on 2Gy TBI, fludarabine and cyclophosphamide (FluCyTBI) associated with post-transplant cyclophosphamide (PTCy) was initially developed in the context of haploidentical transplantation. We previously reported that this platform is well adapted to AML or MDS patients aged ≥70yo, with low incidence of GVHD and prolonged survival. In our center, this regimen was progressively implemented in the setting of mismatched unrelated donor (MMUD) and matched unrelated donor (MUD) for patients ≥60yo or younger in case of comorbidities. Here we report a large single-center retrospective study showing the feasibility and efficacy of FluCyTBI+PTCy as single platform for both haplo and unrelated donor (UD) allo-SCT in AML/MDS pts ≥60y or with comorbidities.

Methods: We included all consecutive patients with following criteria: age ≥60yo or younger if contraindicated to receive busulfan-based regimen; first allo-SCT for AML or high-risk MDS between 2015 and 2024; Haplo or UD allo-SCT; FluCyTBI regimen; PBSC as graft source; PT-Cy, CSA and MMF as GVHD prophylaxis. We evaluated acute and chronic GVHD, NRM, relapse, PFS and OS.

Results: 203 patients were included, with a median age of 69y (IQR 59-73). 94 patients were ≥70yo at the time of allo-SCT. 28 patients were younger than 60y and received NMAC because of comorbidities. Donors were haplo, MMUD and MUD in 131 (65%), 36 (18%) and 36 (18%) patients respectively. 145 and 58 patients had AML and MDS, respectively.
Out of 108 AML in first CR, CRi or MLFS at allo-SCT, ELN2022 risk stratification was favorable, intermediate and adverse in 9 (8%), 48 (44%) and 51 (47%) of cases respectively. Monosomal karyotype (MK) was found in 21 (10%) of the cohort. In the whole cohort, with a median follow-up of 38 months, median OS was not reached. Day+100 grade 2-4 acute, grade 3-4 acute and 3-y all grades chronic and moderate/severe chronic GVHD were 32%, 8%, 33% and 18%, respectively. 1-y and 3-y NRM were 9% and 15%, respectively. 3-y CIR rate was 27%. 3-y OS rates were 61%, 66% and 58% (P=0.937) and 3-y PFS rates were 59%, 63% and 40% (P=0.482) in the haplo, MMUD and MUD cohorts respectively. There was no difference in any endpoint between AML and MDS patients. Outcomes of patients ≥70y were not different from those of younger patients.
In multivariable analysis, MK predicted worse OS and PFS (HR 3.83, 95%CI 1.97-7.45, P<0.001 and HR 4.13, 95%CI 2.16-7.89, P<0.001, respectively). MK as well as MUD predicted increased relapse risk (HR 6.26, 95%CI 2.87-13.66, P<0.001 and HR 2.82, 95%CI 1.4-5.66, P=0.004 respectively). Donor age >35y predicted increased risk of aGVHD II-IV (HR 1.78, 95%CI 1-3.15, P=0.049). Female-to-male sex-mismatch predicted increased risk of moderate/severe chronic GVHD (HR 2.91, 95%CI 1.55-5.45, P=0.001).



Conclusions: We showed in a cohort of 203 homogeneously treated older AML/MDS patients that FluCyTBI NMAC associated with PTCy is safe and produces promising outcomes both in haplo and MMUD settings. Beyond HLA matching and donor type, non-HLA donor-related factors (age and sex) are critical for outcome.

HYPOMETHYLATING AGENTS PLUS VENETOCLAX VS INTENSIVE CHEMOTHERAPY PRIOR TO TRANSPLANT IN HIGH-RISK ACUTE MYELOID LEUKEMIA

Guillaume Berton[1], Jan Philipp Bewersdorf[2], Julia Gilhodes[1], Alexandre Iat[1], Amel Soua[1], Daniel DeAngelo[3], Leora Boussi[4], Rory Shallis[5], Andrius Zucenka[6], Rebecca Bystrom[7], Kelly Ling[3], Luis Aguirre[3], Richard Stone[3], Marlise Luskin[3], Jacqueline Garcia[3], Eric Winer[3], Evan Chen[3], Martha Wadleigh[3], Lourdes Mendez[2], Nikolai Podoltsev[2], Urbain Tauveron-Jalenques[8],

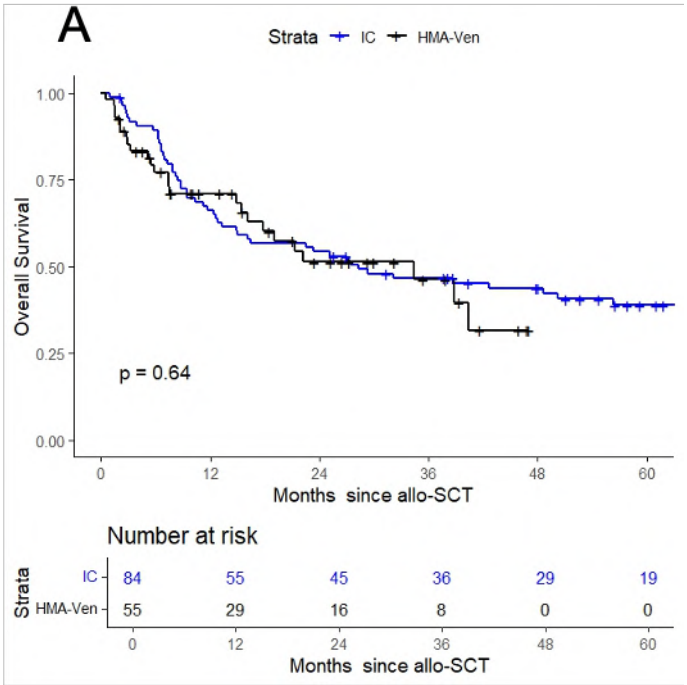
Luca Lanino[2], Eytan Stein[4], Amer Zeidan[2], Edouard Forcade[9], Thomas Cluzeau[10], Pierre-Yves Dumas[9], Mael Heiblig[11], Raynier Devillier[1], Shai Shimony[3], Aaron Goldberg[4], Maximilian Stahl[2], Sylvain Garciaz[1], ***Charlotte Nykolyszyn***[1]
[1]Institut Paoli Calmettes, Marseille, France, [2]Yale University, New Haven, United States of America (the), [3]Dana-Farber Cancer Institute, Boston, United States of America (the), [4]Memorial Sloan Kettering Cancer Center, New York, United States of America (the), [5]Moffit Cancer Center, Tampa, United States of America (the), [6]Vilnius University Hospital Santaros Klinikos, Vilnius, Lithuania, [7]Duke University Medical Center, Durham, United States of America (the), [8]CHU Clermont-Ferrand, Clermont-Ferrand, France, [9]CHU Bordeaux, Bordeaux, France, [10]CHU Nice, Nice, France, [11]Hospices Civils de Lyon, Lyon, France

Background: High-risk AML has a poor prognosis and allo-SCT is the only curative therapy available. Older AML patients 60-74yo represent a high-risk population, with frequent high-risk AML characteristics predicting disease resistance to IC. Thus, there is a need for new therapeutic strategies in this population. The less-intensive regimen combining the hypomethylating agent (HMA) azacitidine (AZA) and the BCL-2 inhibitor venetoclax (VEN) has changed the treatment paradigm for older subjects with newly-diagnosed AML. Yet it still remains an open question whether HMA-VEN is equivalent to IC on post-transplant outcomes in high-risk AML patients.

Methods: We assembled a retrospective cohort of consecutive patients 60-74yo newly-diagnosed with ELN-2022 adverse-risk AML, treated with allo-SCT after prior intensive or less-intensive remission induction therapy. All patients were diagnosed between April 2014 and May 2024 at 3 United-States centers (DFCI, MSKCC, Yale Cancer Center) and 5 European centers (France: IPC Marseille; CHU Nice; HCL Lyon; CHU Bordeaux; Lithuania: Vilnius University Hospital Santaros Klinikos).

Results: We included 139 patients who consecutively underwent allo-SCT after first-line therapy. Median age at diagnosis was 66 years (60-74). Fifty-five patients (40%) had received HMA–VEN as induction treatment (AZA [n = 43] or DEC [n = 12]). Eighty-four patients (60%) had received IC as induction therapy (64 (76%) with 7+3; 20 (24%) with CPX-351).
In the HMA-VEN group, CR, CRi, and MLFS rates were 58.5%, 19%, and 13%, respectively. cCR and OR rates were 77% and 91%. In the IC group, CR, CRi, and MLFS rates were 66%, 5%, and 6%, respectively. cCR and OR rates were 71% and 77%.
Out of 68 patients with MRD status available at best response, 73% and 63% were MRD^- in the HMA-VEN and IC group, respectively.
A total of 31 patients were transplanted with active disease, 5 (9%) in the HMA-VEN group and 26 (31%) in the IC group (P=0.003).
With a median follow-up of 52.3 months, post allo-SCT OS was 34.4 (95%CI, 16.1-NA) and 28.3 months (95%CI, 14.9-56.3) in the HMA-VEN and IC groups, respectively (P=0.636, Figure). NRM and CIR were similar between both groups (NRM at 6 and 12 months: 8% and 11% in the HMA-VEN group vs 5% and 18% in the IC group, P=0.632; CIR at 6 and 12 months: 11% and 25% in the HMA-VEN group, 13% and 23% in the IC group, P=0.643). Multivariable analyses found that induction type (HMA-VEN vs IC) did not impact post allo-SCT OS (HR=0.95, 95%CI=0.54-1.68, P=0.864). The only factor associated with better survival was the achievement of cCR at allo-SCT (HR=0.43, 95%CI=0.26-0.69, P=0.001).

Monosomal karyotype was predictive of worse survival (HR=2.29, 95%CI=1.34-3.92, P=0.003). In subgroup analyses, patients with AML harboring del5q and *TP53*mutations had better OS with HMA-VEN + allo-SCT compared to IC (HR: 0.31; 95% CI: 0.12–0.88; P=0.027, and HR: 0.39; 95% CI: 0.16–0.98; P=0.044, respectively).



Conclusions: Our study provides evidence supporting the use of HMA-VEN as an alternative, less toxic remission induction strategy for patients with ELN-2022 adverse-risk AML who are intended to proceed to allo-SCT.

Disclosure: No COI.

PROGNOSIS ANALYSIS OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE TREATMENT OF MYELOID SARCOMA: A SINGLE-CENTER STUDY

Na Zhang[1], *Zhi-Jie Wei*[1,2], *Yan-Li Zhao*[1,2], *Xing-Yu Cao*[1,2], *Jiang-Ping Zhang*[1,2], *De-Yan Liu*[1,2], *Min Xiong*[1,2], *Jia-Rui Zhou*[1,2], *Rui-Juan Sun*[1,2], *Yue Lu*[1,2]
[1]*Beijing Lu Daopei Hospital, Beijing, China,* [2]*Hebei Yanda Lu Daopei Hospital, Hebei, China*

Background: Myeloid Sarcoma(MS) are solid tumors formed by (mature or immature) myeloid progenitor cells infiltrating extramedullary tissues and disrupting their original structure. MS exhibits heterogeneity, typically affecting a single site, though 30% of patients

experience multi-site involvement. Currently, the optimal treatment has not been established. Therapeutic options include radiotherapy, systemic chemotherapy, targeted therapy, surgical resection, and hematopoietic stem cell transplantation (HSCT). Multiple studies indicate that allogeneic HSCT holds therapeutic potential for MS.

Methods: A retrospective analysis was performed on patients diagnosed with MS and undergoing Allo-HSCT at our center between March 1, 2017 and September 1, 2023. The follow-up period was extended until June 1, 2025.

Results: This study included 25 patients , comprising 20 males (80%) and 5 females (20%). The median age at diagnosis was 27 years (range: 1-49), with 6 pediatric cases (24%). Disease types: The most common diagnosis was MS with AML (13 cases, 52%), followed by IMS (6 cases, 24%) and relapsed MS after AML treatment(6 cases, 24%). By MS involvement sites (Figure1):12 cases (48%) involved a single site, while 13 cases (52%) involved ≥2 sites. According to cytogenetic risk stratification (2025 NCCN guidelines): 12 cases (24%) were low-risk, 6 cases (24%) were intermediate-risk, and 7 cases (28%) were high-risk (Figure 2). Pre-transplant treatments: 15 cases (60%) received chemotherapy alone, while 10 cases (40%) received chemotherapy combined with other therapies (including targeted therapy and radiotherapy). The median time from diagnosis to transplantation was 24.8 months (range: 2-162 months). Disease status before transplantation: 13 cases (52%) achieved first complete remission (CR1),8 cases (32%) achieved ≥CR2, and 4 cases (16%) had no response (NR) or partial response (PR). The donors were classified as Haploidentcal donor (HID) in 19 cases (76%), Matched unrelated donor (MUD) in 4 cases (16%), and matched sibling donor (MSD) in 2 cases (8%). All patients received intensified myeloablative conditioning regimen (MAC). 15 cases (60%) MAC-based with busulfan (BU) and 10 cases (40%) based with total body irradiation (TBI). All patients achieved successful engraftment, with a median follow-up period of 24 months (range: 1-60 months)
The 5-years overall survival (OS) was 68%,5-years leukemia-free survival (LFS) was 60%,5-years cumulative incidence of relapse (CIR) was 18%, and 5-years non-relapse mortality (NRM) was 28%(Figure 3). Univariate analysis(Figure 4) revealed no significant prognostic influence of gender, age at diagnosis, multiple affected sites, cytogenetic status at initial diagnosis, coexisting fusion gene types, coexisting mutation types, pre-transplant therapy, pre-transplant complete remission (CR) status, or donor type. However, high-risk patients (5-years NRM rate: 57.14% vs 17.65%, p=0.0372) showed higher 5-years NRM rates, while children exhibited higher 5-year CIR rates (44.44% vs 0%, p=0.0314). The TBI-based conditioning regimen significantly affected prognosis (5-years OS: BU vs TBI: 46.6% vs 90.05%, p=0.0074; 5-years LFS: BU vs TBI: 40% vs 90%, p=0.0186; 5-years NRM: BU vs TBI: 44.94% vs 0%, p=0.0109).

PATTERNS AND PREDICTORS OF HEMATOLOGIC TOXICITY AFTER BCMA- AND CD19-TARGETED CAR-T THERAPY

*Robert Mikhelashvili[1], Shlomit Kfir-Erenfeld[1], Nathalie Asherie[1], Sigal Grisariu[1], Batia Avni[1], Eyal Lebel[1], Eran Zimran[1], Miri Assayag[1], Nomi Zalcman[1], Alaa Shehadeh[1], Aseel Ishtay[1], Shelly Regev[1], Miriam Schlossberg[1], Elina Zorde-Khevalevsky[1], Elena Karger[1], Marina Krizhevskaya[1], Polina Stepensky[1], **Shlomo Elias**[1]*
[1]Hadassah Medical Center, Jerusalem, Israel

Background: Immune effector cell–associated hematotoxicity (ICAHT) is the most frequent complication following chimeric antigen receptor (CAR) T-cell therapy. Most available data derive from CD19-directed CAR T-cell products, whereas hematotoxicity following B-cell maturation antigen (BCMA)–directed CAR T-cell therapy remains poorly characterized.

Methods: We conducted a retrospective, single-center cohort study analyzed patients treated with CAR T-cell therapy at Hadassah Medical Center between December 2019 and January 2024. Patients were categorized into two cohorts according to underlying disease and CAR T-cell construct. The first cohort comprised patients with relapsed/refractory multiple myeloma (RRMM) (n=77) treated with a locally manufactured BCMA-directed CAR T-cell product (HBI0101). The second cohort included patients with relapsed/refractory (R/R) non-Hodgkin lymphoma (NHL) treated with commercially available CD19-directed CAR T cells (n=67).
In both cohorts, complete blood counts were analyzed at baseline, prior to lymphodepletion, and from day 0 (CAR T-cell infusion) through day 365 post-infusion or until progression, loss to follow-up, or death. Hematologic parameters were graded using CTCAE and ICAHT criteria, and the CAR-HEMATOTOX score was calculated. Grade ≥2 ICAHT was the primary endpoint. Blood count kinetics and associations with clinical and biological factors were analyzed.

Results: Among MM patients, early-stage (day 0 - 30) neutropenia of any grade occurred in 91% (ICAHT grade ≥2: 42.8%), with severe neutropenia (ANC <500/μL) in 87% and profound neutropenia (ANC <100/μL) in 20.7%. Late (day 31-60) neutropenia of any stage was observed in 66.6% (ICAHT grade ≥2: 48.5%), with severe neutropenia in 10.6% and profound neutropenia in 3%. In NHL patients, early-stage neutropenia occurred in 65.7% (ICAHT grade ≥2: 35.8%), with severe neutropenia in 61% and profound neutropenia in 24%; late neutropenia occurred in 56.8% (ICAHT grade ≥2: 40.9%), with severe neutropenia in 18.2% and profound neutropenia in 9%. A multiphasic neutrophil recovery pattern with multiple nadirs <1,000/μL predominated in MM, whereas quick recovery was most common in NHL.
Severe anemia (grade ≥3) occurred in 56% of MM and 36% of NHL patients early post-infusion, and 3% and 11.4% late, respectively. Severe thrombocytopenia (grade ≥3) occurred in 45% of MM and 28% of NHL patients early, and 22.7% and 18.2% late.
In univariate analysis early-phase neutropenia in MM was significantly associated with baseline hemoglobin, platelet count, absolute neutrophil count, ferritin, hematotoxicity index, plasma cell leukemia phenotype, and infusion of fresh CAR T cells. In NHL, early neutropenia correlated with baseline ANC and Jewish ethnicity. Late-phase neutropenia in MM remained associated with baseline ANC, while in NHL no variables reached significance.

Conclusions: Baseline neutropenia was the strongest predictor of post–CAR T-cell neutropenia, highlighting the importance of bone marrow reserve prior to infusion. Neutropenia was more frequent in the multiple myeloma patients treated with a BCMA-directed CAR T-cell construct compared with lymphoma patients, receiving CD19-directed products, likely reflecting differences in disease biology, prior treatment burden, and baseline cytopenias (as shown in supplementary figure baseline neutropenia was more severe in MM patients).

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA/LYMPHOMA: A RETROSPECTIVE STUDY ON PROGNOSTIC FACTORS AND A NOVEL SCORING SYSTEM

Na Tao[1,2,3], *Yanmin Zhao*[1,2,3], *Yi Luo*[1,2,3], *Jian Yu*[1,2,3], *Huaryu Fu*[1,2,3], *Yishan Ye*[1,2,3], *Congxiao Zhang*[1,2,3], *Yi Yu*[1,2,3], *Guanfang Zhang*[1,2,3], *Weiyan Zheng*[1,2,3], *Jie Sun*[1,2,3], *Jingsong He*[1,2,3], *Guoqing Wei*[1,2,3], *Zhen Cai*[1,2,3], *He Huang*[1,2,3], *Jimin Shi*[1,2,3]
[1]*Bone Marrow Transplantation Center of The First Affiliated Hospital & Liangzhu Laboratory, Zhejiang University School of Medicine, Hangzhou, China,* [2]*Institute of Hematology, Zhejiang University, Hangzhou, China,* [3]*Zhejiang Province Engineering Research Center for Stem Cell and Immunity Therapy, Hangzhou, China*

Background: The efficacy of allogeneic hematopoietic stem cell transplantation (allo-HSCT) in patients with T-cell acute lymphoblastic leukemia/lymphoma (T-ALL/LBL) is not well

established, particularly regarding outcomes and prognostic factors. This study aimed to evaluate the efficacy of allo-HSCT for T-ALL/LBL and identify key factors influencing patient survival and relapse.

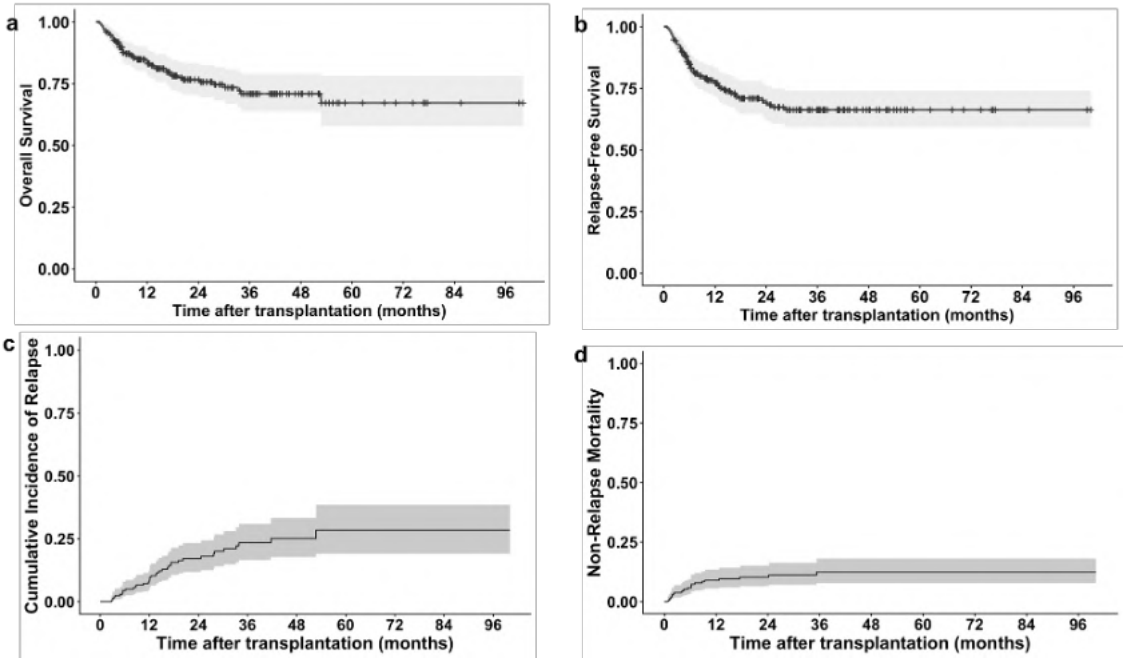
Methods: In this retrospective study, we included 211 patients with T-ALL/LBL who underwent allo-HSCT between March 2017 and June 2025. The median follow-up time for survival patients was 17.5 months (range, 0.8 – 100.1months). Patient characteristics, survival outcomes, and prognostic factors were analyzed.

Results: The estimated 2-year overall survival (OS) and relapse-free survival (RFS) rates were 75.7% ± 3.3% and 68.3% ± 3.6%, respectively. The 2-year cumulative incidence of relapse (CIR) and non-relapse mortality (NRM) were 17.1% ± 2.9% and 10.3% ± 2.2%, respectively. The estimated 2-year OS rates across four distinct cohorts were as follows: 85.7% ± 4.2% for patients in first complete remission with MRD negativity (CR1/MRD$^-$), 80.0% ± 3.7% for CR1/MRD$^+$, 70.5% ± 7.6% for patients not in CR1 but with MRD negativity, and 15.6% ± 14.2% for patients not in CR1 with MRD positivity (P < 0.001). The estimated 2-year CIR was significantly lower in patients with T-ALL compared to those with T-LBL (14.9% ± 3.9% vs. 19.2% ± 4.5%, P = 0.045). On multivariable Cox regression analysis, three factors were identified as independent protective factors associated with significantly improved OS and RFS: MRD negativity before transplantation (OS: HR = 0.35, 95% CI 0.18–0.68, P = 0.002; RFS: HR = 0.42, 95% CI 0.23–0.76, P = 0.004), transplantation during CR1 (OS: HR = 0.45, 95% CI 0.24–0.85, P = 0.013; RFS: HR = 0.50, 95% CI 0.28–0.89, P = 0.019), and the development of chronic graft-versus-host disease (cGVHD) (OS: HR = 0.31, 95% CI 0.15–0.65, P = 0.002; RFS: HR = 0.40, 95% CI 0.21–0.78, P = 0.007). Post-transplant maintenance therapy was an independent protective factor for OS (HR = 0.23, 95% CI 0.07–0.73, P = 0.022) but was not significantly associated with RFS in the multivariable model (HR = 0.49, 95% CI 0.21–1.15, P = 0.099).

Table 1 Characteristics of patients with T-ALL/LBL

Characteristics	All patients (n=211)
Age at transplantion, years, Median (range)	32 [24 - 40]
Gender, male, n (%)	145 (68.7%)
WBC ≥100×10^9, n (%)	14 (6.6%)
Subtype, n (%)	
T-ALL	112 (53.1%)
T-LBL	99 (46.9%)
WT1, n (%)	23 (10.9%)
TP53, n (%)	7 (3.3%)
TCR gene rearrangement, n (%)	11 (5.2%)

MRD negativity before transplantation, n (%)	192 (91.0%)
CR1 at transplantation, n (%)	163 (77.3%)
Stem cell source, n (%)	
MSD	24 (11.4%)
Haplo	149 (70.6%)
MUD	38 (18.0%)
Grade III-IV aGVHD, n (%)	21 (10.0%)
cGVHD, n (%)	94 (44.5%)
Time from diagnosis to transplantation, months, Median (range)	6.5 [2.8 - 146.5]
Maintenance after transplantation	61 (28.9%)



Conclusions: Allo-HSCT provides favorable survival and low relapse rates in patients with T-ALL/LBL. Pre-transplant MRD negativity, transplantation in CR1, development of cGVHD, and administration of maintenance therapy are associated with improved outcomes. This study supports allo-HSCT as a viable and effective consolidative treatment strategy for T-ALL/LBL, particularly in patients with favorable prognostic factors.

OUTCOME OF AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION (AHCT) AFTER PEMBROLIZUMAB IN RELAPSED/REFRACTORY CLASSICAL HODGKIN LYMPHOMA PATIENTS: A RETROSPECTIVE ANALYSIS OF THE KING HUSSEIN CANCER CENTER

Khalid Halahleh[1], *Husam Abu Jazar*[1], *Zaid Abdel Rahman*[1], *Lina Halahleh*[2], *Waleed Da'na*[1], *Saad Jaddoua*[1], *Isra Al Muradi*[3], *Salwa Saadeh*[1], *Nazmi Kamal*[1], *Maher Sughayer*[1], *Hikmat Abdel-Razeq*[1,4]
[1]*King Hussein Cancer Center, Amman, Jordan,* [2]*Al-Quds University, Jerusalem, Palestine, State of,* [3]*Al-Ahliyya Amman University, Al-Salt, Jordan,* [4]*School of Medicine, The University of Jordan, Amman, Jordan*

Background: Autologous Hematopoietic Cell Transplantation (AHCT) remains the standard of care for patients with relapsed refarctory classical Hodgkin lymphoma (rr cHL) with chemosensitive disease after salvage therapy. Historically, patients with refractory disease or multiple relapses have poor outecomes after AHCT. However, novel therapies, including checkpoint inhibitors (CPIs) and brentuximab vedotin (BV) have evolved treatment armamentarium, facilitating more patients to receive AHCT. The use of pembrolizumab can be as monotherapy or in combination regimens at different disease stages. The evidence suggests that pembrolizumab may enhance chemosensitivity and positively impact posttransplant outcomes, though long-term results remain uncertain. The aim of our study to assess survival outcomes of AHCT after pembrolizumab monotherapy in patients with rr cHL from KHCC.

Methods: This is a retrospective single center study from King Hussein cancer Center in Jordan included 48 out of 144 patients who received pembrolizumab as monotherapy for rr cHL and underwent AHCT between 2018–2024 after pembrolizumab. Overall survival (OS) and progression free survival (PFS) were estimated by Kaplan Meier method. Univariate analysis for survival outcomes was performed using log rank test. Patients who failed the first line and at least one salvage regimen before AHCT and received pembrolizumab monotherapy prior to AHCT were included. Patients who received combination of pembrolizumab and chemotherapy and lymphocyte-predominant HL patients were excluded.

Results: Median age was 23 years (IQR:19–32). 26 (54%) were females. 32 (74%) had advanced stage at diagnosis, 37(77%) B-symptoms, 28(58%) extranodal involvement and 15 (31.3%) had disease bulk. Chemo-refractory disease after first line therapy was frequent

(38;79%). Patients received a median of 3 lines (range: 2-8) of chemotherapy prior to pembrolizumab. 75% of patients received pembrolizumab as the last therapy prior to AHCT. 12 patients (25%) received intervening chemotherapy before AHCT. Patients received a median of 4 cycles (range: 3–13) of pembrolizumab.
Objective response (OR) after pembrolizumab was achieved in 31(64.5%) [17(35.4%) CR) and 14(29%) PR].CR was achieved after a median of 3 cycles (2-5). Disease status at AHCT was CR in 56%, and PR in 44%. The median time between last dose of pembrolizumab and AHCT was 6.6months (range:1.26-16).
After a median follow up of 14.6mo (1.1–77.7), 87.5% in CR and 12.5% had progression. 2-year OS and PFS were 83% (95% CI:60–93%) and 85% (95% CI: 65–94%), respectively. Cumulative relapse incidence at 2 years 4.7% (95% CI:0.0–13.8%), and non-relapse mortality (NRM) was 3% (95% CI:0.4-19%) at 1-year. At last encounter, 87.5% of patients still alive, and 12.5% died. In univariate analysis, disease status at AHCT did not impact OS or PFS (P ≥0.50). There was a trend toward relapse reduction in CR patients compared to no CR (P= 0.05). Number of lines of chemotherapy prior to pembrolizumab did not affect post-transplant outcomes(P=≥0.05).

Conclusions: This study demonstrates high PFS and OS outcomes in heavily pretreated rr cHL patients receiving pembrolizumab prior to AHCT compared to historical data. Disease status at the time of AHCT showed a trend toward reduced risk of relapse. Earlier integration of pembrolizumab in pre-AHCT setting is warranted.

A PILOT RANDOMIZED CLINICAL TRIAL OF A VIRTUAL REALITY SUPPORTIVE CARE INTERVENTION FOR PATIENTS UNDERGOING HEMATOPOIETIC CELL TRANSPLANTATION

Hermioni Amonoo[1,2,3], *Richard Newcomb*[4,3], *Isabella Larizza*[1], *Emma Keane*[1], *Areej El-Jawahri*[4,3]
[1]*Mass General Brigham, Boston, United States of America (the),* [2]*Dana-Farber Cancer Institute, Boston, United States of America (the),* [3]*Harvard Medical School, Boston, United States of America (the),* [4]*Massachusetts General Hospital Cancer Center, Boston, United States of America (the)*

Background: Patients undergoing HCT experience substantial physical and psychological symptoms. Scalable supportive care interventions to reduce distress and improve quality of life are limited. Virtual reality (VR), with its three-dimensional capabilities, offers a novel, scalable, patient-centered modality to address these needs.

Methods: We randomized adult patients with hematologic malignancies undergoing autologous or allogeneic HCT to receive either a VR supportive care intervention (BMT-VR) or usual care during hospitalization. BMT-VR consists of six modules focused on: 1) psychoeducation and managing expectations; 2) psychosocial skill-building to promote

coping; and 3) strategies to facilitate acceptance while facing uncertainty. The primary endpoint was feasibility (≥60% enrollment and ≥60% completion of ≥4/6 modules). The secondary outcomes included quality of life (Functional-Assessment-of-Cancer-Therapy-BMT), depression and anxiety symptoms (Hospital-Anxiety-Depression Scale), and post-traumatic stress disorder symptoms (PTSD Checklist) at baseline, 4-, 12-, and 24- weeks post-HCT. The System Usability Scale (≥80 indicates excellent usability) was administered at 4 weeks post-HCT.

Results: We enrolled 59.6% (81/136) of eligible patients (mean age=57.9 (SD=14.7), 51.9% women, 70.4% allogeneic HCT). Among those assigned to BMT-VR, 74.4% completed ≥4/6 modules. After 4 weeks, patients randomized to BMT-VR reported improved quality of life (108.2 vs. 96.8, p=0.014) and anxiety symptoms (3.6 vs. 5.3, p=0.019) compared to usual care. No difference in depression or PTSD symptoms emerged between the groups at 4 weeks. In longitudinal analyses, BMT-VR participants showed greater improvements in quality of life (B=3.8, p=0.002), depression (B=-0.8, p<0.001), and PTSD symptoms (B=-1.7, p=0.006), but no improvement in anxiety symptoms over time, compared to usual care.

Conclusions: A virtual reality delivered supportive care intervention is feasible during hospitalization for autologous or allogeneic HCT and shows promising preliminary effects in improving quality of life and psychological outcomes. A future multi-site trial is needed to assess its efficacy for improving quality of life and psychological distress in HCT recipients.

HARMONIZING HAPLOIDENTICAL STRATEGIES: A FOUR-YEAR COMPARATIVE ANALYSIS OF T-CELL–DEPLETED AND REPLETE PEDIATRIC TRANSPLANTS FROM A DEVELOPING COUNTRY

Chintan Tarunkumar Vyas[1], *Nedunchezhian Murugaiyan*[2], *Vinayak Ananda Katore*[2], *Kriti Tripathi*[1], *Kriti Hegde*[1], *Priti Mehta*[1], *Amol Jaybhaye*[1], *Purna Kurkure*[1]
[1]*SRCC Children's Hospital, Mumbai, India,* [2]*Cytocare Technologies (P) Ltd, Hyderabad, India*

Background: Haploidentical hematopoietic stem cell transplantation (haplo-HSCT) is increasingly being used for children without matched donors, particularly in resource-limited settings. Advances such as TCRαβ/CD19 depletion (TCD) and post-transplant cyclophosphamide (PTCy)-based T-cell–replete (TCR) platforms have significantly reduced immunologic toxicity, yet comparative pediatric data from India remain sparse. This study presents a four-year single-center evaluation comparing TCD and TCR haplo-HSCT across malignant and benign pediatric disorders.

Methods: This retrospective cohort included all pediatric haplo-HSCT performed between 1 September 2021 and 31 August 2025. Sixty-one children (39 males, 22 females; mean age 8 years, range 1–17) underwent 62 transplants for benign (n=35) and malignant (n=27) disorders. Malignant indications comprised ALL (17), AML (5), MPAL (2), MDS (1), and JMML (1), while benign conditions included thalassemia major (26), primary immunodeficiency (4), severe aplastic anemia (3), sickle cell disease (1), and PNH (1). Transplant platforms included Tαβ-depleted (TCD) grafts (n=36; 58%) and TCR grafts with PTCy (n=26; 42%). All grafts consisted of peripheral blood stem cells. Although conditioning was disease-specific, most patients (57/62; 91%) received myeloablative regimens. Rabbit ATG was administered to all, with additional rituximab in TCD recipients. The median $CD34^+$ dose was 18×10^6/kg in TCD grafts and 8×10^6/kg in TCR grafts. TCD grafts targeted $<25\times10^3$/kg αβ T cells with scheduled $CD45RO^+$ add-back in dose escalated manner till day+120.

Results: Engraftment was achieved in 96% of patients with sustained full donor chimerism; median neutrophil and platelet recovery occurred at 13 days (11–21) and 14 days (10–39), respectively, with only two graft failures (one JMML, one thalassemia). Severe acute GVHD (grade III–IV) was lower in TCD (11%) than in TCR (23%). Overall chronic GVHD occurred in 5% (TCD) versus 11% (TCR). No GVHD-related deaths occurred in TCD recipients. TCR recipients had greater GVHD severity, with severe bacterial (30%) and fungal infections (12%) contributing to 10% toxic mortality. Viral reactivations were CMV (33%), BK (8%), adenovirus (9%), and EBV (3%); none caused mortality. Day-100 mean $CD4^+$ counts were higher in the TCD cohort (130 cells/μL) compared to TCR cohort (110 cells/μL). Overall survival (OS) was higher in TCD (89%) compared with TCR (62%), resulting in a combined OS of 79% at a median follow-up of 480 days. Outcomes in benign disorders predominantly in TCD cohort were excellent, with OS 97% and EFS 95% while in malignant indications, OS was 61%, with nine deaths (four toxic, five relapse). The 100-day Transplant-related mortality was low at 2% (0% in TCD), and overall TRM was significantly lower in TCD recipients (6%) compared with TCR recipients (21%). Relapse rates were similar (TCD 28% vs TCR 25%), indicating effective disease control despite profound T-cell depletion.

Conclusions: Pediatric haploidentical HSCT using either TCD or PTCy-based TCR approaches yields robust engraftment and acceptable toxicity. However, TCRαβ-depleted haplo-HSCT provides the most favorable profile, with markedly reduced GVHD, no significant increase in relapse rate, minimal TRM, and excellent survival. These results support broader adoption of TCD haplo-HSCT in resource-limited settings and warrant future comparative studies with matched unrelated donor transplants.

PERFORMANCE AND VALIDATION OF THE SIMPLIFIED COMORBIDITY INDEX IN PREDICTING NON-RELAPSE MORTALITY AFTER ALLOGENEIC HCT IN THE CURRENT ERA

Omar Eduardo Fernandez-Vargas[1,2], *Jean Roy*[1,2], *Sandra Cohen*[1,2], *Sylvie Lachance*[1,2], *Jean-Sébastien Delisle*[1,2], *Léa Bernard*[1,2], *Thomas Kiss*[1,2], *Denis-Claude Roy*[1,2], *Guy Sauvageau*[1,2], *Daiana Gisela Rodriguez*[1,2], *Imran Ahmad*[1,2]
[1]*Université de Montréal, Montreal, Canada,* [2]*Hôpital Maisonneuve-Rosemont, Montreal, Canada*

Background: The Hematopoietic Cell Transplantation Comorbidity Index (HCT-CI), developed two decades ago to predict non-relapse mortality (NRM) and survival after allogeneic hematopoietic cell transplantation (alloHCT), has been widely validated, but recent studies have questioned its consistency in contemporary practice. AlloHCT has evolved substantially, with greater use of unrelated and haploidentical donors, new conditioning regimens, improvement of GVHD prophylaxis, and declining overall NRM. More recently, the Simplified Comorbidity Index (SCI) was developed to predict NRM in the setting of CD34-selected alloHCT and subsequently validated in unmanipulated reduced-intensity alloHCT. We performed a comparison of the performance of HCT-CI and the SCI to predict NRM in a modern adult alloHCT cohort.

Methods: We conducted a retrospective single-centre study of consecutive adults undergoing first alloHCT between July 2020 and December 2024. The primary endpoint was 24-month NRM, studied using competing-risk methods. Predictive performance of SCI and HCT-CI were evaluated by ROC analysis. Multivariable Fine-Gray models adjusted for Karnofsky Performance Status (KPS), Disease Risk Stratification System (DRSS), type of transplant (matched vs. mismatched), Transplant Conditioning Intensity (TCI) and age for HCT-CI.

Results: A total of 346 patients were included (median age 55 years; 42% female) (**Table 1**). Donors included MUD (51%), Haplo (17%), MSD (13%), CB (13%), and MMUD (6%). Most (66%) patients received ATG-based GvHD prophylaxis, while 20% received PTCy. By TCI, 22% received low intensity, 60% intermediate, and 18% high intensity conditioning. By DRSS, 14% of patients were low, 29% intermediate-1, 42% intermediate-2, 11% high, and 0.3% very high. Median follow-up was 29.4 months.
In univariate analyses, the HCT-CI was not associated with NRM, whether evaluated as individual scores or in grouped categories: NRM at 24 months for 0, 1-2 and ≥3 was 8.99% (95%CI: 4.17–16.10), 6.80% (95%CI: 3.45–11.70), and 9.96% (95%CI: 4.84–17.25), respectively. In contrast, the SCI showed a significant association with NRM both by individual values and grouped categories ($p<0.001$ for both), with 24-month NRM of 5.0% for SCI 0–2 (95%CI: 2.7–8.4), 10.8% for SCI 3 (95%CI: 4.4–20.7) and 29.9% for SCI ≥4 (95%CI 14.1–47.6) (**Figure 1**).
Concordance between HCT-CI and SCI was modest (correlation 0.40; 95%CI 0.30–0.48). For NRM prediction, the HCT-CI had an AUC of 50.6% ($p=0.919$), while the SCI achieved 64.1% ($p=0.015$).

In multivariable analysis, the SCI remained independently associated with NRM (Wald X^2=20.7, p<0.001). Relative to SCI 0-2, patients with SCI=3 had an adjusted sHR of 2.4 (95%CI 0.8–7.1; p=0.100) and SCI ≥4 had an sHR of 7.0 (95%CI 3.0–16.3; p<0.001). HCT-CI categories were not independently associated with NRM (Wald test: X^2=0.51, p=0.78).

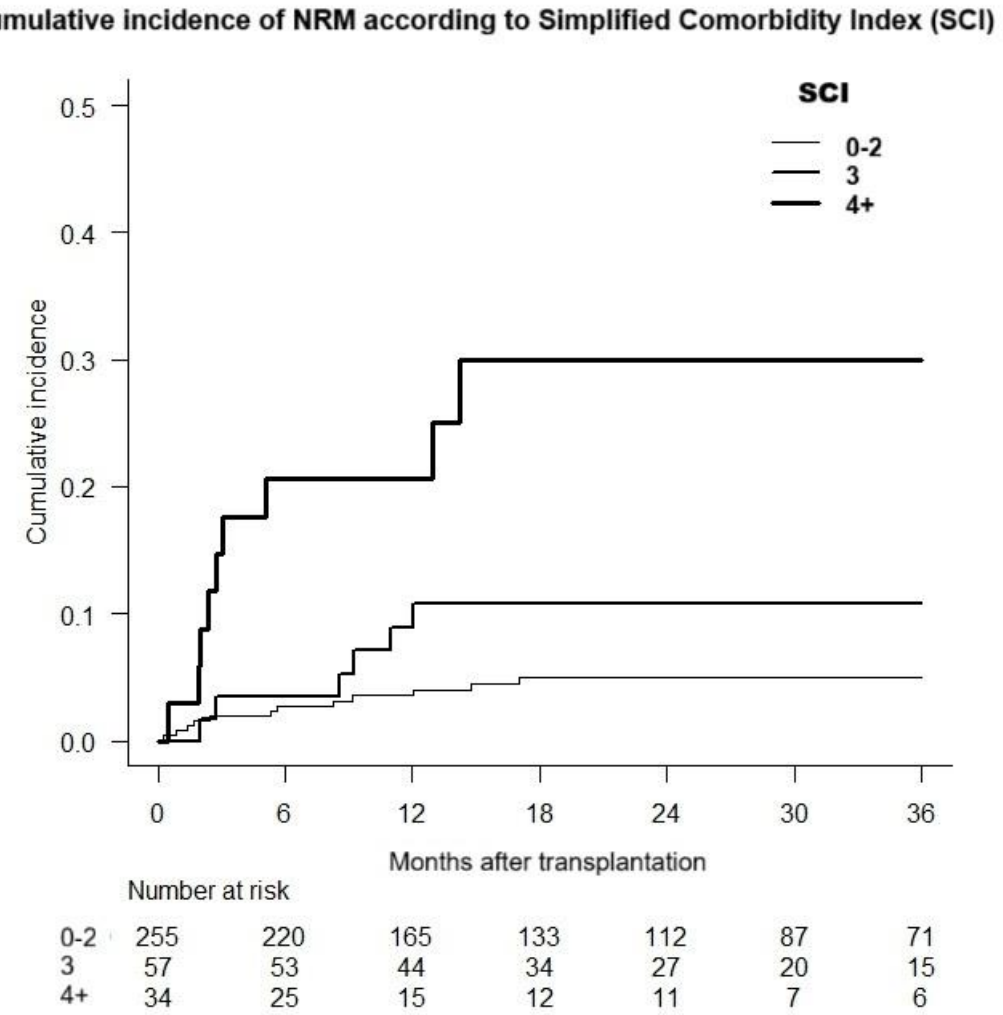
Figure 1 – Cumulative incidence of non-relapse mortality according to the Simplified

Comorbidity Index



Conclusions: In this modern alloHCT cohort, including varied donor sources, the SCI demonstrated superior predictive performance for NRM compared with the HCT-CI, and remained independently associated with NRM after multivariable adjustment. Prospective validation in larger cohorts and various alloHCT platforms is necessary to determine whether the SCI should replace the HCT-CI in current clinical practice.

GRAFT-VERSUS-HOST DISEASE, RELAPSE, AND A SIMPLE GRFS RISK GROUPING IN HAPLOIDENTICAL TRANSPLANTATION WITH PTCY

Gonzalo Bentolila[1], *Cristian Rodriguez*[2], *Jorge Arbelbide*[3], *Georgina Bendek*[4], *Gonzalo Ferini*[3], *Mercedes García*[2], *Juliana Martinez Rolon*[1], *Ana Lisa Basquiera*[2]
[1]*Fundacion contra la Leucemia (FUNDALEU), Ciudad Autonoma de Buenos Aires, Argentina,* [2]*Hospital Privado Universitario de Córdoba-Instituto Universitario de Ciencias Biomédicas de Córdoba, Ciudad de Cordoba, Argentina,* [3]*Hospital Italiano, Ciudad Autonoma de Buenos Aires, Argentina,* [4]*Hospital Italiano, San Justo, Argentina*

Background: Haploidentical hematopoietic cell transplantation (haplo-HCT) with post-transplant cyclophosphamide (PTCy) is widely used, but data on graft-versus-host disease–free, relapse-free survival (GRFS) and simple bedside risk stratification remain limited. We aimed (1) to describe GVHD, relapse, non-relapse mortality (NRM) and GRFS in a homogeneous haplo-PTCy cohort, and (2) to derive and internally validate a simple pre-transplant GRFS risk grouping.

Methods: We retrospectively analyzed adults receiving a first Haplo-HCT with PTCy across three Argentinian centers (2017–2024). Median Follow up was 37.7 month. Underlying diseases included acute myeloid leukemia (30%), acute lymphoblastic leukemia (25%), non-Hodgkin lymphoma (15%), Hodgkin lymphoma (9%), myelodysplastic syndromes (8%), aplastic anemia (5%), myelodysplastic/myeloproliferative neoplasms (3%), myelofibrosis (2%), chronic myeloid leukemia (2%), multiple myeloma (0.5%) and hemoglobinopathies (1%). Disease Risk Index (DRI) and HCT-Comorbidity Index (HCT-CI) were assessed before transplant.
Cumulative incidence of acute GVHD (aGVHD) grade II–IV and III–IV by day 100, chronic GVHD (cGVHD), relapse and NRM was estimated using competing-risks methods. GRFS, was analyzed with Kaplan–Meier and Cox models. A binary GRFS risk grouping was built from two pre-transplant factors: DRI high/very high and HCT-CI >3. Patients with neither factor were classified as low risk, and those with ≥1 factor as high risk. Multivariable Cox models for GRFS adjusted for conditioning intensity. Internal validation of the GRFS grouping used 2000 bootstrap resamples; discrimination was assessed by the C-index. Findings were similar in malignant-only analyses.

Results: We included 193 patients (median age 45). DRI was low/intermediate in 63% and high/very high in 37%; HCT-CI >3 was present in 22%. Conditioning was reduced-intensity in 100 and myeloablative in 93; peripheral blood was the graft source in 98%. By day 100, cumulative aGVHD grade II–IV and III–IV incidence was ~17–18% and ~11%. At 3 years, the cumulative incidence of cGVHD, relapse and NRM was 19%, 21% and 23%. Median GRFS was 6.4 months; 1-, 2-, and 3-year GRFS 38.6%, 36.5% and 35.8%. By GRFS risk group, 89 patients (46%) were low risk and 104 (54%) high risk. Twelve-, 24- and 36-month GRFS were 48%, 46% and 46% in the low-risk group vs 31%, 29% and 27% in the high-risk group; median GRFS was 10.8 vs 3.3 months. On multivariable analysis, high vs low-risk status had a higher hazard of GRFS failure (HR 1.9; 95% CI 1.3–2.8), independent of

conditioning intensity (HR 1.6; 95% CI 1.1–2.4). The C-index for GRFS was 0.61. Bootstrap internal validation yielded a bias-corrected 95% CI for the log-HR consistent with a stable effect size.

COX GRFS	Comparison	HR for GRFS	95% CI	p-value
Sex match	Female→Male vs Female→Female	1.10	0.54–2.24	0.79
	Male→Female vs Female→Female	1.18	0.56–2.49	0.66
	Male→Male vs Female→Female	1.35	0.68–2.66	0.39
Conditioning	RIC vs MAC	**1.62**	1.12–2.33	**0.010**
DRI	Low/Intermediate vs High/Very high	**0.69**	0.47–0.96	**0.045**
HCT-CI	≤3 vs >3	**0.46**	0.31–0.69	**<0.001**

Conclusions: In this multicenter haplo-PTCy cohort, relapse incidence was relatively low, but NRM and GVHD remained substantial, resulting in GRFS below 50% at 3 years. A simple pre-transplant GRFS risk grouping based solely on DRI and HCT-CI identified a high-risk subgroup with nearly doubled risk of GRFS failure. This may provide a simple bedside framework to identify higher-risk patients, although its discriminative ability is modest and it should be considered hypothesis-generating pending external validation.

Disclosure: The authors report no conflicts of interest.

Research Center for Translational Medicine at Shanghai, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, [2]Department of Hematology and Oncology, Shanghai Children's Medical Center, School of Medicine, Shanghai Jiao Tong University, Shanghai, China, [3]GoBroad Medical Institute of Hematology (Shanghai Center), Liquan Hospital, Shanghai, China, [4]Collaborative Innovation Center of Hematology, Shanghai Jiao Tong University School of Medicine, Shanghai, China

Background: Refractory/resistant (R/R) Epstein–Barr virus (EBV) infection after allogeneic hematopoietic cell transplant (allo-HCT) carries a poor prognosis. Survival is particularly low when EBV-driven disease does not respond to rituximab, with or without chemotherapy, underscoring the need for alternative treatments. Memory T cells, defined by expression of CD45RO and absence of CD45RA isoform, possess adaptive immunity against common virus infections, including EBV. CD45RA-depleted donor lymphocyte infusion shown a promising result of an effective antiviral boost after TCRαβ-depleted haploidentical (HID) HCT. However, limited data yet on therapeutic CD45RA-depleted ACT in broader allo-HCT populations, including adults, and transplant modalities except for HID HCT. In this multicenter study, we evaluated this novel approach for clearing EBV infection after allo-HCT across a mixed adult/paediatric cohort and multiple donor platforms.

Methods: This multicenter study was conducted at Shanghai Ruijin Hospital, Shanghai Children's Medical Center, and Liquan Hospital. Eligible participants were allo-HCT recipients diagnosed with R/R EBV infections who received at least one dose of CD45RA-depleted T-cell ACT.

Results: A total of 17 allo-HCT subjects with R/R EBV infections were enrolled between September 2023 and July 2025 (Figure 1A). The last follow-up was conducted on October 31, 2025. All CD45RA-depleted T-cell products were obtained from EBV-seropositive donors.The first CD45RA-depleted T-cell infusion was administered at a median of 117 days (range: 50–696) after allo-HCT, at a cumulative dose of 20×10^6 cells/kg (range: 8.09–51.13), and four patients also received intrathecal ACT concurrently. The overall response was similar for the adult (85.71%) and pediatric (90%) group. The median duration of response did not differ between two groups. The objective response rate was 100% for EBV DNAemia, 100% for EBV-related disease, and 80% for EBV-PTLD. The source of CD45RA donors did not influence the efficacy of the treatment. Objective response rates were comparable across subgroups. EBV DNA was detected in the cerebrospinal fluid of four patients with central nervous system (CNS) symptoms (one adult, three paediatric), two of whom were diagnosed with CNS PTLD. All these patients received intrathecal CD45RA-depleted T-cell infusions, with a median of 3 cycles (range: 1–4 cycles) at a cumulative dose of 4.16×10^6/kg (range: $1.5–7.86 \times 10^6$/kg). No additional adverse effects were observed. EBV DNA cleared in 3 patients, and 1 patient with CNS PTLD achieved CR.
At last follow-up, 13/17 (76.47%) patients were alive. The 1-year OS was 67.57% (95% CI: 30.89%–87.74%) (Figure 1B). One patient experienced relapse 91 days after ACT. The 1-year non-relapse mortality was 25.8% (95% CI: 4.04%–56.5%; 3 patients), with causes including severe infection related to PTLD in 2 patients and possible transplant-associated thrombotic microangiopathy secondary to GvHD in 1 patient. Univariable analyses of baseline characteristics and overall survival likewise showed no major differences in efficacy.

HCT-CI FAILS TO PREDICT OUTCOMES OR TOXICITY IN A LARGE REAL-WORLD LBCL COHORT TREATED WITH AXICABTAGENE CILOLEUCEL: THE AUSTRALIAN CAR-T REAL-WORLD CONSORTIUM EXPERIENCE

Safia Belbachir[1], *Mark Dowling*[2], *Thomas Buss*[1], *Jian Li*[3], *Anthony Jeffrey*[4], *Catelyn Cashion*[5], *Stephen Boyle*[6], *Sergio Farina*[2], *Ross MacDonald*[7], *Shafqat Inam*[3], *Vinay Vanguru*[4], *Emily Blyth*[5], *Andrea Henden*[7], *Allison Barraclough*[1]
[1]*Fiona Stanley Hospital, Murdoch, Australia,* [2]*Peter MacCallum Cancer Centre and Royal Melbourne Hospital, Melbourne, Australia,* [3]*Alfred Hospital, Melbourne, Australia,* [4]*Royal Prince Alfred Hospital, Sydney, Australia,* [5]*Westmead Hospital, Sydney, Australia,* [6]*Royal Brisbane and Women's Hospital, Metro North Hospital and Health Service, Brisbane, Australia,* [7]*Royal Brisbane and Women's Hospital, Brisbane, Australia*

Background: The Hematopoietic Cell Transplantation-Comorbidity Index (HCT-CI) is a validated risk assessment tool for allogeneic stem cell transplantation. Its utility in predicting

outcomes and toxicity following Chimeric Antigen Receptor (CAR) T-cell therapy, particularly in large, real-world cohorts, remains uncertain. We assessed the prognostic value of HCT-CI in patients with relapsed/refractory Large B-cell Lymphoma (LBCL) treated with axicabtagene ciloleucel (axi-cel) as standard-of-care in Australia.

Methods: We conducted a retrospective, multicentre analysis of patients with LBCL infused with axi-cel between January 2020 and September 2025 at 6 sites participating in the Australian CAR-T Real World Consortium (AusCART). Comorbidity data were assessed at the time of T-cell collection and HCT-CI score was calculated as per Sorror *et al.* (2005). Patients were stratified by HCT-CI score into Low(0), Intermediate(1-2), and High(≥3) risk groups. Associations of HCT-CI risk categories with efficacy and toxicity outcomes were evaluated using Kaplan–Meier and chi-square tests.
The primary endpoints were progression-free survival (PFS) and overall survival (OS). Secondary endpoints included toxicity profiles (cytokine release syndrome [CRS], immune effector cell-associated neurotoxicity syndrome [ICANS], immune effector cell-associated hematotoxicity [ICAHT]) and response rates.

Results: From an intention-to-treat cohort of 404 apheresed patients, 384 (95%) proceeded to infusion, with no difference in infusion rates observed across HCT-CI risk categories (Low:96%, Intermediate:94%, High:95%; p=0.828). The 384 infused patients included for analysis were stratified into three HCT-CI groups: Low(n=192, 50%), Intermediate(n=110, 29%), and High(n=82, 21%). Baseline characteristics , prior therapies, and pre-lymphodepletion disease status were balanced across groups with a median age of 65 years (range 16-85), 52% with primary refractory disease and 90% needing bridging therapy.
With a median follow-up of 12.3 months, the overall complete response (CR) rate for the cohort was 69%, with comparable rates across HCT-CI groups: 69% in the Low , 67% in the Intermediate , and 71% in the High categories. No significant differences in survival outcomes were observed between groups. The overall 12-month progression-free survival (PFS) was 50% (Low 50%, Intermediate 50%, High 52%; p=0.94), and 12-month overall survival (OS) was 69%(Low 69%, Intermediate 70%, High 71%; p=0.80).
The incidence and severity of acute toxicities were comparable across HCT-CI categories. Neither cytokine release syndrome (CRS) nor immune effector cell-associated neurotoxicity syndrome (ICANS) correlated with HCT-CI burden (Grade ≥3 CRS:5%, p=0.614; Grade≥3 ICANS:22%, p=0.517). Rates of intensive care unit (ICU) admission(23%, p=0.913) and use of toxicity-directed interventions including tocilizumab (81%), corticosteroids (70%) and anakinra (20%) were likewise consistent across groups. Length of hospital stay also did not differ by HCT-CI (p = 0.830) .
The incidence of clinically significant early immune-effector cell-associated hematotoxicity (Grade≥3 ICAHT:31%) and the rates of prolonged cytopenias (>3 months) were also similar across HCT-CI groups.

Conclusions: In this large, multicentre Australian real-world cohort, the HCT-CI did not meaningfully stratify survival, response, or toxicity outcomes. Those findings suggest that transplant-era comorbidity indices may have limited discriminatory power for excluding otherwise appropriate CAR-T candidates and highlight the need for CAR-T specific tools that integrate comorbidity, frailty, and disease biology to refine patient selection and eligibility assessments.

SURVIVAL OUTCOMES FOLLOWING ALLOGENEIC TRANSPLANT FOR *TP53*-MUTATED MYELOID MALIGNANCY IN IRELAND

Sarah Kelliher[1], *James Dillon*[1,2], *Carmel Ann Galligan*[1], *Mairéad Ní Chonghaile*[1], *Leslie Ann Sutton*[1], *Eibhlin Conneally*[1,2], *Catherine Flynn*[1,2], *Chris Armstrong*[1,2], *Nina Orfali*[1,2]
[1]*St. James's Hospital, Dublin, Ireland,* [2]*Trinity College Dublin, Dublin, Ireland*

Background: Mutations in the *TP53* tumour suppressor gene are a poor prognostic marker in myeloid malignancies. Retrospective series report suboptimal responses to conventional therapy and dismal outcomes following allogeneic transplant. However, prospective identification of *TP53* mutations at diagnosis facilitates tailored management of the peri-transplant period which may improve survival. We aimed to examine treatment practices and outcomes following allogeneic transplant in *TP53*-mutated myeloid malignancy since the incorporation of next-generation sequencing into myeloid diagnostics.

Methods: Patients undergoing allogeneic transplant for *TP53*-mutated myeloid malignancy at the National Adult Stem Cell Transplant Centre, St James' Hospital between 2021-2025 were evaluated. This cohort included referrals from 11 hospitals nationwide. Survival estimates were calculated using Kaplan–Meier and Cox proportional- hazards model was used for multivariable regression.

Results: Twenty-six patients (AML=17, MDS=8, MPN=1) were transplanted for *TP53*-mutated myeloid malignancy. Median age at time of transplant was 58 years (range 18-70), with 54% being female. *TP53* aberrations were biallelic in 62%, monoallelic in 27% and subclonal in 12%. Additional high risk features included complex karyotype (48%), therapy-related disease (15%) and prior myeloid malignancy (19%). Nineteen percent were refractory to first-line therapy.
Eight patients (31%) were treated with myeloablative and 18 (69%) with reduced-intensity conditioning (RIC). Busulfan was chosen as alkylation for 85%, with melphalan employed in 15%. Donor selection included 8 sibling, 14 matched-unrelated, 3 mismatched-unrelated, and 1 haploidentical graft. Twelve individuals (46%) received donor lymphocyte infusions (DLI; 1=prophylactic, 3=pre-emptive, 8=therapeutic) and 8 (31%) were treated with upfront maintenance azacitidine. Full donor chimerism was achieved in 85%, and 69% developed graft-versus-host disease (GVHD).
At a median follow up of 686 days, median overall survival was not reached. One and 2 year overall survival (OS) post-transplant were estimated at 69% (CI 0.53-0.91) and 55% (CI

0.37-0.81) respectively. Relapse free survival for the entire *TP53* mutated cohort was 54% (CI 0.37-0.80) and 48% (CI 0.31-0.76) at 1 and 2 years post-transplant.
Variable analysis was limited by sample size, however biallelic *TP53* mutations were not associated with excess mortality (HR 0.7, CI 0.2–2.5). RIC trended toward a lower rate of death than myeloablative conditioning (HR 0.67, CI 0.17-2.61). Two patients died from early transplant related mortality after myeloablation such that OS at 6 months in this group was estimated at 73% versus 100% in the RIC arm. Patients conditioned with melphalan (n=4, follow-up 223-844 days) had 2-year OS estimated at 100% versus 47% for those with busulfan (HR 0.67, CI 0.17-2.6).
While no significant association was identified between use of donor lymphocyte infusion (DLI) or development of GVHD, attainment of full donor chimerism was strongly associated with reduced mortality (HR 0.18, CI 0.05-0.71, p=0.015). Two-year OS was estimated at 63% for those with full chimerism versus 0% without.

Conclusions: Compared to published studies, these data demonstrate improved survival post-allogeneic transplant for *TP53*-mutated myeloid malignancy. Myeloablative conditioning conferred no advantage over RIC, however melphalan may offer superior anti-leukaemic effect to busulfan. Strategies that promote full donor chimerism, including early immunosuppression taper and DLI, appear critical to optimising outcomes in this high-risk population.

Disclosure: Nothing to declare.

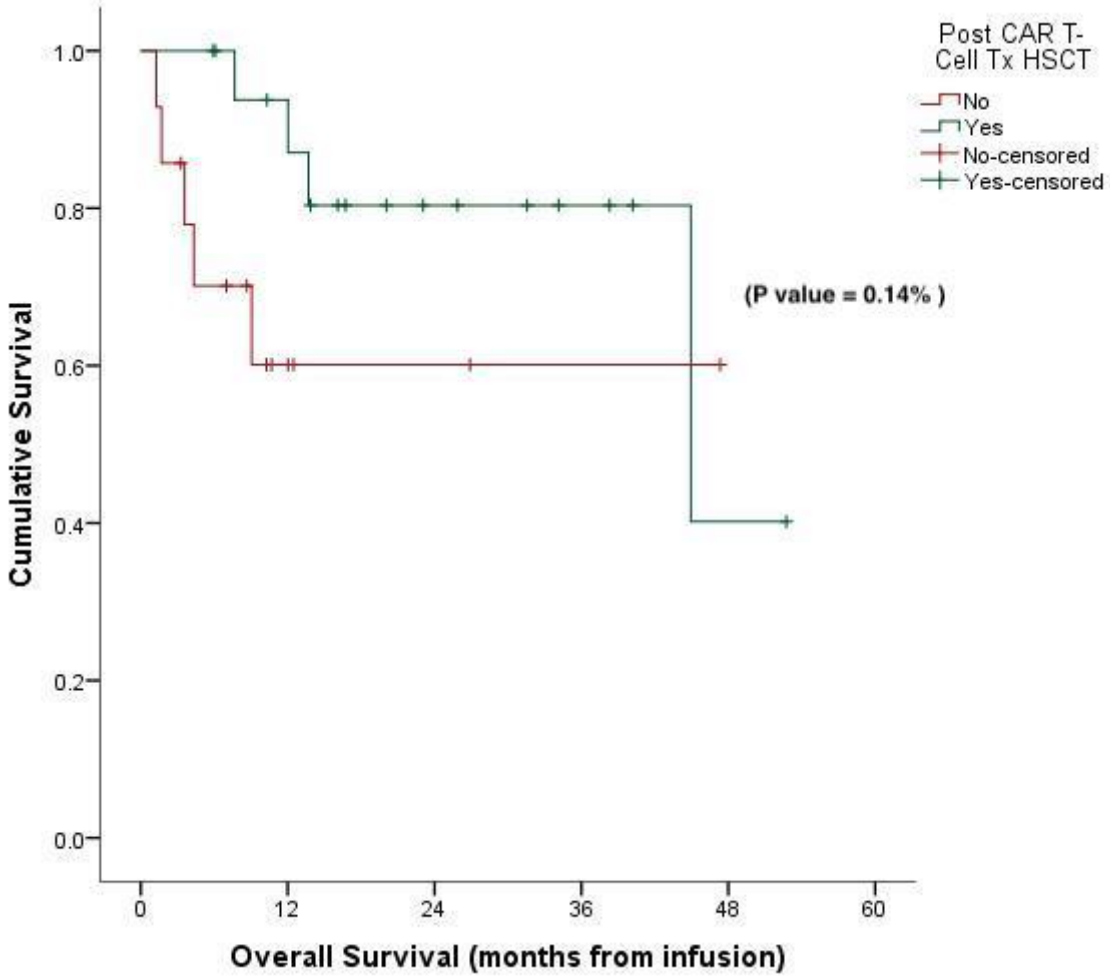
OUTCOME AND TOXICITY PROFILE OF CAR T-CELL THERAPY IN PEDIATRIC RELAPSED/REFRACTORY B ACUTE LYMPHOBLASTIC LEUKEMIA: SINGLE-CENTER EXPERIENCE FROM SAUDI ARABIA

Alaa Alzahrani[1], *Ibrahim Ghemlas*[1], *Hawazen Alsaedi*[1], *Mouha Ayas*[1], *Abdullah Aljefri*[1], *Awatif Alanazi*[1], *Saadiya Khan*[1], *Sara Ramiz*[1], *Mohamad Ballourah*[1], *Khawar Siddiqu*[1], *Ali Al-Ahmari*[1]
[1]*King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia*

Background: Relapsed or Refractory B-cell ALL (R/R B-ALL) poses a significant treatment challenge. Tisagenlecleucel, an anti-CD19 chimeric antigen receptor (CAR) T-cell therapy, has shown promising efficacy. However, real-world data, especially from Middle Eastern centers, remains limited. This study aims to evaluate outcomes and toxicities of tisagenlecleucel in pediatric B-ALL at a single center in Saudi Arabia.

Methods: This observational study included 32 pediatric patients (≤14 years) with (R/R B-ALL) treated with tisagenlecleucel between December 2020 and January 2025. We evaluated patient demographics, disease features, treatment parameters, toxicity profiles, cytokine release syndrome, and immune effector cell-associated neurotoxicity syndrome, response rates, survival outcomes, and post-infusion HSCT.

Results: The cohort had a median age of 8.2 years; 43.8% had undergone prior HSCT, and 43.8% had high disease burden (≥5% marrow blasts). CRS occurred in 75% of patients, with a median onset of 1.5 days post-infusion; 25% experienced severe (Grade 3–4) CRS events, which were managed successfully with tocilizumab and corticosteroids. ICANS was reported in 9.4%, with a median onset of 3 days after infusion. Post-infusion cytopenia (Grade 2–3) anemia was observed in all patients, with a median recovery time of 35.5 days. 87.5% had severe neutropenia, with a median recovery time of 17 days, and 28.1% had thrombocytopenia, with a median recovery time of 54 days. B-cell aplasia persisted for a median of 3.7 months; 33.3% exhibited early B-cell recovery within 6 months. All but three patients (90.6%) demon.strated a response to therapy, as determined by bone marrow MRD assessment at Day 28 following CAR T-cell infusion. Of the 29 responders, 10 (34.4%) had relapse disease, with a median follow-up of 16.7 months. Their 1-year and 2-year overall survival (OS) rates were 79.7% and 74%, respectively. Event-free survival (EFS) rates were 73.9% and 50% at one year and 2 years, respectively. Of the whole cohort including the refractory patients the 1-year and 2-year overall survival (OS) rates were 75.4% and 70.4%, respectively and the 1-year and 2-year overall survival (EFS) rates were 57% and 45.3%, respectively. Among the responding patients (n = 29), ten (34.4%) proceeded to HSCT consolidation while in remission. However, no statistically significant survival advantage was observed compared with patients who did not receive HSCT consolidation (EFS at 24 months: 72.9% vs. 37.8 %; p = 0.14).



Conclusions: Tisagenlecleucel is effective and feasible in heavily pretreated pediatric B-ALL in this regional cohort, with manageable toxicity profiles consistent with global experience. High rates of relapse and post-infusion cytopenias highlight the need for improved monitoring and consolidation strategies to optimize long-term outcomes.

INDIVIDUALIZED BUSULFAN COMPARED TO FIXED-DOSE IN HEMATOPOIETIC STEM CELL TRANSPLANT FOR AML/MDS: RESULTS FROM A SINGLE CENTER

Roberto Bono[1], *Cristina Rotolo*[1], *Giuseppe Sapienza*[1], *Corinne Spoto*[1], *Carmelo Costanza*[1], *Sergio Indelicato*[2], *Luca Castagna*[1]
[1]*UOSD UTMO, AOR Villa Sofia-Cervello, Palermo, Italy,* [2]*U.O.C. Controllo Qualità e Rischio Chimico, AOR Villa Sofia-Cervello, Palermo, Italy*

Background: Busulfan (Bu) exposure is a critical determinant of outcomes in allogeneic hematopoietic stem cell transplantation (HSCT). Fixed-dose strategies may lead to substantial intra and inter-patient variability, affecting toxicity and efficacy. Pharmacokinetics (PK) of Bu can maximize his antitumoral activity with an acceptable toxicity profile.

Methods: We conducted a retrospective single-center analysis of consecutive AML/MDS patients who underwent a myeloablative HSCT. Patient received either fixed-dose Bu (2010-2020) or individualized Bu dosing adjusted to achieve a predefined target area-under-the-curve (AUC) (2021-2025). PK was measured after the first fixed dose of BU (100 mg/m2) and after the 3rd dose. Two AUC levels were selected: AUC16 for patients aged 65-70 years and in patients with comorbidity index (HCT-CI) ≥3, and AUC20 for the remaining patients. GVHD prophylaxis was different, according to the donor type. Primary endpoints included overall survival (OS), progression-free survival (PFS). Secondary endpoints were incidence of sinusoidal obstruction syndrome (SOS), graft-versus-host disease (GvHD), non-relapse mortality (NRM) at day+100 and 1 year and cumulative incidence of relapse (CIR) at 1 year.

Results: From January 2010 to August 2025, 267 AML/MDS patients were included: 51in PK-BU cohort while 216 patients received fixed dose BU. Patient characteristics were reported in Table. The median follow-up was 18 months in the PK-BU cohort (2-35 months) and 72 months (2 -189 months) in fixed-BU.
In PK-BU cohort, 35 patients (69%) had AUC16 target and 16 (31%) AUC20 target. Median neutrophil engraftment was 17 (9-38) and 16 days (12-23) in the fixed dose and PK-BU cohort respectively, while platelet engraftment was 14 (8-72) and 13 days (10-46). The incidence of graft failure was 2% in the PK-BU cohort and 1% in the fixed-BU cohort (3/216). 100-day NRM was 12% and 18% in the fixed-BU cohort and PU-BK cohort, respectively (p value 0.79). 1-y NRM was 24 % and 21% in the fixed-BU cohort and PK-BUcohort, respectively (p value 0.79). The 1-year CIR was 28% in the fixed-dose cohort while 17% in the BU-PK (p value 0.21).
1 year OS and PFS were 65.2% and 55.2%,respectively.
In the fixed-BU cohort, the CI grade 3-4 aGVHD was 8.3% compared to 6% in the PK-BU cohort (p value 0.76). Cgvhd in the PK-BU cohort was 11% while 2% in the fixed-Bu cohort (p value 0.08).
In the PK-BU cohort, the incidence of grade 3-4 mucositis was 23% while 36.6% in the fixed-BU cohort (p value 0.0021). In the PK-BU cohort incidence of VOD/SOS was 8% (4/51) while 2.5% in the fixed-BU(5/216) (p value 0.14).

Patient characteristics	Patients N=267	BU_NO_PK N=216	BU_PK N=51	pvalue
Disease				0,3936
AML	234 (87.6%)	187 (86.6%)	47 (92.2%)	
MDS	33 (12.4%)	29 (13.4%)	4 (7.8%)	
HCT-CI				0,4019
<=2	53 (58.9%)	26 (65%)	27 (54%)	
>2	37 (41.1%)	14 (35%)	23 (46%)	
Disease status				0,1992
CR	216 (80.9%)	171 (79.2%)	45 (88.2%)	
NO CR	51 (19.1%)	45 (20.8%)	6 (11.8%)	
Donor				0,1977
APLO	54 (20.3%)	40 (18.6%)	14 (27.5%)	
HLAid	104 (39.1%)	90 (41.9%)	14 (27.5%)	
mMUD	35 (13.2%)	29 (13.5%)	6 (11.8%)	
MUD	73 (27.4%)	56 (26%)	17 (33.3%)	
TCI				<0,0001
high	89 (33.3%)	89 (41.2%)	0 (0%)	
int	178 (66.7%)	127 (58.8%)	51 (100%)	
low	0 (0%)	0 (0%)	0 (0%)	

Conclusions: A PK-guided BU-based conditioning regimen is safe and effective for AML/MDS patients undergoing allo-SCT. We observed a trend towards a lower CIR and better OS and PFS in PK-BU compared to fixed dose BU. Mucosal toxicity was reduced with PK-BU.

IMMUNE EFFECTOR CELL ASSOCIATED NEUROTOXICITY (ICANS) IN PAEDIATRIC PATIENTS FOLLOWING CHIMERIC ANTIGEN RECEPTOR (CAR) T-CELL THERAPY: EXPERIENCE FROM A TERTIARY CARE CENTER

Nazaret Sanchez-Sierra[1], *Alicia Pablos-Lopez*[1], *Anna Alonso-Saladrigues*[2], *Jordi Muchart*[3], *Maria Victoria Toffoli*[3], *Federico Ramos*[3], *Sara Bobillo-Perez*[3], *Iolanda Jordan*[3], *Susana Rives*[4]
[1]*Pediatric Cancer Center Barcelona (PCCB), Hospital Sant Joan de Déu, Barcelona, Spain,* [2]*Pediatric Cancer Center Barcelona (PCCB), Hospital Sant Joan de Déu, University of Barcelona, Barcelona, Spain,* [3]*Hospital Sant Joan de Déu, Barcelona, Spain,* [4]*Pediatric Cancer Center Barcelona (PCCB), Hospital Sant Joan de Déu, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Instituto de Salud Carlos III, Barcelona, Spain*

Background: ICANS is a serious complication of CAR T-cell therapy. Diagnostic and treatment approaches rely mainly on expert consensus, with limited paediatric data. This study describes clinical features and management of ICANS in a paediatric cohort receiving 4-1BB CAR-T19 therapy at a single center.

Methods: Patients aged 1–25 years with R/R B-cell ALL treated between April 2016 to September 2025 were included. ICANS severity was graded according to ASTCT criteria. All patients underwent baseline brain MRI and neurological evaluation, with post-infusion follow-up. Individuals with prior neurological symptoms, CNS involvement, or abnormal imaging received prophylactic antiepileptics initiated 5 days before infusion. From March 2021, patients deemed at high risk for neurotoxicity additionally received intravenous prophylactic anakinra (2mg/kg/day) starting on infusion day. Demographic and clinical data were retrospectively collected.

Results:

Variables	Overall cohort n=37	Non-ICANS neurotoxicity n=13	ICANS grade 1-2 n=11	ICANS grade 3-4 n=13

CRS present, n(%) • CRS onset median (days) (range); IQR • CRS severity 1. Grade 1-2 2. Grade 3-4 - Tocilizumab treatment (number of doses)	34 (91.9%) 1(0-18);3 20 (38.8%) 24 (70.6%)	11 (84.6%) 1(0-3); 3 6 (46%) 5 (38.4%) 6 (2 doses in 4 cases)	11 (100%) 2(0-9); 2 5 (45.5%) 6 (54.5%) 8 (2 doses in 4 cases)	12 (92.3%) 1(0-18);2.5 9 (75%) 10 (83.3%) 10 (2 doses in 7 cases)
Neurotoxicity onset median (days) (Range); IQR	6(1-16); 4	4(1-16); 3	6(1-12); 5	7(3-11); 4

Among 111 patients treated with 4-1BB CAR-T19 therapy (Tisa-cel=88; ARI-0001=23), 37(33%) developed neurotoxicity (Tisa-cel=32; ARI-0001=5). Twenty-four (65%) presented ICANS (grade 1–2=11; grade 3–4=13), while 13 experienced isolated tremor.
Among patients who developed neurotoxicity, almost half (17/37;45.9%) had a previous history of CNS-3 without involvement in the 30 days prior to infusion, and 10(27%) had neurological symptoms related to prior treatments. Most ICANS patients (18/24;75%) had high tumor burden (≥5% blasts) before infusion. CRS occurred in 23/24 ICANS cases,12 (50%) severe, requiring prolonged PICU stays.
Neurological manifestations included seizures (n=7), decreased consciousness (n=6), speech impairment (n=4), hallucinations (n=5), cranial nerve deficits (n=3), and PRES (n=1). Median onset was 6 days post-infusion (range 1–16), and all cases resolved within 4 days (range 1–296), except one patient with persistent facial paralysis refractory to treatment.
Diagnostic tests during neurotoxicity included EEG in 11 patients (8 diffuse slowing; 1 epileptiform discharges; 2 normal), brain MRI in 12 (1 cerebral oedema;1 PRES;6 stable pre-existing white matter changes; 4 normal), and CSF analysis in 5 (hyperproteinorachy in all; HHV-6 in two).
Prophylactic antiepileptics were administered to 11 patients, four also receiving anakinra. ICANS treatment included intravenous anakinra 10mg/kg/8hours (16/24;67%), siltuximab (9/24;38%), and corticosteroids (10/24;42%), mainly methylprednisolone (2mg/kg/day), except for two cases with dexamethasone. Twelve patients received antiviral therapy: two for HHV-6 and two empirically until CSF herpes studies were negative. The OS at 2 years of patients with ICANS compared to those without was 46.1%(95%CI 24.8-65.1) and 68.8%(95%CI 57.3-77.8) (p=0.046) and the EFS was 32.3%(95%CI 14.0-52.1) and 53.1%(95%CI 41.5-63.4) (p=0.09), respectively.

Conclusions: The incidence of severe ICANS (grade ≥3) was 11.7%, comparable to real-world paediatric cohorts and lower than rates reported in adults treated with CD28-based constructs. Except for one case, severe ICANS did not occur with ARI-0001, suggesting a lower neurotoxicity profile compared with tisa-cel. Neurotoxicity resolved without sequelae in all but one patient. Brain MRI was the primary diagnostic tool both at baseline and during

neurotoxicity, while CSF analysis was reserved for atypical presentations due to coagulopathy risk. Management primarily involved corticosteroids and anti-cytokine agents (anakinra, siltuximab). OS at 2 years was lower in patients with ICANS; however, larger paediatric series are required to better elucidate risk factors and prognostic indicators.

A SINGLE CENTRE RETROSPECTIVE REVIEW OF DONOR LYMPHOCYTE INFUSION - INDICATIONS, OUTCOMES AND TOXICITY

*Martin Loader[1], Francisca Vasconcelos[1], Faisal Basheer[1], Helen Bentley[1], Duncan Brian[1], Louise Corbett[1], Claire Cowling[1], Charles Crawley[1], Kushani Ediriwickrema[1], Zoe Edwards[1], Nungamu Gunasekara[2], Jo Hall[1], Shenbagaram Kasivisvanathan[3], Ram Malladi[1], Kiran Tawana[1], Simon Richardson[1], **Catharina Tao**[1], Ben Uttenthal[1], Chi Wong[1], Andrew King[1]*
[1]Cambridge University Hospitals, Cambridge, United Kingdom of Great Britain and Northern Ireland (the), [2]Kings College University Hospital Trust, London, United Kingdom of Great Britain and Northern Ireland (the), [3]Portsmouth Hospitals University Trust, Portsmouth, United Kingdom of Great Britain and Northern Ireland (the)

Background: The use of donor lymphocyte infusions (DLI) post allogeneic stem cell transplant remains common with DLI being given prophylactically to improve mixed T cell chimerism (pDLI), or therapeutically to treat relapsed disease (tDLI). Whilst its efficacy is established DLI is associated with toxicity, particularly Graft versus host disease (GVHD), and there remains a need to optimise its use to improve patient outcomes.

Methods: This retrospective single centre study reviewed outcomes of patients undergoing allogeneic stem cell transplantation at our institution between 2019-2024 who subsequently received DLI. DLI dose was dependent on the donor and the indication with further infusions given at escalated doses as per local policy.

Results: 456 patients underwent allogeneic transplantation with 11 patients receiving 2 transplants and 467 transplants being performed in total.
As of 19/11/2025 (Median follow up 973 days) DLI has been administered following 142/467 (30.4%) transplants and to 141/456 (30.9%) patients with 257 infusions being administered in total.
The median age of patients receiving DLI was 61 years (16-73). 68.3% were male. 35.3% of patients receiving reduced intensity conditioning regimes required DLI compared to 13.3% myeloablative. 83.1% of DLI was given in the context of Fludarabine/Melphalan/Alemtuzumab (FMC) conditioning with 45.7% of all FMC conditioned transplants requiring DLI.

105 patients received pDLI. The median T Cell chimerism pre infusion was 41% donor (1-91) and the median number of days between transplant and first infusion was 217 (125-576). The median number of infusions given was 1 (1-6) with a median total dose received of 5x10^5 CD3/kg (5x10^5 –1.35x10^8 CD3/kg). Overall survival (OS) in this cohort was 78.1% (Median follow up 866 days) (Figure 1). The median T cell chimerism at first reassessment (2-3 months post DLI) was 70% donor (3-100). 51 (48.6%) of patients reverted to full donor chimerism (T Cell chimerism >95%) following 1 infusion with 71 (68.3%) achieving full donor chimerism in total. 9 (8.7%) of patients relapsed despite DLI. 37 patients received tDLI either alone or in combination with other therapy. The median number of days between transplant and first infusion was 653 (157-1465). The median number of infusions given was 2 (1-4) and the median total dose was 4x10^6 CD3/kg (1x10^6-4.4x10^7). 19 patients (51.3%) received DLI for relapsed AML and the remainder for other indications. OS was 62.2% (Median follow up 1260 days). 12 patients (32.4%) achieved disease control and remain in remission, 11 (29.7%) remain alive with active disease and 14 (37.8%) have died.
38 (27%) of all patients receiving DLI suffered from GVHD with 12 (8.5%) having confirmed grade III/IV GVHD. 14 (9.9%) patients died with GVHD felt to be a contributing factor in their death. 92.1% cases of GVHD occurred in patients receiving pDLI with 7.9% receiving tDLI.

Figure 1: Kaplan-Meier curve of overall survival (OS) in patients receiving pDLI

Conclusions: This study demonstrated high rates of DLI use particularly in the context of reduced intensity conditioning regimes. We provide further evidence of the of efficacy of DLI particularly in preventing disease relapse however GVHD remains a significant complication. Further strategies to reduce DLI use in future and to manage its toxicity are required.

Clinical Trial Registry: Not applicable.

Disclosure: Nothing to declare.

REAL-WORLD OUTCOMES OF AUTOLOGOUS BONE MARROW TRANSPLANTATION IN RELAPSED/REFRACTORY HODGKIN LYMPHOMA: A MULTICENTER RETROSPECTIVE ANALYSIS FROM THE UKRAINIAN NATIONAL BMT REGISTRY

Serhii Horbachov[1], *Alevtyna Burtna*[2], *Anastasiia Maliar*[2], *Kateryna Moiseienko*[2], *Yehor Skibytskyi*[2], *Sergiy Klymenko*[3], *Olga Mishcheniuk*[3], *Nataliia Shudrak*[2], *Bohdan Skulskyi*[1], *Olena Lukianets*[1], *Oleksandr Lysytsia*[4], *Oleksandr Istomin*[4], *Solomiia Hlukhovska*[5], *Anastasiia Chuchvych*[5], *Yana Stepanishyna*[6], *Kateryna Semenchenko*[2], *Sybiryna Korenkova*[7], *Nadiia Skyrda*[1], *Kseniia Bolharina*[2], *Orest Tsyapka*[8], *Irina Kryachok*[2], *Nazarii Shokun*[2]
[1]*Cherkasy Clinical Oncology Center, Cherkasy, Ukraine,* [2]*National Cancer Institute, Kyiv, Ukraine,* [3]*Feofaniya Clinical Hospital, Kyiv, Ukraine,* [4]*National Specialized Children's Hospital "Okhmatdyt", Kyiv, Ukraine,* [5]*First Lviv Medical Union, Lviv, Ukraine,* [6]*Institut Jules Bordet, Bruxelles, Belgium,* [7]*Kyiv Center of Nephrology and Dialysis, Kyiv, Ukraine,* [8]*Institute of Blood Pathology and Transfusion Medicine of NAMS of Ukraine, Lviv, Ukraine*

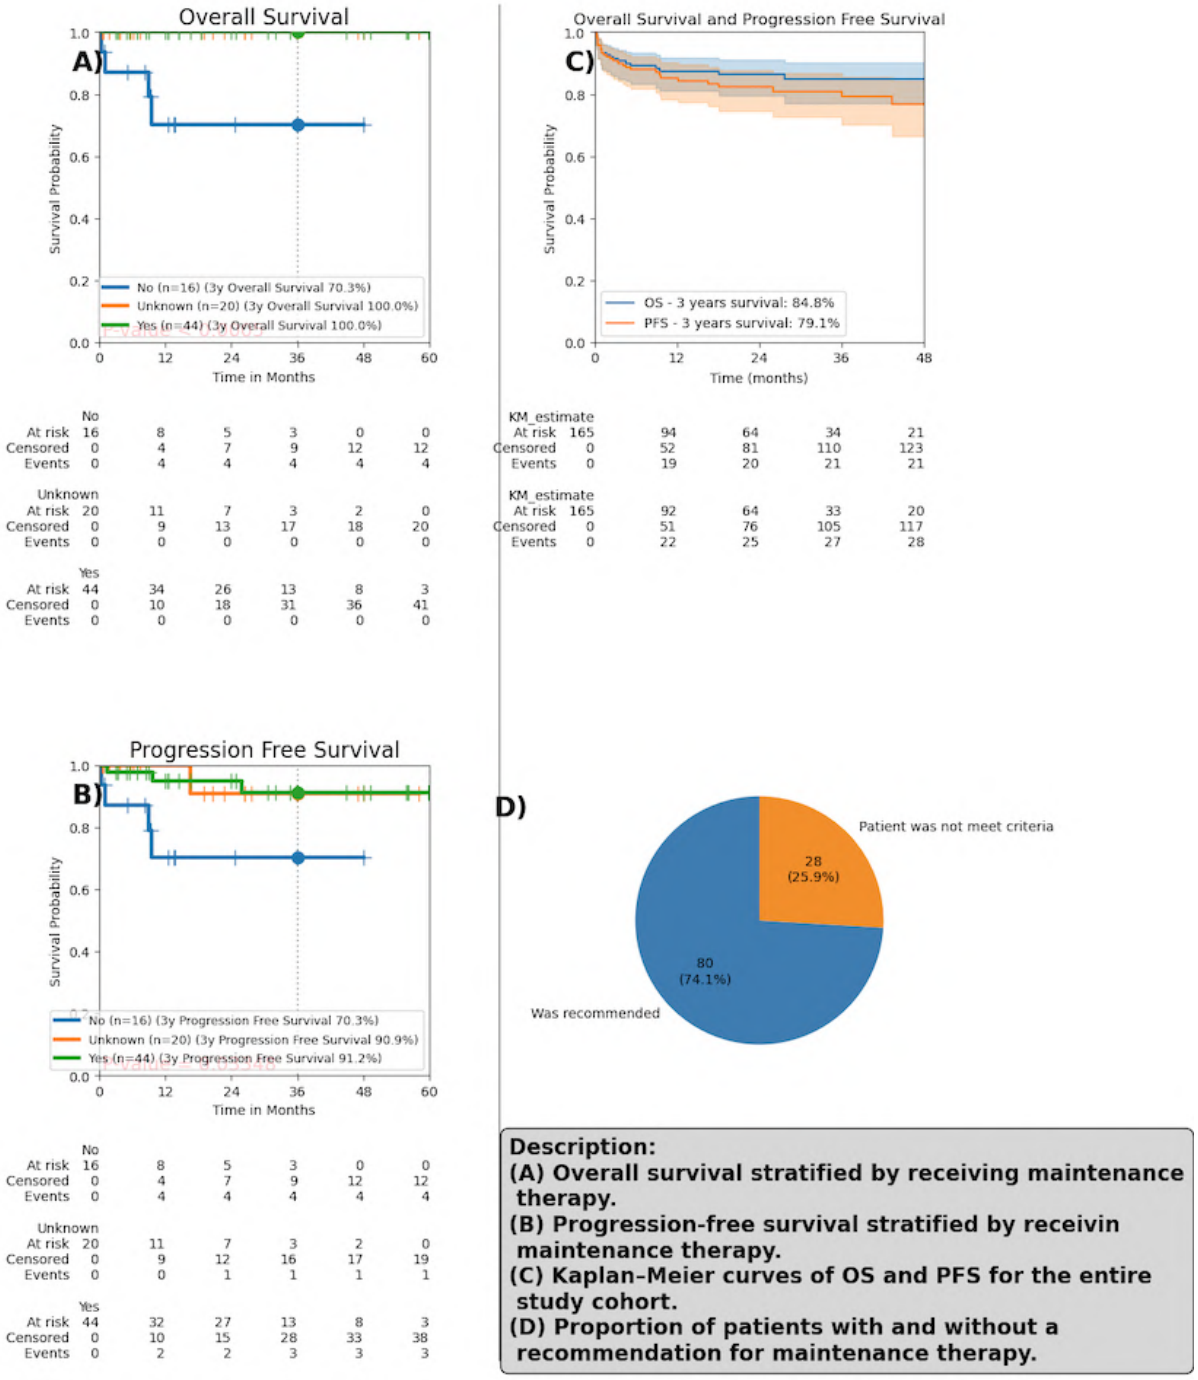
Background: The Hodgkin lymphoma (HL) is a potentially curable lymphoma with a cure rate in first line around 85- 90%. In relapsed cases, autologous stem cell transplantation (ASCT) offers a 60% chance of long-term remission. In 2024-2025, ASCT was performed for 747 patients in 11 centers across Ukraine. Real-world data from transplant registries provides region-specific insights into treatment practices and outcomes, reflecting variations in healthcare infrastructure, drug availability, and clinical decision-making across different geographic settings.

Methods: Restrospective analysis of 179 cases that underwent ASCT from the National Bone Marrow Transplantation Registry, coordinated by the Ukrainian Bone Marrow Transplantation Association. Data were collected from 6 Ukrainian transplant centers using REDCap software from 2016 - 2025. We provide descriptive analysis of clinical characteristics, estimate 3-year OS and PFS using the Kaplan-Meier Curve.

Results: Ninety-one patients (51.4%) were male; median age at ASCT was 30 years (range 14–60). At diagnosis, 89 patients (53.6%) had advanced disease (stage III–IV). In 83 of 123 evaluable cases (67.5%), the indication for ASCT was relapse; the median time from initial diagnosis to relapse was 4.1 years (range 0.7–19).
Salvage therapy data were available for 124 patients. The median number of treatment lines

prior to ASCT (including first line) was three (range 1–6). The most frequently used salvage regimens were IGEV (63 patients, 50.8%) and DHAP (57 patients, 46.0%); 17 patients (14.0%) received both regimens sequentially. Brentuximab vedotin (BV) was administered in 44 patients (35.5%), including 26 (21.0%) as monotherapy. Complete remission prior to ASCT was achieved in 99 of 124 evaluable patients (79.8%).
Conditioning data were available for 131 patients. LEAM was the most commonly used regimen (108 patients, 82.4%), followed by BuCyE (15 patients, 11.5%). Although 80 of 108 patients fulfilled criteria for BV maintenance after ASCT, only 44 received maintenance therapy. Follow-up data were available for 169 patients (94.4%), with a median follow-up of 2.1 years (range 0.1–6.9) from ASCT.
Twenty-two patients died after ASCT, and eight experienced relapse. Transplant-related mortality was observed in 14 patients (8.7%). Three-year OS and PFS were 84.8% (95% CI 66–89) and 79.1% (95% CI 66–88), respectively. BV maintenance was associated with superior 2-year OS and PFS (100% and 91.2%) compared with no maintenance (70.3% and 70.3%).

Figure 1



Description:
(A) Overall survival stratified by receiving maintenance therapy.
(B) Progression-free survival stratified by receivin maintenance therapy.
(C) Kaplan-Meier curves of OS and PFS for the entire study cohort.
(D) Proportion of patients with and without a recommendation for maintenance therapy.

Conclusions: This first multicenter analysis from the Ukrainian National Bone Marrow Transplantation Registry confirms that ASCT remains an effective strategy for

relapsed/refractory HL in a real-world setting, with encouraging three-year survival outcomes. At the same time, the registry highlights important gaps in care, including limited access to novel agents and inconsistent use of post-transplant maintenance therapy. These findings underscore the value of a national registry for identifying country-specific barriers to optimal care and for guiding future efforts to improve access to evidence-based treatments.

Disclosure: Nothing to disclosure.

A175

TREOSULFAN COMPARED WITH BUSULFAN-BASED CONDITIONING FOR ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN HEMATOLOGICAL MALIGNANCIES

Anna Czyż[1], *Magdalena Karasek*[1], *Bartłomiej Kuszczak*[1], *Maciej Majcherek*[1], *Maciej Sławomir Tomasiewicz*[1], *Tomasz Wróbel*[1]
[1]*Wrocław Medical University, Wrocław, Poland*

Background: The randomized MC-FludT.14/L Trial II demonstrated that conditioning with fludarabine plus treosulfan (total dose 30 g/m²), compared with reduced-intensity busulfan (total dose 6.4 mg/kg), improved transplantation outcomes in older patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). However, data directly comparing treosulfan-based conditioning with higher-dose busulfan regimens (total dose 9.6 mg/kg) remain limited. We therefore performed a single-center retrospective analysis comparing treosulfan- and busulfan-based conditioning in patients with hematological malignancies undergoing allogeneic hematopoietic stem cell transplantation (alloHCT).

Methods:

Between 2018 and 2025, 121 consecutive patients (median age 65 years, IQR 56–65) underwent alloHCT for acute leukemia, myelodysplastic or myeloproliferative neoplasms, or lymphoma. Disease Risk Index (DRI) was low in 10, intermediate in 71, and high or very high in 40 patients. Donors included matched sibling (n = 16), matched unrelated (n = 97), and haploidentical donors (n = 8).

Conditioning consisted of fludarabine (total dose 150 mg/m²) combined with busulfan 9.6 mg/kg (FluBu3; n = 36) or treosulfan 36 g/m² (FluTreo12; n = 40) or 30 g/m² (FluTreo10; n = 45). Patients receiving FluBu3 were younger than those treated with FluTreo12 and FluTreo10 (median 56, 62, and 66 years, respectively; p = 0.014). Other baseline characteristics, including diagnosis, DRI, donor type, CMV serostatus, and graft-versus-host disease (GvHD) prophylaxis, were comparable across groups.

Results:

With a median follow-up of 26 months (range 1–93), 3-year overall survival (OS) for the entire cohort was 65.7% (95% CI 56.0–75.4), and 3-year progression-free survival (PFS) was 63.0% (95% CI 53.2–72.8). OS and PFS did not differ significantly between conditioning

regimens. Three-year OS was 72.7% for FluBu3, 73.1% for FluTreo12, and 56.4% for FluTreo10 (p = 0.95), while corresponding PFS rates were 69.7%, 70.6%, and 56.6%, respectively (p = 0.84).

The 3-year cumulative incidence of relapse (RI) was 25.9% (95% CI 18.3–36.7) and non-relapse mortality (NRM) was 11.1% (95% CI 6.5–18.9). RI did not differ between conditioning regimens (p = 0.87), with rates of 24.4% (FluBu3), 16.6% (FluTreo12), and 34.9% (FluTreo10). Similarly, NRM was comparable across groups (p = 0.55), at 6.2%, 12.2%, and 13.9%, respectively.

Rates of severe infectious complications, acute GvHD grade II–IV, and extensive chronic GvHD were similar across groups. In contrast, severe non-infectious complications (grade 3–4) occurred more frequently after FluBu3 (36.1%) than after FluTreo12 (12.5%) or FluTreo10 (13.3%), mainly due to severe mucositis (p = 0.014).

Conclusions: Treosulfan-based conditioning provides comparable survival and disease control to FluBu3 in patients not eligible for fully myeloablative busulfan dosing, with significantly lower rates of severe non-infectious toxicity. Importantly, both OS and PFS were satisfactory when interpreted in the context of the DRI distribution of this cohort, which included a substantial proportion of patients with intermediate- and high-risk disease.

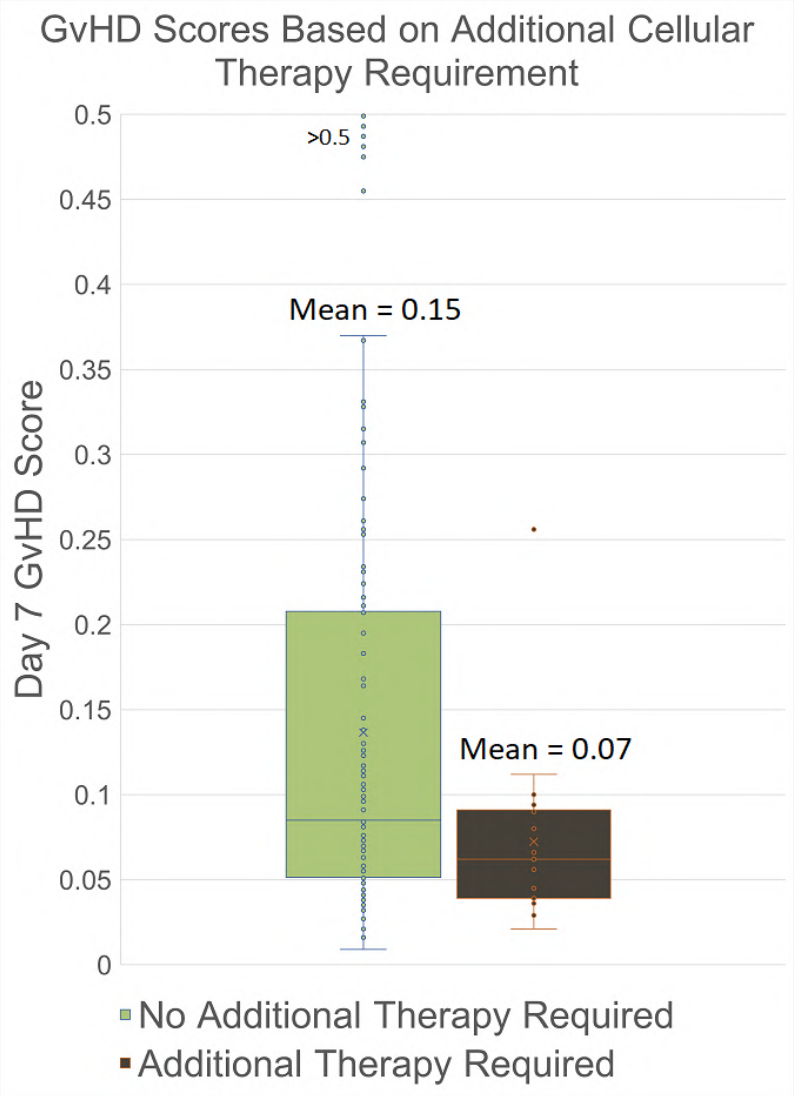
UTILIZING GVHD BIOMARKERS TO PREDICT POOR ENGRAFTMENT: THE GOLDILOCKS PHENOMENON OF ALLOREACTIVE T CELLS IN HEMATOPOIETIC STEM CELL TRANSPLANTATION

Clayton Long[1,2], *Celeste Cleveland*[1,2], *Andrés Vásconez Samaniego*[1,2], *Robert Lisac*[1,2], *Toshihiro Onishi*[1,2], *Dana Salzberg*[1,2], *Roberta Adams*[1,2,3], *Holly Miller*[1,2,3]
[1]*Phoenix Children's, Phoenix, United States of America (the),* [2]*University of Arizona College of Medicine, Phoenix, United States of America (the),* [3]*Mayo Clinic, Phoenix, United States of America (the)*

Background: T cells play a critical role in hematopoietic stem cell transplant (HSCT). They assist with engraftment but are also directly related to graft-versus-host disease (GvHD). Attempts have been made to decrease GvHD through the reduction of alloreactive T cells in stem cell products prior to transplant, processes that also result in higher rates of graft failure. Biomarker assays have been utilized to predict therapy resistant GvHD when obtained at day +7 after HSCT. High biomarker scores predict an increased risk of developing therapy resistant acute GvHD. Our objective was to evaluate the association of low day +7 GvHD biomarker scores with rates of graft failure requiring additional cellular therapy after initial HSCT in pediatric patients. We hypothesized that a low day +7 GvHD score would be associated with an increased risk of graft failure, though this has not been previously studied.

Methods: We performed a retrospective review of all pediatric patients who underwent allogeneic HSCT at Phoenix Children's Hospital over a 5-year period (1/1/2018 - 12/31/2023). Patients were included if they survived to day +30 and had both a day +7 GvHD biomarker assay and day +30 T-cell chimerism available. Of 160 transplants performed, 137 patients were included in analysis. Day +7 biomarker values were compared between patients who did or did not require additional cellular therapy after initial transplant. Statistical analysis included Mann-Whitney U tests and odds ratios.

Results: Of the 137 patients, 116 did not require additional cellular therapy, while 21 did. Of the 21 patients, 5 required additional therapy due to relapse of malignant disease. Of these 5 patients, 3 had falling chimerisms prior to relapse and were included in the analysis while 2 patients documented 100% T cell chimerism at the time of relapse and were excluded from analyses. Mean day +7 biomarker values were significantly lower in patients requiring additional therapy with a value of 0.07 (95% CI 0.05 – 0.09) compared to those who did not with a value of 0.15 (95% CI 0.12 – 0.18). The Mann-Whitney U test demonstrated statistical difference ($z = 2.29$, $p = 0.02$). Patients with very low GvHD biomarker scores (≤0.1) had an odds ratio of 7.4 (95% CI 1.6–33.5) for graft failure requiring additional cellular therapy.



Conclusions: Our study demonstrates that very low day +7 GvHD biomarker assays (≤0.1) are significantly associated with an increased risk of graft failure requiring additional cellular therapy in pediatric HSCT recipients. While prior studies have focused on the predictive value of these assays relating to acute GvHD, our findings suggest they may also have utility in identifying patients at risk for poor engraftment outcomes.
These results highlight the need to refine biomarker cutoff thresholds and to incorporate additional variables into predictive models. Larger, multi-institutional studies are warranted to validate these findings and determine how biomarker-guided risk stratification may inform early intervention strategies to improve transplant outcomes.

IMMUNE EFFECTOR CELL ASSOCIATED HAEMATOTOXICITY (ICAHT) AND CORRELATION WITH CLINICAL OUTCOMES POST CD19 CAR-T; A SINGLE CENTRE RETROSPECTIVE EXPERIENCE FROM THE ROYAL MARSDEN HOSPITAL

Nida Shafique[1], *Katy Smith*[2], *Nelson Chan*[2], *Jack Taylor-Stuart*[2], *Sandra Easdale*[2], *Alan Dunlop*[2], *Celvin Maycock*[2], *Eva Gancheva*[2], *Dima El-Sharkawi*[2], *Sunil Iyengar*[2], *Emma Nicholson*[2], *Francesca Sillito*[2]
[1]*Royal Marsden Hospital/Institute of Cancer Research, Sutton, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Royal Marsden Hospital, Sutton, United Kingdom of Great Britain and Northern Ireland (the)*

Background: There is increasing recognition of immune effector cell-associated haematotoxicity (ICAHT) as a distinct CAR-T toxicity with important consequences on patient survival outcomes and quality of life. Rejeski et al. proposed a grading system for thrombocytopenia[SF1] [NS2] , referred to as T-ICAHT and described prognostic implications of this score, building on their previously described N-ICAHT grading system. We applied both grading systems to a large real-world cohort and explored associations with clinical outcomes.

Methods: We retrospectively analysed 102 adult patients treated with CAR-T at our centre for B-Non-Hodgkin lymphoma (B-NHL) between 2019-2025. Data was collected from patient's electronic record. Early ICAHT day 0–30 post-infusion; late >30 days.

Results: Patient characteristics including CAR-T product and disease status prior to infusion are described in table 1. For early N-ICAHT there was 86% concordance with T-ICAHT. For late ICAHT, 60% of patients with grade 3-4 T-ICAHT had a corresponding lower N-ICAHT grade of 0-2(figure 1).Significant bleeding complications were observed in two patients, Gastrointestinal/intracranial bleed due to ICANS; early T-ICAHT score 2, Rectal bleeding;ICAHT grade 4. Within 30 days following CAR-T infusion, 41 patients (40.19%) received red cell transfusions, 37 patients (36.27%) platelet transfusions. Patients requiring transfusions had worse OS, red cell transfusion HR 0.37 (95% CI 0.20–0.68; p = 0.00128) and platelet transfusion HR 0.57 (95% CI 0.31–1.04; p = 0.069). One patient with grade 4 early T-ICAHT was commenced on TPO agonist. Univariable analysis showed significant correlation between early N-ICAHT and PFS (P = 0.009) (Figure 1). There was no significant correlation between T-ICAHT or late N-ICAHT and OS/PFS.There was a strong correlation between OS and pre-lymphodepletion Hb (HR 0.51 (95% CI 0.28–0.92; p = 0.0266), LDH (HR 0.35 (95% CI 0.19–0.65; p = 0.00095), albumin(HR 0.41 (95% CI 0.21–0.83; p = 0.0124), CRP (HR 0.52 (95% CI 0.25–1.05; p = 0.0674) and alkaline phosphatase(HR 0.55 (95% CI 0.29–1.03; p = 0.0616).EASIX score demonstrated moderate correlations with T-ICAHT grade, with strongest association for EASIX Day 3 and early T-ICAHT. For late T-ICAHT, the highest correlation was seen with EASIX Day -5[SF1].Modified EASIX (M-EASIX) showed weaker associations overall, particularly for Day 3 and late T-ICAHT(Figure1d).ICAHT grade did not correlate with the use of steroids for toxicities;(p=0.214 for early N-ICAHT, p=0.448 for late N-ICAHT, early T-ICAHT (p = 0.133) and late T-ICAHT (p = 0.621).

Grades of late T-ICAHT Grade 0-2 Grade 3-4 Unknown	 74(72.54) 9(8.73) 19(18.44)
Grades of early N-ICAHT Grade 0-2 Grade 3-4 Unknown	 48(47.05) 53(51.96) 1(0.98)
Grades of late N-ICAHT Grade 0-2 Grade 3-4 Unknown	 75(73.52) 8(7.84) 19(18.62)

Conclusions: ICAHT grading systems are feasible to use in practice. We show there is concordance between severe grade 3-4 early T-ICAHT and N-ICAHT, however severe late T-ICAHT correlated with milder grade 1-2 N-ICAHT, emphasising that late T-ICAHT may identify a separate risk-group; however, interpretation is limited by small numbers.EASIX correlates with T-ICAHT severity as a dynamic biomarker of inflammation and warrants further evaluation in predictive modelling of toxicity.M-EASIX provides limited additional value. Baseline LDH and cytopenia's were significantly associated with OS. There is need to investigate optimal management of ICAHT including the timing of GCSF, TPO agonists and stem cell rescue.

DUAL T-CELL DEPLETION WITH ANTITHYMOCYTE GLOBULIN AND POST-TRANSPLANT CYCLOPHOSPHAMIDE IN PERIPHERAL BLOOD ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION FOR ACUTE LEUKEMIA AND MYELODYSPLASTIC SYNDROME

*Dong Hyun Kim[1], **Soyean Kwon**[2], Sin Young Park[1], Hyunsoo Cho[1], Ja Min Byun[1], Dong-Yeop Shin[1], Youngil Koh[1], Inho Kim[1], Junshik Hong[1]*
[1]Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea (the Republic of), [2]Seoul National University Boramae Medical Center, Seoul, Korea (the Republic of)

Background: This study evaluates the efficacy of a dual T-cell depletion strategy in peripheral blood hematopoietic cell transplantation (PBSCT) for acute leukemia and myelodysplastic syndrome (MDS), compared with standard post-transplant cyclophosphamide (PTCy)-based graft-versus-host disease (GVHD) prophylaxis using propensity score matching.

Methods: This retrospective study included adult patients with acute leukemia or MDS who underwent PBSCT at Seoul National University Hospital between 2017 and 2025. Patients conditioned with busulfan and fludarabine and receiving either PTCy alone or antithymocyte globulin (ATG)/PTCy as in vivo T-cell depletion were eligible. In the ATG/PTCy group, ATG was administered at a total dose of 3.0–4.0 mg/kg according to the absolute lymphocyte count on day −3, and PTCy was given at 50 mg/kg on day +3 and 30 mg/kg on day +4. A 1:1 nearest-neighbor matching method using propensity scores was performed based on key covariates, including recipient age, disease type, DRI, donor type, donor sex, conditioning intensity, and infused $CD34^+$ cell dose.

Results: A total of 97 patients were analyzed (54 ATG/PTCy, 43 PTCy). In the overall cohort, the ATG/PTCy group was older (median, 59 vs. 52 years) and had higher proportions of MDS (40.7% vs. 11.6%) and high/very high disease risk index (DRI) (55.6% vs. 30.2%) (Table 1). After propensity score matching (n = 27 per group), baseline characteristics were well balanced.

Variable	Overall cohort			Propensity score matching cohort		
	ATG/PTCy (N=54)	PTCy (N=43)	P-value	ATG/PTCy (N=27)	PTCy (N=27)	P-value
Median age at HCT, years (range)	59 (19 - 75)	52 (19 - 69)	0.017	51 (23 - 69)	55 (19 - 69)	0.938

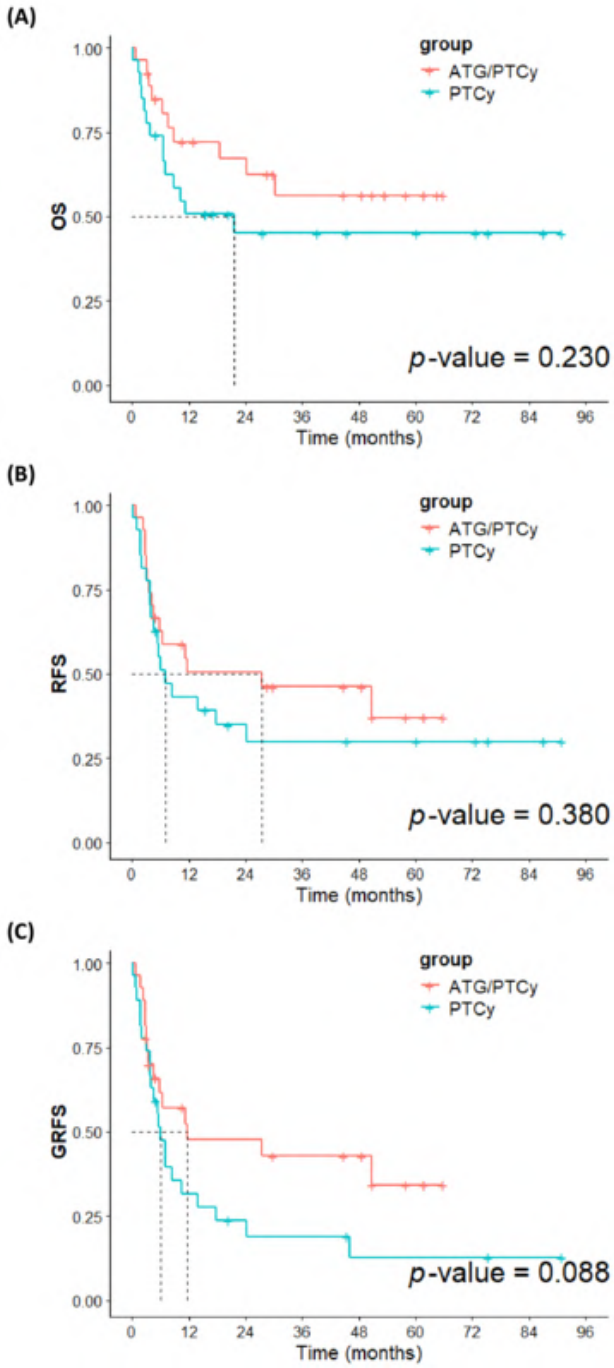
Donor age, years (range)	33 (13 - 64)	33 (11 - 65)	0.999	31 (13 - 64)	37 (11 - 65)	0.251
Donor sex, n (%) Female donor to male recipient Others	6 (11.1) 48 (88.9)	11 (25.6) 32 (74.4)	0.111	3 (11.1) 24 (88.9)	2 (7.4) 25 (92.6)	0.999
Conditioning intensity, n (%) MAC RIC	13 (24.1) 41 (75.9)	13 (30.2) 30 (69.8)	0.653	9 (33.3) 18 (66.7)	7 (25.9) 20 (74.1)	0.766
CD34+ cell dose, median (range)	5.12 (3.07 - 8.36)	5.00 (1.42 - 7.58)	0.170	5.00 (3.07 - 6.96)	5.15 (2.95 - 7.58)	0.771

In the overall cohort, there were no significant differences in overall survival (OS), relapse-free survival (RFS), and GVHD-free, relapse-free survival (GRFS). In the propensity score matched cohort, the median OS, RFS, and GRFS were not reached, 27.5 months, and 11.6 months, respectively, in the ATG/PTCy group. Corresponding values in the PTCy group were

21.5, 7.0, and 6.0 months. Four-year OS was similar between the ATG/PTCy and PTCy groups (56.3% [95% CI, 38.6–82.0] vs. 45.1% [95% CI, 28.9–70.2]; *P* = 0.230), as was 4-year RFS (46.2% [95% CI, 30.4–70.3] vs. 30.0% [95% CI, 16.3–55.2]; *P* = 0.380). A trend toward higher 4-year GRFS was observed with ATG/PTCy (42.8% [95% CI, 26.7–68.6] vs. 12.6% [95% CI, 4.0–39.8]; *P* = 0.088) (Table 1).
In the overall cohort, multivariate Cox analysis demonstrated that low/intermediate DRI, MDS, and use of reduced-intensity conditioning were significantly associated with improved GRFS. ATG/PTCy showed a trend toward superior GRFS compared with PTCy (HR 0.60; 95% CI, 0.33–1.05; *P* = 0.074). After propensity score matching, the favorable impact of low/intermediate DRI (HR 0.18; 95% CI, 0.07–0.42; *P* < 0.001) and MDS (HR 0.22; 95% CI, 0.06–0.79; *P* = 0.021) on GRFS remained significant. Notably, ATG/PTCy emerged as an independent predictor of superior GRFS (HR 0.45; 95% CI, 0.21–0.93; *P*= 0.031).



Conclusions: Dual T-cell depletion with low-dose ATG plus attenuated-dose PTCy may offer enhanced protection against clinically significant GVHD without compromising relapse control, thereby improving GRFS in PBSCT for acute leukemia and MDS. Given the central

role of PTCy in current practice, these findings support continued exploration of the potential added value of incorporating ATG as part of combination GVHD prophylaxis.

Background: The HLA-B leader polymorphism encodes either methionine (M) or threonine (T) at position -21, generating the MM, MT, or TT genotypes. This study aimed to evaluate the impact of this dimorphism on transplant outcomes in unrelated allogeneic stem cell transplant (ASCT) patients with single locus mismatch.

Methods: This was an observational, retrospective, multicenter cohort study. Adult patients (n = 276) with newly diagnosed acute myeloid leukemia (AML), myelodysplastic syndrome (MDS), or acute lymphoblastic leukemia (ALL) in first complete remission (CR1) and

undergoing single HLA-mismatched unrelated ASCT (national/international: 95%/5%) between January 2021 and August 2025 were included in the study. B-leader genotypes were determined using the HLA-B Leader Assessment Tool (BLEAT), and their impact on clinical outcomes was evaluated using multivariate Cox proportional hazards regression.

Results: Data from 276 individuals (138 patients and 138 donors) from 20 transplant centers were analyzed. The median ages of patients and donors were 47.5 (range, 18-74) and 31 (range, 19-52), years respectively. Of the patients 69 (50%), and donors 113 (82%) were male; ASCT indications were AML, ALL and MDS 82 (60%), 39 (28%), 17 (12%), respectively. Hematopoietic Cell Transplantation–Comorbidity Index (HCT-CI) scores were low in 70 patients (51%), moderate in 43 (31%), and high in 25 (18%). Disease Risk Index (DRI) of the cohort were low in 2 (2%), intermediate in 71 (51%), and high/very high in 65 (47%). Conditioning regimens included myeloablative in 84 patients (61%), reduced intensity in 49 (35%), and non-myeloablative in 5 (4%). The median follow-up was 8.8 months (range, 0.2–50.9).Single HLA mismatches involved HLA-A (55%), HLA-B (15%), HLA-C (10%), HLA-DRB1 (13%), and HLA-DQB1 (7%). TT, MT, and MM B-leader genotypes were observed in 66%, 30%, and 4% of patients, respectively. Allele-level mismatches occurred in 22% and antigen-level mismatches in 78% of the cohort.
Table 1 summarizes the results of the multivariable Cox proportional hazards regression models evaluating the association between HLA-B leader genotypes and key clinical outcomes, including overall survival (OS), progression-free survival (PFS), and transplant-related mortality (TRM) (Figure 1).
Patients <60 years carrying the MM genotype had significantly lower PFS and OS than those with TT or MT genotypes (PFS: p = 0.016 and p = 0.023; OS: p = 0.001 and p = 0.002, respectively). The prognostic effect of the HLA-B leader genotype was more evident in this younger group. Among patients with a single HLA-A, -C, -DRB1, or -DQB1 mismatch (n=117), MM carriers showed higher TRM100 and overall TRM, a difference confined to patients <60 years (p<0.05).
GVHD prophylaxis was categorized as ATG alone, PTCy alone, or combined ATG+PTCy, with the reference group defined as TT-genotype patients receiving ATG only. Compared with ATG, PTCy was associated with lower mortality (p = 0.009; HR 0.38; 95% CI, 0.18–0.78). Additionally, among MT-genotype patients, PTCy use was associated with an increased risk of acute GVHD compared with the reference group (p = 0.007; HR 5.1; 95% CI, 1.5–17).

Table 1: Impact of B-Leader Genotypes on Clinical Outcomes: Multivariable Cox Regression Analysis

Outcome	Variable	HR	**95% CI**	P-value*

ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION USING DECEASED DONOR DERIVED CRYOPRESERVED BONE MARROW: A FIRST-IN-HUMAN REPORT OF SUCCESSFUL ENGRAFTMENT IN PRESERVE 1

*Sagar Patel[1], **Sagar Munjal**[2], Brian McClune[1], Lauren Lee[1], Preethi Prasad[2], Vicki Graves[2], Erik Woods[2], Scott Goebel[2], Daniel Couriel[1]*
[1]Transplant and Cellular Therapy Program, Huntsman Cancer Institute, University of Utah, Salt Lake City, United States of America (the), [2]Ossium Health, San Fransisco, United States of America (the)

Background: Allogeneic hematopoietic cell transplantation (alloHCT) is a potentially curative therapy for many hematologic diseases. Historically, outcomes reflect the degree of HLA-matching between the donor and recipient, with worse survival associated with higher degrees of HLA-mismatch. Ethnically diverse patients often lack a suitable HLA-matched donor and require HLA-mismatched donor options. PRESERVE 1 (NCT05589896) is a first-in-human clinical trial studying safety and efficacy of 4-8/8 HLA-matched cryopreserved hematopoietic progenitor cells (HPC) obtained from bone marrow (BM) of vertebral bodies harvested from deceased, solid organ donors (age 7-55 years). Here we report results of the first enrolled patient in the PRESERVE study infused with Ossium HPC Marrow.

Methods: PRESERVE 1 is a multicenter, open-label clinical trial sponsored by Ossium Health and conducted by the CIBMTR. This is a 52 year old Hispanic patient with T-cell ALL in CR1 who lacked a suitable donor. The patient's baseline organ function was normal, Karnofsky performance status was 90%, and HCT-CI was 2. The patient received myeloablative conditioning with fludarabine 30 mg/m^2 (days -6 through -2) and TBI 200 cGy BID (days -3 through -1) and graft-versus-host disease (GvHD) prophylaxis with tacrolimus, mycophenolate mofetil, and post-transplant cyclophosphamide (days +3 and +4). On day 0, the patient received 4/8 HLA loci (HLA-A, B, C and DRB1) cryopreserved BM allograft from a deceased donor. The patient received 5.63 million CD34 cells/kg (TNC 2.03 x10e8) Ossium HPC Marrow (5% DMSO). G-CSF (5 µg/kg/day) started on day +1 and continued until first day of neutrophil engraftment.

Results: BM product was thawed at bedside and no infusion-related adverse events occurred. Transplant-related complications included grade 3 mucositis and culture-negative neutropenic fever. The first day of neutrophil engraftment (ANC >500/µL for 3 consecutive days) occurred on day +15 post-alloHCT with an ANC of 500, an ANC of 1100 on day +16, and by day +17 an ANC of 4200. The first day of platelet engraftment (transfusion-independent platelet >20,000/µL for 7 consecutive days) occurred on day +16. Day +90 bone marrow biopsy showed 100% donor chimerism in both unsorted and sorted T cell compartments. The patient completed 1 year follow up, post-Ossium HPC Marrow infusion with no acute or chronic GvHD, serious infection, end-organ injury, or disease relapse have occurred in the patient who maintains hematopoietic engraftment without need for cytokine

augmentation or transfusion.

Fig 1: Patient safety journey

Conclusions: The patient demonstrated robust engraftment with no major safety issues or complications. These early results confirm the proof of concept of building an off-the-shelf bank of allogeneic marrow grafts to expedite time to transplant and provide a source of stem cells for recipients who lack access to suitable living donors. The clinical trial is actively recruiting patients to further characterize the efficacy and safety of these novel grafts.

Clinical Trial Registry: NCT05589896

EFFICACY OF UNRELATED ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN SEVERE APLASTIC ANEMIA: A SINGLE-CENTER RETROSPECTIVE STUDY OF 206 PATIENTS

Jinrong Zhao[1], *Yuping Zhang*[2], *Shunqing Wang*[2]
[1]*Department of Hematology, Guangzhou First People's Hospital, South China University of Technology, Guangzhou, China,* [2]*Guangzhou First People's Hospital, South China University of Technology, Guangzhou, China*

Background: Unrelated allogeneic hematopoietic stem cell transplantation (URD-HSCT) is an important treatment modality for aplastic anemia.

Methods: To evaluate its efficacy, this study retrospectively analyzed the clinical data of 206 patients with severe aplastic anemia (SAA) who underwent URD-HSCT at a single center between November 2012 and December 2024.

Results: The results showed that the median age was 28 years (range: 5–64 years), 57.3% were male, and 13.6% had received immunosuppressive therapy (IST) prior to transplantation. The median time to neutrophil and platelet engraftment was 12 days (range: 9–22 days / 8–55 days), respectively, and the graft failure rate was 3.4%. CD8+ T lymphocytes returned to normal levels by 2 months post-transplantation, CD19+ B cells by 6 months, and CD4+ T lymphocytes approached normal levels by 1 year. The cumulative incidence of grade II–IV acute graft-versus-host disease (aGVHD) was 21.7% (95% CI: 16.6%–27.8%), and that of chronic GVHD (cGVHD) was 20.4% (95% CI: 15.4%–26.6%). The primary cause of death was infection (64.7%, 11/17). Survival analysis revealed a 4-year overall survival (OS) rate of 91% for the entire cohort. Notably, the 4-year OS rate was significantly higher in the donor age ≤30 years group compared to the >30 years group (97% vs 85%, $P = 0.0028$), and in the HLA 10/10 matched group compared to the 9/10 matched group (95% vs 86%, $P = 0.023$). The optimal donor profile was defined as a donor aged ≤30 years with HLA 10/10 matching, which was associated with a 4-year OS of 98% compared to 88% in other groups ($P = 0.023$). Multivariate analysis identified male sex, donor age >30 years, and HLA 9/10 matching as independent risk factors for inferior OS, while donor age >30 years and HLA 9/10 matching were also independent risk factors for worse graft-versus-host disease-free, relapse-free survival (GRFS).

Conclusions: In conclusion, URD-HSCT is an effective treatment for SAA, and selecting an appropriate donor can significantly improve therapeutic outcomes.

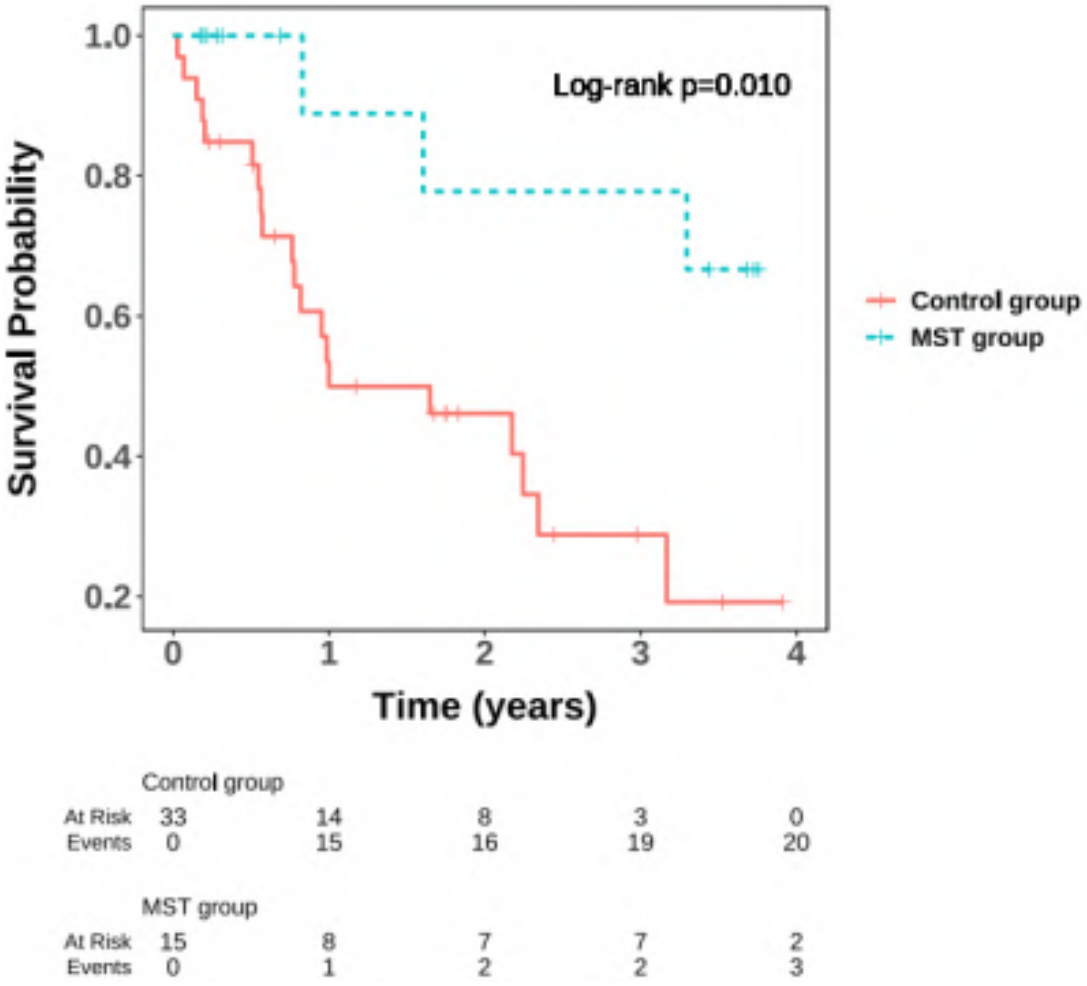
UMBILICAL CORD BLOOD MICROTRANSPLANTATION PLUS CHEMOTHERAPY FOR AML AND HIGH-RISK MDS POST-CR1

Yao Xiao[1], ***Jing Zheng***[1]
[1]*China Three Gorges University, Yichang Central People's Hospital, Yichang, China*

Background: Acute myeloid leukemia (AML) and high-risk myelodysplastic syndrome (HR-MDS) patients face high relapse risk after first induction complete remission.

Methods: This was a single-center retrospective study. A total of 48 patients with AML and HR-MDS who achieved first complete remission after induction therapy were enrolled and divided into MST combined with chemotherapy group (MST group, n=15) and chemotherapy alone group (control group, n=33). The primary endpoints were DFS and OS. Kaplan-Meier method was used for survival analysis, log-rank test was applied to compare differences between groups, and multivariate Cox regression model was employed to control for potential confounding factors.

Results: The MST group demonstrated significantly superior DFS: 1-year, 2-year, and 3-year DFS rates were 88.9%, 77.8%, and 77.8% respectively, compared to 50.0%, 46.1%, and 28.8% in the control group (p=0.010). Median DFS was not reached in the MST group versus 1.0 years in controls. Multivariate Cox analysis confirmed MST independently improved DFS (adjusted HR=0.24, 95% CI: 0.07-0.85, p=0.027). OS showed an improving trend: 3-year OS rates were 71.8% (MST) versus 34.9% (control), with median OS 3.9 years versus 1.9 years (p=0.064). Subgroup analysis revealed pronounced DFS benefit in patients ≥60 years (adjusted HR=0.11, p=0.039). No severe acute GVHD occurred; cord blood infusion was well tolerated with no serious adverse events.



Conclusions: Umbilical cord blood stem cell microtransplantation combined with chemotherapy significantly prolongs disease-free survival in AML and HR-MDS patients post-first complete remission, with a clear trend toward improved overall survival, particularly benefiting elderly patients. This strategy provides a safe, effective treatment option for patients ineligible for traditional allogeneic transplantation, supported by robust evidence for clinical practice.

CLINICAL IMPACT OF IN-SILICO HISTOCOMPATIBILITY ALGORITHMS IN 9/10 MISMATCHED DONOR ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATIO

Rodrigo Gil Manso[1,2], *Francisco Javier Gil Etayo*[1,2,3], *Almudena Cabero*[1,2], *Estefanía Pérez-López*[1,2], *Mónica Cabrero Calvo*[1,2], *Alejandro Avendaño Pita*[1,2], *María del Carmen Gilabert Gutiérrez*[1,2], *Ana García-Bacelar*[1,2], *Ana África Martín-López*[1,2], *Mónica Baile González*[1,2], *Lourdes Vázquez López*[1,2], *Jenifer Alonso Rodríguez*[1,2], *Antonio Costa*[1,2], *Juan López Pérez*[1,2], *Sara Marcos Asensio*[1,2], *Almudena Navarro Bailón*[1,2], *Pilar Terradillos Sánchez*[1,2], *Irene Jiménez Hernaz*[1,2], *Ariadna Vicente Parra*[1,2], *Ana Balanzategui Echevarría*[1,2], *Nuria Calzada Nieto*[1,2], *Fermín Sánchez-Guijo*[1,2,4], *Amalia Tejeda-Velarde*[1,2], *Lucía López-Corral*[1,2,4]
[1]Hospital Universitario de Salamanca, Salamanca, Spain, [2]Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, Spain, [3]Centro de Investigación del Cáncer (CIC, CSIC), Salamanca, Spain, [4]Centro de Investigación Biomédica en Red del Cáncer (CIBERONC), Madrid, Spain

Background: Donor selection in 9/10 HLA-mismatched donor (MMD) allo-HCT remains challenging due to higher risks of GVHD and non-relapse mortality (NRM). In-silico histocompatibility models, including PIRCHE, HLA-B leader status, and immunopeptidome-based approaches, aim to refine donor–recipient matching beyond conventional HLA typing. However, comparative real-world evaluations integrating these tools in the MMD setting are limited.

Methods: We conducted a retrospective single-center study of 93 adults undergoing 9/10 MMD allo-HCT (2014–2024). Median age at transplant was 53 years. Median follow-up was 41.7 months (IQR 93.47) PIRCHE scores (class I/II, GVH/HVG directions), donor and recipient B-leader genotypes, and immunopeptidome mismatch categories were calculated for each pair. Outcomes included grade 3–4 aGVHD, cGVHD (overall and moderate–severe), incidence of relapse, NRM, PFS, GVHD-relapse-free survival (GRFS), and OS. Variables with $p<0.10$ in univariate analysis were evaluated in multivariable Cox or Fine-Gray models.

Results: Cumulative incidence of G3-4 aGVHD was 21.5% at 100 days. No clinical or immunogenetic variables predicted grade 3–4 acute GVHD. HCT-CI≥3 showed a trend toward increased risk (HR 1.86, 95% CI 0.86–4.06, p=0.12), while higher infused mononuclear cell dose (>9×10⁸/kg) showed a nonsignificant protective trend (SHR 0.35, 95% CI 0.11–1.14, p=0.081).
cGVHD developed in 36.6% of patients. In multivariable analysis, only recipient age >60 years remained independently associated with chronic GVHD (HR 2.73, 95% CI 1.19–6.31, p=0.018). When focusing on moderate–severe chronic GVHD, independent predictors included HLA-B allelic mismatch (HR 2.64, 95% CI 1.13–6.15, p=0.025), recipient HLA-B leader MM genotype (HR 5.66, 95% CI 1.31–24.41, p=0.020), and age>60 years (HR 3.70, 95% CI 1.22–11.19, p=0.021). PIRCHE-C score in the GvH direction>4.5 showed a borderline association (HR 2.46, 95% CI 0.89–6.78, p=0.082).
The cumulative incidence of relapse and NRM at last follow-up was 38.1% and 23.6%, respectively. In multivariable analysis, relapse was independently predicted by PIRCHE-B≥4.5 in GvH direction (HR 6.57, 95% CI 1.76–24.50, p=0.005) and PIRCHE-II≥17.5 in HvG direction (HR 3.22, 95% CI 1.34–7.70, p=0.0087). A higher infused mononuclear cell dose (>9×10⁸/kg) showed an unexpected association with relapse (HR 2.65, 95% CI 1.05–6.70, p=0.04).
None of the algorithm-derived parameters predicted NRM.
PFS was adversely impacted by DRI-very high risk (HR 6.80, 95% CI 2.18–21.28,

p=0.0009). GRFS was similarly impaired by DRI-very high risk (HR 4.29, 95% CI 1.44–12.81, p=0.009), while higher donor age also exerted an independent negative effect (HR 1.03 per year, 95% CI 1.00–1.05, p=0.025). OS was independently influenced by DRI-very high risk (HR 5.94, 95% CI 1.66–21.23, p=0.006), HCT-CI≥3 (HR 2.57, 95% CI 1.22–5.44, p=0.013), and donor age>35 years (HR 3.28, 95% CI 1.57–6.86, p=0.001), whereas no in-silico algorithm retained independent prognostic significance for OS.

Conclusions: In this 9/10 MMD cohort, in-silico histocompatibility algorithms provided outcome-specific prognostic information. PIRCHE-derived metrics independently predicted relapse, while HLA-B leader status was associated with chronic GVHD severity. NRM and survival outcomes were driven by established clinical factors. These findings support selective integration of immunogenetic algorithms into MMUD donor-selection strategies.

INTRARENAL ARTERIAL INFUSION OF MESENCHYMAL STEM CELLS FOR THE TREATMENT OF TRANSPLANTATION-ASSOCIATED ACUTE RENAL FAILURE: A CASE REPORT

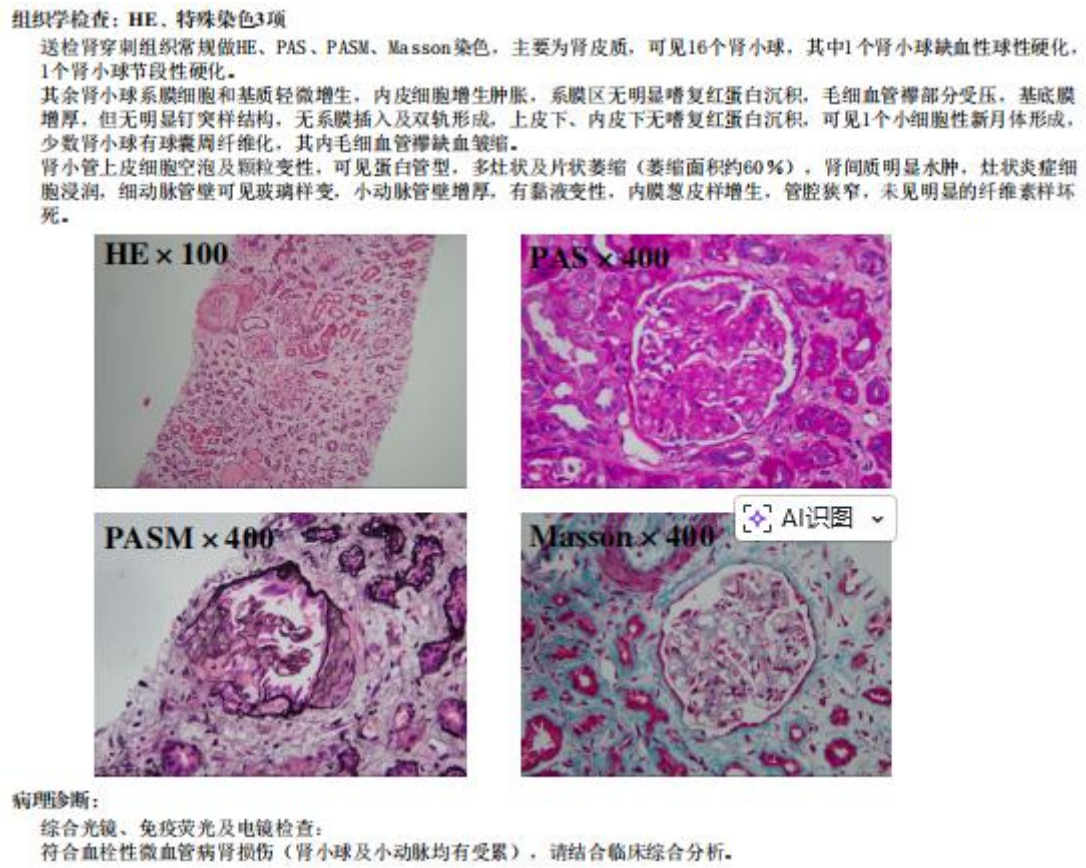
Yuanying Zeng[1], *Chunjin Lai*[2], *jiangxia Zhang*[3], *Caini Xie*[3], *Chunfu Li*[1]
[1]*GoBroad Chunfu Institute of Hematology & Oncology, Dongguan Taixin Hospital, Dongguan, China,* [2]*Cardiovascular Department, Dongguan Taixin Hospital, Dongguan, China,* [3]*Department of Nephrology, Dongguan Taixin Hospital, Dongguan, China*

Background: Acute renal failure (ARF) is a severe complication of allo-HSCT. Its pathophysiology involves the necrosis of renal proximal tubular epithelial cells due to ischemic or toxic injury. This subsequently triggers a cascade of events including loss of autoregulation, tubular obstruction, and exacerbated renal vasoconstriction, ultimately resulting in a sudden decline in the glomerular filtration rate (GFR).Currently available treatments primarily consist of renal replacement therapy (e.g., dialysis) and kidney transplantation. However, these approaches are expensive, require ongoing maintenance, and the procurement of donor organs is challenging. Consequently, there is an urgent clinical need to identify novel, safe, and effective therapies for ARF.

Methods: A 14-year-old boy was diagnosed with chronic active Epstein-Barr virus disease. Genetic testing revealed multiple germline mutations (TCS2, ATM, BAX, CASP10, IRF7, FAT4, LCK). Following immunochemotherapy and chemotherapy (CHOP and ESCAP), he underwent allogeneic hematopoietic stem cell transplantation from a 9/10 HLA-matched unrelated Chinese donor on June 16, 2023. EBV-DNA turned negative by day +3 post-transplantation, and neutrophil and platelet engraftment were achieved by day +20. However, around day +50, the patient developed pancytopenia (WBC 2.57×10^9/L, HGB 78 g/L, PLT 51×10^9/L), followed by hypertension, proteinuria, and an increase in schistocytes (6%-9%). With progressive elevation of LDH, transplantation-associated thrombotic microangiopathy (TA-TMA) was diagnosed according to the Harmonization Panel Consensus criteria. Despite

treatment with defibrotide and plasma exchange, his condition deteriorated rapidly, progressing to acute renal failure. Concurrently, he experienced transient blindness, and magnetic resonance imaging of the head led to a diagnosis of posterior reversible encephalopathy syndrome. Hemodialysis was initiated on day +98 due to anuria, initially performed every other day. After two months of dialysis, some experts considered renal transplantation necessary.
Given the regenerative and immunomodulatory properties of mesenchymal stem cells (MSCs) and the limitation that intravenous infusion leads to significant pulmonary sequestration with minimal renal delivery, we proposed intrarenal arterial infusion of MSCs. After detailed discussion, the patient and his family provided informed consent. Consequently, on day +130, umbilical cord blood-derived MSCs were administered via renal artery interventional radiology, once every other week for a total of four infusions(one course). Following the third infusion, urine output began, initially at 30 mL/day and gradually increasing. After completing the four infusions, urine output exceeded 300 mL/day. We then progressively extended the dialysis intervals: to twice weekly, then once weekly as urine output continued to increase, to twice monthly after two months, and once monthly after four months when urine output reached approximately 2000 mL/day. Dialysis was completely discontinued eight months post-MSC therapy. No other major treatment adjustments were made during this period. We believe that if the TA-TMA was not self-limiting, the renal recovery observed in this patient is likely associated with the intrarenal arterial MSC infusion.

Results: Kidney biopsy 3 months after intrarenal arterial infusion of MSC



Conclusions: Currently, the patient is 2.5 years post-transplantation, continues to take antihypertensive medication orally, and has returned to school. Although his renal function has not fully normalized, it has not impacted his daily life or studies.

Disclosure: Nothing to declare.

A187

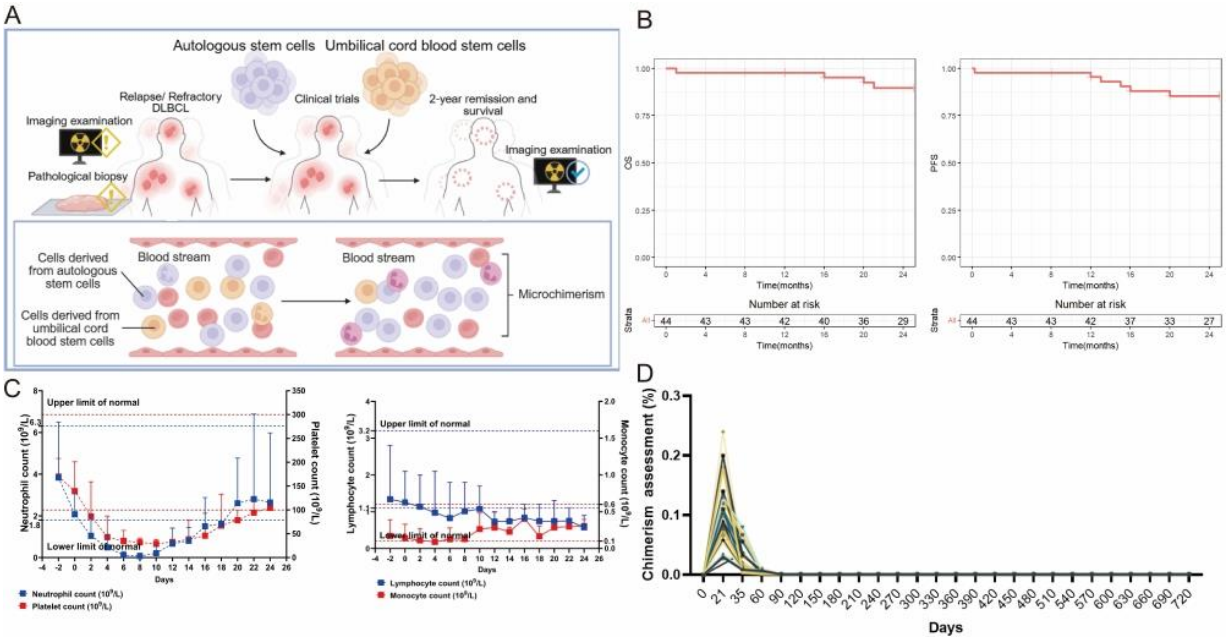
CLINICAL STUDY OF AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION PLUS UMBILICAL CORD BLOOD STEM CELL TRANSPLANTATION FOR THE RELAPSED AND REFRACTORY DIFFUSE LARGE B-CELL LYMPHOMA

Zhengchang He[1], *Yongqian Jia*[2], *Xi Zhang*[1]
[1]*Second Affiliated Hospital of Army Medical University of the Chinese People's Liberation Army, Chongqing, China,* [2]*West China Hospital of Sichuan University, Chengdu, China*

Background: Autologous hematopoietic stem cell transplantation (auto-HSCT) depends on conditioning for the maximal elimination of lymphoma cells to attain long-term survival. In the absence of the graft-versus-tumor (GVT) of allogeneic hematopoietic stem cell transplantation (allo-HSCT), auto-HSCT results in a 50–60% recurrence rate for MRD-positive or chemotherapy-resistant relapsed/refractory diffuse large B-cell lymphoma (R/R DLBCL). Is it possible to establish a new transplantation model to achieve the dual efficacy of auto-HSCT and allo-HSCT? Human umbilical cord blood stem cells (hUCBSCs) are a potential option for exerting the GVT effect with low immunogenicity, robust immune reconstitution and good biosafety. This study aims to evaluate the efficacy and safety of auto-HSCT combined with unrelated hUCBSCs infusion in the treatment of R/R DLBCL.

Methods: This single-center, single-arm prospective clinical trial recruited patients with R/R DLBCL confirmed in tertiary grade A hospitals in China. Participants received unrelated hUCBSCs infusion on Day 2 after auto-HSCT. The unrelated hUCBSCs units must satisfy the requirement of HLA matching ≥ 5/10 loci and blood type-compatible units will be prioritized for selection. Unrelated hUCBSCs was infused as a single dose, with the total nucleated cell (TNC) count ranging from 5 - 15 × 10^8 and $CD34^+$ cell count from 1.5 - 3.5 × 10^6. The BEAM conditioning included carmustine (300 mg/m^2), etoposide (200 mg/m^2), cytarabine (300 mg/m^2), and melphalan (140 mg/m^2). Primary endpoints were 2-year overall survival (OS), relapse-free survival (RFS) and progression-free survival (PFS); secondary endpoints included neutrophil and platelet engraftment times.

Results: A total of 44 patients were enrolled in this study from September 27, 2023 to November 27, 2023. The median age was 37 years (range, 18–65 years), including 20 males and 24 females. Among these patients, 23 cases (55.6%) were relapsed and 21 cases (44.4%) were refractory. The percentage of cells derived from unrelated hUCBSCs in peripheral blood remained below 0.01% after 90 days. The 2-year overall survival (OS) rate was 90.9%, and the 2-year progression free survival (PFS) rate was 86.3%, with the median survival time not reached. The median time to neutrophil engraftment was 11 days (range, 10–21 days), and the median time to platelet engraftment was 14 days (range, 12–31 days).



Conclusions: The findings of this study suggest that auto-HSCT combined with unrelated hUCBSCs infusion markedly enhances patients' quality of life. Further validation of the regimen's feasibility will rely on an expanded patient cohort and prolonged follow-up for in-depth assessment.

Disclosure: Nothing to declare.

A188

POST-TRANSPLANT MONITORING OF NGS-BASED MINIMAL RESIDUAL DISEASE AND DONOR CHIMERISM AS A PROGNOSTIC TOOL IN OLDERLY PATIENTS WITH AML/MDS

Seong Kyu Park[1], *Se Hyung Kim*[1], *Jina Yun*[1], *Kyoung Ha Kim*[2], *Jong Ho Won*[2], *Chan Kyu Kim*[1]
[1]*Soonchunhyang University Bucheon Hospital, Bucheon-Si, Korea (the Republic of),*
[2]*Soonchunhyang University Seoul Hospital, Seoul, Korea (the Republic of)*

Background: Next-generation sequencing (NGS)-based monitoring of minimal residual disease (MRD) and complete donor chimerism status plays a critical role in predicting post-transplant survival outcomes in patients with acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS). Compared to traditional techniques such as flow cytometry or quantitative PCR, NGS offers superior sensitivity in detecting MRD, enabling earlier identification of residual leukemic cells. The prognostic accuracy can be further

enhanced by integrating donor chimerism analysis, allowing for early risk stratification and timely intervention.

Methods: This retrospective study analyzed clinical outcomes of 113 patients with AML or MDS who underwent reduced-intensity conditioning (RIC) allogeneic hematopoietic stem cell transplantation (allo-HSCT) between January 2018 and May 2025. Eligible patients were aged ≥60 years, or ≥55 years if considered ineligible for standard-intensity SCT. Post-transplant monitoring included NGS-based MRD testing and assessment of donor chimerism at 2–3 months post-transplant.

Results: A total of 31 patients (27.4%) had MRD-positive results after transplantation. MRD positivity was significantly associated with reduced overall survival (OS) (hazard ratio [HR], 4.705; P < .001). Full donor chimerism (FDC) was observed in 82 patients (72.6%), and these patients had improved OS compared to those with mixed donor chimerism (HR, 0.361; P = .002). Based on MRD and chimerism status during post-transplant follow-up, patients were stratified into four groups: (1) MRD(−)/FDC(+), (2) MRD(−)/FDC(-), (3) MRD(+)/FDC(+), (4) MRD(+)/FDC(-).
Disease status before hematopoietic stem cell transplantation (HSCT) differed significantly (P < 0.001), with fewer patients in the MRD(+) groups achieving complete remission prior to transplantation. High-risk HCT-CI scores were more common in the MRD(+) groups (P < .001). MRD positivity prior to HSCT seemed to be more frequently observed among patients who remained MRD-positive post-transplant (P=0.169). There were no significant differences in the incidence of major post-transplant complications among the groups. In survival analysis, non-relapse mortality (NRM) at 100 days was significantly higher in the MRD(−)/FDC(+) group (P=0.004). Relapse rates differed markedly among the groups (P<0.001), as did overall mortality (P<0.001). The MRD(+)/FDC(-) group had the poorest prognosis, characterized by the highest relapse rate and lowest OS. In multivariate Cox regression analysis, both MRD positivity and incomplete donor chimerism at 3 months post-transplant were independently associated with inferior survival outcomes.

Conclusions: Integrated post-transplant monitoring of NGS-based MRD and donor chimerism is a critical prognostic tool in elderly AML/MDS patients undergoing RIC allo-HSCT. Early identification of MRD positivity or mixed chimerism can facilitate timely risk-adapted interventions. In patients with high-risk post-transplant molecular profiles, preemptive strategies such as donor lymphocyte infusion (DLI) may be considered to reduce relapse risk and improve long-term outcomes.

Clinical Trial Registry: None.

PTCY VERSUS ATLG IN ALLOGENEIC HSCT FOR ACUTE LEUKEMIA WITH HIGH DISEASE BURDEN: A REAL-WORLD STUDY

Xiaoyong Man[1], Lei Yuan[1], Jingbo Wang[1], Rongmu Luo[1], Qihang Man[1], ***Minglu Li***[1,1]
[1]*Aerospace Clinical Medical College, Peking Universit, Beijing, China*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the primary curative treatment for relapsed or refractory acute leukemia. However, patients with non-remission still face high post-transplant relapse rates and transplant-related mortality. For graft-versus-host disease (GVHD) prophylaxis, the PTCY (Baltimore protocol) and Beijing protocol (G-ATG-based combination regimen) are commonly used, but systematic studies comparing the efficacy of ATLG and PTCY are lacking.

Methods: We retrospectively analyzed patients with non-remission acute leukemia who underwent allo-HSCT at Peking University Aerospace Clinical Medical College between 2020 and 2024. A total of 275 patients were included, with 229 in the ATLG group (83.3%) and 46 in the PTCY group (16.7%). Baseline imbalances were adjusted using inverse probability of treatment weighting (IPTW), and a multivariate model was further applied to account for residual confounding. Outcome measures included overall survival (OS), disease-free survival (DFS), cumulative incidence of relapse (CIR), non-relapse mortality (NRM), and acute/chronic GVHD (aGVHD/cGVHD).

Results: Compared with the ATLG group, the PTCY group had significantly shorter 5-year OS (HR=1.88, 95% CI: 1.02–3.46, P=0.043) and a trend toward shorter 5-year DFS (HR=1.66, 95% CI: 0.98–2.82, P=0.059). Competing risk analysis showed that the PTCY group had significantly higher 5-year CIR (SHR=1.49, 95% CI: 1.04–2.14, P=0.031) and NRM (SHR=1.55, 95% CI: 1.03–2.34, P=0.035). There were no significant differences in the incidence of aGVHD (SHR=1.23, 95% CI: 0.77–1.95, P=0.38) or 5-year cGVHD (SHR=0.51, 95% CI: 0.20–1.32, P=0.17) between the two groups.

Conclusions: For GVHD prophylaxis, PTCY and ATLG have comparable efficacy in reducing GVHD risk. However, the PTCY group was associated with lower OS and DFS, as well as higher CIR and NRM. Due to the small sample size of the PTCY group, these findings require further validation.

Disclosure: Nothing to declare.

A190

ADMISSION TO INTENSIVE CARE UNIT (ICU) OF ADULT HEMATOPOIETIC TRANSPLANT RECIPIENTS: SINGLE CENTER EXPERIENCE

Laura Contreras Rujas[1]
[1]*Hospital Univrsitario de La Princesa, Madrid, Spain*

Background: Hematopoietic stem cell transplantation (HSCT) can entail significant morbidity during the procedure. Published series in HSCT report a range of ICU admission rates from 24-25% of transplant patients and is associated with poor prognosis (75% mortality rate). Most frequent reasons involve respiratory failure, septic shock, and veno-occlusive disease. The aim of this study was to analyze outcome of HSCT patients requiring ICU admission in our center.

Methods: We retrospectively analysed outcomes of 903 patients who underwent HSCT in our centre from January/2008 to June/2025. Data were collected from patients' clinical records.

Results:

Median age (range)	52 (20 – 70)
Sex: male/female	79 (60%) / 53 (40%)
Underlying disease: - AML /ALL / MDS **-** Myeloma / NHL / HL/ Other	48 (36%) / 16 (12%) / 23 (17%) 9 (7%) / 13 (10%) / 6 (5%) / 17 (13%)
Type of HSCT: **- Allogeneic:** Sibling donor / Unrelated donor / Haploidentical **- Autologous**	**111 (84%)** 40 (30%) / 49 (37%) / 22 (17%) **21 (16%)**
Conditioning regimen: Myeloablative / RIC	98 (74%) / 34 (26%)
GVHD: acute/chronic	40 (30%) / 6 (5%)

Table 1. Patients' basal characteristics.

Of the 903 HSCT recipients, 122 (14%) required ICU admission (baseline and HSCT characteristics on table). Median time to ICU admission was 46 days (–2-1765). Ten of these patients required two ICU admissions, resulting in a total of 132 ICU admissions available for analysis.

Main reason for ICU admission was respiratory distress (86; 65%), mainly due to pneumonia (51%) (43% caused by gram-negative bacteria and only 3% by COVID-19), pulmonary edema (26%) and pulmonary hemorrhage (8%). Septic shock was second most common cause of ICU admission (37; 28%), attributed to gram-negative bacilli (52%), fungal (16%), gram-positive (15%), virus (10%), and others/idiopathic (17%).

Other less frequent causes included veno-occlusive disease (11; 8%), hemorrhagic complications (8; 6%), encephalopathy (7; 5%), cardiogenic shock (4%), graft-versus-host disease (2%), and one case of cardiorespiratory arrest due to vasospastic angina.

During the 132 ICU admissions, 78 patients (59%) died in the ICU, of these, 27 had received unrelated donor HSCT, 26 sibling donor, 12 haploidentical and 13 autologous. Median ICU length of stay was 9 days (1–82). In addition, 54 patients (41%) required hemofiltration and 92 (70%) required endotracheal intubation; 43 patients (33%) required both interventions,

of whom only 6 survived the ICU admission.
Of the 132 admissions, 76 (58%) occurred during the pre-engraftment period, with the remainder taking place post-engraftment. These admissions had a median ICU stay of 13 days (1–76) and a mortality rate of 64% (49/76). Mortality was higher among allogeneic HSCT recipients (82%). The cause of death was the same reason for ICU admission. Eight patients (10.5%) were discharged from the ICU but died before hospital discharge, whereas 19 were ultimately discharged home; among these, 11 patients (15%) remain alive, while the remaining 8 (10.5%) died due to disease progression or complications post-HSCT.

Conclusions: In our study, 14% of hematopoietic stem cell transplant recipients were admitted to the ICU, a low percentage compared to the literature and associated with higher survival rates, with an in-ICU mortality rate of 59%. Higher death rate was observed in allogeneic transplantation and those requiring aggressive ICU treatments such as mechanical ventilation or haemodialysis. The most common cause of admission was respiratory failure, similar to published series. Therefore, although admission to the ICU after HSCT is associated with a poor prognosis, it should be considered, as it may improve survival.

DETERMINANTS OF GVHD AND SURVIVAL AFTER HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR ACUTE MYELOID LEUKEMIA: A SINGLE-CENTER ANALYSIS OF 169 PATIENTS

Fei Pan[1], *Guanlan Yue*[2], *Kun Wang*[2], *Xingyu Cao*[2,1], *Yue Lu*[2,1], *Huili Zhu*[2], *Kang Gao*[2], *Jing Long*[3], *Zhijie Wei*[2,1]
[1]*Beijing Lu Daopei Hospital, Beijing, China,* [2]*Hebei Yanda Lu Daopei Hospital, Langfang, China,* [3]*Beijing Lu Daopei Institute of Hematology, Beijing, China*

Background: Haploidentical hematopoietic stem cell transplantation (haplo-HSCT) , including haploidentical transplantation combined with third-party unrelated cord blood (haplo-cord HSCT) and intensified BU+MEL/TT-based conditioning, is a widely used curative approach for acute myeloid leukemia (AML), yet post-transplant outcomes remain heterogeneous. Identifying independent determinants of GVHD, viral reactivation, and long-term survival is critical for optimizing transplant strategies.

Methods: We retrospectively analyzed 169 consecutive AML patients undergoing first haplo-HSCT at our center, all treated with a uniform Bu/Cy–based myeloablative conditioning and standardized GVHD prophylaxis. Multivariable Cox and competing-risk analyses were used to identify independent predictors of survival, GVHD, relapse, and viral reactivation.

Results: The median age was 14 years (IQR, 3–34), and 55.0% were male. Haplo-cord transplantation was performed in 76.3% of patients, while 23.7% received haplo-HSCT alone. HLA matching was 5/10 in 64.5% and ≥6/10 in 35.5%. BU+MEL/TT-based intense conditioning was used in 84.0%, and 60.4% received anti-CD25 monoclonal antibody. Pre-

transplant MRD positivity was observed in 41.4%. At transplantation, 68.1% were in CR1, 16.0% in ≥CR2, and 16.0% in NR/PR. Median infused cell doses were 16.01×10⁸/kg for MNCs, 9.27×10⁶/kg for CD34⁺ cells, and 3.37×10⁸/kg for CD3⁺ cells. Median neutrophil and platelet engraftment occurred at 14 and 11 days, respectively.

With a median follow-up of 3.4(0.1- 10.9）years, multivariable analyses demonstrated that disease status at transplantation was the dominant determinant of post-transplant outcomes. Compared with CR1, patients transplanted in NR/PR had significantly inferior OS (HR 5.58, 95% CI 2.17–14.3; P<0.001) and LFS (HR 5.45, 95% CI 2.12–13.9; P<0.001), along with a markedly increased risk of NRM (HR 4.67, 95% CI 1.53–14.3; P=0.007). HLA matching, donor source, and age showed no independent impact on long-term survival. Haplo-cord transplantation showed a trend toward improved OS and LFS after adjustment, although statistical significance was not reached (Figure 1).

For GVHD, BU+MEL/TT-based intense conditioning was independently associated with a reduced incidence of grade II–IV (HR 0.32, 95% CI 0.14–0.74; P=0.008) and grade III–IV aGVHD (HR 0.26, 95% CI 0.08–0.82; P=0.022). NR/PR status significantly increased the risk of grade III–IV aGVHD (HR 5.11, P=0.039). Use of unrelated cord blood grafts and higher infused CD34⁺ cell dose (>9×10⁶/kg) were associated with a lower incidence of grade II–IV aGVHD. No transplant-related variables were independently associated with CMV or EBV DNAemia (Figure 1).

Figure 1. Multivariable Cox and competing-risk analyses results to identify independent predictors of survival, GVHD, relapse, and viral reactivation.

Conclusions: Haplo-HSCT in CR remains the most critical determinant of survival in AML. BU+MEL/TT-based intense conditioning, higher CD34⁺ cell dose, and haplo-cord transplantation confer protective effects against aGVHD, with a favorable trend toward

improved survival. These findings provide clinically relevant evidence for risk-adapted transplant optimization in AML patients undergoing haplo-HSCT.

ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION FOR THERAPY-RELATED MYELOID NEOPLASMS: LONG-TERM OUTCOMES AND PROGNOSTIC DETERMINANTS FROM A SINGLE-CENTER COHORT

Yunsuk Choi[1], *Eun-Ji Choi*[1], *Hyunkyung Park*[1], *Joon Young Hur*[1], *Jung-Hee Lee*[1], *Yu_Eun Lee*[1], *Jisoo Jung*[1], *Seungah Cha*[1], *Young-Shin Lee*[1], *Mijin Jeon*[1], *Ji Min Woo*[1], *Young-Ah Kang*[1], *Hyeran Kang*[1], *Je-Hwan Lee*[1]
[1]*Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea (the Republic of)*

Background: Therapy-related acute myeloid leukemia or myelodysplastic syndromes (t-AML/MDS) arise after exposure to cytotoxic chemotherapy and/or radiation therapy, and represent a biologically and clinically distinct entity from de novo AML/MDS. Although allogeneic hematopoietic cell transplantation (HCT) has expanded in this population over the past decade, data on post-HCT outcomes and prognostic factors remain limited. We aimed to evaluate HCT outcomes and identify prognostic factors in patients with t-AML/MDS.

Methods: We retrospectively analyzed 1,626 patients with AML or MDS who underwent HCT at Asan Medical Center between 2005 and 2024, including 86 patients with t-AML/MDS. Clinical data were obtained from the Asan Medical Center HCT registry and medical records.

Results: The t-AML/MDS cohort consisted of 53 patients with t-AML and 33 patients with t-MDS. Patients with t-AML/MDS were younger than those with de novo AML/MDS (median age, 50 vs. 54 years, P=0.024), but had a higher HCT-comorbidity index score (median, 4 vs. 3; P<0.001), and a higher frequency of adverse-risk cytogenetics at diagnosis (59.4% vs. 35.3%, P=0.039). The median latency from prior cancer and t-AML/MDS diagnosis was 50.5 months (range, 4.0-299.6 months).
5-year event-free survival (EFS) rate post HCT was significantly inferior in t-AML/MDS compared with de novo AML/MDS (31.8% vs 42.7%, P=0.033), whereas overall survival (OS) did not differ between the two groups (46.2% vs. 41.1% at 5 years, P=0.255). Within the t-MDS/AML cohort, OS and EFS were comparable between t-MDS and t-AML (P=0.631 and P=0.743, respectively).
In univariate analysis, a lower mutational burden (0-1 mutations) on targeted next generation sequencing was associated with superior OS (P=0.027) and showed a trend toward improved EFS (P=0.086). In multivariate analysis, prior cancer types was independent prognostic factor; antecedent AML or lymphoma was associated with significantly superior OS and EFS (hazard ratio [HR], 0.364, P=0.007; HR 0.338, P=0.003, respectively), and prior breast cancer with improved OS (HR, 0.479, P=0.036), compared with other solid cancers showed significantly better survival. Poor performance status (Karnofsky score ≤ 80, HR for OS, 4.401, P=0.021), high-risk disease status at HCT (HR for

OS, 1.949, P=0.929; HR for EFS, 1.851, P=0.033, respectively), and older age (≥ 60 years, HR for EFS, 1.926, P=0.023) were independently associated with inferior post-HCT outcomes.

Conclusions: Allogeneic HCT provides comparable long-term OS in patients with t-AML/MDS and denovo AML/MDS despite inferior EFS in the t-AML/MDS setting. Post-HCT outcomes in t-AML/MDS are strongly influenced by antecedent cancer type, performance status, disease risk at HCT, and age. These findings support refined risk stratification and individualized HCT strategies for patients with t-AML/MDS.

Disclosure: Nothing to disclose.

A194

EFFICACY AND SAFETY OF COMBINING BCL-2 INHIBITORS WITH HYPOMETHYLATING AGENTS IN PATIENTS WITH ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROME AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

*Anastasia Pichugina[1], **Larisa Kuzmina**[1], Vera Vasilieva[1], Olga Koroleva[1], Olga Pokrovskaya[1], Liubov Ovsiannikova[1], Yulia Chabaeva[1], Sergey Kulikov[1], Irina Galtseva[1], Alina Kokhno[1], Elena Parovichnikova[1]*
[1]National Medical Research Center for Hematology, Ministry of Health of Russia, Moscow, Russian Federation (the)

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a cornerstone treatment for patients with acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS). However, disease relapse occurs in approximately 50% of AML patients in the post-transplant period. With current salvage therapies, long-term overall survival rates remain poor, ranging from 10% to 20%. Consequently, relapse is now one of the leading causes of treatment failure in AML and MDS patients after allo-HSCT. This has prompted active investigation into both maintenance therapy for patients who are minimal residual disease (MRD)-negative after allo-HSCT and preemptive therapy upon MRD detection. Additionally, efforts are ongoing to identify the most rational and effective treatment strategies to reduce relapse risk in high-risk AML patients following allo-HSCT.
Aim: To evaluate the efficacy and safety of maintenance and preemptive therapy using selective BCL-2 inhibitors in combination with hypomethylating agents in high-risk patients with AML or MDS after allo-HSCT.

Methods: This study included 37 patients who had undergone allo-HSCT: 32 with AML and 5 with MDS. Patient characteristics are summarized in Table 1.

Table 1. Clinical and demographic characteristics of patients (n=37)

Parameter	Characteristics

Sex, n (%)	
Male/Female	8 (21.6)/29 (78,4)
Age, years	
Median (range)	47 (21-66)
Diagnosis, n	
AML/MDS	32/5
Disease status of AML at allo-HSCT, n	
First complete remission (CR1)/Second complete remission (CR2)	22/10
Pre-transplant MRD status in AML, n	
MRD-positive/MRD-negative	15/17
Post-transplant MRD status in AML (pre-therapy), n	
MRD-positive/MRD-negative	7/25
Time from allo-HSCT to therapy initiation, days	
Median (range)	98 (34–264)
Number of therapy cycles	
Median (range)	6 (1–17)
Follow-up from therapy initiation, days	
Median (range)	205 (20-675)

After allo-HSCT (median time to therapy initiation, 98 days) patients received a BCL-2 inhibitor (venetoclax 200 mg/day) on days 1–5 of each cycle in combination with a hypomethylating agent — either azacitidine (32 mg/m²) or decitabine (10 mg/m²) — on days 1–3. Donor lymphocyte infusion (DLI) was additionally administered in 9 patients (1–2 infusions).

Results:

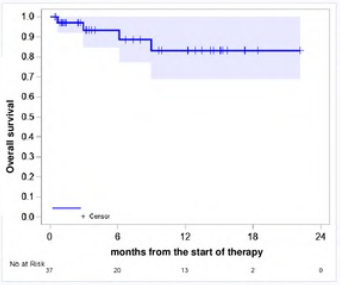

Fig. 1. Overall survival of patients with AML and MDS after allo-HSCT during therapy with selective BCL-2 inhibitors in combination with hypomethylating agents

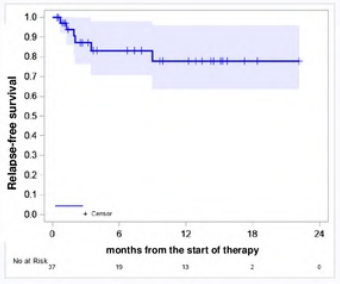

Fig. 2. Relapse-free survival of patients with AML and MDS after allo-HSCT during therapy with selective BCL-2 inhibitors in combination with hypomethylating agents

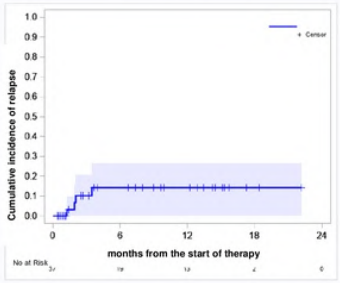

Fig. 3. Cumulative incidence of relapse in patients with AML and MDS after allo-HSCT during therapy with selective BCL-2 inhibitors in combination with hypomethylating agents

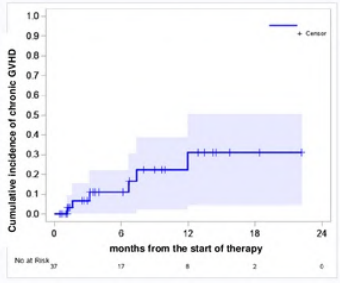

Fig. 4. Cumulative incidence of chronic GVHD in patients with AML and MDS after allo-HSCT during therapy with selective BCL-2 inhibitors in combination with hypomethylating agents

At the time of analysis, 33 patients remained alive. Disease relapse occurred in four AML patients: the median time to relapse after allo-HSCT was 125 days (range: 84–219 days), and from initiation of therapy it was 60 days (range: 38–106 days). Two patients died due to infectious complications. No cases of acute graft-versus-host disease (GvHD) of grade II–IV were observed following the start of maintenance therapy. Chronic GvHD developed in five patients, with a 12-month cumulative incidence of 31% after allo-HSCT. Hematologic toxicity (grade II–IV) was observed in four patients. The 12-month relapse-free survival rate after allo-HSCT was 78%, and the cumulative incidence of relapse was 14%.

Conclusions: Preliminary results suggest that maintenance and preemptive therapy with selective BCL-2 inhibitors combined with hypomethylating agents is both effective and well-

tolerated in high-risk patients with AML or MDS following allogeneic hematopoietic stem cell transplantation.

SECONDARY MYELODYSPLASTIC SYNDROME AFTER CAR-T THERAPY: AN EMERGING LATE TOXICITY

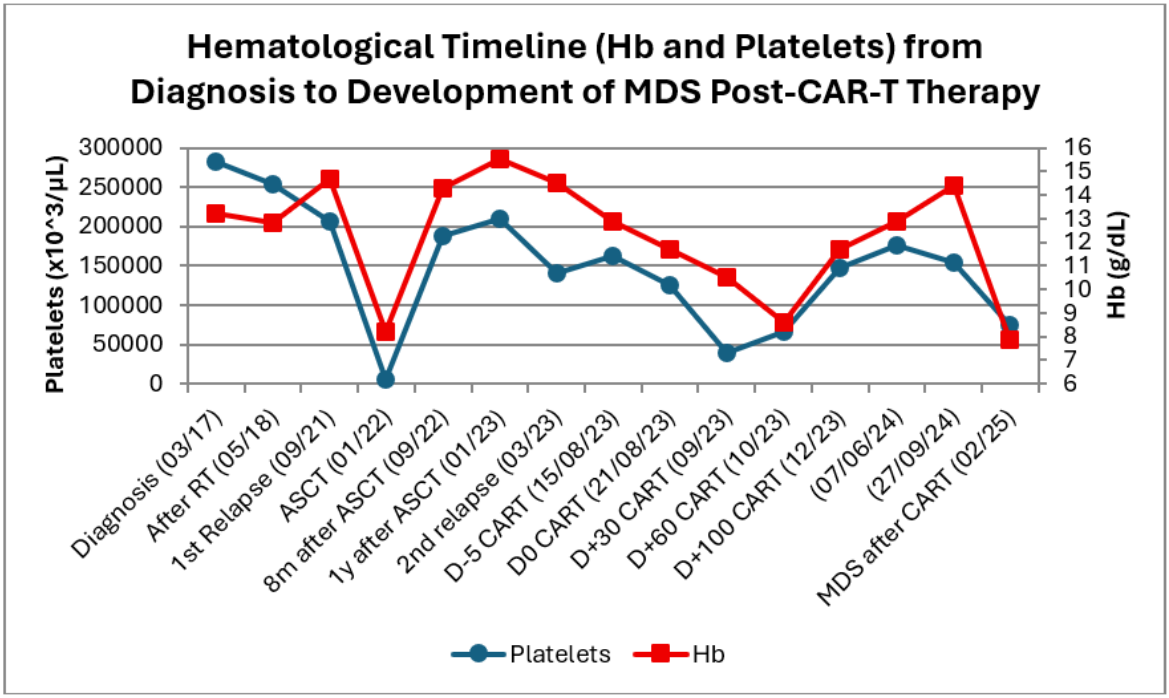
Juliana Bosco Santos[1], *Fernando Gibran-Nunes*[1], *Anita Cortez*[1], *Aliana Ferreira*[1], *Maria Cristina Seiwald*[1], *Yana Novis*[1], *Ana Rita Fonseca*[1]
[1]*Hospital Sírio Libanês, São Paulo, Brazil*

Background: Persistent cytopenias and secondary myeloid neoplasms are increasingly recognized as late complications following chimeric antigen receptor T-cell(CAR-T) therapy. However, available evidence remains limited and largely derived from isolated case reports and small series.

Methods: We performed a structured literature review of myelodysplastic syndromes(MDS) occurring after CAR-T therapy, searching publications from 2016 to 2025 in PubMed/MEDLINE, Scopus, and Embase. A total of 48 cases describing new-onset myeloid neoplasms following CAR-T therapy were included. Clinical, epidemiological, cytogenetic/molecular, and outcome data were extracted, including demographics, underlying malignancy, prior therapies, CAR-T product/target, latency to diagnosis, cytogenetic and next-generation sequencing findings, and clinical outcomes. In addition, we report a case from our institution of a patient diagnosed with high-risk MDS following CAR-T therapy.

Results: Among reported cases, 56.5%(13/23) were male, with a median age of 57 years (range, 6–78). The most common underlying malignancy was diffuse large B-cell lymphoma or high-grade B-cell lymphoma (63.2%, 24/38), followed by acute lymphoblastic leukemia (15.8%, 6/38), multiple myeloma (13.2%, 5/38), follicular lymphoma (5.3%, 2/38), and mantle cell lymphoma (2.6%, 1/38). Prior autologous HSCT was reported in 55.0%(22/48) and allogeneic HSCT in 12.5%(6/48) of patients. Anti-CD19 CAR-T products predominated (82.1%, 32/39). The median time to cytopenia onset was 8 months (range, 1–78). MDS was developed in 79.5%(35/44), acute myeloid leukemia (AML) in 9.1% (4/44), MDS/AML overlap in 4.5%(2/44), clonal cytopenia of undetermined significance (CCUS) in 4.5%(2/44), and myeloid sarcoma in 2.3% (1/44). Cytogenetic and/or molecular data were available in 47.9%(23/48). The most frequent non–mutually exclusive alterations included TP53 mutations (53.6%, 15/28), complex karyotype (42.9%, 12/28), chromosome 7 abnormalities [−7/del(7q)](28.6%, 8/28), and DNMT3A mutations(25.0%, 7/28). Among cases with available risk stratification, high or very high-risk disease predominated (69.2%, 9/13). Reported mortality reached 59.1%.
We report a 70-year-old male with follicular lymphoma grade 3B, relapsed after three prior lines of therapy including autologous HSCT, who achieved a complete metabolic response

after CAR-T therapy (tisagenlecleucel) despite developing grade 1 cytokine release syndrome(CRS) and grade 4 immune effector cell–associated neurotoxicity syndrome(ICANS). Eighteen months after CAR-T, he developed progressive cytopenias and was diagnosed with high-risk therapy-related myelodysplastic syndrome(t-MDS). Bone marrow evaluation revealed marked hypoplasia, dysmegakaryopoiesis, 7q deletions, and a TP53 mutation. The patient was initiated on azacitidine, with treatment delays due to intercurrent clinical complications, and after three cycles, follow-up molecular assessment demonstrated clonal evolution, including clearance of the initial TP53 mutation and the emergence of additional TP53 variants, as well as NF1 and PPM1D mutations, consistent with treatment-related selective pressure. He remains on azacitidine without evidence of AML transformation as of November 2025.



Conclusions: Secondary myeloid neoplasms after CAR-T therapy, although rare, are frequently associated with high-risk biological features, particularly TP53 alterations, as demonstrated in our review and illustrated by our case of high-risk TP53-mutated MDS. These findings underscore the importance of close and long-term hematologic monitoring following CAR-T therapy. In the future, pre–CAR-T clonal hematopoiesis screening and risk assessment tools integrating clinical and molecular variables may represent strategies to identify patients at higher risk and guide surveillance.

EARLY CYCLOSPORINE TAPERING AND PROPHYLACTIC DONOR LYMPHOCYTE INFUSION FOR POST-TRANSPLANT IMMUNOMODULATION IN HIGH-RISK HEMATOLOGIC MALIGNANCIES: A SINGLE-CENTER FEASIBILITY STUDY

*Cristina Rotolo[1], Corinne Spoto[1], **Roberto Bono**[1], Giuseppe Sapienza[1], Carmelo Costanza[1], Luca Castagna[1]*
[1]AOOR Villa Sofia Cervello, Palermo, Italy

Background: Relapse remains the principal cause of treatment failure after allogeneic hematopoietic stem cell transplantation (allo-HSCT) in patients with high-risk hematologic malignancies. Early post-transplant immunomodulation (IM), based on accelerated cyclosporine tapering and prophylactic donor lymphocyte infusion (DLI), has been proposed as a strategy to enhance graft-versus-leukemia (GVL) effects, although its adoption in routine clinical practice is challenging due to concerns regarding feasibility and toxicity. Evaluating the feasibility of IM strategies and their potential impact on relapse and survival outcomes is clinically relevant.

Methods: We retrospectively analyzed two high-risk allo-HSCT cohorts treated at a single center (Table 1). Group A (IM cohort, n=35; 2022–2025) underwent cyclosporine tapering starting around day +60 followed by scheduled prophylactic DLIs from approximately from day +120. Group B (historical non-IM cohort, n=33; 2017–2021) received standard immunosuppressive management. Median follow-up was 1010 days. High-risk criteria included MRD-positive AML/ALL, ELN high-risk AML, active MDS/MPN, or lymphoma in partial remission. The primary endpoint was the feasibility of the IM program; secondary endpoints included the cumulative incidence (CI) of relapse at 6 months, overall survival (OS), and progression-free survival (PFS) at 1 year in both cohorts.

Variable	All patients (N=68)	Group A (N=35)	Group B (N=33)	pvalue
Sex				0,0923

Results: In Group A, IM was initiated in 22/35 patients (63%), with cyclosporine tapering starting at a median of day +61 (range 57–84). IM was not initiated in 13/35 (37%) due to early complications, including acute GVHD (n=6,) infection (n=1), relapse (n=1), death (n=2,) other causes (n=3). Among patients in whom IM was initiated only 7/22 patients (31%) subsequently received prophylactic DLI and completed the full IM program. IM discontinuation in the other 15 patients was due to GVHD (n=6), relapse (n=3), death (n=1), or donor-related issues in MUD transplants (n=5). The 6-month CI for relapse was 8.5% in Group A compared with 33% in Group B (p=0.35). At 1 year, no statistically significant difference was observed between Group A and Group B in OS (73% vs 57%) or PFS (61% vs 42%).

Conclusions: In this single center retrospective study, early immunomodulation showed limited in feasibility, primarily due to early post-transplant complications. A lower relapse incidence was observed in immunomodulate patients, suggesting a potential antileukemic effect, although no statistically significant differences in survival outcomes were observed. These findings support the need to optimize immunomodulation strategies, in terms of timing, patient selection, and personalized strategy to improve feasibility while preserving antileukemic efficacy.

LONG-TERM OUTCOMES OF ADULT PH+ ALL TREATED WITH DASATINIB OR IMATINIB BEFORE THE BLINATUMOMAB ERA: A RETROSPECTIVE ANALYSIS OF 250 PATIENTS FROM THE PALG REGISTRY

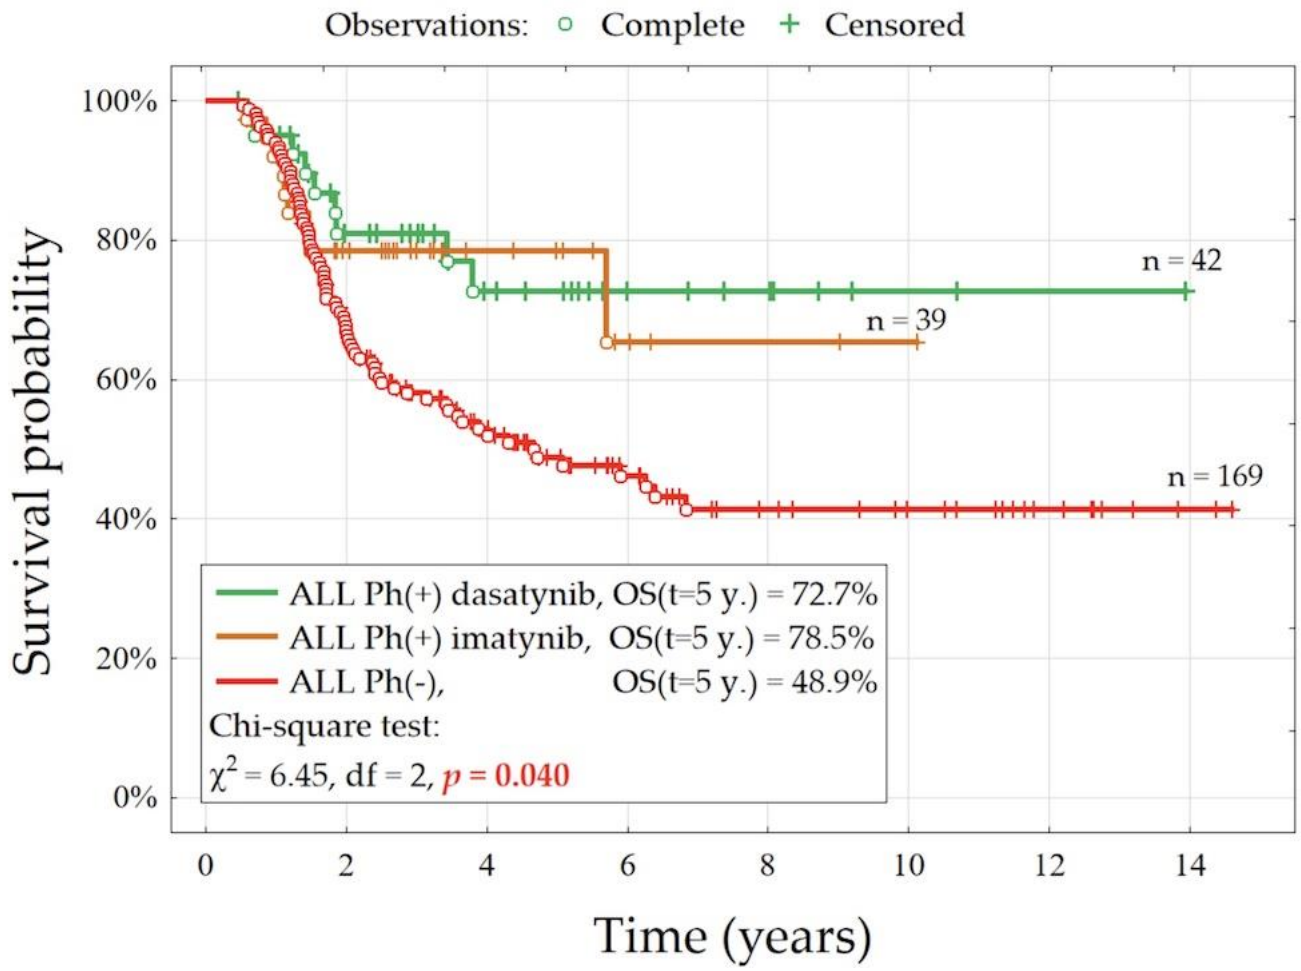
Ugo Giordano[1,2], *Monika Mordak-Domagała*[2], *Agnieszka Piekarska*[3], *Alicja Sadowska-Klasa*[3], *Anna Płotka*[4], *Małgorzata Sobczyk-Kruszelnicka*[5], *Sebastian Giebel*[5], *Lidia Gil*[4], *Krzysztof D. Dudek*[6], *Jarosław Dybko*[2,6]
[1]*Wroclaw Clinical Hospital, Wroclaw, Poland,* [2]*Lower Silesian Center of Oncology, Pulmonology and Hematology, Wroclaw, Poland,* [3]*University Clinical Center, Medical University of Gdańsk, Gdańsk, Poland,* [4]*Poznań University of Medical Sciences, Poznań, Poland,* [5]*Maria Skłodowska-Curie National Research Institute of Oncology (MSCNRIO), Gliwice, Poland,* [6]*Wroclaw University of Science and Technology, Wroclaw, Poland*

Background: The prognosis of Philadelphia chromosome–positive acute lymphoblastic leukemia (Ph+ ALL) has improved substantially with the introduction of tyrosine kinase inhibitors (TKIs). Modern chemotherapy-free and stem cell transplantation (SCT)-free regimens, such as ponatinib combined with blinatumomab as first line therapy, provide excellent survival outcomes. However, before the widespread use of blinatumomab, many high-risk patients proceeded to allogeneic hematopoietic SCT (allo-HSCT). We present a retrospective analysis of transplanted adults with Ph+ ALL treated with either imatinib or dasatinib, compared with a Ph-negative cohort, presenting long-term survival outcomes and transplant-related complications in the pre-blinatumomab era.

Methods: We analyzed 250 adult ALL patients undergoing allo-HSCT between 2010 and 2022, including 42 with Ph+ ALL treated with dasatinib, 39 with Ph+ ALL treated with imatinib, and 169 with Ph-negative ALL. Baseline characteristics, conditioning intensity, donor features, and graft-versus-host disease (GvHD) incidence and severity were compared using chi-square or Fisher exact tests. Overall survival was assessed using Kaplan–Meier estimates. Ten-year OS probabilities were estimated for all three groups. Causes of death were evaluated using separate 2×2 independence tests for each category.

Results: Patients receiving dasatinib or imatinib were older than those with Ph-negative ALL, and most Ph+ ALL patients suffered from B-cell phenotype ALL. Conditioning intensity and donor characteristics were mostly comparable. The overall incidence of acute GvHD differed significantly among groups (31.0%, 61.5%, and 41.4% for the dasatinib, imatinib and Ph− cohorts, respectively; p=0.040). Skin aGvhD was more frequent in the imatinib group, whereas gastrointestinal and hepatic involvement showed no statistically significant differences. Chronic GvHD rates and severity were similar across all groups. At a median follow-up of 3.9 years, OS differed between groups. The dasatinib group demonstrated significantly higher OS than the Ph-negative cohort (p=0.010). The comparison between imatinib and Ph-negative patients did not yield statistical significance (p=0.059). Similarly, OS did not differ between dasatinib and imatinib recipients (p=0.735). Ten-year OS probabilities were 72.7% for dasatinib, 65.4% for imatinib, and 41.4% for Ph-negative ALL.

No substantial discrepancies in causes of death were observed among the three groups.



Conclusions: In this pre-blinatumomab era subgroup analysis, adults with Ph+ ALL undergoing allo-HSCT achieved favorable long-term outcomes. Despite being part of a clinically high-risk subgroup (imatinib resistance or central nervous system involvement), patients receiving dasatinib demonstrated promising 10-year OS probability, exceeding that of imatinib and yielding statistical significance compared to that the Ph-negative ALL group. Rates, grades and involved sites of aGvHD, cGvHD, and causes of death did not differ significantly between groups, suggesting that survival differences may be driven mainly by disease control rather than transplant-related toxicity. Compared with modern chemotherapy-free regimens using ponatinib plus blinatumomab with 3-year OS yielding 91%1, the high-risk dasatinib cohort patients also achieved positive survival outcomes, underscoring the effectiveness of TKI-based strategies in Ph+ ALL prior to the immunotherapy era.

OVERCOMING ULTIMATE RESISTANCE: EFFICACY AND SAFETY OF RECIPIENT-DERIVED (DONOR-CHIMERIC) CAR-T THERAPY COMBINED WITH MULTIMODAL STRATEGIES FOR EARLY RELAPSE POST-ALLO-HSCT: A SINGLE-CENTER CASE SERIES

Guoai Su[1], Peihao Zheng[1], Huihui Zhao[1], Fangfang Cheng[1], Yue Wu[1], Ruijiao Zhang[1], Ruijie He[1], Chen Zheng[1], Xuelin Han[1], ***Yajing Zhang***[1]
[1]*Beijing Gobroad Boren Hospital, Beijing, China*

Background: Early relapse within 12 months after allogeneic hematopoietic stem cell transplantation (allo-HSCT), especially with extramedullary disease (EMD), confers a dismal prognosis. Salvage options are limited by toxicity and the risk of exacerbating Graft-versus-Host Disease (GvHD). Chimeric antigen receptor (CAR) T-cell therapy is a promising modality, but its application in the post-allo-HSCT setting remains underexplored. This series assesses the feasibility and efficacy of using CAR-T cells derived from two distinct donor sources to overcome resistance and serve as a bridge to curative second transplantation.

Methods: Four patients (2 MM, 1 T-LBL, 1 AML; median age 37 years) with early relapse (6-12 months post-HSCT) and EMD were enrolled. At relapse, all patients had >98% donor chimerism and no history of severe GvHD. Three patients received CAR-T cells manufactured from their post-transplant peripheral blood (functionally "host-environment-educated" donor-origin cells): two MM patients received BCMA-targeted (n=1) or sequential BCMA/GPRC5D-targeted (n=1) CAR-T, and the T-LBL patient received CD7-targeted CAR-T. The fourth patient (AML with aberrant CD7 expression) received CD7 CAR-T manufactured from the original healthy haploidentical donor. Pre-infusion lymphodepletion was fludarabine/cyclophosphamide. Responses were assessed by IMWG/ELN criteria. The study was approved by the institutional ethics committee (ChiCTR1900025419).

Results: All four patients achieved rapid, MRD-negative remissions with manageable toxicity. Remarkably, the T-LBL patient, who had previously failed both autologous CD7 CAR-T and a subsequent allo-HSCT, achieved a second systemic remission with the donor-origin CD7 CAR-T. Both MM patients with EMD achieved stringent complete response; the patient treated with sequential BCMA/GPRC5D therapy remains in CR >8 months. The other MM patient died of septic shock at 5 months while in CR. Safety was favorable: Cytokine Release Syndrome was Grade 1 (n=4) , with no ICANS. Critically, no GvHD was induced or exacerbated by CAR-T therapy. The T-LBL and AML patients were successfully bridged to a second Haploidentical allo-HSCT and remain in continuous remission.

Table 1. Patient Characteristics and Outcomes

	Patient	Diagnosis	Age/Sex	EM Sites	CAR-T Type/Source	Dose (×10^6/kg)	Response (IMWG/ELN)	MRD Status	Follow-up (m)	Outcome	Toxicity

	1	MM	45/M	Bone marrow/ soft tissue	BCMA/Recipient PB	2	CR	Negative (flow)	5	Death while in CR(sepsis)	CRS G1, infection 5m post CART
	2	MM	42/M	Liver/lymph nodes/Bone marrow	Sequential BCMA+GPRC5D/ Recipient PB	2+2	CR	Negative (flow)	8	Ongoing CR; bridged HSCT	CRS G1
	3	T-LBL	32/F	CNS/multi-site EMD	CD7/Recipient PB	1	CR	Negative (flow)	2	Ongoing CR; bridged HSCT	CRS G1
	4	AML (CD7+)	32/M	bone marrow/ no EMD	CD7/Donor-derived	1	CR	Negative (flow)	4	Ongoing CR	CRS G1, infection gr2

Conclusions: This series provides powerful proof-of-concept that donor-origin CAR-T therapy is a feasible and highly effective strategy for patients at the frontier of treatment failure. We demonstrate that potent CAR-T cells can be generated from both "host-educated" and "pristine" donor lymphocytes, effectively eradicating EMD and overcoming serial resistance to both CAR-T and allo-HSCT. This "bridge-to-cure" approach transforms a terminal scenario into a potential planned, curative pathway. Limited by small sample size, short follow-up, and single-center design, these findings warrant prospective studies to optimize patient selection, timing, chimerism monitoring, and integration with consolidation therapies. While follow-up is ongoing, these findings offer a tangible new therapeutic paradigm for the most challenging post-transplant relapses and warrant validation in larger, prospective trials.

GEMTUZUMAB OZOGAMICIN ENABLES BRIDGING TO 2ND/3RD ALLO-HSCT WITH FAVORABLE OUTCOMES IN CD33-HIGH RELAPSED/REFRACTORY AML WITH POST–ALLO-HSCT RELAPSE

Xiaohong Liu[1], *Min Xiong*[2,1], *Jian-ping Zhang*[2,1], *Yue Lu*[2,1], *Xingyu Cao*[2,1], *Jing Long*[3], *Deyan Liu*[2,1]
[1]*Beijing Lu Daopei Hospital, Beijing, China,* [2]*Hebei Yanda Lu Daopei Hospital, Langfang, China,* [3]*Beijing Lu Daopei Institute of Hematology, Beijing, China*

Background: Post-transplant relapse of CD33-high AML is associated with extremely poor outcomes, particularly in patients(pts) refractory to salvage therapy. Gemtuzumab ozogamicin (GO), a CD33-directed antibody–drug conjugate, may provide disease control and enable subsequent transplantation. We evaluated GO in heavily pretreated CD33-high R/R AML relapsing after allo-HSCT, focusing on response, safety, and feasibility as a bridge to 2nd/3rd allo-HSCT.

Methods: We retrospectively analyzed R/R AML pts treated between September 2021 and March 2025 at Yanda and Beijing Lu Daopei Hospitals. All pts relapsed after allo-HSCT, had CD33 expression ≥80%, and failed conventional chemotherapy. Patients received GO monotherapy (3 mg/m² on days 1, 4, and 7) or GO combined with chemotherapy or targeted agents. Responses were assessed within 30 days, and responders were bridged to 2nd/3rd allo-HSCT. Follow-up was censored on October 1, 2025.

Results: Thirty-six pts were enrolled, and 34 were evaluable for analysis, median age was 38 years (range, 7–68), and 24 were male (70.6%). First HSCT was predominantly haplo (64.7%), with median time to relapse of 6.2 months (range, 1.7–25.9). Before GO, pts had received a median of 7 prior chemotherapy lines; 65% had complex karyotypes, and TP53 (n=5) 、FLT3-ITD (n=8) mutations , MLL rearrangements (n=7). Median BM blasts and MFC-MRD were 20.5% (5–79.5) and 16.9% (0.12–84.9), respectively. GO was administered in combination in 27 pts (79.4%) and as monotherapy in 7 (20.6%).
The overall response rate(ORR) was 61.8%(21/34), including CR in 20 pts (95.2%) and PR in 1 (4.8%), while 13 pts (38.2%) had no response. Among CR patients, 9/20 (45%) achieved MRD-negative CR. No moderate or severe GO-related adverse events were observed.
With a median follow-up of 4.8 months (0.2–31.4) after GO, 16 of 20 CR pts (80.0%) proceeded to 2nd/3nd allo-HSCT within 7–29 days (haplo n=13, MUD n=3). After HSCT, median follow-up was 11.8 months (0.4–30.5), with 1-year OS and LFS both 60.9% (95% CI, 36.4–85.47) (Figure 1A) and a 100-day incidence of grade III–IV aGVHD of 18.75% (95% CI, 6.76–52). Pts achieving MRD-negative CR had significantly superior 1-year OS/LFS compared with MRD-positive CR (87.5% [95% CI, 64.58–100] vs. 30% [95% CI, 0–64.37], p=0.041) (Figure 1B). Six post-transplant deaths occurred due to CD33-positive relapse (n=2), severe pneumonia or diffuse alveolar hemorrhage (n=3), and veno-occlusive disease (n=1).
Among 4 CR pts not bridged to HSCT, three relapsed and died at 1 and 7.5 months, while one survived 2.6 months and lost to follow-up (Figure 1A). Among 14 pts with NR/PR after GO, 12 received conventional therapy, and 11 died of CD33-positive relapse within 100 days;

the remaining two underwent salvage 2nd allo-HSCT at days 10 and 11 after GO and remain disease-free at 3.7 and 27.5 months.

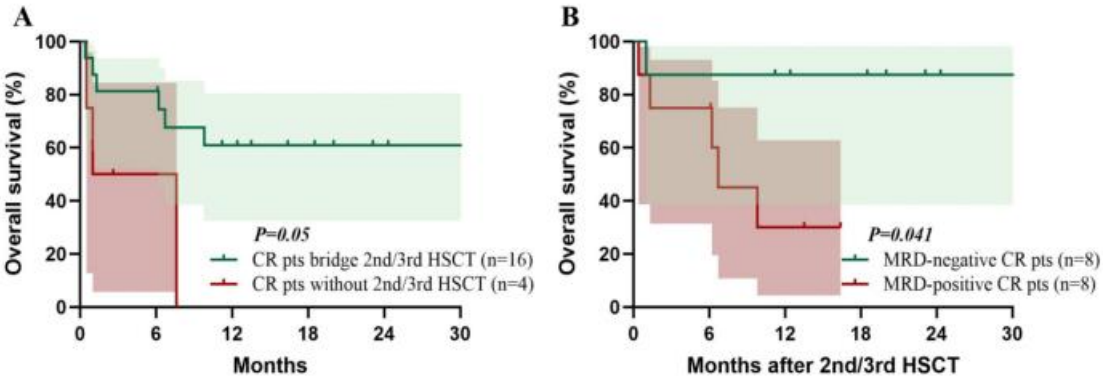

Figure 1. Survival of GO-induced CR patients stratified by bridging to 2nd/3rd allo-HSCT (A) and by MRD status (MRD-negative vs MRD-positive CR) among those undergoing 2nd/3rd allo-HSCT (B).

Conclusions: In heavily pretreated CD33-positive R/R AML pts relapsing after allo-HSCT, GO is an effective and well-tolerated therapy, achieving a high CR rate.Early bridging to second/third allo-HSCT in CR markedly improves survival, particularly in those with MRD-negative.The role of salvage second/third allo-HSCT in GO-refractory pts warrants further evaluation in larger cohorts.

LONGITUDINAL IMPROVEMENT IN SURVIVAL AFTER ALLOGENEIC STEM CELL TRANSPLANTATION: A 15-YEAR SINGLE-CENTRE EVALUATION OF QUALITY INITIATIVES

Safia Belbachir[1], *Bianca Nguyen*[1], *Celeste Hill*[1], *Kathryn Cassidy*[1], *Diane Sutherland*[1], *Julian Cooney*[1], *Matthew Wright*[1], *Usha Chandra Sekaran*[1], *Paul Cannell*[1], *Duncan Purtill*[1]
[1]*Fiona Stanley Hospital, Murdoch, Australia*

Background: Outcomes following allogeneic haematopoietic stem cell transplantation (allo-HSCT) have improved over time, although the relative contribution of evolving clinical practice and structured quality initiatives remains unclear. At our centre, several major practice changes were implemented sequentially over a 15-year period, including relocation to a new hospital site(2015), introduction of intravenous busulfan with pharmacokinetic dose adjustment(2016), FACT accreditation(2018), and adoption of antithymocyte globulin (ATG) for unrelated donor transplantation(2020). We examined longitudinal survival outcomes to evaluate temporal trends and their association with these changes.

Methods: We included consecutive adult patients undergoing first allo-HSCT between 2008 and 2023 . Patient, transplant, and outcome data were obtained from the CIBMTR registry and supplemented by a FACT-validated local quality database. Survival analyses were performed using Kaplan–Meier methods and multivariable Cox regression. To explore temporal effects, the cohort was analysed both as a continuous function of transplant year and across four sequential eras: 2008–2014, 2015–2017, 2018–2020, and 2021–2023.

Results: Among 581 consecutive adult patients undergoing first allogeneic stem cell transplantation between 2008 and 2023 , the median follow-up was 74.2 months (range 15–277), and the median age at transplant was 49 years (range 16–71). Patients stratified into the four transplant eras were approximately equal in size : 2008–2014 (n=187), 2015–2017 (n=112), 2018–2020 (n=130), and 2021–2023 (n=153).
Recipient age and comorbidity burden increased progressively over time (median age by era: 45, 51, 50, and 53 years; p<0.001), alongside a marked shift toward reduced-intensity conditioning, which increased from 9% to 45% of transplants across eras (p<0.001).
Overall survival (OS) improved significantly over calendar time, corresponding to a 4.7% relative reduction in mortality per transplant year (HR 0.953, 95% CI 0.928–0.979; p=0.0004). In multivariable analysis, later year of transplant remained independently associated with improved survival, even after adjustment for increasing age, which was itself an independent risk factor for higher mortality (HR 1.014 per year, 95% CI 1.004–1.023; p = 0.004). Disease risk index (rDRI), donor type, and HCT-CI were not significantly associated with OS.

One-year OS for the entire cohort was 74% and increased sequentially by era: 71% in 2008–2014, 72% in 2015–2017, 76% in 2018–2020, and 77% in 2021–2023 (p=0.037), with the most pronounced improvement observed after 2018 coinciding with the period following FACT accreditation . NRM remained low across eras (3.8% vs 2.9% at day100; 9.7% vs 7.0% at 1year), while the later period was characterised by significantly reduced relapse incidence (sHR 0.51; p<0.001) and numerically lower rates of moderate-to-severe chronic GVHD (15% vs 24%,p=0.057).
Conclusions: Survival outcomes improved sequentially over time at our program despite an increasingly older and more comorbid transplant population, demonstrating that sustained systematic evolution can offset rising patient-related risk. Interestingly, the most pronounced improvement occurred after 2018, coinciding temporally with the period following FACT accreditation, while other major practice changes were not associated with effects of similar magnitude. These findings suggest that structured quality management frameworks may contribute to improved allogeneic transplant outcomes.
Disclosure: None to disclose.

Background: Endothelial activation plays a key role in CAR T-cell therapy-related complications, such as CRS, ICANS and HLH. CAR-T patients are potentially at increased risk for thrombotic microangiopathy (TMA) and we here present the first case series from EBMT centres, collected by the Transplant Complications Working Party (TCWP).

Methods: EBMT CAR-T centres were contacted by e-mail to identify cases. A retrospective collection of detailed data was subsequently carried out with a study specific form. TMA was defined according to diagnostic criteria described by Schoettler et al (Transplant Cell Ther 2023).

Results: We identified six cases of CAR T-cell associated TMA: one patient with B-ALL and five with malignant B-cell lymphoma: large B-cell lymphomas (n=3), follicular lymphoma (n=1), mantle cell lymphoma (n=1). Overall, 215 EBMT CAR-T centres were contacted, and 90 responded indicating that they had no eligible patients.
Among lymphoma patients, CAR T-cell products included axi-cel (n=3), brexu-cel (n=1) and tisa-cel (n=1). Median age at CAR-T infusion was 63 years (range, 41–75). Median time from lymphoma diagnosis to infusion was 25.6 months. No patients had previous autologous HCT, median ECOG at CAR-T was 2, and only one patient was in CR at infusion. Three patients received two prior lines of therapy, 1 received three and 1 received five or more. TMA developed after a median of 8 days after CAR-T infusion (range, 6–237). Diagnostic features included anemia (60%), elevated LDH above threshold (100%), thrombocytopenia (100%), proteinuria (60%), hypertension (80%) and elevated schistocytes (40%), C5b-9 was assessed in four of the five patients and none showed elevated levels. One case was biopsy-proven. Four patients met high-risk criteria with peak LDH >2×ULN. Clinically significant renal involvement with proteinuria ≥30 mg/dL occurred in two patients and pulmonary involvement in two. Three were given treatment for their TMA (corticosteroids, antihypertensive therapy, or ravulizumab). Before TMA onset, all patients had experienced CRS (mostly grade II), which overlapped temporally with TMA; four patients also developed ICANS (grade 1–4). All patients developed infectious complications post-CAR T, though only one had a clinically active infection at TMA onset.
Two patients achieved complete remission (CR) of their lymphoma. Three patients died from disease progression at 20, 31 and 203 days post CAR-T. The two remaining patients were still

alive at last follow up.
The identified case of B-ALL was a 42-year-old woman who had undergone allogeneic HCT 33 months prior to brexu-cel infusion. She developed TMA 442 days after CAR-T infusion, with anemia, thrombocytopenia, elevated LDH, schistocytes, elevated C5b9, biopsy confirmation, and LDH >2× ULN. Multisystem involvement (cardiovascular, serosal, gastrointestinal, CNS) was observed. Treatment included corticosteroids, plasma exchange, tocilizumab, and long-term eculizumab. She remains in CR of her B-ALL, 699 days after CAR-T.

Conclusions: This case-series suggests that TMA after CAR T-cell therapy, although rare, is clinically significant and frequently requires management. All patients exhibited preceding CRS and most ICANS, hinting that inflammatory triggers may play a relevant role. Continued vigilance and dedicated prospective data collection are needed to characterise incidence and treatment strategies of TMA after CAR-T-cell therapy.

THE IMPACT OF PRE-TRANSPLANT ISOAGGLUTININ REDUCTION IN MAJOR AND BIDIRECTIONAL ABO-MISMATCHED ALLOGENEIC STEM CELL TRANSPLANTATION – A TWO CENTRE COMPARISON

*Xiaowen Wu[1], Eric B.N. Evans[2], **Safia Belbachir**[2], Annette Le Viellez[3], Julian Cooney[2], Devendra Hiwase[1]*
[1]Royal Adelaide Hospital, Adelaide, Australia, [2]Fiona Stanley Hospital, Perth, Australia, [3]Pathwest Laboratory Medicine, Perth, Australia

Background: ABO incompatibility occurs in 40-50% of allogeneic haematopoietic stem cell transplants (alloHSCT). In major/bidirectional ABO mismatch, high recipient isoagglutinin titres are associated with increased risk of pure red cell aplasia (PRCA) and delayed erythroid engraftment. Pre-transplant interventions to reduce titres are widely used; however, their efficacy remains uncertain, and no consensus exists regarding the optimal approach.

Methods: We conducted a retrospective study of all major and bidirectional ABO-mismatched alloHSCTs performed at two centres in Australia to evaluate whether pre-transplant isoagglutinin reduction is effective in reducing PRCA incidence and red blood cell (RBC) transfusion requirement. The two centres are Royal Adelaide Hospital (RAH), South Australia, which routinely performed isoagglutinin reduction using donor secretor plasma and/or plasma exchange in patients with high baseline titres (defined as ≥32), and Fiona Stanley Hospital (FSH), Western Australia, which did not. Transplants performed between 2012-2021 at RAH and 2016-2023 at FSH were included. Data collected included baseline characteristics, ABO blood groups, recipient isoagglutinin titres, pre-alloHSCT interventions, day-60 haemoglobin level, cumulative RBC transfusions (total units transfused at 6 months post-transplant, censored at death/relapse) and incidence of PRCA (defined as persistent

anaemia with reticulocytopenia beyond day 60, transfusion dependence beyond day 60 and bone marrow erythroblasts <5%). Umbilical cord blood transplants and patients with deaths before day-60 were excluded.

Results:
A total of 148 major/bidirectional ABO-mismatched alloHSCTs were performed during the study period (61 at RAH and 87 at FSH). The median baseline isoagglutinin titre were 64 (IQR 16-256) at RAH and 64 (IQR 16-128) at FSH (figure 1A). There were 97 patients with high titres (≥32) and 35 (36%) of them received pre-transplant interventions. PRCA occurred less frequently in those who received intervention compared to the non-intervention group but this was not statistically significant (5.7% vs 16.1%, p=0.135). At day 60, the median haemoglobin level was significantly lower in patients who developed PRCA compared to non-PRCA patients (69g/L vs 95g/L, p<0.0001, figure 1B) and significant higher in the low titre group compared to the high titre group (99g/L vs 92g/L, p=0.023, figure 1C). There was a trend towards higher haemoglobin level at day 60 in the intervention group compared to the non-intervention group (96g/L vs 89g/L, p=0.054, figure 1D). Patients who developed PRCA had significantly higher RBC transfusion requirement compared to non-PRCA patients (median 19 vs 10 units, p=0.003, figure 1E). There was no statistically significant difference in RBC transfusion requirement between the intervention and non-intervention group (median 9 vs 14 units, p=0.633, figure 1F).

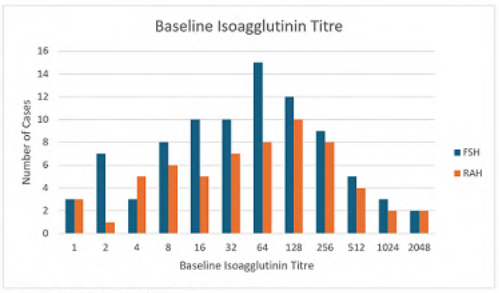

Figure 1A: Baseline isoagglutinin titre

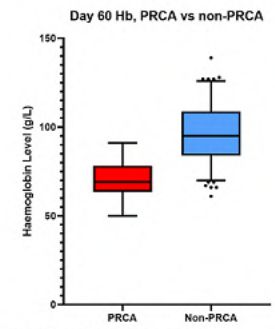

Figure 1B: Day 60 Hb, PRCA vs non-PRCA

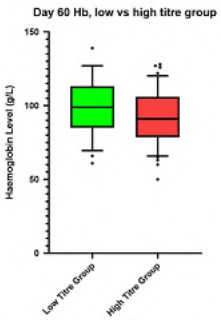

Figure 1C: Day 60 Hb, low titre vs high titre group

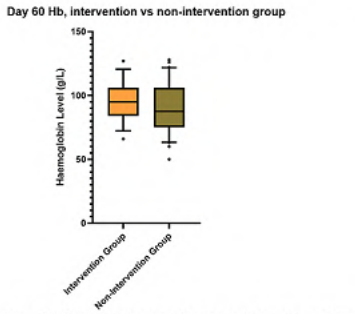

Figure 1D: Day 60 Hb, intervention vs non-intervention group

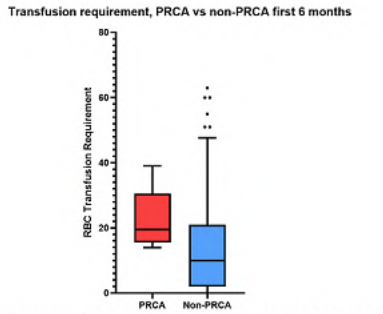

Figure 1E: RBC transfusion requirement, PRCA vs non-PRCA

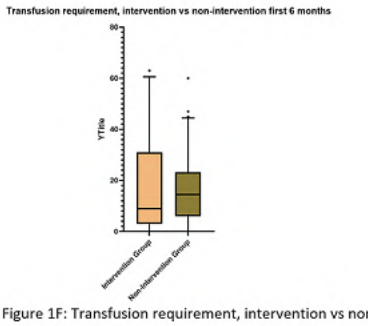

Figure 1F: Transfusion requirement, intervention vs non-intervention group

Conclusions: Pre-transplant isoagglutinin reduction was not associated with a statistically significant reduction in PRCA incidence or cumulative RBC transfusion requirement following major/bidirectional ABO mismatched alloHSCT due to the relative small sample size of our study. High baseline isoagglutinin titres and development of PRCA were associated with lower

day-60 haemoglobin level and higher RBC transfusion requirement. These findings, although limited by the study's retrospective design and sample size, highlight the need for larger prospective randomised trials to definitively assess the utility of titre-reduction strategies.

A204

SAFETY AND EMERGING CLINICAL IMPACT OF CD19 CAR T-CELL THERAPY IN SEVERE AUTOIMMUNE RHEUMATIC DISEASES: A SINGLE-CENTRE CASE SERIES

Aitomi Bittner[1,2], *Fredrik Albach*[1], *Mareike Frick*[1], *Frederik Damm*[1], *Gogolok Julia*[1], *Sebastian Serve*[1], *Benjamin Nick Locher*[1], *Ioanna Minopoulou*[1], *Arnd Kleyer*[1], *Robert Biesen*[1], *Vincent Casteleyn*[1], *Elise Siegert*[1], *Edgar Wiebe*[1], *Anne Pankow*[1], *Marie Rehm*[1], *Christian Furth*[1], *Kamran Movassaghi*[1], *Eva Schrezenmeier*[1], *Udo Schneider*[1], *Lars Bullinger*[1], *Gerhard Krönke*[1], *David Nils Simon*[1], *Olaf Penack*[1]
[1]*Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany,* [2]*Berlin Institute of Health, Berlin, Germany*

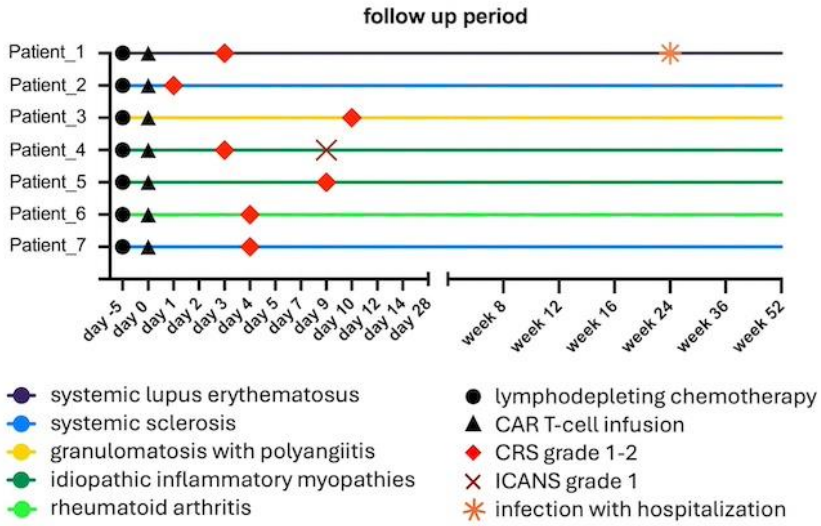
Background: Autoimmune rheumatic diseases (ARDs) can cause progressive organ damage and substantial disability despite modern immunosuppression, partly due to persistent pathogenic B-cell activity. Current B-cell-directed therapies often achieve incomplete depletion, allowing autoreactivity to recur. CD19-directed CAR T-cells enable deeper B-cell depletion with the potential for an immune "reset", yet clinical data in ARDs remain very limited. This study reports feasibility, immune-cell dynamics, toxicity, and emerging clinical impact following autologous CD19 CAR T-cell therapy with KYV-101, a fully human, anti-CD19 CAR T-cell with CD28 costimulation, in a cohort with severe, refractory ARDs.

Methods: Seven adult patients (age 32–71 years; 4/7 female) with severe, treatment-refractory ARDs, including idiopathic inflammatory myopathies (n=2), systemic sclerosis (n=2), rheumatoid arthritis (n=1), systemic lupus erythematosus (n=1), and granulomatosis with polyangiitis (n=1) were treated under a named-patient (individual therapeutic use) approach after multidisciplinary review and informed consent. All patients received lymphodepletion (mainly fludarabine/cyclophosphamide; dose-adjusted fludarabine for renal impairment; bendamustine as alternative in severe renal dysfunction) followed by a single KYV-101 infusion. Inpatient monitoring was performed for at least 10 days, followed by outpatient longitudinal follow-up for ≥12 months.

Results: CAR T-cell expansion peaked at a median of day 10 (IQR 10–12), reaching a median peak of 366.7 CAR T-cells/µL (IQR 136.6–384.4) and a median of 31.5% of circulating T cells at peak. $CD19^+$ B cells became undetectable in all patients within 24 hours after infusion followed by B-cell reconstitution occurring in 4/7 between weeks 8–24. All patients experienced a clinical response and are currently off background medications. Cytokine Release Syndrome (CRS) was observed in all patients but remained uniformly mild, limited to grade 1 (4/7) or grade 2 (3/7), with a median onset on day 4 (IQR 3–9). All cases

responded promptly to tocilizumab, and four patients received additional dexamethasone. No intensive care support was required. Immune Effector Cell-Associated Neurotoxicity Syndrome (ICANS) was infrequent and mild (1/7, grade 1, ICE 9/10) and resolved within 24 hours following dexamethasone. Anticipated early (within 30 days) Grade 3-4 neutropenia occurred in 5/7, infections were observed in 2/7 and responded to antibiotics. Late-onset severe neutropenia (immune effector cell-associated haematotoxicity grade 3) occurred in 2/7 (weeks 8 and 24) and recovered after G-CSF, including one episode complicated by neutropenic pneumonia. Additionally, some patients experienced transient, localised, disease-site specific inflammation likely connected to CAR T-cell activity. These events were self-limiting or manageable with supportive care.

Figure 1:
Timeline of patients with ARDs treated with CD19 CAR T-cells



Conclusions: In this cohort of patients with severe, treatment-refractory ARDs, KYV-101 induced rapid, profound B-cell depletion, leading to a durable, drug-free response with a manageable safety profile over ≥12 months. CRS events were uniformly low grade and controllable with early, protocolised intervention. Haematotoxicity, particularly neutropenia, including delayed episodes, represented a relevant component of the adverse event spectrum and responded to supportive care. Overall, these findings support the feasibility of CD19 CAR T-cell therapy in ARDs, provided it is administered in centres with established expertise in cell therapy.

SINGLE CENTRE EXPERIENCE OF USING A THERAPEUTIC PLATELET REGIME DURING AUTOLOGOUS STEM CELL TRANSPLANT

*Thomas Taylor[1], Alexander Glover[1], Alexander Bashford[1], Gerardo Errico[1], **Malik Saeed**[1], Yadanar Lwin[1], Jenny Byrne[1]*
[1]Nottingham University Hospitals, Nottingham, United Kingdom of Great Britain and Northern Ireland (the)

Background: Historically, our centre administered prophylactic platelet transfusions during autologous transplantation when counts fell below 10 $\times 10^9$/L. However, updated guidance from the BSH, EBMT, and JCO has questioned the necessity of routine prophylaxis in this setting. Following the UK national platelet shortage in 2022, we implemented a therapeutic platelet transfusion strategy for a carefully selected cohort of patients undergoing autologous stem cell transplantation. Under this approach, platelet transfusions are reserved for episodes of bleeding (WHO grade ≥1) or for pre-procedural optimisation.

Methods: Beginning in 2022, eligible patients were identified prior to admission for transplant based on the following criteria: first high-dose procedure, age <65 years, absence of CNS disease, no increased risk of falls, and no additional bleeding risk factors as determined by the treating physician. Under the therapeutic protocol, platelet transfusions were administered only for bleeding or for pre-procedural optimisation to achieve guideline recommended target values. Patients admitted to the intensive care unit were automatically removed from the therapeutic strategy, due to the high prevalence of sepsis and frequent need for procedures. Bleeding events were captured retrospectively from patient records. The therapeutic platelet cohort was compared with a demographically matched historical cohort meeting identical inclusion criteria and managed with prophylactic platelets. Statistical comparisons were performed using a t-test for parametric values and a Mann-Whitney test for non-parametric values.

Results: A total of 50 patients were included in each cohort. Most underwent high-dose melphalan-conditioned autologous transplantation (41/50 in the prophylactic group and 43/50 in the therapeutic group). Mean age was 52 in both cohorts. Median platelet engraftment was similar: 12 days (IQR [11-14]) in the prophylactic group versus 13 days (IQR [13–15]) in the therapeutic group. Median platelet nadir was lower in the therapeutic group (5 $\times 10^9$/L, IQR [2–8]) than in the prophylactic group (8$\times 10^9$/L, IQR [5–11]) ($p = 0.003$). Patients in the prophylactic group spent a median of 1 day (IQR [0-1]) with platelet counts <10 $\times 10^9$/L versus 2 days (IQR [1–4]) in the therapeutic group ($p < 0.0001$). Bleeding events were low in both groups: five patients in the prophylactic group experienced WHO grade 1 bleeding versus seven in the therapeutic group, with an additional two WHO grade 2 events in the therapeutic cohort. No grade 3 or 4 bleeding episodes were observed.

Significantly fewer platelet transfusions were used in the therapeutic cohort (14 vs. 66; $p < 0.001$), with 13 patients receiving at least one transfusion versus 42 in the prophylactic group. The therapeutic approach resulted in £11,500 less spent on platelet provision for the 50 patients based on NHSBT component pricing alone.

Conclusions: A therapeutic platelet transfusion strategy is feasible in selected patients undergoing autologous stem cell transplantation. This approach significantly reduces platelet usage and associated costs, without increasing clinically significant bleeding. Limitations of this study include the low number of severe bleeding events, which may limit statistical power. Our centre has now stopped the use of prophylactic platelets in autologous transplantation when the above criteria are met.

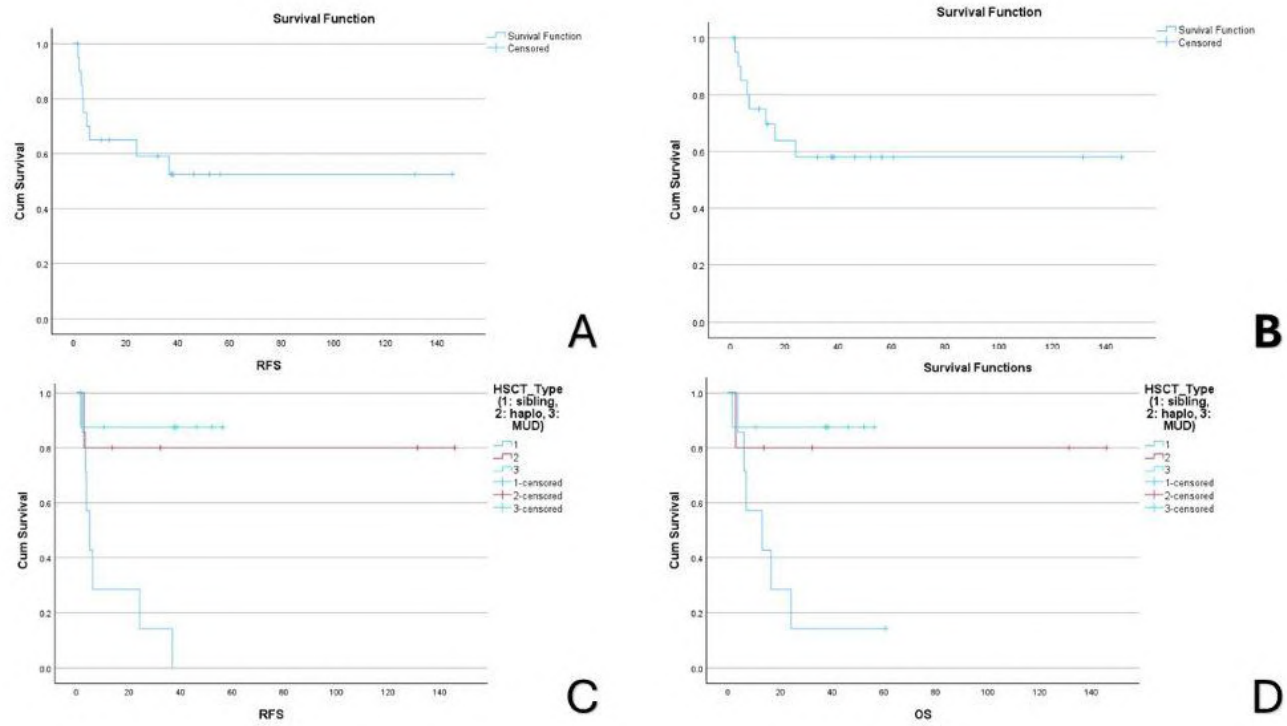
ALLOGENEIC HSCT FOR ADVANCED STAGE AND RELAPSED/REFRACTORY EXTRANODAL NK/T CELL LYMPHOMA (ENKTCL): A SINGLE INSTITUTION EXPERIENCE IN L-ASPARAGINASE ERA

Thomas Sau Yan Chan[1], *Garret Leung*[1], *Yok Lam Kwong*[2], *Eric Tse*[2]
[1]*Queen Mary Hospital, Hong Kong, China,* [2]*The University of Hong Kong, Hong Kong, China*

Background: Extranodal NK/T-cell lymphoma (NKTCL) is an aggressive lymphoma with poor prognosis, especially in advanced or relapsed/refractory cases. L-asparaginase–based regimens have improved outcomes in newly-diagnosed cases. For relapsed/refractory cases, use of immune checkpoint inhibitors induces high response rates. Hence, although allogeneic hematopoietic stem cell transplantation (allo-HSCT) offers the potential to achieve durable remission through a graft-versus-lymphoma effect, it is infrequently needed. Recent international data of allo-HSCT in NKTCL showed 3-year progression-free-survival and overall-survival (OS) of 48% and 55%. However, factors influencing allo-HSCT outcome, including donor types and prior exposure to immune checkpoint inhibitors, remain undefined. We conducted a retrospective single-center analysis to address these issues.

Methods: Consecutive NKTCL patients undergoing allo-HSCT in an 18-yer period were analyzed. There were no exclusion criteria. Analyzed outcomes included incidence and severity of acute and chronic graft-versus-host disease (GVHD), non-relapse mortality (NRM), relapse-free-survival (RFS) and OS.

Results:



From 2007 to 2025, twenty-one patients underwent allo-HSCT for ENKTCL. There were fourteen men and seven women, at a median age of 41(Table 1). Five patients had previously been reported. Indications for allo-HSCT included high-risk disease in first complete remission (CR1) (N=11, 52%), relapsed disease in CR2 (N=7, 33%), and refactory disease (N=3, 14%). Donors were voluntary unrelated (N=9, 43%), matched sibling (N=7, 33%) and haploidentical (N=5, 24%). In the majority of cases, peripheral blood HSC (N=17, 81%) and myeloablative conditioning (N=14, 67%) were used. GVHD prophylaxis were summarized in table 1.

Prognostic factors including pre-transplant disease status (CR1 vs. CR2; CR vs. <CR), PINK-E risk categories and circulating EBV DNA load did not significantly predict survival. However, recipients of matched sibling donor grafts demonstrated inferior RFS and OS compared with unrelated or haploidentical donor recipients ($P < 0.01$ and $P = 0.03$, respectively) (Figure 1). Regarding toxicity, the 1-year non-relapse mortality (NRM) was 20%. Grade 3–4 acute GVHD occurred in three patients (14.3%), while moderate-to-severe chronic GVHD occurred in five patients (24%) by one year. Eight patients had received a PD-1 inhibitor as part of their last regimen prior to HSCT. Our standard practice mandates discontinuing PD-1 inhibitors at least four weeks before stem cell infusion to mitigate GVHD risk; the median washout period in this cohort was 114 days. Prior exposure to PD-1 inhibitors did not increase the risk of grade 3–4 acute GVHD or moderate-to-severe chronic GVHD.

Parameters	Value	

Age	Median 41 (range: 25-66)	
Sex	M: 14 (67%), F: 7 (33%)	
Stage at HSCT	Stage II: 1 (5%), stage IV: 20 (95%)	
Bone marrow involvement	Yes: 12 (57%), No: 9 (43%)	
Primary site	Nasal: 16 (76%), non-nasal: 5 (24%)	
PINK-E score risk group	Low (0-1): 4 (19%) Intermediate (2): 8 (38%) High (< or =3): 9 (43%)	
L-asparaginase based therapy	Yes: 21 (100%)	
Regimens:	First line regimens	SMILE: 7 (33%) SIMPLE: 7 (33%) SMILE + PD-1 inhibitor: 1 (5%) SIMPLE + PD-1 inhibitor: 1 (5%) GDP + L-asparaginase: 1 (5%) Non-asparaginase based: 4 (19%)
	Second line regimens	SMILE: 4 (29%) PD-1 inhibitor alone: 3 (21%) GDP: 2 (15%) PD-1 inhibitor + chemotherapy: 4 (29%)
	Third line regimens	PD-1 inhibitor + chemotherapy: 2 (40%) SIMPLE: 1 (20%) SMILE: 1 (20%) Daratumomab: 1 (20%)
	Fourth line regimens	ESHAP: 1 (50%) PD-1 inhibitor: 1 (50%)

PD-1 inhibitors prior to HSCT	Yes:11 (52%) No: 10 (48%)	
Disease status prior to HSCT	CR1: 11 (52%) CR2: 7 (33%) PR: 1 (5%) PD: 2 (10%	
Conditioning regimens	Flu-TBI-PTCY: 7 (33%) Cy-TBI: 7 (33%) TBF-PTCY: 3 (14%) Flu-Bu: 3(14%) Big CBV: 1 (5%)	
GVHD prophylaxis	PTCY, CsA, MMF: 10 (48%) ShMTX, CsA, MMF: 5 (24%) ShMTX, CsA: 6 (28%)	
Table 1		

Conclusions: Allogeneic HSCT remains a potentially curative option for advanced stage ENKTCL, achieving durable survival in over half of the cohort. While pre-transplant disease depth did not statistically stratify outcomes in this series, donor selection emerged as a significant prognostic factor, with unrelated and haploidentical grafts yielding superior RFS and OS compared to matched sibling transplants. Furthermore, prior exposure to PD-1 inhibitors did not significantly increase the risk of severe GVHD, supporting the safety of sequencing checkpoint inhibition before transplantation when an appropriate washout period is observed.

Disclosure: None

A207

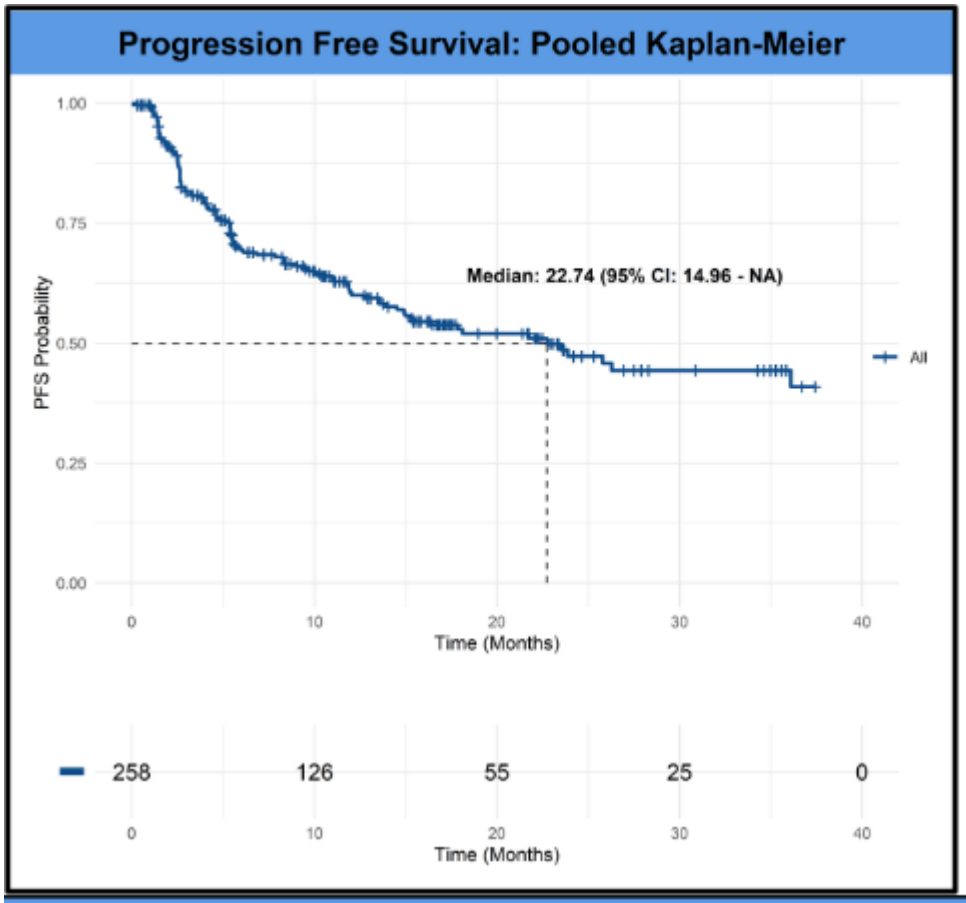
EFFICACY AND SAFETY OF CD20XCD3 BISPECIFIC ANTIBODIES IN RELAPSED OR REFRACTORY INDOLENT B-CELL NON-HODGKIN LYMPHOMAS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Fernando Gibran-Nunes[1], *Henrique Pêcego*[2], *Juliana Bosco Santos*[1], *Letícia Graciolli*[3], *Igor Costa*[4], *Jacqueline Rena*[1], *Marcos Fogale*[1], *Ana Fonseca*[1], *Anita Cortez*[1], *Aliana Ferreira*[1], *Maria Seiwald*[1], *Erick Xavier*[1], *Mariana Serpa*[1], *Luciana Tucunduva*[1], *Yana Novis*[1]
[1]*Hospital Sirio Libanês, São Paulo, Brazil,* [2]*D'Or Institute for Research and Education, Rio de Janeiro, Brazil,* [3]*Faculdade de Medicina de Jundiaí, Jundiaí, Brazil,* [4]*Universidade Estadual Paulista - UNESP, Botucatu, Brazil*

Background: Patients with relapsed/refractory (R/R) indolent non-Hodgkin lymphoma (iNHL) have limited therapeutic options and progressively shorter durations of response with subsequent therapies. CD20xCD3 T-cell engaging bispecific antibodies (BsAbs) are a novel therapeutic class designed to redirect T-cells to eliminate malignant B-cells.

Methods: We conducted a systematic review and meta-analysis to evaluate efficacy and safety of CD20xCD3 BsAbs (mosunetuzumab, epcoritamab, odronextamab, and glofitamab) in patients with R/R iNHL. Following a pre-registered protocol (PROSPERO CRD420251158501), we systematically searched PubMed, Cochrane, and Embase for studies evaluating CD20xCD3 BsAbs in R/R iNHL. Binary outcomes were pooled using random-effects proportional meta-analyses with Freeman-Tukey double arcsine transformation. We reconstructed individual patient data (IPD) from published Kaplan-Meier (KM) curves to synthesize time-to-event outcomes, generating pooled KM estimates.

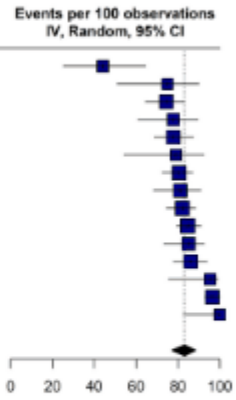
Results:



Overall Response Rate

Study	Event	Total	Weight	Prevalence	95% CI
Budde 2024 (Mosunetuzumab / MCL)	11	25	5.5%	44.00	[25.17; 64.62]
Wang 2023 (Mosunetuzumab / MCL)	15	20	5.0%	75.00	[50.86; 89.95]
Bartlett 2024 (Mosunetuzumab / FL)	70	94	7.6%	74.47	[64.44; 82.92]
Bannerji 2020 (Odronextamab/ FL cohort)	28	36	6.2%	77.78	[60.73; 89.48]
Sehn 2025 (Mosunetuzumab / FL)	70	90	7.6%	77.78	[68.49; 87.25]
Goto 2025 (Mosunetuzumab / FL)	15	19	4.9%	78.95	[54.26; 92.30]
Kim 2024 (Odronextamab/ FL)	103	128	7.9%	80.47	[72.53; 86.94]
Morschhauser 2021 (Glofitamab / FL) - Monotherapy cohort	43	53	6.9%	81.13	[68.18; 90.90]
Linton 2024 (Epcoritamab / FL) - Pivotal cohort	105	128	7.9%	82.03	[74.34; 88.36]
Iacoboni 2024 (CD20/CD3-targeted BsAbs / FL)	143	169	8.1%	84.62	[79.20; 90.96]
Phillips 2024 (Glofitamab / MCL)	51	60	7.0%	85.00	[73.18; 92.47]
Linton 2024 (Epcoritamab / FL) - Optimisation cohort	74	86	7.5%	86.05	[77.81; 93.94]
Izutsu 2025 (Epcoritamab / FL)	20	21	5.1%	95.24	[75.49; 99.20]
Falchi 2024 (Epcoritamab / FL)	107	111	7.8%	96.40	[92.65; 99.99]
Morschhauser 2021 (Glofitamab / FL) - Combination therapy cohort	19	19	4.9%	100.00	[82.28; 100.00]
Total (95% CI)	**874**	**1059**	**100.0%**	**83.06**	**[76.95; 88.44]**

Heterogeneity: $Tau^2 = 0.0160$; $Chi^2 = 60.18$, $df = 14$ ($P < 0.0001$); $I^2 = 76.7\%$



We included 13 studies with a total of 1059 patients. The pooled overall response rate (ORR) for the entire cohort was 83.06% (95% CI: 76.95-88.44), and the complete response rate (CRR) was 67.43% (95% CI: 60.63-73.90). ORR in high-risk groups was 77.08% (95% CI: 69.88-83.65) in double-refractory patients and 81.57% (95% CI: 74.45-87.83) in the POD24 population. No significant difference was found between treatment-to-progression (83.15%) and fixed-duration (81.90%) strategies (p=0.7870). Reconstructed time-to-event data showed a pooled median progression-free survival (PFS) of 22.74 months (95% CI: 14.96 – NA; n=258), with a 36-month PFS rate of 44.3%. For 156 responders, the median duration of response (DOR) was 34.48 months (95% CI: 16.52 – NA). The median overall survival (OS) was not reached (95% CI: Not Estimable; n=239), with a 36-month OS rate of 74.1%. Key safety findings included an incidence of any-grade cytokine release syndrome (CRS) of 56.55% (95% CI: 48.41-64.53) and any-grade ICANS of 2.30% (95% CI: 0.66-4.61). Treatment discontinuation due to adverse events occurred in 9.98% (95% CI: 5.81-15.00) of patients.

Conclusions: CD20xCD3 bispecific antibodies demonstrate substantial clinical activity and induce high, durable complete response rates in heavily pretreated patients with R/R iNHL, including those with high-risk features. The safety profile is manageable, with CRS being the most common adverse event of special interest, although predominantly low-grade. These findings support BsAbs as a new, effective therapeutic class for indolent lymphomas.

Disclosure: Nothing to declare.

ACCESS TO CAR-T CELL THERAPY IN CENTRAL AND EASTERN EUROPE (CEE) – PERSISTENT DISPARITIES

Karolina Liszka[1], *Grzegorz Basak*[2], *Anca Colita*[3], *Renata Formankova*[4], *Lidia Gil*[5], *Borko Gobeljić*[6], *Oleksandr Istomin*[7], *Simona Ivančan*[8], *Krisztián Kállay*[9], *Annalisa Ruggeri*[10], *Zrinko Šalek*[11], *Lucie Sramkova*[4], *Peter Švec*[12], *Andrej Vranovsky*[13], *Tomasz Wróbel*[1], *Juergen Kuball*[14], *Krzysztof Kałwak*[1]

Background: CAR-T therapy represents a major advancement in the treatment of hematological malignancies. Despite improved access and introduction of new commercial

products, significant disparities in availability persist across the Central and Eastern European region.

Methods: We surveyed representatives from 15 countries in the region. Participation in the survey was voluntary. Ethics approval was considered unnecessary due to the use of non-identifiable institutional data. Respondents provided information current as of October/November 2025. No response was received from Bulgaria. Lithuania withdrew from participation, but basic data were found in open access sources. Respondents answered six questions regarding access to CAR-T therapy in both adult and pediatric patients in their countries.

Results: The findings reveal substantial inequality in access to CAR-T therapy across the region. The earliest accreditation for adult *tisagenlecleucel* therapy in the region was granted in Czech Republic in 2019, while the first pediatric accreditation was issued in Poland the same year. These two countries were the first to administer CAR-T cells to adult patients in 2019, followed by the first pediatric infusions in 2020. Both countries have since established national CAR-T programs, performing hundreds of infusions across multiple certified centers. Slovenia and Croatia began treating both adult and pediatric patients in 2020. Belarus reported its first adult treatment in 2020. Russia initiated CAR-T cell therapy in pediatric patients in 2018 and in adults in 2022. Romania reported the simultaneous initiation of adult and pediatric treatments in 2022. Hungary began treating adults in 2022 and children in 2024. Slovakia treated its first adult patient in 2023, with the first pediatric infusion conducted in November 2025. Several countries in the region have not yet received accreditation for any commercial CAR-T products. Ukraine, Latvia, Estonia and Serbia, currently lack access to CAR-T therapies. Belarus and Lithuania report using domestically produced, academic, point of care CAR-T cells. The majority of countries provide reimbursement for CAR-T therapy. In Belarus, access to CAR-T cell treatment is provided through state-funded academic programs. Russia reported region-specific reimbursement since 2025, with full government reimbursement expected in 2026. The most commonly reported barriers of limited availability and difficulty in introducing CAR-T therapy to the market include insufficient funding, regulatory obstacles and lack of commercial incentives for pharmaceutical companies in smaller markets. In Ukraine, the ongoing war and reimbursement challenges significantly impede implementation. Notably, access for pediatric patients remains more restricted than for adults, both in terms of the number of accredited centers and the availability of commercial products.

Number of patients treated with CAR-T cell therapy

Table 1: Number of adult and pediatric patients treated with CAR-T cells in the Central and Eastern European region
Legend: A – adult, P – pediatric; n/a – data not available

Conclusions: Our results highlight an urgent need for coordinated regional efforts to reduce disparities in access to CAR-T therapy across the region. Development of national reimbursement systems, investment in healthcare infrastructure, optimizing of referral pathways and strengthened international collaboration are essential. Supporting the development of both commercial and academic CAR-T programs is necessary. Sustained efforts in data collection, outcome monitoring and sharing of best practice are crucial for shaping effective policies and ensuring equitable access to CAR-T therapies for residents of CEE countries.

HYPOFIBRINOGENEMIA AND SYSTEMIC INFLAMMATION FOLLOWING BCMA-DIRECTED CAR-T THERAPY: A RETROSPECTIVE STUDY

Almudena Zaratiegui[1], *Jose María Sánchez-Pina*[1], *Natalia Vega-Larburu*[1], *Magdalena Corona*[1], *María de las Nieves López-Muñoz*[1], *Adolfo Jesús Sáez Marín*[1], *Guillermo Ramos-Moreno*[1], *Daniel Gil Alós*[1], *María Pilar Martínez-Sánchez*[1], *Rafael Alberto Alonso-Fernández*[1], *María Calbacho*[1], *Joaquín Martínez-López*[1]
[1]*12 de Octubre University Hospital, Madrid, Spain*

Background: Hypofibrinogenemia is a common complication following CAR-T therapy and has been linked to systemic inflammation, CRS/ICANS, and other hemostatic disturbances. Reported bleeding rates range from 10–30%, but early fibrinogen replacement often makes it difficult to assess its natural course. Data on anti-BCMA CAR-T products remain limited. This study aims to evaluate the incidence, risk factors, and clinical impact of hypofibrinogenemia in patients receiving BCMA-directed CAR-T therapy.

Methods: In this single-center, retrospective study, 71 adult multiple myeloma patients treated with Cilta-cel, Ide-cel, or ARI-0002h between 2020 and 2025 were analyzed. Patients were stratified by fibrinogen nadir, with clinically relevant hypofibrinogenemia defined as a fibrinogen level ≤150 mg/dL and hemorrhagic events defined as events grade ≥2.

Results: Hypofibrinogenemia occurred in 46.5% (n=33) of patients, with 42.4% (n=14) presenting fibrinogen levels <100 mg/dL and 6.1% (n=2) <50 mg/dL. The incidence of hypofibrinogenemia did not differ significantly between CAR T-cell products (cilta-cel 40%, ide-cel 50%, ARI-0002h 61.1%; p = 0.3). The median duration of hypofibrinogenemia was 13 days (IQR 8–20). Prolonged hypofibrinogenemia (≥14 days) was observed in 42% of affected patients (n=14). The median time to onset was 13 days (IQR 10–18), nadir at day +15 (IQR 13–21), and recovery by day +25 (IQR 18–38). Prophylactic fibrinogen supplementation was administered in 15.5% of cases, at a median fibrinogen level of 84 mg/dL at supplementation. Bleeding events occurred in 9.1% (n=3), all in the setting of concurrent hypofibrinogenemia, with no significant association between fibrinogen nadir and bleeding (p=0.109) (Table 1).

Table 1: Demographic and clinical characteristics of study population

	Total (n=71)[1]	Fibrinogen ≥150 mg/dL (n=38)[1]	Fibrinogen <150 mg/dL (n=33)[1]	p-value[2]
Age at infusion	62 (51-69)	62 (51-69)	62 (50-68)	0.7
Female sex	33 (46%)	17 (45%)	16 (48%)	0.8

ARI-0002h	18 (25%)	7 (18%)	11 (33%)	
Ide-cel	8 (11%)	4 (11%)	4 (12%)	
CRS	64 (90%)	31 (82%)	33 (100%)	0.004
Grade 1	46 (72%)	25 (81%)	21 (67%)	
Grade 2	9 (14%)	5 (16%)	4 (12%)	
Grade 3	9 (14%)	1 (3%)	8 (24%)	
CRS onset	6 (5-8)	6 (5-7)	6 (4-8)	0.123
Duration (days)	2 (1-3)	2 (1-3)	2 (1-4)	0.047
ICANS	8 (11%)	4 (10%)	4 (12%)	0.8
Grade ≥3	0	0	0	
Anti-IL6 treatment	60 (84%)	27 (71%)	33 (100%)	<0.001
Cummulative dose	1 (1-2)	1 (0-2)	2 (1-3)	<0.001
Fibrinogen nadir (mg/dL)	150 (118-268)	264 (176-368)	114 (82-132)	
Bleeding grade ≥2	3 (4%)	0	3 (9%)	0.109

[1] Median (IQR); n (%).
[2] Fisher's exact test; Chi-squared test; Wilcoxon rank sum test

Any-grade CRS increased the risk of hypofibrinogenemia (OR 2.17; 95% CI 1.66–2.84; p = 0.011) and was associated with lower nadir levels (160 vs 150.5 mg/dL; p = 0.001). Greater CRS severity correlated with higher incidence (OR 2.43; 95% CI 1.06–5.56; p = 0.035) and

deeper fibrinogen depletion (p = 0.002) (Figure 1). Longer CRS duration and cumulative anti–IL-6 therapy were also linked to increased incidence (OR 1.67; 95% CI 1.05–2.64; p = 0.03; and OR 3.08; 95% CI 1.70–5.56; p < 0.001 respectively) and lower fibrinogen levels (rho -0.39, p = 0.001; rho -0.62, p < 0.001). No significant association was observed between ICANS and hypofibrinogenemia. Hypofibrinogenemia did not impact overall survival (median follow-up 7 months).

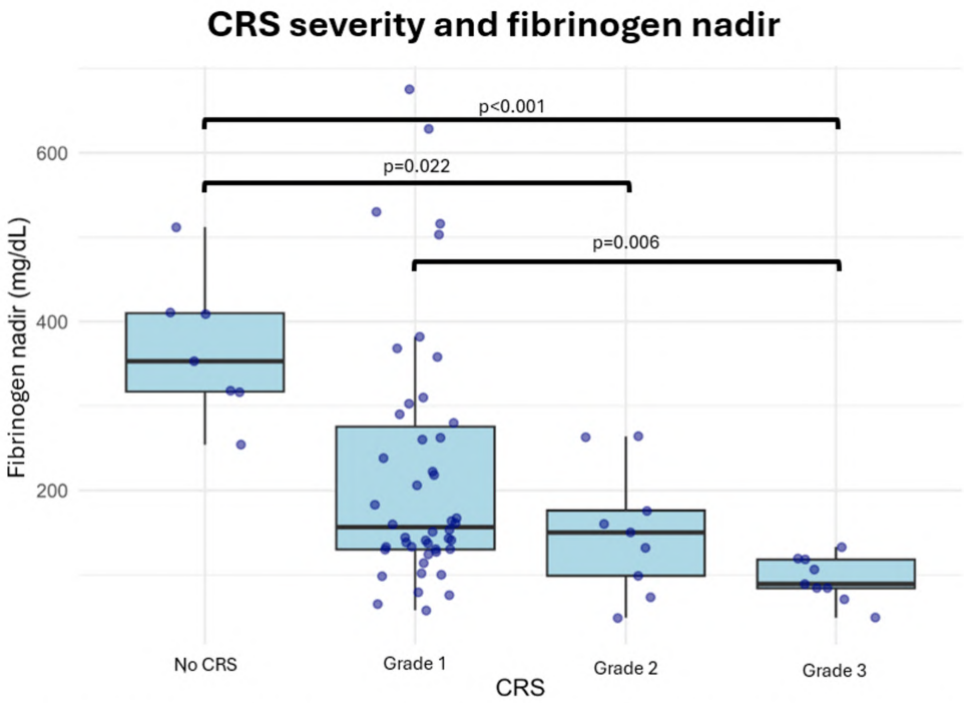

Figure 1: Fibrinogen nadir according to CRS severity. Increasing CRS grade is associated with progressively lower fibrinogen levels.

Conclusions: Hypofibrinogenemia is frequent after BCMA-directed CAR-T therapy and reflects the systemic inflammatory response rather than isolated hemostatic dysfunction. Its severity is moderately inversely correlated with CRS grade, CRS duration, and cumulative anti–IL-6 therapy, without significantly increasing bleeding risk. These results support the concept of a unified inflammatory syndrome in CAR-T recipients, with fibrinogen serving as a measurable marker of inflammatory burden. Routine monitoring may aid in early detection and assessment of systemic inflammation.

Disclosure: Nothing to declare.

A212

SURVIVAL AND OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN OLDER ADULTS WITH ACUTE MYELOID LEUKEMIA: A SINGLE-CENTER, DECADE-LONG ANALYSIS

Noa Holtzman[1], *Sunwoo Han*[2], *Trent Wang*[1], *Denise Pereira*[1], *Amer Beitinjaneh*[1], *Jay Spiegel*[1], *Mark Goodman*[1], *Pepita Jean*[1], *Cara Benjamin*[1], *Eric Wieder*[1], *Damian Green*[1], *Lazaros Lekakis*[1], *Antonio Jimenez Jimenez*[1]
[1]*Sylvester Comprehensive Cancer Center, University of Miami Miller School of Medicine, Miami, United States of America (the),* [2]*Florida International University, Miami, United States of America (the)*

Background: The median age at diagnosis for acute myeloid leukemia (AML) is in the seventh decade, and yet little progress has been made in improving outcomes for older adults undergoing allogeneic hematopoietic stem cell transplantation (alloHSCT). Herein, we report the clinical outcomes and associated factors for older AML patients undergoing alloHSCT.

Methods: Patients with AML (n=279) who underwent alloHSCT between January 2014 and August 2024 at our institution were identified. Patients were analyzed in two subgroups based on age (years): younger (age <65) vs older (age ≥65). Overall survival (OS), defined as the time from date of alloHSCT to death or last follow-up (FU), was estimated using the Kaplan-Meier method. Cox proportional-hazards models were used to identify prognostic factors for OS. Cumulative incidence of non-relapse mortality (NRM) was reported using competing-risk analysis, accounting for relapse or relapse-related mortality (RRM). Fine and Gray regression models were used to analyze NRM.

Results: Median age at HSCT was 55 years (interquartile range (IQR): 45-64), 51% were male, 66% with HCT-CI≥3, and 54% with KPS ≥90%. 61% underwent MAC, 40% with MUD, and GVHD prophylaxis was Tac/MTX in 27%, Tac/MTX/ATG in 47%, and PTCy in 26%. When comparing younger (n=211) and older (n=68) cohorts, baseline demographics were similar except for a higher proportion of men in the older cohort: 44.1% vs 72.1%(P<.0001).
With a median FU of 27 months (IQR: 9.4-59.6), median OS was not estimable (NE) for younger vs 20.1 months for older. Univariable Cox models identified age ≥65 (HR=1.86, 95%CI:1.26-2.73, P=0.002), RIC HSCT (HR=1.56, 95%CI:1.07-2.20, P=0.019), HCT-CI≥3 (HR=1.78, 95%CI:1.17-2.70, P=0.007), and KPS<80 (HR=2.24, 95%CI:1.38-3.63, P=0.001) as significantly associated with worse OS (P<.05). These associations remain significant in the multivariable model except for RIC HSCT (P=0.646). In age-stratified analyses, HCT-CI≥3 predicted poorer OS in the younger cohort (HR=1.95, 95%CI: 1.18-3.23, P=0.009) but this association did not hold for older patients (P=0.769).
OS at 2 years was 64.3% (95%CI:58.2-69.7%), with 55% of deaths due to RRM. In contrast, among older patients, NRM accounted for 68% of deaths. The cumulative incidence of NRM at 2-years was more than double in older vs younger cohort: 33.7% (95%CI:22.4-45.3%) vs 11.1% (95%CI:7.3-15.8%). Univariable Fine and Gray models showed that older age (HR=3.44, 95%CI:2.03-5.82, P<.0001), male sex (HR=1.80, 95%CI:1.04-3.11, P=0.035), RIC (HR=2.77, 95%CI:1.63-4.71, P=0.0002), and HCT-CI≥3 (HR=1.91,

95%CI:1.01-3.63, P=0.048) associated with higher NRM. On multivariable analysis, only age ≥65 years remained significantly associated with NRM (HR=2.35, 95%CI:1.01-5.45, P=0.047).
The cumulative incidence rate of relapse at 2-years was 24.7%, with no difference between older and younger groups (P=0.146). Within the older cohort, no significant difference in OS was observed between patients aged 65-69 and ≥70 years (P=0.319).

Conclusions: Older adults with AML (≥65 years) have inferior post-transplant OS and higher NRM than their younger counterparts. HCT-CI≥3 is not associated with NRM or OS in those age ≥65, suggesting that conventional comorbidity indices may have limited discriminatory ability in carefully selected older adults and highlighting the need for improved frailty-based risk assessment in older patients undergoing alloHSCT.

AGE AT TRANSPLANT DETERMINES OUTCOME FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR MITOCHONDRIAL NEURO-GASTROINTESTINAL ENCEPHALOPATHY (MNGIE)

Patel Zeeshan Jameel[1], *Simon A. Jones*[1], *Arunabha Ghosh*[1], *Claire Horgan*[1], *Srividhya Senthil*[1], *Ramya Hanasoge-Nataraj*[1], *Karolina M. Stepien*[2], *Denise Bonney*[1], *Robert F. Wynn*[1]
[1]*Royal Manchester Children's Hospital, Manchester University NHS Foundation Trust, Manchester, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Salford Royal Hospital, Northern Care Alliance NHS Foundation Trust, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Mitochondrial neuro-gastrointestinal encephalopathy (MNGIE) is a rare autosomal recessive disorder caused by pathogenic variants in the *TYMP* gene, leading to thymidine phosphorylase (TP) enzyme deficiency resulting in the accumulation of toxic nucleosides (dThd and dUrd). Hematopoietic stem cell transplantation (HSCT) is effective in MNGIE to restore TP enzyme activity via engrafted donor-derived leukocytes, enabling detoxification of accumulated metabolites but outcomes vary significantly due to factors like patient age at transplant, disease severity, and donor characteristics, with treatment-related risks remaining substantial.
Here, we describe our experience of HSCT in four siblings having same mutation transplanted with the same donor but at different stages in disease course, to more exactly determine the influence of age on disease response.

Methods: Four siblings diagnosed with MNGIE disease, from a single family with consanguineous parentage (first-degree cousins) were referred for allogeneic-HSCT. These siblings shared the same donor - a fifth, wild-type (non-carrier) but HLA-matched sibling. The four affected siblings, representing a spectrum of disease severity—from asymptomatic to severely affected—underwent HSCT from this unaffected matched sibling donor, offering a unique opportunity to observe differential disease responses to transplantation within a

genetically and environmentally similar cohort. Data collected included demographic information, symptomatology, serum dUrd/dThd levels, TYMP mutations, pre-transplant characteristics, conditioning regimen, chimerism, post-transplant survival, long term follow-up and outcomes.

Results: Pre-transplant nutritional status was poor in all four patients. Severe neurological disease was seen in two patients whilst the youngest sibling was asymptomatic and had normal MRI and NCS. Two patients received fludarabine, treosulfan, and thiotepa (FTT) whilst two received busulfan and fludarabine conditioning. All had alemtuzumab as part of the institutional protocol for non-malignant disease. All patients engrafted successfully, with mean neutrophil engraftment on day +11.5±1.3 and platelet engraftment by day +15.3±5.9. At median follow-up of 6.75 years,we report 100% survival. No significant GvHD was seen. Notably, the second sibling had developed a severe acute stroke like-episode resembling those in MELAS. She eventually made remarkably recovery with minimal residual right hemiparesis. No other patient has demonstrated such progressive neurological decline post-HSCT. Pre-existing neurological deficits have remained largely unchanged. Two older siblings developed intestinal failure requiring prolonged TPN. One of them has been transitioned to enteral feeding, but both continue to experience GI symptoms and difficulty gaining weight. Third sibling also continues to struggle with GI symptoms but manages on high calorie enteral feeds. The youngest has not required nutritional support. Biochemically these 4 siblings have shown a dramatic decrease in disease related metabolites.

Transplant characteristics	**Patient A**	**Patient B**	**Patient C**	**Patient D**
Age at HSCT	16	15	13	5
Donor	10/10 HLA MSD	10/10 HLA MSD	10/10 HLA MSD	10/10 HLA MSD
Conditioning regimen	F - 40 mg/m2 T – 10 mg/Kg T – 14000 mg/m2 Alemtuzumab – 0.1 mg/Kg	F - 40 mg/m2 T – 10 mg/Kg T – 14000 mg/m2 Alemtuzumab – 0.1 mg/Kg	Bu – 1.9 mg/Kg (AUC – 80 mg/L/h) Flu – 40mg/m2 Alemtuzumab – 0.1 mg/Kg	Bu – 2.4 mg/Kg (AUC – 80 mg/L/h) Flu – 40mg/m2 Alemtuzumab – 0.1 mg/Kg
HSC source	PB	PB	PB	PB
TNC (x10^8/Kg)	4.18	4.18	6.25	6.35
CD34+ cell count (x106/Kg)	4.87	4.86	5.24	5.33
GVHD prophylaxis	CsA/MMF	CsA/MMF	CsA/MMF	CsA/MMF

Neutrophil engraftment	D+11	D+10	D+12	D+13
Platelet engraftment	D+12	D+13	D+12	D+24
Most recent chimerism	100%	100%	100%	100%
Outcomes	Post-Tx intestinal failure but currently on high calorie enteral feeds. Nil neurological progression.	Intestinal failure on TPN, Stroke like episode	Ovarian failure on HRT, Vitiligo, Nil neurological progression.	Ovarian failure on HRT, Vitiligo, Nil neurological progression. Gastrostomy in-situ to help with nutrition. Nil neurological progression.

Conclusions: Our unique experience highlights the critical importance of timing of HSCT in MNGIE in determining outcome. Those without disease manifestations do not develop them, but those with them do not improve. This persistent morbidity underscores the importance of considering MNGIE for inclusion in newborn screening programs to enable the earliest possible therapeutic intervention. This observation includes the GI manifestations, related to autonomic neuropathy, and there remains persistent nutritional difficulties and this long-term morbidity must form part of pre-transplant patient planning for the affected child.

Clinical Trial Registry: Not applicable

A214

LONG-TERM OUTCOMES OF HAPLOIDENTICAL AND MATCHED UNRELATED DONOR HEMATOPOIETIC STEM CELL TRANSPLANTATION IN COMPLETE REMISSION NON-DS-AMKL: A SINGLE-CENTER COHORT STUDY

Fei Pan[1], *Jing Long*[2], *Xingyu Cao*[3,1], *Yue Lu*[3,1], *Min Xiong*[3,1], *Jian-ping Zhang*[3,1], *Zhijie Wei*[3,1]
[1]*Beijing Lu Daopei Hospital, Beijing, China,* [2]*Beijing Lu Daopei Institute of Hematology, Beijing, China,* [3]*Hebei Yanda Lu Daopei Hospital, Langfang, China*

Background: Acute megakaryoblastic leukemia without Down syndrome (non-DS-AMKL) is a rare subtype of pediatric AML with limited evidence guiding optimal transplantation

strategies. This study aimed to compare the efficacy and safety of haplo-HSCT versus MUD-HSCT in non-DS-AMKL patients in complete remission (CR).

Methods: We retrospectively analyzed 63 pediatric non-DS-AMKL patients who underwent allo-HSCT in CR at our center between July 2016 and January 2025. Fifty-one patients received haplo-HSCT and 12 underwent MUD-HSCT. Clinical characteristics, engraftment kinetics, graft-versus-host disease (GVHD) incidence, viral reactivation, relapse, transplant-related mortality (TRM), and survival outcomes were compared. To identify independent prognostic determinants, multivariate Cox proportional hazards models were applied for OS and LFS, while Fine–Gray competing-risk models were used to evaluate relapse and NRM in the full cohort of 63 patients.

Results: Baseline characteristics of the 63 children with non-DS-AMKL undergoing allo-HSCT (51 haplo-HSCT; 12 MUD-HSCT) were overall comparable . All patients (100%) achieved WBC engraftment by day 28 post-HSCT. Platelet engraftment by day 28 occurred in 94.1% (48/51) of patients in the haplo-HSCT group and in 100% (12/12) of the MUD-HSCT group (P = 1.00). With the median follow-up 30.8 months (range, 2.0–105.3), the 5-year overall survival (OS) was 65.8% in the haplo-HSCT group versus 58.3% in the MUD-HSCT group (P = 0.40) (Figure 1A); 5-year leukemia-free survival (LFS) was 65.1% versus 58.3% (P = 0.40) (Figure 1B), respectively. 5-year Cumulative incidence of relapse was 20.1% in the haplo-HSCT group and 25.0% in the MUD-HSCT group (P = 0.64), while 5-year non-relapse mortality (NRM) was 22.8% and 25.0% (P = 0.73) (Figure 1 C/D), respectively. The incidence of grade III–IV aGVHD and severe chronic GVHD was higher in the haplo-HSCT group, but without statistical significance (all P>0.05).
Multivariate Cox and Fine–Gray analyses (Table 1) identified complex cytogenetics as the only consistent adverse prognostic factor, significantly worsening OS (HR 2.79; 95% CI, 1.14–6.87; P = 0.03), LFS (HR 2.88; 95% CI, 1.18–7.08; P = 0.02), and RI (HR 4.05; 95% CI, 1.03–15.99; P = 0.05). A higher MNC dose (>15 $\times 10^8$/kg) showed a trend toward improved survival, though without statistical significance for OS (HR 0.19; P = 0.07) or LFS (HR 0.17; P = 0.06). Notably, a higher $CD34^+$ cell dose (>8 $\times 10^6$/kg) was associated with better OS and LFS (both P = 0.05), but this observation requires further validation given the CI width. Use of a MEL+BU–based conditioning regimen significantly reduced relapse risk (HR 0.27; 95% CI, 0.08–0.96; P = 0.04). In contrast, donor type (MUD vs haplo), fusion gene status, $CD3^+$ T-cell dose, and age showed no measurable impact on OS, LFS, RI, or NRM.

Table 1. Multivariate analysis Results

Variables	**OS**		**LFS**		**RI**		**NRM**	
	HR (95% CI)	*P-vaule*	HR (95% CI)	*P-vaule*	HR (95% CI)	*P-vaule*	HR (95% CI)	*P-vaule*

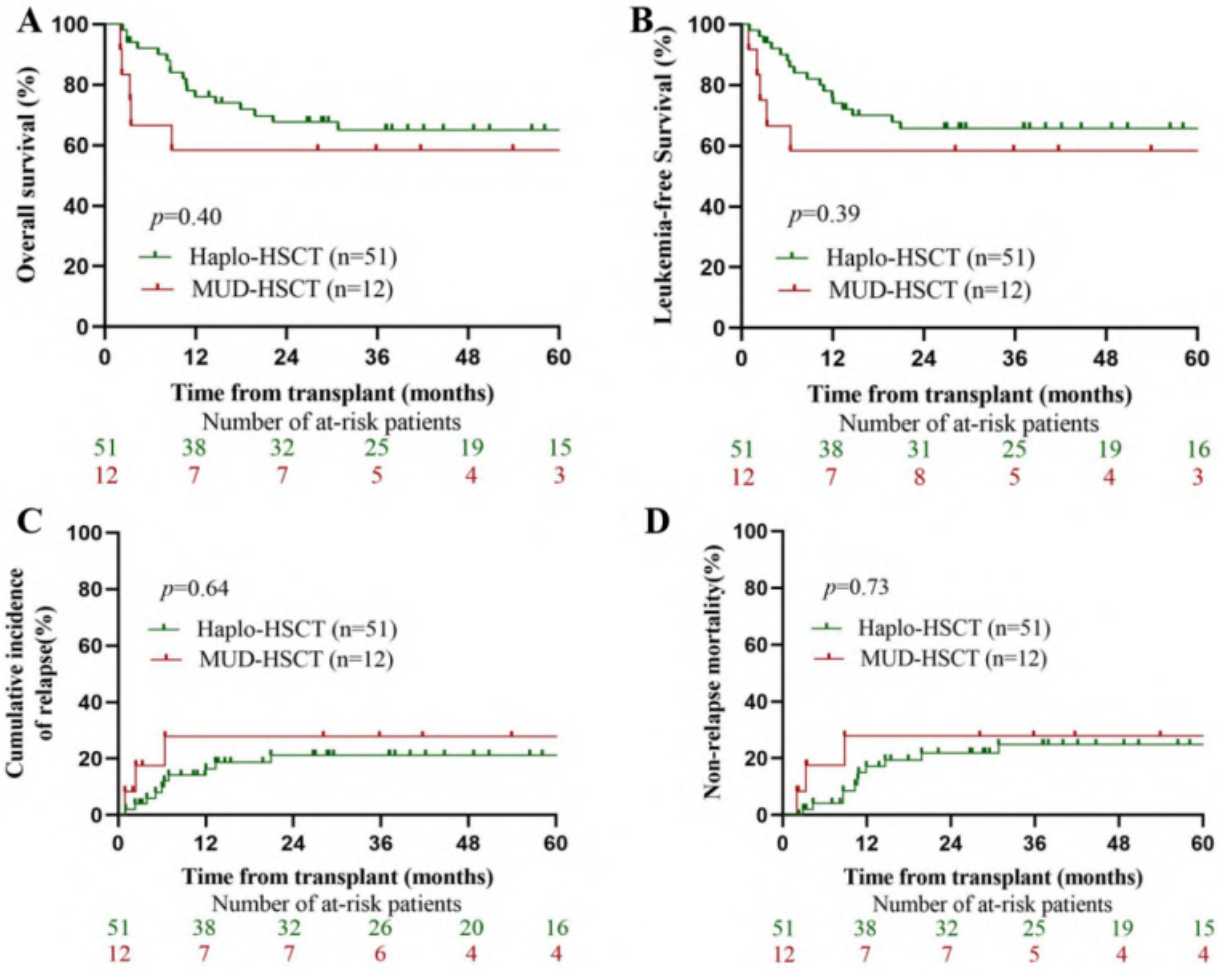
Figure 1. Long-term outcomes in 63 patients with non-DS-AMKL



Conclusions: In pediatric non–DS-AMKL patients undergoing allogeneic HSCT in complete remission, haplo-HSCT yielded long-term outcomes comparable to MUD-HSCT, with similar relapse risks and survival. These findings support haplo-HSCT as an effective and practical alternative when a matched unrelated donor is unavailable or when timely transplantation is essential.

Disclosure: Nothing to declare

A215

IMPACT OF HEPATITIS E VIRUS INFECTION ON ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION AND CURRENT TREATMENT STATUS

Ting Liu[1], *Xingyu Cao*[1,2], *Wei Ma*[1], *Yunchao Su*[2], *Song Xue*[2], *Deyan Liu*[1,2], *Ruijuan Sun*[1,2]
[1]*Hebei Yanda Lu Daopei Hospital, Langfang City, China,* [2]*Beijing Lu Daopei Hospital, Beijing, China*

Background: Hepatitis E virus (HEV) is a single-stranded RNA virus. Besides its hepatotropism, it may also cause extrahepatic damage to systems such as the nervous, urinary, and hematological systems. In patients undergoing allo-HSCT, the inability to spontaneously clear the virus predisposes them to chronic infection upon exposure. Reports on its impact on allo-HSCT are scarce.

Methods: A retrospective analysis was conducted on clinical cases of HEV infection among allo-HSCT patients at Hebei Yanda Lu Daopei Hospital and Beijing Lu Daopei Hospital from January 2023 to November 2025. HEV infection was diagnosed via NGS and/or PCR. Clinical manifestations and outcomes of HEV infection in transplant patients were analyzed.

Results: Among 3,393 transplant patients, four were diagnosed with hepatitis E virus infection, comprising one male and three females, with a median age of 33.5 years(8~52years). Diagnoses included AML (n=3) and B-ALL(n=1). All patients received myeloablative conditioning regimens and underwent haploidentical hematopoietic stem cell transplantation. The GVHD prophylaxis regimen consisted of CSA, sMTX, and MMF. HEV was detected at a median time of −5.5 days relative to transplantation (−17~+69d). Specimen types included blood (n=2), cerebrospinal fluid (n=1), and bronchoalveolar lavage fluid (n=1). Clinical presentations included asymptomatic HEV viremia (n=2), HEV-associated encephalitis (n=1), and HEV-associated pneumonia (n=1). The median NGS read count was 316.5 (4~73,311), and the median PCR viral load was 3.8E+07copies/mL (1.2E+07~6.4 E+07copies/mL). Serology showed HEV IgM-positive and IgG-negative in one patient; IgM-negative and IgG-negative in one patient ;two patients were not tested. Two patients received ribavirin with or without interferon therapy, while two did not. The median treatment duration was 50 days (30~60d). The median time to viral clearance by PCR was 341days (259~423d). Clinical features of HEV infection included elevated transaminase and bilirubin levels, pneumonia, encephalitis, and symptoms such as limb weakness and dysphagia. Imaging of HEV encephalitis typically revealed multiple brain lesions, predominantly in the white matter. All four patients with HEV infection achieved successful engraftment of granulocytes and platelets. Complications included CMV reactivation (n=1), EBV reactivation (n=1), HHV-6 reactivation (n=1), and pancytopenia (n=1). No ADV reactivation was observed. aGVHD occurred in three cases, and cGVHD occurred in two. One patient died from cerebral hemorrhage, and one patient was lost to follow-up due to limb weakness.

Conclusions: Hepatitis E virus infection is not exclusively hepatotropic and can involve multiple organ systems. Time to viral clearance is prolonged in allo-HSCT patients, and HEV may exert a non-negligibie impact on transplantation outcomes. Further studies with larger

sample sizes are warranted to clarify its clinical significance and optimize management strategies.

Disclosure: Nothing to declare.

A216

IMPACT OF THERAPEUTIC PLASMA EXCHANGE ON PAN-REACTIVE HLA ANTIBODY TITRES IN PATIENTS WITH TRANSFUSION-DEPENDENT THALASSEMIA UNDERGOING MATCHED RELATED DONOR HSCT: A SINGLE-CENTRE STUDY

*Nirali Sanghvi[1], **Santanu Sen**[1], Manam Mehra[1]*
[1]Kokilaben Dhirubhai Ambani Hospital, Mumbai, India

Background: Donor non-specific HLA antibodies or pan-reactive antibodies (PRA) in paediatric transfusion-dependent thalassemia (TDT) patients may impact the outcomes of HSCT by increasing the blood-product transfusion requirement, graft-failure, and post-transplant complications. Therapeutic plasma-exchange (TPE) prior to transplant might assist in optimising outcomes in PRA positive patients.

Methods: Children with TDT undergoing HSCT with fully-matched related donors were included in this study (period:January-December,2024). All patients were screened for class I and II PRA using Immunoassay on Luminex solid-phase technology. Pre-transplant PRA levels were evaluated and PRA-positive (n = 22) children were included in the study. Patient characteristics: age, gender and stem-cell source, were analyzed. Depending upon the MFI value, they were planned for TPE prior to conditioning chemotherapy. MFI value >1200 was considered positive and those with MFI>3000 warranted TPE. TPE cycles were done at approximately 1.2-1.5 times blood-volume. For MFI of upto 5000, 5000 to 10000, 10000 to 15000, 15000 to 20000, and >20000, the TPE cycles done were respectively 1,2,3,4 and 5. PRA were repeated thereafter and compared. Transplant outcomes, including engraftment and graft failure were compared with the data available from previous studies.

Results: Out of 49 total HSCT in 2024, 22children(males=11, females=11), who underwent HSCT for TDT in the age-group 2-12 years with PRApositive status, were included in the study. Out of this,15 were from PBSC(68%), rest bone-marrow(32%). All these patients had positive HLA class I antibody level(100%), however 15 out of 22 had class II positive antibody titre(68%). There was reduction in antibody-titres of class I panel in 78% (17) patients; no reduction in 22% (5) patients, reduction in antibody-titres of class II panel in 94%(14) patients; no reduction in 6% (1)patient. Engraftment occurred in 20 patients out of 22 (90%); 1 had primary graft failure due to CMV reactivation and 1 died of gram-negative sepsis pre-engraftment. Median platelet engraftment occurred on day +19.

Parameter	Result
Total Patients Included	22 PRA-positive pediatric thalassemia
Gender Distribution	11 Male (50%), 11 Female (50%)
Stem Cell Source	68% PBSC, 32% Bone Marrow
Class I PRA Reduction	17 / 22 patients (77%)
Class II PRA Reduction	14 / 15 patients (93%)
TPE Cycles per Patient	1–6, based on MFI levels
Neutrophil Engraftment	20 / 22 patients (91%), Day +14
Platelet Engraftment	20 / 22 patients (91%), Day +19
Graft Failure	1 patient (4.5%) — CMV reactivation
Pre-Engraftment Mortality	1 patient (4.5%) — Sepsis
Comparison with Literature	Engraftment timelines comparable (WBC: 11–21d, Platelets: 14–24d)

Conclusions: Patients with TDT need repeated red-cell transfusions leading to alloimmunization with PRA, which hamper HSCT by increasing the transfusion requirement, delayed platelet engraftment and causing primary graft failure. By doing TPE to reduce PRA positivity, 90%patients engrafted and none had delay in platelet-engraftment, thereby improving the overall transplant outcomes. Although, TPE is well-studied in solid organ transplantation to reduce anti-HLA antibodies, including DSAs and PRA, there is no direct evidence that specifically evaluates TPE to lower anti-HLA antibody levels before HSCT in matched related donor patients. As per our experience, TPE might be an effective technique in reducing PRA and thereby decreasing the chances of primary graft failure and delay in platelet engraftment.

Disclosure: Nothing to declare.

A217

RISK FACTORS FOR REFRACTORY CYTOMEGALOVIRUS INFECTION IN HEMATOPOIETIC STEM CELL AND SOLID ORGAN TRANSPLANT RECIPIENTS

Wenjian Mo[1], Jingyi Wu[2], Tingting Wang[2], ***Shunqing Wang***[1]
[1]Department of Hematology, Guangzhou First People's Hospital, South China University of Technology, Guangzhou, China, [2]Medical Affairs, Takeda (China) International Trading Company, Shanghai, China

Background: Refractory cytomegalovirus (CMV viral load <1 $\log_{10}$ reduction after 2 weeks' antiviral therapy) and resistant CMV (with specific genotypic mutations in refractory CMV) could portend poor outcomes including increased mortality, end-organ disease, and graft failure. Meanwhile, patients with refractory CMV infection face prolonged antiviral treatment. A thorough understanding of the risk factors for refractory CMV is important for improving disease management and prognosis. This scoping review identifies key risk factors to guide clinical decision.

Methods: This study employed a scoping review framework (PRISMA-ScR guidelines) to systematically search PubMed, EMBASE, the Cochrane Library, Web of science, CNKI, Wanfang, VIP and CBM (2010-2023) for literature on risk factors for refractory CMV infection after transplantation.

Results: A total of 13 studies were included (hematopoietic stem cell transplantation (HSCT): 10 studies involving 946 patients; solid organ transplantation (SOT): 3 studies involving 101 patients). Based on the 13 studies, 15 risk factors for refractory CMV infection were identified and stratified as follows: 1) There were 14 HSCT-specific factors, including 4 host-related factors [acute graft-versus-host disease, Epstein-Barr virus viremia, NKG2C del/del genotype, platelet count at 90 days after transplant <= 86×10^9/L], 8 transplant-related factors [CMV serological status of donor$^{(-)}$ and recipient$^{(+)}$ (vs donor$^{(+)}$ and recipient$^{(+)}$), ATG used in conditioning therapy total body irradiation/mycophenolate mofetil used in prophylactic immunosuppression (vs busulfan/mycophenolate mofetil used in prophylactic immunosuppression), mycophenolate mofetil used in Prophylactic immunosuppression (vs mizoribine), steroid use >=1 (vs <1) mg/kg/day, umbilical cord blood/bone marrow transplantation, haploidentical/mismatched transplantation, white blood cell at 14 day after transplant < 4×10^9/L], and 2 viral-related factors [highest CMV load > 10^4 copies/mL, CMV-specific $CD8^+$ TcM at day 30 <0.032 μL)] factors . Moreover, 2) 5 SOT-specific risk factors for refractory and resistance CMV included 2 anti-CMV drug-related factors [history of Valganciclovir underdosing or low plasma concentration, breakthrough infection during the use of valganciclovir], 2 host-related factors [persistent clinical disease and younger recipient age], and 1 transplant-related factor [CMV serological status of donor$^{(+)}$ and recipient$^{(-)}$ (vs others)].

Transplant type	Factor category	Factors	Number of refractory reference	Number of resistance reference
Haematology transplant (n=10)	Host-related factors	aGVHD (grade II-IV vs. grade 0-I)	4	
		aGVHD (yes vs. no)	2	
		EB viremia (yes vs. no)	1	
		NKG2C (del/del vs. wt/del)	1	
		NKG2C (del/del vs. wt/wt)	1	
		Platelet count at day 90 after transplant ($\times 10^9$/L) (≤86 vs. >86)	1	
	Transplantation-related factors	ATG used in conditioning therapy (yes vs. no)	1	
		CMV serostatus (D-/R+ vs. D+/R+)	1	
		Conditioning regimen (TBI/Cy vs. Bu/Cy)	1	
		Donor type (cord blood vs. non-cord blood)	1	
		Donor type (Haplo or MUD vs. MSD)	1	
		Donor type (HBMT vs. MSD)	1	
		Donor type (mismatched family vs. MSD)	1	
		Prophylactic immunosuppression (MMF vs. MZR)	1	
		Stem cell source (BM or CB vs. PB or PB+BM)	1	
		Steroid use (MP, mg/kg/day) (≥1 vs. <1)	1	
		WBC at 14 day after transplant ($\times 10^9$/L) (<4 vs. ≥4)	1	
	Viral-related factors	CMV-specific CD8+ TcM at day 30 (μL) (<0.032 vs. ≥0.032)	1	
		Highest CMV viral load ($\times 10^4$ copies/mL) (>1 vs. ≤1)	2	
Organ transplant (n=3)	Anti-CMV drug-related factors	History of VGCV underdosing or low plasma concentration (yes vs. no)		1
		VGCV prophylaxis at infection onset (yes vs. no)		1
	Host-related factors	Persistent clinical disease (yes vs. no)		1
		Younger recipient age		1
	Transplantation-related factors	CMV serostatus (D+/R- vs. others)	1	1

Figure 1. Hot map of risk factors for refractory or resistance CMV infection.
Notes: The numbers in the hot map indicate the number of articles corresponding to the factors.
Abbreviations: aGVHD, acute graft-versus-host disease; ATG, anti-thymocyte globulin; CMV: cytomegalovirus; BM: bone marrow; BU: busulfan; CB: cord blood; Cy: cyclophosphamide; EB, Epstein-Bar; MMF: mycophenolate mofetil; MP: methylprednisolone; MSD: matched sibling donor; MUD: matched unrelated donor; MZR: mizoribine; PB: peripheral blood; TBI: total body irradiation; VGCV: valganciclovir; WBC: white blood cell.

Conclusions: The HSCT-specific risk factors for refractory CMV infection included host immune status, transplantation regimens and viral load, genotypes and blood parameters, while, CMV serological status of donor and recipient, anti-CMV drug exposure, and persistent disease were SOT-specific risk factors for refractory and resistance CMV. Early identification of patients at risk of refractory CMV infection can help guide the selection of drugs that can quickly achieve CMV clearance and have better tolerance when CMV infection occurs, thereby improving the clinical prognosis of patients.

Disclosure: Jingyi Wu and Tingting Wang are employees of Takeda (China) International Trading Co., Ltd. The authors declare that there were no commercial or financial relationships that could be interpreted as potential conflicts of interest in the conduct of this study.

A218

PROGNOSTIC AND SAFETY PREDICTIVE VALUE OF THE SYSTEMIC IMMUNE-INFLAMMATION INDEX IN R/R B-CELL LYMPHOMA PATIENTS UNDERGOING CAR-T CELL THERAPY

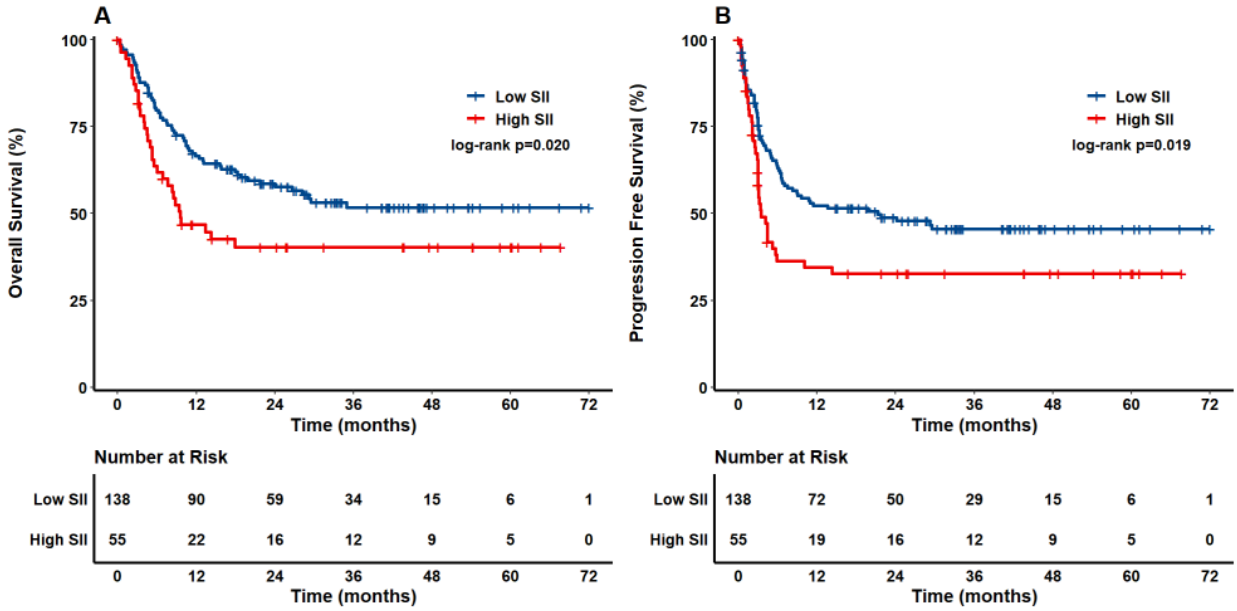
*Na Zhang[1], Rui Liu[1], Zhonghua Fu[1], Shilin Gan[1], Menglu Pei[1], **Jing Liu**[1], Yanhong Zhang[1], Miaomiao Cao[1], Lixia Ma[1], Yuelu Guo[1], Fan Yang[1], Biping Deng[2], Alex H. Chang[3], Xiaoyan Ke[1], Kai Hu[1]*
[1]Beijing GoBroad Hospital, Beijing, China, [2]Beijing GoBroad Boren Hospital, Beijing, China, [3]Engineering Research Center of Gene Technology, Ministry of Education, Institute of Genetics, School of Life Sciences, Fudan University, Shanghai, China

Background: Chimeric antigen receptor T-cell (CAR-T) therapy has emerged as an effective treatment option for relapsed or refractory (R/R) lymphomas. However, simple and reliable biomarkers capable of predicting survival outcomes and treatment-related toxicities remain lacking. The systemic immune-inflammation index (SII), which reflects a patient's inflammatory and immune status, has been recognized as a prognostic marker in various malignancies. This study aimed to evaluate the predictive value of pre-lymphodepletion SII levels for survival and safety outcomes in R/R B-cell lymphoma patients receiving CAR-T therapy.

Methods: We retrospectively analyzed 504 patients who underwent CAR-T therapy in our department from December 2018 to January 2024. The SII was calculated before lymphodepletion chemotherapy using the formula: platelet count × neutrophil count / lymphocyte count. The optimal cutoff value for overall survival (OS) was determined using a Cox regression model. To minimize baseline imbalances, patients were divided into Low-SII and High-SII groups using propensity score matching (PSM). Adverse events, treatment response, and survival outcomes were analyzed using Kaplan–Meier curves, log-rank tests, and Cox proportional hazards models.

Results: A total of 193 patients were included (median age 50; 75.6% male; median BMI 22.7 kg/m²). Disease subtypes were predominantly DLBCL (n=144). ECOG ≥2, IPI ≥3, and stage ≥III were observed in 34.2%, 46.6%, and 92.2% of patients, respectively.The optimal SII cutoff for OS was 1499.65, resulting in 138 patients in the Low-SII group and 55 in the High-SII group after PSM.
CRS occurred in 78.8% of patients, including 14.5% with grade ≥2 events. ICANS occurred in 2.6% (all grade ≥3). Grade ≥3 hematologic toxicities were common: neutropenia 92.7%, thrombocytopenia 66.3%, anemia 64.2%.
High SII was associated with a significantly higher incidence of grade ≥2 ICANS (7.3% vs. 0.7%; P=0.0239; OR=10.746), while rates of CRS and hematologic toxicity were comparable between groups.
The ORR was 62.7%, with a CR rate of 46.6%. High-SII patients had lower ORR (50.9% vs. 67.4%; P=0.0472) and CR rates (34.5% vs. 51.4%; P=0.0384).
At a median follow-up of 34.29 months, median PFS was 9.04 months and median OS was 29.52 months; 5-year PFS and OS rates were 42.03% and 48.39%. Low-SII patients showed significantly better survival (5-year PFS 45.56% vs. 32.73%; P=0.019; 5-year OS 51.65%

vs. 40.25%; P=0.020). High SII remained an independent predictor of inferior PFS (HR=1.599) and OS.



Conclusions: High pre-treatment SII is an independent and powerful biomarker for predicting inferior survival (shorter OS and PFS) and reduced treatment response in R/R B-cell lymphoma patients undergoing CAR-T therapy. In addition, elevated SII is significantly associated with a higher risk of severe neurotoxicity (ICANS). As a readily obtainable inflammatory marker, SII may facilitate risk stratification prior to CAR-T therapy and support individualized decision-making in clinical practice.

BONE MARROW TRANSPLANTATION IN SICKLE, ACCORDING TO DONOR STATUS: COMPARISON AND DIFFERENCES IN CLINICAL OUTCOMES

*Jose Manuel Marco-Sanchez[1,2,3], **Eduardo J. Bardón-Cancho**[1,2,3], Elena Cela[1,2,3], Teresa Martín-Aláez[1,2,3], María Salvador-Rodríguez[1,2,3], Alba González[1,2,3], Mario Gutiérrez[1,2,3], David Díaz[1,2,3], Jorge Huerta[1,2,3], Cristina Mata[1,2,3], Marina Corchete[1,2,3], Mónica Carrasco[1,2,3], Pablo González[4,1,3], Cristina Beléndez[1,2,3], Marina García-Morín[1,2,3]*
[1]Hospital General Universitario Gregorio Marañon, Madrid, Spain, [2]Fundación Investigación Biomédica Hospital Gregorio Marañón, Madrid, Spain, [3]Universidad Complutense de Madrid, Madrid, Spain, [4]Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Spain

Background: The primary objective of allogeneic hematopoietic stem cell transplantation (HSCT) in sickle cell disease (SCD) patients is to prevent irreversible organ damage that occur during the natural progression of the disease. The donor's status (AA vs. AS carrier) directly influences the proportion of haemoglobin S and A after HSCT. With AS donors, HbS final proportion is around 35-40%, so to correct haemolysis, >50% chimerism is required. Currently, there are no descriptive studies comparing the impact of donor status (AA vs AS) on HSCT outcomes and chimerism.

Methods: A single retrospective center study conducted in SCD children, who underwent allogeneic HSCT of HLA-identical sibling donor, between may 2010 and October 2025 in the Pediatric Oncohematology area of Hospital Gregorio Marañon. We excluded haploidentical donor transplants, in order to homogenize the results.
Clinical characteristics pre-HSCT and complications after the transplant were analyzed, differentiating between AA or AS carrier donors. Epidemiological and clinical parameters were collected.

Results: 69 HSCT were performed. Excluding haploidentical transplants, 63 allo-HSCT were included in 62 SCD patients (54.4% males, 45.6% females), median age 7.63 years (p25 3.23; p75 10.47). All were HLA-identical 10/10 sibling donor. The source of stem cells were bone marrow in all cases, median $CD34^{+}$ number infused $6.52^{x10e6/Kg}$. Regarding donor status (AA or AS carrier), 57.6% were AA donors and 42.4% were AS donors.

- In the HSCT of carrier AS donors cohort (30 HSCT): median time for neutrophil engraftment was 18.5 days (p25 16.75; p75 22), and the median time for platelets engraftment was 21 days (p25 18; p75 28,75). 71.4% developed reactivation CMV, 71.4% mucositis, 46.4% acute GvHD, 22.2% neurologic complications and 21.4% AKI renal complications. 2 patients developed graft rejection, currently asymptomatic. 1 patient of this cohort died, due to refractory grade IV GvHD and multiorgan failure at day +51.
- In the HSCT of AA donors cohort (33 HSCT): median time for neutrophil engraftment was 19 days (p25 17; p75 22.74), and the median time for platelets engraftment was 24.5 days (p25 20; p75 28,75). 61.5% developed reactivation CMV, 38.5% mucositis, 33.5% acute GvHD, 17.9% neurologic complications and 17.9% AKI renal complications. 3 patients (9%) developed chronic GvHD. 1 patient developed graft rejection, with recurrence of vasoocclusive crisis on day +180, so we did a second HSCT from the same donor. 1 patient of this cohort died, due to refractory hemophagocytic lymphohistiocytosis on +2 years after HSCT, secondary to VEB infection and cholestatic liver disease.
- Regarding chimerism, in the cohort of AS donors: 4 patients (14%) had mixed chimerism at +1 year posHSCT, and 8 patients (28.6%) at the time of last appointment. In the cohort of AA donors: 11 patients (29.7%) had mixed chimerism at +1 year posHSCT, and 10 patients (26.5%) at the time of last appointment. No statistically significant evidence was found between the percentage of patients with mixed chimerism or time of engraftment, and AA vs. AS donors.

Conclusions: The need for prospective comparative studies or randomised controlled trials, directly comparing transplants according to AA or AS donors, is emphasised.

Disclosure: Nothing to declare.

THE PROGNOSTIC IMPACT OF CEBPA MUTATIONS IN ACUTE MYELOID LEUKEMIA PATIENTS UNDERGOING ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Xianjing Zhang[1], Dan Feng[1], Yigeng Cao[1], Mingyue Xu[1], Yuqing Liu[1], Junren Chen[1], ***Erlie Jiang***[1]
[1]*Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Tianjin, China*

Background: Myelodysplasia-related gene mutations and cytogenetic abnormalities in acute myeloid leukemia (AML) patients are strongly associated with clinical outcomes and play a pivotal role in guiding therapeutic strategies. The presence of mutations in the basic leucine zipper (bZIP) region of the CEBPA gene in patients with AML is defined as a favorable risk marker according to the guidelines. However, the value of allogeneic hematopoietic stem cell transplantation (allo-HSCT) in AML patients with CEBPA mutations remains to be clarified.

Methods: We retrospectively enrolled 173 patients with de novo AML who had undergone their first allo-HSCT between January, 2014 and March, 2025 in the IHCAMS (Institute of Hematology and Blood Diseases Hospital, Peking Union Medical College). Moreover, we enrolled 345 patients with newly diagnosed AML without CEBPA mutations, who received first allo-HSCT as the control group. Genomic DNA of all patients was extracted from BM cells for next-generation sequencing (NGS).

Results: In total, 204 (12.57%) of the 1600 patients with AML receiving allo-HSCT were detected CEBPA mutations. After excluding ineligible patients, 173 de novo AML patients with $CEBPA^{mut}$ detected before induce chemotherapy were enrolled in our study compared with 345 $CEBPA^{wt}$. The median follow-up time was 37.9 months (95% CI, 31.6-43.9 months) from transplantation. Patients carrying $CEBPA^{mut}$ had a significantly higher complete remission (CR) rate after first induction chemotherapy (80% vs. 68%, $P < 0.006$) and had a better 5-year PFS than $CEBPA^{wt}$ group (60.8% vs. 55.0%, $P = 0.016$). Failure to achieve remission after first induction chemotherapy as well as before transplantation, the presence of CEBPA mutation before allo-HSCT and the absence of maintenance therapy were proven to be statistically significant factors for worse overall survival (all $P < 0.001$). Univariate and multivariate Cox proportional hazards models were applied to evaluate risk factors and confirmed that $CEBPA^{mut}$ was an independent prognostic factors associated with improved PFS after allo-HSCT (HR, 0.68; 95% CI, 0.48 - 0.96, $P = 0.03$). Surprisingly, survival analysis revealed that patients with nontypical in-frame bZIP mutations had a favorable outcome of PFS than typical bZIP mutations ($CEBPA^{no\ in\text{-}frame\ bZIP}$ 63.3% vs. $CEBPA^{in\text{-}frame\ bZIP}$ 59.9% vs. $CEBPA^{wt}$ 55.0%, $P = 0.045$). Furthermore, the most common frequently co-mutated genes were WT1 (48 of 173, 28%), GATA2 (35 of 173, 20%), NRAS (33 of 173, 20%), FLT3-ITD (32 of 173, 19%), TET2 (28 of 173, 16%), NPM1 (21 of 173, 12%), and KIT (19 of 173, 11%). Interestingly, patients harboring both FLT3-ITD and CEBPA mutations had a significantly longer 5-year PFS than other groups ($CEBPA^{mut}$/$FLT3\text{-}ITD^{mut}$ 75.9% vs. $CEBPA^{mut}$/$FLT3\text{-}ITD^{wt}$ 57.3% vs. $CEBPA^{wt}$ 55.0%, $P = 0.02$). Conversely, the presence of GATA2 mutations (PFS: $CEBPA^{mut}$/$GATA2^{mut}$ 43.2% vs. $CEBPA^{mut}$/$GATA2^{wt}$ 63.8% vs. $CEBPA^{wt}$

55.0%, *P* = 0.04) showed no benefit.

Figure 1

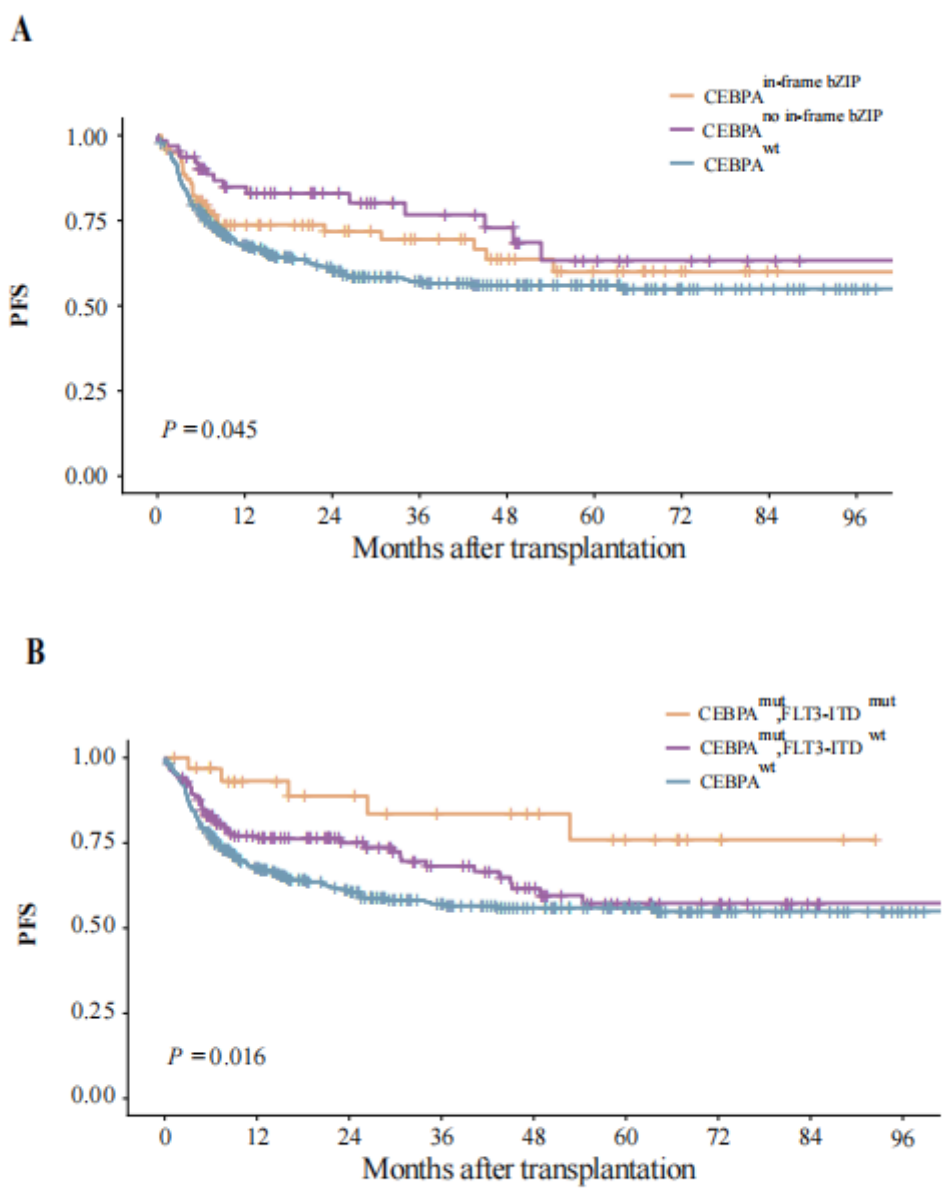

Fig 1. PFS in patients stratified by CEBPA mutation status and frequent concurrent co-mutations.
A.CEBPA in-frame bZIP vs. CEBPA no in-frame bZIP
B.CEBPAmut with or without the co-mutation of FLT3-ITD

Conclusions: CEBPA^{mut} patients achieving CR after initial therapy and before transplantation, without the presence of mutations and receiving maintenance therapy three

months after allo-HSCT had a superior probability of longer survival. Our findings suggest that CEBPA^{mut} patients with nontypical in-frame shift in bZIP region or with the co-mutation of FLT3-ITD could benefit from allo-HSCT.

Disclosure: Nothing to declare.

MESENCHYMAL STEM CELL TRANSPLANTATION IN PATIENTS WITH GRAFT HYPOFUNCTION AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

*Aksana Marozava[1], Natalya Milanovich[1], **Tatsiana Talako**[1], Oksana Nechay[1], Yury Strongin[1], Helena Dzyuba[1], Svyatlana Kryvenko[1], Natalya Dedyulya[1], Anatoly Uss[1]*
[1]Minsk Scientific and Practical Center of Surgery, Transplantology and Hematology, Minsk, Belarus

Background: Graft hypofunction (GH) with preserved donor chimerism, the absence of drug toxicity, disease recurrence, or severe infectious complications poses a challenge in post-transplant patient management. Causes of GH may include HLA incompatibility or haploHSCT, toxicity of conditioning regimens, patient status, graft cellularity by CD34, graft source, and others. Treatment of GH: use of growth factors, transfusion of donor red blood cells and platelets, re-transplantation, correction of immunosuppressive therapy. At the Minsk Scientific Practical Center for Surgery, Transplantology, and Hematology, we use mesenchymal stem cell (MSCs) transplantation to treat various autoimmune diseases, GVHD, and GH therapy. MSCs exert a immunosuppressive effect, inhibit the proliferation of T- and B-lymphocytes, and activate anti-inflammatory pathways in vitro and in vivo. Their immunomodulatory properties offer clinical advantages in the treatment and prevention of GVHD, and they promote tissue repair and graft engraftment afterg hematopoietic stem cell transplantation (HSCT).

Methods: We used TMSC obtained from adipose tissue of an unrelated donor in 13 patients with HFT: 6 women, 7 men, aged from 24 to 51 years (Me 37). Diagnoses, patients : myelofibrosis - 2, chronic myelogenous leukemia - 2, severe aplastic anemia - 3, myelodysplastic syndrome - 2, acute myeloid leukemia - 4. Conditioning regimens: MAC in 6 patients, RIC - in 7, post-transplant cyclophosphamide were used in 6 patients, in 5 patients the HSC transplantation was from a 9/10, in one - haploSCTl (6/10), Mediana CD34+ was 6.02x106/kg (from 3.2 to 13.99), BM -1 patients (1.16 x106/kg). ABO incompatibility - in 8 patients (major 2, minor -3, major+minor -3), the donor was female in 6 patients.
Three patients had 3-lineage GH, five patients had 2-line GH (neutrophils and platelets), and five patients had 2-line GH (platelets only).
Was performed from 1 to 20 (Me 3) MSCs transplantation.
We considered a complete response (CR) to treatment as a neutrophil level greater than 1x109\l without the use of CSF, a hemoglobin level greater than 90 g\l, a platelet level greater than 50x109\l, improvement - neutrophils 0.5-1x109\l without the use of CSF, no need for blood or platelets transfusion, no response (NR) - no changes in laboratory tests.

Results: In the 3-line GH group, there was no response: 2 patients died from infection, and 1 patient underwent haploHSCT.
In the 2-line GH group: 2 patients were improved, and 3 patients achieved CR.
In the 1-line GH group, all 5 patients achieved CR.

Conclusions: Allo-MSC may be used to improve graft function in patients with GH after allogenic HSCT.
The best result was observed in patients with 1-line and 2-line GH.

Disclosure: No conflict

A222

REFINING HLA-DPB1 MISMATCH (PERMISSIVENESS/NON PERMISSIVENESS) ASSESSMENT IN ALLOGENEIC STEM CELL TRANSPLANTATION

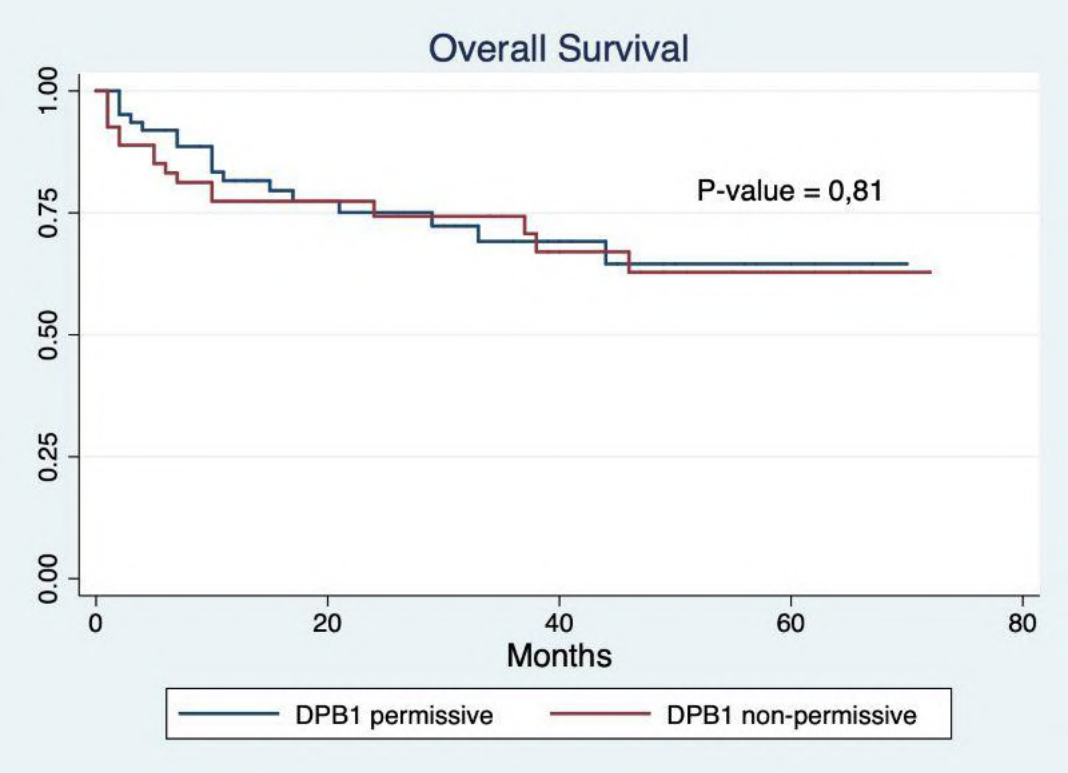
Chiara Camerini[1], *Mauro Leucio Mattei*[1], *Sara Iozzi*[1], *Simona Palchetti*[1], *Martina Betti*[1], *Antonella Gozzini*[1], *Ilaria Cutini*[1], *Irene Donnini*[1], *Edoardo Simonetti*[1], *Giacomo Coltro*[1], *Mirella Giordano*[1], *Roberta Lepori*[1], *Gaia Mirabella*[2], *Sabrina Castiglione*[1], *Elisabetta Pelo*[1], *Chiara Nozzoli*[1]
[1]*Careggi University Hospital, Florence, Italy,* [2]*University of Florence, Florence, Italy*

Background: While high-resolution compatibility across HLA Class I and II loci (HLA-A, -B, -C, -DRB1, -DQB1) is a priority criterion for MUD donor selection, HLA-DPB1 locus is highly polymorphic and frequently mismatched. DPB1 disparities are conventionally classified as permissive or non-permissive, based on T-Cell Epitope (TCE) grouping, aiming to predict the risk of acute Graft-versus-Host Disease (aGvHD) and relapse. However, the clinical utility of this binary classification remains controversial, prompting the need for quantitative molecular assessment methods to accurately predict alloreactivity and clinical outcomes.

Methods: This retrospective study evaluates the influence of non-permissive HLA-DPB1 mismatch, as defined by the T-cell Epitope (TCE) Algorithm version 2.0 and 3.0, on clinical outcomes especially in GvH in a cohort of UD allo-HSCT patients. We analyzed retrospectively data from 122 consecutive patients who underwent UD allo-HSCT at our Center between 2020 and 2025. All patients received grafts from highly matched unrelated donors: 98 patients with HLA 10/10 match and 24 patients with HLA 7/8 match. High-resolution HLA typing was performed by next-generation sequencing (NGS) with AlloSeq Tx17 (CareDx) or AllType FASTplex (OneLambda) assay. We divided patients into two conventional groups, based on TCE Algorithms: permissive versus non-permissive mismatch. Primary endpoints included overall survival (OS), relapse, the incidence of acute GvHD (grade II-IV) and chronic GvHD (moderate/severe). Statistical analysis was performed using the Kaplan-Meier method.

Results: The patient cohort had a median age of 54 years (21-71).
HLA-DPB1 mismatch permissive was present in 65 patients (53%), while 56 (47%) were classified as non-permissive.

- Survival: our analysis showed that the presence of a non-permissive HLA-DPB1 mismatch was associated with a no difference in OS (CI=95%; p-value=0.81) [Fig. 1]. The 5-year overall survival was 69% in the non-permissive group compared to 68% in the permissive group.
- Relapse: the data point out not statistically significant difference between relapsed patients who received non-permissive HLA-DPB1 mismatch (23%) and patients who received permissive HLA-DPB1 mismatch (21%).
- Acute GvHD (II-IV): the 100-day incidence of acute GvHD (grade II-IV) was respectively in HLA 10/10 12% and in HLA 7/8 16%. It was found to be not significantly different in patients with non-permissive HLA-DPB1 mismatch compared to those with permissive mismatch (14% vs 9%).
- Chronic GvHD (Moderate/Severe): incidence of chronic GvHD was 34% in patients who received 10/10 donor; 44% in patients who received 7/8 donor. Similarly, no difference emerged in non-permissive versus permissive HLA-DPB1 mismatch (27% vs 35%).



Conclusions: In our analysis based on conventional TCE grouping, there were no statistically significant differences between the permissive and non-permissive mismatch groups regarding OS, relapse or the incidence of acute or chronic GvHD. This failure to differentiate clinical outcomes highlights the limitations of the binary TCE classification. Although our study is limited for its retrospective design and small cohort size, these findings underscore the necessity to move beyond the traditional definition and adopt quantitative molecular approaches to potentially reveal clinically relevant differences in alloreactivity, enabling better prediction of outcome, risk stratification, maintaining potential GvL effect, and personalized prophylactic regimen adjustments for UD-HSCT recipients.

Disclosure: Nothing to declare.

DYNAMIC CHANGES IN PHASE ANGLE ASSESSED BY BIOELECTRICAL IMPEDANCE ANALYSIS AS A MARKER OF TOXICITY IN PATIENTS UNDERGOING CAR-T CELL THERAPY

Mirko Farina[1], *Giulia Brambilla*[1], *Enrico Morello*[1], *Gabriele Magliano*[1], *Vera Radici*[1], *Silvia Zanon*[1], *Rachele De Domenico*[1], *Laura Donatoni*[1], *Beatrice Battaglio*[2], *Federica Re*[3], *Alessandro Leoni*[3], *Besjana Xhahysa*[3], *Simona Bernardi*[3], *Marco Andreoli*[4], *Daniele Avenoso*[1], *Michele Malagola*[1], *Domenico Russo*[1]
[1]*Unit of Blood Diseases and Bone Marrow Transplantation, Department of Clinical and Experimental Science, University of Brescia, ASST Spedali Civili di Brescia, Brescia, Italy,* [2]*Hematology and Bone-Marrow Transplant Unit, Department of Medicine, Verona University, Verona, Italy,* [3]*Unit of Blood Diseases and Bone Marrow Transplantation, Department of Clinical and Experimental Science, University of Brescia, ASST Spedali Civili di Brescia; Centro di Ricerca Emato-Oncologica AIL (CREA), ASST Spedali Civili di Brescia, Brescia, Italy,* [4]*Dietetics and Clinical Nutrition Unit, ASST-Spedali Civili Brescia, Brescia, Italy*

Background: Chimeric Antigen Receptor T-cell (CAR-T) therapies are highly effective treatments for several hematologic malignancies, but their use is frequently complicated by acute immune-mediated toxicities, mainly cytokine release syndrome (CRS) and immune effector cell–associated neurotoxicity syndrome (ICANS). Early identification of these events is critical, as prompt intervention can optimize clinical management. The phase angle (PhA), derived from bioelectrical impedance analysis (BIA), reflects cellular integrity and body composition, and has emerging value as a biomarker of inflammation. Prospective data on PhA behavior during CAR-T cell therapy are lacking. We investigated whether serial PhA measurements correlate with the onset and course of CRS/ICANS.

Methods: Patients older than 18 years treated since July 2023 with commercial anti-CD19 CAR-T products (axi-cel, tisa-cel, or brexu-cel) were included. Bioelectrical impedance analysis (BIA) and phase angle (PhA) were prospectively measured at pre-lymphodepleting conditioning, on the day of infusion, twice weekly until discharge, and at the onset of CRS/ICANS. An additional assessment was performed on day +30. CRS and ICANS were graded according to ASTCT criteria. Changes in PhA were analyzed in relation to toxicity onset, severity, and subsequent clinical recovery.

Results: Thirty patients were included: 19 (63%) had Diffuse Large B-Cell Lymphoma (10 treated in second line), 5 (17%) Follicular Lymphoma, 3 (10%) Mantle Cell Lymphoma, 2 (7%) Acute Lymphoblastic Leukemia and 1 (3%) Primary Mediastinal B-cell Lymphoma. Products infused were axi-cel (n=18; 60%), tisa-cel (n=7; 23%), and brexu-cel (n=5; 17%). The median age was 62 years (IQR 51-70), and 20 (66%) were male.
Twenty-five patients (83%) developed CRS and/or ICANS (severe CRS 1/30 [3%], severe ICANS 1/30 [3%]), while 5 (17%) experienced no acute toxicity.
A consistent and statistically significant PhA decline was observed in all patients who

developed CRS/ICANS, temporally coinciding with toxicity onset. The median PhA reduction was –1.0° (IQR -0.6° to –1.4°), whereas patients without toxicity showed no PhA decline (median change +0.1°; IQR 0.08°–0.48°; p<0.001) (Figure 1). Patients with severe acute toxicities had higher PhA variation (ΔPhA). During active toxicity, PhA values remained diminished. Following CRS/ICANS resolution, PhA values returned toward or above baseline, reflecting restoration of cellular homeostasis (Figure 1). The PhA decline was associated with CAR-T-related acute toxicities, regardless of the CAR-T product used, the underlying disease, response status at infusion, or any other clinical characteristic analyzed.
No association was found between baseline BMI or nutritional status and either PhA values or ΔPhA, indicating that the observed PhA decline was not driven by differences in body composition.

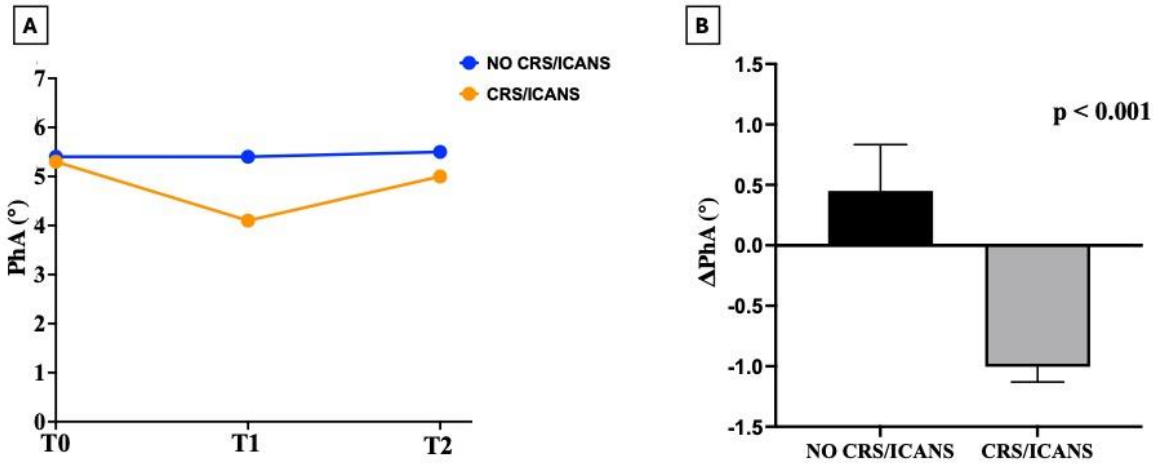

Figure 1. Serial PhA assessment via BIA in patients receiving CAR-T cells.
(A) Variation in phase angle (°) in patients who developed CRS/ICANS (orange) versus those who did not (blue). T0 = lymphodepleting therapy; T1 = onset of CRS/ICANS or day +3 after infusion; T2 = CRS/ICANS resolution or day +6/+9.
(B) Change in phase angle (ΔPhA, °) between day 0 and toxicity onset, or between day 0 and days +3/+6 in patients without toxicity.

Conclusions: Serial PhA assessment via BIA provides a non-invasive, rapid, and sensitive biomarker of immune activation and cellular homeostasis in patients undergoing CAR-T cell therapy. A PhA decrease has been specifically associated with CRS/ICANS and normalizes after recovery, while remaining stable in toxicity-free patients. These findings support integrating PhA monitoring into routine post-CAR-T assessment and suggest its potential utility for early prediction and real-time monitoring of acute toxicities, especially in the growing outpatient CAR-T setting.

Clinical Trial Registry: Not applicable.

A224

HYPOMETHYLATING AGENTS AND VENETOCLAX FOR RELAPSE PREVENTION IN PATIENTS WITH HIGH-RISK MYELOID MALIGNANCIES AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Huiying Qiu[1], *Yu Cai*[1], *Jun Yang*[1], *Jiahua Niu*[1], *Chongmei Huang*[1], *Kun Zhou*[1], *Baoxia Dong*[1], *Ying Tong*[1], *Jie Shao*[1], *Lu Gao*[1], *Xianmin Song*[1], *Liping Wan*[1]
[1]*Shanghai Jiao Tong Univerisity School of Medicine Affiliated Shanghai General Hospital, Shanghai, China*

Background: Allogeneic stem cell transplantation is an effective modality for hematological malignancies. However, disease relapse is still the major barrier for high-risk patients. It was reported that the 1 year recurrence rate was 22.2%，1 year leukemia free survival was 41.5%. The overall survival was less than 10% if patients had disease relapse after transplant. Hypomethylating Agents (azacytidine or decitabine) and venetoclax were effective in myeloid malignancies.

Methods: This is a prospective single arm study. Patients with high-risk AML or MDS aged between 18-70 years old and underwent allogeneic stem cell transplantation will be included if they fulfill the following criteria: adverse risk group of AML by European LeukemiaNet；MDS with high-risk or very high-risk IPSS-R scores or Presence of TP53 mutation；Presence of measurable residual disease at the time of HSCT, requirement of more than 2 courses of induction chemotherapy to reach complete remission (CR), Extramedullary myeloid malignancy, ≥CR2. All patients will be given hypomethylating agents (azacytidine 32mg/m2 or decitabine 5mg/m2) for 5 days and venetoclax 400mg/d for 7 days after allogeneic hematopoietic stem cell transplantation，when their CBC reach the following criteria: ANC ≥ 1.0 × 10e9/L, Hb ≥ 80g/L, and PLT ≥ 50 × 10e9/L；Patients will be excluded if they have concurrent use of target drugs, such as FLT-ITD inhibitor, active aGVHD or chronic GVHD, diseases recurrence, donor chimerism of bone marrow <90% or graft rejection, or active uncontrolled systemic fungal, bacterial, or viral infection. The maintenance therapy will start from 60th days posttransplant, repeated every 28 days until up to 1-year posttransplant. The 1-year leukemia-free survival rate，1-year cumulative recurrence rate and 1-year overall survival will be analyzed.

Results: A total of 39 patients enrolled the study, male: female=20:19, the median age was 48 (18~66) years old. Thirty-two patients were diagnosed with AML, the other 7 patients were diagnosed with MDS. after a median follow-up of 15.6 months, 10 patients relapsed; 5 patients died, 4 of them died of disease relapse, 1 patient died of hepatic failure. The 1-year and 2-year leukemia free survival was 77.24% and 69.51% respectively, the 1-year overall survival was 91.74%. the 1-year cumulative recurrence rate was 22.70%. The most common side effects were cytopenia. Leucopenia developed in 29 (74.35%) patients, 3 of them had grade 3 leucopenia, 1 patient had grade 4 leucopenia, the other 25 patients had grad 1 or 2 leucopenia. Thrombocytopenia developed in 20(51.28%) patients, 3 patients had grad 3 thrombocytopenia, no one with grade 4 thrombocytopenia.

Conclusions: Maintenance therapy with low dose hypomethylating Agents (azacytidine or decitabine) and venetoclax was effective and well-tolerated in relapse prevention for high-risk myeloid malignancies after allogeneic hematopoietic stem cell transplantation. The majority of adverse events were reversible and manageable.

Clinical Trial Registry: The study was approved by the institutional review committee of the ethics committee of Shanghai General Hospital, and registered at clinicaltrials. gov (NCT 05841771)

Disclosure: No.

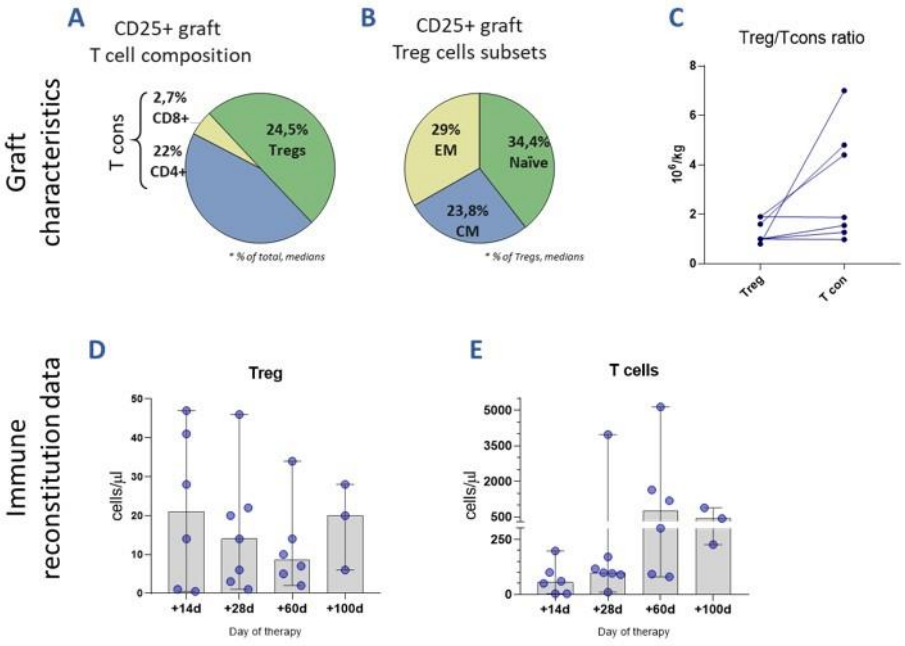
A SIMPLIFIED APPROACH TO GENERATE TREG-ENRICHED GRAFT: TECHNICAL AND EARLY CLINICAL DEVELOPMENT OF CD3-DEPLETION AND CD25-SELECTION

*Viktoria Vedmedskaia[1], Mariia Fadeeva[1], Ekaterina Malakhova[1], Tatiana Sozonova[1], Elena Kulakovskaya[1], Oiuna Lodoeva[1], Elvira Musaeva[1], Elena Osipova[1], Alex Kazachenok[1], Vladislav Belchikov[1], Anastasia Melkova[1], Kirill Butov[1], Ivan Zvyagin[2], Anna Bogoiavlenskaia[1], Larisa Shelikhova[1], **Dmitry Pershin**[1], Mihael Maschan[1]*
[1]Dmitry Rogachev National Medical Research Center Of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation (the), [2]Department of Genomics and Postgenomic Technologies, Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, Moscow, Russian Federation (the)

Background: The primary challenge in allo-HSCT graft engineering is balancing GVHD prevention against immune reconstitution and infection control. Engineering Treg: Tcon composition of the graft is a novel approach to achieve this balance, reducing dependence on pharmacological immunosuppression and its associated toxicity (DiIanni 2011, Marteli 2014, Pierini 2021). We propose a simplified approach to engineer Treg-enriched graft by combining a CD3-depleted graft with a concurrent CD25-enriched product containing T-memory cells and Tregs, designed to promote tolerance while supporting antiviral immunity.

Methods: A clinical-grade protocol for manufacturing two-component haploidentical grafts (CD3-depleted/CD25-enriched) was developed. Following six validation runs, the protocol received approval from the local independent ethics committee and was applied for seven ALL-patients.
Grafts were manufactured from a single stimulated donor apheresis product using the CliniMACS Plus system. The CD3-depleted grafts were generated using CD3 Nanobeads (*CytoSinct*). The CD25-enriched grafts were isolated as the non-target cell fraction from a CD25-depletion procedure (*CliniMACS CD25 Reagent GMP, Miltenyi Biotec)*. The cellular composition of both graft components was assessed by FC. All manufactured grafts met the established release criteria. Patients were monitored for engraftment, immune reconstitution, GVHD, viral infections and virus-specific T cells response (IFNγ ELISpot assay).

Results: Graft characteristic: CD3+ T cells were depleted by *lg* 3,34 (2,9–3,8), a median dose was 0.15×10⁶/kg (0.05-0.64). CD34⁺ stem cells median administrated dose was 9,9×10⁶/kg (7-11,8). Treg recovery was 50.4% (42.3–64.8%) across all CD25+products (including validation). The median administered Treg dose was 1×10⁶/kg (0.8-2). The median total dose of T-cons was 1,8×10⁶/kg (0,84-7,03) for both-component grafts. Tcon composition: Naïve 16.3% (3-27%), Memory 83.7% (72-97%).
No infusion-related toxicities, aGVHD, or early inflammatory or neurotoxic events were observed. All patients achieved primary engraftment, with medians of day 10 (8-14) for neutrophils/platelets and day 15 (11-20) for WBC.
By day +14 marked expansion of Tregs was detected of a median of 28 cells/μL (1-47) (34% among CD4+ T-cells 29-74%)), and by day +28 to a median of 14 cells/μL (1-46) (13% among CD4+ T-cells 5-26%)) in patient's peripheral blood. The median total T-cell count was 100 cells/μL (10-3900) by day +28 (*fig.1*). By day 60, virus-specific T cells were detected in 3/7 patients.



Conclusions: These early results demonstrate the safety and feasibility of a combined CD3-depleted + CD25+enriched graft, which was well-tolerated, supported prompt engraftment, and induced Treg expansion. This approach may provide antiviral protection through a preserved memory T-cell compartment. A prospective trial testing this approach is ongoing.

Disclosure: Nothing to declare.

A226

REAL-WORLD OVERALL SURVIVAL OUTCOMES AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ACUTE LYMPHOBLASTIC LEUKEMIA: EXPERIENCE FROM A MEXICAN CENTER

Rosa Adriana Alvidrez-Gonzalez[1], *Andrés Yesid Bonilla-Salcedo*[1], *Mistral Castellanos-Mares*[1], *Victor Iván Salinas-Herrera*[1], *Vicky Margarita Moncada-Gardea*[1], *Grecia Pamela Martínez-Vázquez*[1], *Irma Karen Pellon-Tellez*[1], *Omar Eduardo Fernandez-Vargas*[1], *Luis Manuel Valero-Saldaña*[1], *Victor Itai Urbalejo-Ceniceros*[1]
[1]*Instituto Nacional de Cancerologia, Mexico City, Mexico*

Background: In Mexico, ALL ranks tenth in cancer frequency, with 7,457 new cases and 5,126 deaths reported by Globocan 2022, and an annual incidence of 4.2 cases per 100,000 people. HSCT remains a potentially curative strategy for adults with ALL; however, real-world outcomes and access to transplantation remain variable.

Methods: We conducted a retrospective study focused on patients diagnosed with ALL, using the historical registry of the National Cancer Institute, covering the period from January 2018 to December 2024, reviewing 303 medical records. A total of 261 adult patients with ALL were included in the analysis.

Results:

The median age at diagnosis was 32 years. Gender distribution was balanced, with 50.6% females and 49.4% males. Most patients were younger than 40 years (68.6%). B-cell ALL was observed in 93.9% of cases, while 6.1% had T-cell ALL. High-risk disease was present in 82.8% of patients.

Regarding cytogenetics, 38.3% had a normal karyotype and 32.6% showed hypodiploidy. KMT2A/MLL rearrangements were identified in 10.7%. Complex karyotype was observed in 5.0%, and other very high-risk abnormalities were infrequent. BCR-ABL positivity was documented in 17.2% of patients.

Induction therapy most commonly consisted of CALGB 10403 (45.6%), followed by Hyper-CVAD (31.0%) and BFM (10.7%). CALGB 10403 achieved the highest complete remission (CR) rate (76.2%), followed by BFM (75.0%) and Hyper-CVAD (66.2%).

A total of 58 patients (22.2%) underwent HSCT. Haploidentical transplantation was the most frequent modality (55.2%), followed by matched related donor (MRD) transplantation (39.7%); only two patients received matched unrelated donor transplants. Myeloablative conditioning was used in 89.5% of cases. The most commonly used conditioning regimens were FluBuCy (56.1%) and FluBu (29.8%).

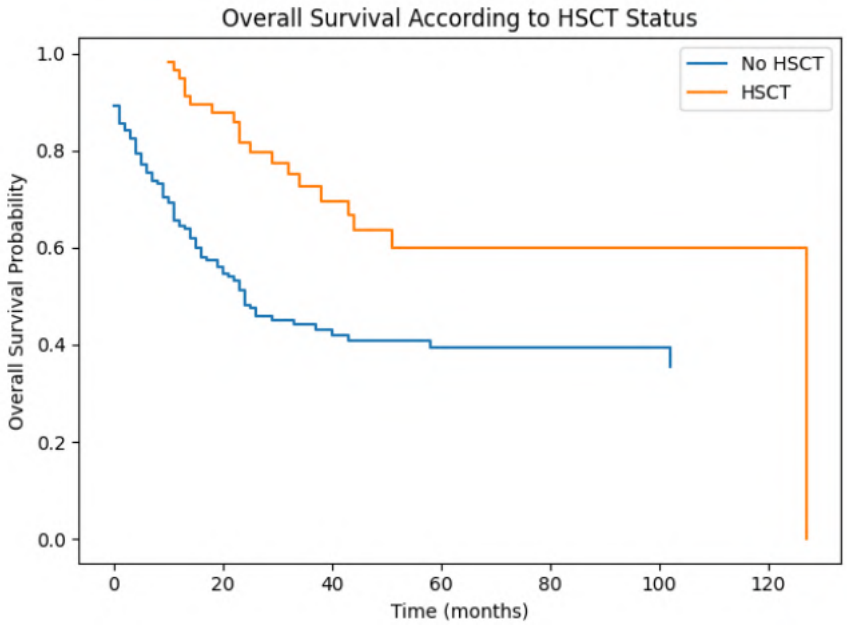
Post-transplant complications were frequent. Graft-versus-host disease (GVHD) accounted for 61% of reported complications, followed by mucositis (30%) and infections (9%).

In the overall cohort (n = 261), median overall survival was 24 months. When stratified by transplant status, patients undergoing allogeneic HSCT demonstrated significantly improved

survival compared with non-transplanted patients (median OS 35 vs 14 months; HR 0.42, 95% CI 0.26–0.69; log-rank p < 0.001).

When stratified by transplant subtype, median OS was 36.5 months for MRD and 36 months for haploidentical transplantation, with no significant difference between groups (log-rank p = 0.696). Conditioning intensity did not significantly impact OS, with median OS of 34 months for myeloablative conditioning and 44.5 months for RIC (p = 0.650). The number of prior treatment lines before HSCT was also not associated with significant differences in OS (p = 0.84).

The most frequent causes of death were infection (19.6%) and disease progression (18.1%). Mortality increased over the study period, peaking in 2023 and remaining high in 2024.



Variable	No HSCT(n)	Median OS no HSCT(mo)	HSCT(n)	Median OS HSCT (mo)	HR HSCT vs No(95% CI)	p value
Overall	203	14	58	35	0.42(0.26-0.69)	<0.001
Lines of therapy ≤2	165	22	42	35	0.41 (0.23–0.73)	0.002
Lines of therapy ≥ 3	38	23	16	41	0.44 (0.20–0.98)	0.039

Standard risk	43	16	2	75	0.50 (0.07–3.88)	0.490
High risk	159	14	56	34	0.44 (0.26–0.73)	0.001
MRD (-) post induction	110	NR	36	35	0.68 (0.35–1.33)	0.255
MRD(+) post induction	57	9	22	35	0.32 (0.15–0.69)	0.002
Conditioning MAC	-	-	52	35	0.41 (0.25–0.69)	<0.001
Conditioning RIC	-	-	6	NR	0.55 (0.18–1.66)	0.280

Table.1 Overall survival according to HSCT status across clinical subgroups. NR=Not Reached

Conclusions:

In this real-world cohort of adult patients with ALL, allogeneic HSCT was associated with improved overall survival, confirming its key role in high-risk disease. Comparable outcomes between haploidentical and matched related donor HSCT support alternative donor strategies to expand timely access and improve outcomes in resource-limited healthcare systems.

Disclosure: Nothing to declare.

A227

EFFICACY AND SAFETY OF GRANULOCYTE COLONY STIMULATING FACTOR (GCSF) USE FOLLOWING CHIMERIC ANTIGEN RECEPTOR T CELL THERAPY (CAR-T): A SYSTEMATIC REVIEW

*Samuel Sherng Young Wang[1], Kai Lin Chan[2], **Xiao Ran Luo**[2], Keerthana Mallavarapu[2], Haotian Tong[2], Esther Chan[3], Edwin Thong[3], Samuel Miny[4], Michelle Poon[3]*
[1]SingHealth Medicine Academic Clinical Programme, Singapore, Singapore, [2]Duke-NUS Medical School, Singapore, Singapore, [3]Department of Haematology, National University Cancer Institute, Singapore, Singapore, [4]Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore

Background: CAR-T therapy, effective for hematologic malignancies, can cause complications like hematologic toxicities, cytokine release syndrome (CRS), and immune

effector cell-associated neurotoxicity syndrome (ICANS). Early use of granulocyte colony-stimulating factor (G-CSF) for neutropenia post-CAR-T is controversial due to CRS and ICANS risks, with limited and conflicting clinical data.

Methods: Our systematic review aims to review the literature of early G-CSF administration post CAR-T therapy on the duration and severity of neutropenia, prevalence of early infections and risks of CRS and ICANS.

A systematic literature search from the inception of each database to August 2025 identified 515 studies from Medline, Embase, and the Cochrane Library. After review, 10 studies (involving 1203 participants) were included. All studies on CAR-T in approved indications, evaluating the safety and efficacy of G-CSF use on clinical outcomes compared to its omission, were included.

Results: Among the 10 retrospective studies, 3 were multicentre and 7 single centre, primarily in the USA (n=5) or China (n=3). All examined GCSF use post-CD19 CAR-T, with 6 focusing on B-NHL, 3 on B-ALL, and 1 on both. GCSF timing varied significantly amongst studies. 7 studies used it pre-emptively for neutropenia, 2 as primary prophylaxis, and 1 without a defined rationale. CAR-T types included axi-cel, tisa-cel, brexa-cel, and lisocel.

All studies assessed the impact of GCSF on CRS, ICANs, and neutropenia duration, with 8 also reporting on neutropenia severity. Infectious complications were noted in all studies, but outcomes varied, with some reporting febrile neutropenia rates, others severe infection rates, or specific infection types.

For CRS, 5 studies showed increased incidence of all grades (14-43%) or severe CRS (>G2) (33-36%) with GCSF, 1 showed increased CRS duration (4.5 vs 8 days), and 4 showed no impact, including one using propensity score matching. For ICANS, only 1 study showed increased incidence (17% vs 0%) with GCSF.

Regarding neutropenia duration, 4 studies showed improvement, 4 no benefit, and 2 prolonged neutropenia with GCSF. Among 8 studies on neutropenia severity, only 1 showed reduced G3/4 rates with GCSF. Infection impact analysis showed 1 study with improved FN rates (56% vs 81%, p =0.018) in the GCSF group, and another with higher severe infection rates (61 vs 27%, p=0.007). These findings were likely limited by heterogeneity in GCSF timing and patient populations, affecting conclusions on its efficacy regarding infective risks.

Conclusions: Our findings demonstrated that GCSF use may potentially exacerbate the rates and severity of CRS rates associated with CAR-T cell therapy. Given above, the routine use GCSF to reduce infection risks post CAR T cell therapy should be avoided while awaiting randomized, prospective data confirming the efficacy of growth factors in preventing infections without exacerbating CRS.

Disclosure: Nothing to declare.

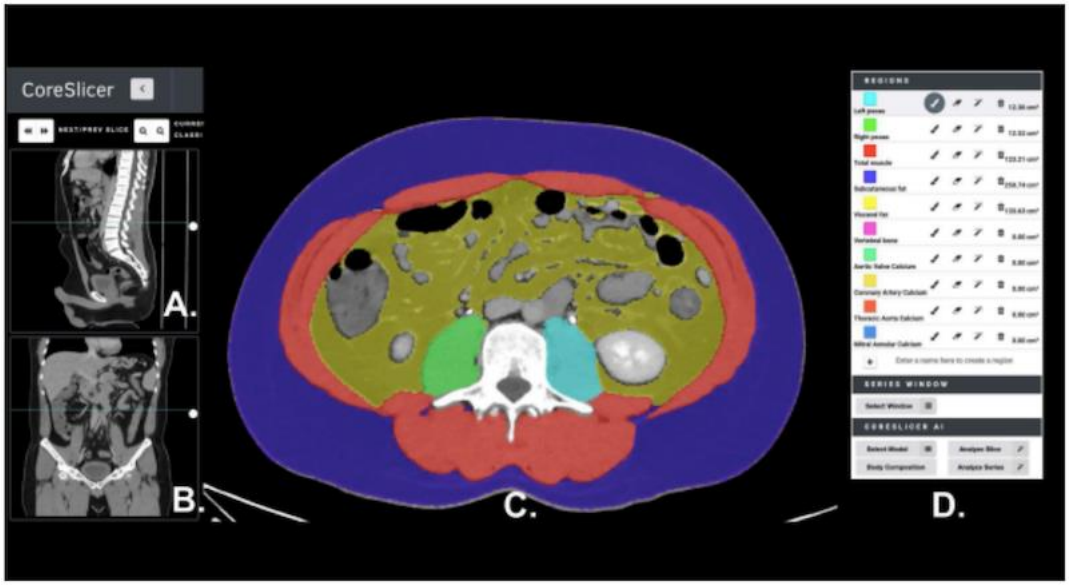
A228

COMPUTED TOMOGRAPHY-DERIVED MUSCLE QUALITY PREDICTS LENGTH OF HOSPITALIZATION AFTER STEM CELL TRANSPLANTATION

Sebastian Burgos-Canales[1], Diego Ruiz-Ruiz[1], América Iliana Valencia-Huerta[1], José Manuel Moreno-Mirón[1], Jonahi Siloe Serrano-Heredia[1], Flor María Armillas-Canseco[1], Eucario León-Rodríguez[1], ***Christianne Bourlon-De los Ríos***[1]
[1]*Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico*

Background: Poor muscle quality, reflected by low skeletal muscle attenuation (SMA) on computed tomography (CT), has emerged as a potential marker of adverse outcomes across hemato-oncological populations. However, its association with post-transplant recovery remains unclear. We aimed to evaluate the relationship between CT-derived muscle quality and length of hospitalization (LOH) in patients undergoing hematopoietic stem cell transplantation (HSCT).

Methods: We retrospectively analyzed a cohort of 49 patients from Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán (INCMNSZ), a tertiary referral center in Mexico, who underwent HSCT from 2015 to 2025. We included patients who underwent autologous or allogeneic HSCT and had a CT scan available for body composition analysis from 30 days before to 7 days after conditioning. Body composition was assessed at the third lumbar vertebra (L3) to derive lean body mass (LBM), skeletal muscle index (SMI), and adipose tissue indices. All CT datasets were processed using the CoreSlicer platform following a standardized segmentation workflow (Figure 1). Muscle quality was evaluated using mean SMA expressed in Hounsfield units (HU). Sarcopenia was defined a priori using sex-specific SMI cut-offs (SMI <52.4 cm^2/m^2 in men and <38.5 cm^2/m^2 in women). Length of hospitalization was analyzed as a continuous variable and stratified into tertiles. Continuous variables are presented as median (Q1–Q3), and categorical variables as counts and percentages. Associations were assessed using non-parametric tests and Spearman correlation.



Results: Median age was 46 years (IQR: 29–52), 51% were male, and 59% underwent allogeneic HSCT (Table 1). Median hospitalization duration was 28 days (IQR: 21–37). CT-defined sarcopenia was present in 37% of patients. SMA decreased progressively across increasing tertiles of hospitalization (38 [33–43], 34 [29–39], and 30 [20–34] HU; p = 0.029), and correlated inversely with hospitalization length (Spearman ρ = −0.33; p = 0.021). In contrast, SMI, LBM, and FFMI showed no significant associations with hospitalization duration (p > 0.5). Subcutaneous adipose tissue index (SATI) differed across tertiles (p = 0.032) but lacked a consistent trend. As expected, hospitalization was longer among allogeneic vs autologous transplant recipients (p < 0.001).

Table 1. Distribution of clinical and body composition variables across tertiles of length of hospitalization

	T1 (Shorter LOH) n= 17	**T2 (Intermediate LOH) n= 16**	**T3 (Longer LOH) n= 16**	**p value***

Sarcopenia, n(%) Non-sarcopenic Sarcopenic	9 (53) 8 (47)	10 (62) 6 (38)	12 (75) 4 (25)	0.5

*Fisher's exact test; Kruskal-Wallis rank sum test. Abbreviations: BMI = body mass index; LBM = lean body mass; FFMI = fat-free mass index; SMI = skeletal muscle index; SATI = subcutaneous adipose tissue index; VATI = visceral adipose tissue index; SMA = skeletal muscle attenuation; HU = Hounsfield units.

Conclusions: In this HSCT cohort, lower skeletal muscle quality—but not muscle mass—was significantly associated with prolonged hospitalization. These findings suggest that SMA may serve as a more sensitive imaging biomarker of functional reserve than traditional measures of muscle quantity. Lower skeletal muscle attenuation was consistently linked to longer inpatient stay, suggesting that muscle quality may better capture early post-transplant vulnerability. Larger and multivariate studies are warranted to validate these findings and to explore whether CT-derived body composition phenotypes such as myosteatosis, lean mass depletion, or combined phenotypic patterns independently predict inpatient utilization and early transplant morbidity.

Disclosure: Nothing to declare.

A229

THE ROLE OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH CHRONIC MYELOMONOCYTIC LEUKEMIA

*Ksenia Tsvirko[1], Svetlana Ziganshina[1], **Nikolay Tsvetkov**[1], Yulia Vlasova[1], Tatiana Gindina[1], Elena Morozova[1], Alexander Kulagin[1]*
[1]Pavlov University, RM Gorbacheva Research Institute, Saint Petersburg, Russian Federation (the)

Background: Chronic myelomonocytic leukemia (CMML) is a myeloid neoplasm characterized by persistent monocytosis and morphological features of both myelodysplastic and myeloproliferative syndromes. The median overall survival for high-risk CMML patients receiving conventional therapy is 18-22 months [Tremblay D. et. al., Leukemia, 2025]. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) remains the only potentially curative treatment modality for CMML, offering a chance for long-term remission and improved overall survival (OS).

Methods: A retrospective study included 112 patients with a confirmed diagnosis of CMML who were managed at the RM Gorbacheva Research Institute, Pavlov University from 2011 to 2025. OS was analyzed using the Kaplan-Meier method, and factors affecting OS were assessed by Cox regression analysis. The median age at diagnosis was 56 years (range: 18-88), with males comprising 66% (n=74) and females 34% (n=38). According to the 2016 World Health Organization classification, 38 (34%) patients were classified as CMML-0, 31 (28%) as CMML-1, and 43 (38%) as CMML-2 at diagnosis. During the follow-up period, transformation to acute myeloid leukemia (AML) was documented in 33 (29%) patients. The median follow-up was 16.5 months.

Results: The 2-year OS for the entire cohort was 57% (95% CI 47.0-68.5%), with a median OS of 44 months. The median time to transformation to AML from diagnosis was 6.5 months. The presence of constitutional symptoms was identified as a factor significantly associated with worse OS (HR = 2.38, p = 0.009). The following factors showed a trend towards statistical significance: documented transformation to AML (HR = 1.84, p = 0.052), bone marrow blast count (HR = 1.02, p = 0.079), and absolute monocyte count in peripheral blood (HR = 1.03, p = 0.088)at disease onset. The 2-year OS for CMML patients with and without blast transformation was 38.8% (95% CI 26.0-48.0%) and 59.9% (95% CI 48.5-69.0%), respectively (p=0.05). The highest number of complete responses was observed with hypomethylating agent-based therapy; however, this difference did not reach statistical significance (p=0.31).
Allo-HSCT was performed in 24 (21%) patients, all of whom were classified as intermediate-2 or high-risk according to the CMML-specific prognostic scoring system (CPSS). At the time of transplant, 15 (62%) patients had a bone marrow blast count exceeding 10%. 9 (38%) patients underwent allo-HSCT in the chronic phase (CP), including those who achieved CP

after blast transformation, with a bone marrow blast count of <5% at the time of transplantation; the 2-year OS in this group was 100%. In contrast, the 2-year OS for patients with a blast count >10% at the time of allo-HSCT was 34.4% (95% CI 17.0-67.5%, p=0.014). The causes of death after allo-HSCT were: disease relapse in 6 (46%) patients, primary graft failure in 1 (8%), and infectious complications in 6 (46%) patients.

Conclusions: Allo-HSCT remains the only potentially curative treatment for patients with CMML. A bone marrow blast count of less than 5% is associated with superior post-transplantation survival. To further improve transplant outcomes, future efforts should focus on determining the optimal timing for the procedure and selecting the most effective pre-transplantation therapy.

Disclosure: Nothing to declare.

A230

TRANSITIONING CAR-T CELL THERAPY FOR MYELOMA TO THE OUTPATIENT SETTING: FIRST EXPERIENCE FROM A GERMAN CENTER

Philipp Gödel[1], *Tim Richardson*[1], *Ruth Flümann*[1], *Christian Funke*[1], *Eva Heger*[1], *Malte Kiehl*[1], *Udo Holtick*[1], *Christof Scheid*[1]
[1]*University of Cologne, Cologne, Germany*

Background: The BCMA-targeting CAR-T cell product ciltacabtagene autoleucel (cilta-cel) is increasingly used as standard-of-care therapy in relapsed or refractory multiple myeloma (MM). Due to safety concerns, treatment is usually administered with inpatient monitoring for 14 to 20 days. With growing experience in risk stratification and management of acute toxicities, outpatient treatment is emerging as a potential alternative.

Methods: At a tertiary care center in Germany treating approximately 100 CAR-T cell patients annually, we identified patients suitable for outpatient treatment based on predefined criteria: reliable adherence, good performance status, adequate organ function, absence of relevant comorbidities (e.g. cardiovascular or neurologic disease), low tumor burden (assessed by paraprotein levels and PET/CT) or response to bridging therapy, travel time of less than 60 minutes to the center, availability of a caregiver in the same household. Patients received standard lymphodepleting chemotherapy in the outpatient setting. Cilta-cel was infused on day 0 at our center, followed by a 6-hour observation. Post-infusion monitoring consisted of outpatient visits 3 times/week including clinical assessment and laboratory testing, daily telephone contact by trained medical staff, and patient-performed monitoring of vital signs and ICE scores at home.
Round-the-clock availability of CAR-T–experienced physicians as well as immediate access to emergency and intensive care facilities, including tocilizumab, was ensured. Dexamethasone 10 mg and oral standby antibiotics were prescribed as standby medication and used only after medical consultation. Data was retrospectively analyzed, CRS and ICANS grading per ASBMT consensus criteria.

Results: Between 08/2023 and 06/2025, 11 myeloma patients were treated in the outpatient setting. Median age was 61 years (range 47–73), median ECOG was 0 (range 0–1), median number of prior therapy lines before apheresis was 2 (range 1–9), median vein-to-vein time 88 days (range 55–123).
Acute toxicity was generally mild. Nine patients developed CRS, which was grade 1 in eight cases and grade 2 in one case with no ICANS observed. Within the first 30 days after infusion, four patients (36.4%) required hospitalization, with a median length of stay of 3 days (range 1–5). Two patients presented to the emergency department due to fever and were admitted at their own request, while two patients were after a second consecutive day of fever during scheduled outpatient follow-up. Reasons for hospitalization were grade 2 CRS in one patient and persistent fever with neutropenia in three patients. Tocilizumab was administered in all readmitted patients, leading to rapid symptom resolution after a single dose in each case. Antibiotic therapy for neutropenic fever was initiated in one outpatient and three inpatients with no infection documented in any of those.
Median absolute lymphocyte count on day 10 post-infusion was 0.58 $\times 10^9$/L (range 0.09–3.71). Best overall response was complete response in 10 patients and stable disease in one patient. No deaths occurred within the first 6 months after infusion.

Patient Characteristic	**Value (n = 11)**		
Age at infusion, years	61 (47–73)		
Sex, n (%)	Male 9 (82%)	Female 2 (18%)	
ECOG performance status at CAR-T, n (%)	0: 8 (73%)	1: 3 (27%)	
ISS stage at diagnosis, n (%)	I: 3 (27%)	II: 4 (36%)	III: 4 (36%)
High-risk cytogenetics, n (%)	6 (55%)		
Median number of prior therapy lines	2 (1–9)		
Triple- or penta-refractory disease, n (%)	8 (73%)		
Prior BCMA-directed therapy, n (%)	2 (18%)		
Bridging therapy administered, n (%)	10 (91%)		
Response to bridging therapy, n (%)	≥PR: 8 (73%)	SD/PD: 3 (27%)	
Vein-to-vein time, days	88 (55–123)		
Baseline creatinine at CAR-T, mg/dL	0.86 (0.59–1.19)		
Baseline albumin at CAR-T, g/L	42 (33–46)		
CRS occurrence, n (%)	9 (82%)		
CRS grade ≥2, n (%)	1 (9%)		

ICANS, n (%)	0		
Hospitalization within 30 days, n (%)	4 (36%)		
Length of inpatient stay, days	3 (1–5)	12 days in total	
Best overall response, n (%)	CR 10 (91%)	SD 1 (9%)	

Conclusions: In a selected patient population within an experienced center, outpatient administration of cilta-cel appears safe and feasible. This approach may reduce unnecessary hospital stays while preserving patient quality of life and conserving medical and financial resources.

Disclosure: Nothing to declare.

THE PRACTICAL DIFFICULTIES OF DLI THERAPY: A SINGLE-CENTRE AUDIT OF DLI COLLECTION AND USE

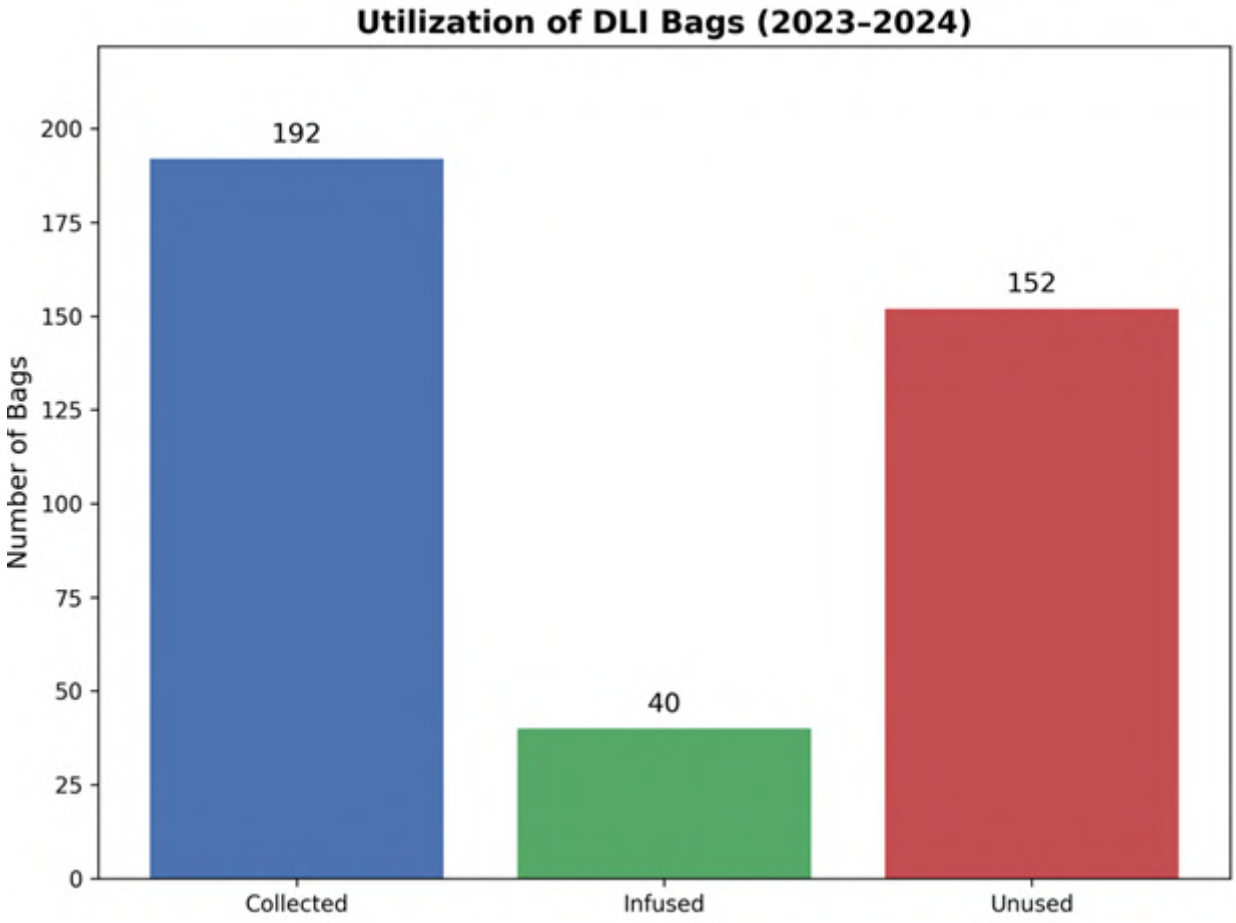
William Fischer[1,2], *Luani Barge*[1,3], *Victoria Potter*[1], *Anna Sargent*[1], *Shreyas Hanmantgad*[1], *Michelle Kenyon*[1], *Madson Correia de Farias*[1], *Mili Shah*[1], *Varun Mehra*[1], *Patricia Cardoso*[1], *Sotiria Besikli*[1], *Rodrigo Nogueira*[1], *Maise Dias*[1,2], *Pramila Krishnamurthy*[1]
[1]*King's College Hospital, London, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Hospital das Clinicas da Universidade de Sao Paulo, Ribeirao Preto, Brazil,* [3]*University of Queensland, Brisbane, Australia*

Background: Donor lymphocyte infusion (DLI) is an important strategy after haematopoietic cell transplantation (HCT), particularly following T-cell–depleted conditioning where mixed or falling chimerism may occur. DLI can be administered prophylactically, pre-emptively (falling chimerism or MRD positivity), or therapeutically (frank relapse). At our centre, bulk DLI are harvested at a second collection and then cryopreserved in aliquots. However the clinical picture is dynamic, and anticipating the timing of requesting a new donor apheresis can be difficult to predict e.g. if chimerism or MRD improves as a result of immune suppression wean, or a patient is too unwell after chemotherapy to receive DLI. This present an ethical issue around requesting second donations and we wished to audit our practice.

Methods: We retrospectively analysed all DLI collections over a 2-year period in adult patients undergoing HCT at King’s College Hospital.

Results: Between January 2023 and December 2024, DLI were requested for 49 patients (AML, n=26 or MDS, n=12). Of 49 requests, 43 were collected and 24 (55.8%) infused (15 pre-emptive, 9 therapeutic); 6 were cancelled due to T-cell Chimerism recovery, relapse, or donor issues. Of the 19 DLIs not infused, reasons included death (n=7), chimerism recovery (n=5), GVHD (n=4), MRD negativity (n=2), and relapse (n=1). Within the pre-emptive group, 11 patients (73.3%) had falling chimerism, while 4 (26.6%) were MRD positive before infusion.Median time from transplant to request was 116 days (33–5230). Eight (16%)

patients were on immunosuppression at request, only one at collection. Timing after transplant that the new collection was organized (<100 vs >100 days) showed no correlation with the likelihood of infusion or mortality. Median time from request to collection was 45 days (20–231) and from collection to infusion 33.5 days (4–219). A total of 192 bags were prepared (median 4.8 per patient), but only 40 were used (median 2 doses per patient), leaving 152 unused.
Regarding patient outcomes, 8 patients relapsed after pre-emptive DLI, 5 of whom had falling chimerism; only one MRD-positive patient relapsed and died. Among these, 4 achieved remission with full donor chimerism. Overall, higher or full donor chimerism was achieved in 7 patients (63.6%), with a median time to best response of 171 days (IQR 125–241). In the therapeutic group, 5 patients died due to relapse. The remaining 4 achieved disease control when DLI was combined with additional therapies (Gilteritinib, n=1; Venetoclax + Azacitidine, n=3).



Category	Total number and/or Median	Notes
Patient with DLI requested	49	AML (N=26) MDS(n=12)

Collection performed	43	6 cancelled (recovery, relapse, donor issues)
Infusions performed	24 (55.8%)	Pre-emptive (n=15), Therapeutic (n=9)
Not infused	19 (44.2%)	Death (N=7), Recovery (N=5), GVHD (N=4), MRD- (N=2), Relapse (N=1)
Median Time: • Transplant to request • Request to collection • Collection to infusion	• 116 days (33-5230) • 45 days(20-231) • 33.5 days(4-219)	8 patients on immunosuppression at request No correlation with <100 or >100 days post-transplant
Pre-emptive DLI subgroup	11 falling chimerism, 4 MRD+	
Therapeutic DLI subgroup	9 infused	

Conclusions: DLI planning is complex. Nearly half of collected DLIs were never used, mainly due to chimerism recovery or clinical deterioration, causing major resource waste (152 unused bags) and risk to the donor. Delays and repeated donor collections further complicate care. To reduce waste and improve efficiency, we propose requesting fewer bags, infusing the first dose fresh when feasible, and freezing only the remaining doses. For patients who relapse, there may be scope to assess response to first cycle of salvage before requesting new donor lymphocyte collection, although this must be balanced by donor/procedural availability. These changes could simplify logistics, minimize donor burden, and optimize DLI utilization.

Disclosure: Nothing to declare.

A232

EARLY STEROID PROPHYLAXIS AS A STRATEGY TO REDUCE CAR T-CELL TOXICITIES WITHOUT AFFECTING EFFICACY

*Alessio Maria Edoardo Maraglino[1], **Simona Sammassimo**[1], Anna Vanazzi[1], Simonetta Viviani[1], Tommaso Radice[1], Paulina Nierychlewska[1], Irene Monella[1], Rocco Pastano[1], Enrico*

Derenzini[1]
[1]*Division of Oncohematology, IEO European Institute of Oncology IRCCS, Milan, Italy*

Background: CD19-directed chimeric antigen receptor T-cell (CAR T-cell) therapy is associated with potentially life-threatening toxicities, primarily cytokine release syndrome (CRS) and immune-effector-cell–associated neurotoxicity syndrome (ICANS). Higher-grade CRS and ICANS occur more frequently in patients with high disease burden and poor response to bridging. The prophylactic use of corticosteroids before CAR T-cell infusion has been proposed to mitigate these toxicities, but supporting evidence remains limited to the ZUMA-1 study (cohort 6) and real-world evidence is lacking.

Methods: We performed a retrospective analysis of 23 consecutive adult patients with lymphoproliferative disorders who received CD19-directed CAR T-cell therapy (axicel and brexucel) at our institution between June 2023 and May 2025. Per institutional guidelines, prophylactic steroids were administered according to the ZUMA-6 schedule following axicel and brexucel, in case of less than complete response to bridging therapy, residual bulky masses and elevated LDH at the time of CAR-T cell infusion. Early use of anakinra for grade 1 ICANS was implemented as well, in order to further reduce the incidence of severe neurotoxicity.

Results: After a median of 15 months from diagnosis (range 4–143), all patients (N=23) underwent lymphodepleting therapy with fludarabine and cyclophosphamide, followed by autologous CD19-directed CAR T-cell infusion. In line with approved indications, 18 patients (78%) with relapsed/refractory (r/r) diffuse large B-cell lymphoma (DLBCL, n = 13), r/r primary mediastinal large B-cell lymphoma (PMBCL, n = 2) or r/r follicular lymphoma (FL, n = 3) received axicabtagene ciloleucel (Yescarta), whereas 5 patients (22%) with r/r mantle cell lymphoma (MCL, n = 4) and r/r B-cell acute lymphoblastic leukemia (B-ALL, n = 1) received brexucabtagene autoleucel (Tecartus). 18 patients (78 %) received histology-specific bridging therapy. According to our institutional policy, 21 (91%) patients received prophylactic corticosteroids (11 DLBCL, 3 FL, 2 PMBCL, 4 MCL, 1 B-ALL). At the time of CAR T-cell therapy, the median age was 53 years (range 24–69) and 2 patients (9%) achieved a complete response (CR). Prophylactic steroid therapy consisted in dexamethasone 10 mg per day on days 0, +1, and +2 following CAR T-cell infusion. After a median of 4 days (range, 1–7), 23 patients (100 %) developed grade ≤2 CRS. For persistent fever >72 hours or grade 2 CRS, all patients received a maximum of two 8-mg/kg IV doses of tocilizumab. 14 patients (61%) were also treated with dexamethasone 10 mg every 6 hours for refractory CRS until symptoms resolution. On day +7, 2 patient (9%) experienced grade 1 ICANS (ICE score 7–9) and received dexamethasone 10 mg every 6 hours and required anakinra 100 mg SC every 6 hours until resolution. All patients (100%) were discharged with no recurrent CRS or ICANS. After a median follow-up of 13 months (range 3–26) from day 0, 16 patients (69%) showed a complete response to CAR T-cell therapy.

Conclusions: Prophylactic dexamethasone before CAR T-cell infusion appears to be feasible and may reduce the incidence of severe CRS and ICANS without compromising clinical efficacy in the world practice. Larger prospective studies are warranted to confirm these findings.

SEQUENTIAL IMMUNOMODULATION WITH PRE-APHERESIS PRIMING AND POST-INFUSION BOOST TO RESTORE T-CELL FITNESS AND IMPROVE ANTI-CD19 CAR-T EXPANSION IN BENDAMUSTINE-EXPOSED R/R B-NHL: A PILOT STUDY

Fangfang Cheng[1], Peihao Zheng[1], Guoai Su[1], Huihui Zhao[1], Yue Wu[1], Ruijie He[1], Chen Zheng[1], Xuelin Han[1], ***Yajing Zhang***[1]
[1]*Beijing Gobroad Boren Hospital, Beijing, China*

Background: Bendamustine exposure in relapsed/refractory (R/R) B-cell non-Hodgkin lymphoma (B-NHL) is associated with prolonged T-cell dysfunction, which may compromise autologous CAR-T manufacturing and in vivo expansion. We explored a sequential immunomodulatory approach incorporating pre-apheresis priming to improve T-cell fitness prior to leukapheresis and an early post-infusion boost to support CAR-T expansion and response depth.

Methods: This investigator-initiated, single-center pilot study enrolled 7 adults (median age 59; range 48-76) with bendamustine-exposed within the previous 3 months R/R B-NHL (DLBCL n=4; tFL n=1; MCL n=1; Richter transformation n=1) treated between March 2024 and December 2025. Pre-apheresis priming consisted of ibrutinib (420-560 mg/d) plus camrelizumab (200 mg IV q21d) for 1–2 cycles, followed by leukapheresis. Patients received standard lymphodepletion and autologous anti-CD19 CAR-T infusion (0.7–1.6×10^6 CAR+ cells/kg). Pomalidomide (2-4 mg PO daily, 14 days) was planned from day +3 as a post-infusion boost if clinically tolerated. CD3+ T cells subsets were assessed by flow cytometry before priming and immediately pre-apheresis (TN: CD45RA+CCR7+; TCM: CD45RO+CCR7+; TSCM: CD45RA+CCR7+CD95+). CAR transgene levels were monitored by qPCR performed at prespecified time points (e.g., days 0, 4 , 7 , 11, 15, 21, 28).

Results: Leukapheresis and manufacturing were successful in 7/7 patients. Pre-apheresis priming was associated with increases in less-differentiated T-cell compartments (TN, TCM, and TSCM) compared with baseline (Table 1). Post-infusion CAR-T expansion median peaked at day +11, with Cmax ranging from 38,101 to 108,661 copies/μg gDNA. The best overall response rate was 86% (6/7) with best CR 71% (5/7). With a median follow-up of 9 months (range 4–19), 6-month PFS was 57%. CRS occurred in 5/7 patients (all grade 1–2), with no grade ≥3 CRS and no ICANS. Grade 3–4 neutropenia occurred in 4/7 (57%); no treatment-related mortality .

Table 1: Impact of Sequential Immunomodulation on T-Cell Fitness and Clinical Outcomes (N=7)

Category	Parameter	Baseline (Median)	Post-Priming / Outcome	P Value / Note
T-Cell Fitness	Naïve T-cells (TN, %)	0.08 (0.03-0.12)	5.95 (3.78-8.12)	< 0.001
	Central Memory (TCM, %)	0.90 (0.26 - 1.53)	7.92 (5.07 - 10.78)	0.002
Exhaustion	PD-1+ T-cells (%)	65.51 (48.62 - 80.79)	19.80(14.71 - 24.95)	0.008
Expansion	Cmax (copies/µg gDNA)	-	64,500 (38,101–108,661)	-
Efficacy	Best ORR	-	85.7% (6/7)	-
	Best CR	-	71.4% (5/7)	-
Survival	Median follow-up, months		9	
	6-month PFS	-	57%	-
Safety	CRS (Grade ≥≥3)	-	0%	-
	ICANS (Any Grade)	-	0%	-
	Grade 3–4 neutropenia		57% (4/7)	
	Treatment-related mortality		0%	

Conclusions: This sequential strategy of pre-apheresis T-cell priming and post-infusion boosting appears feasible and demonstrates a manageable safety profile in heavily pre-treated, bendamustine-exposed R/R B-NHL patients. The intervention was associated with favorable changes in T-cell subsets and encouraging CAR-T expansion kinetics. These biological effects translated into a high initial response rate in a population with an otherwise poor prognosis. These preliminary findings provide a compelling rationale for this approach and warrant further validation in a larger, prospective study to confirm its potential to improve outcomes in this high-risk setting.

REDEFINING CURATIVE HORIZONS IN THALASSEMIA MAJOR: 100% SURVIVAL FOLLOWING ALTERNATIVE DONOR HSCT IN A RESOURCE-LIMITED SETTING

Chintan Tarunkumar Vyas[1], *Nedunchezhian Murugaiyan*[2]
[1]*SRCC Children's Hospital, Mumbai, India,* [2]*Cytocare Technologies (P) Ltd, Hyderabad, India*

Background: β-thalassemia major remains a significant global health challenge, particularly in regions with limited transfusion and chelation support. Hematopoietic stem cell transplantation (HSCT) is the only curative option, and broader use of matched unrelated (MUD) and haploidentical donors has expanded access. However, graft failure, graft-versus-host disease (GVHD), infection, and treatment-related mortality remain major concerns in this non-malignant setting. This report summarizes a four-year real-world pediatric experience using alternative donor HSCT—employing MUD and haploidentical grafts with modern TCRαβ depletion, PBSC grafts, Treosulfan-based conditioning, and structured immune-reconstitution approaches—to improve safety and curative outcomes.

Methods: This retrospective cohort study evaluated 33 consecutive children (20 males, 13 females; median age 8 years, range 1–16) with transfusion-dependent β-thalassemia major who underwent alternative-donor HSCT between September 2021 and August 2025. Donor types included TCRαβ-depleted (TCD) haploidentical donors (n=24, 72%), T-cell–replete (TCR) haploidentical donors (n=2, 6%), and MUD (n=7, 22%). All patients received peripheral blood stem cell grafts. Conditioning was standardized with thiotepa, treosulfan, fludarabine, and antithymocyte globulin (administered distally in TCD/TCR grafts and proximally in MUD transplants). GVHD prophylaxis comprised of cyclosporine alone in TCD recipients, post-transplant cyclophosphamide, cyclosporine with mycophenolate mofetil (MMF) in TCR recipients and cyclosporine with MMF in MUD recipients; TCD patients additionally received rituximab on day −1. Median $CD34^+$ doses were 18×10^6/kg (TCD) and 10×10^6/kg (MUD). TCRαβ depletion targeted $<25\times10^3$/kg αβ T cells, supported by a structured $CD45RO^+$ add-back strategy from day 0 to +120.

Results: Engraftment occurred in 94% of patients, with sustained full donor chimerism at last follow-up. Median neutrophil and platelet recovery occurred by day +13 (range 11–21) and day +16 (range 12–31), respectively. Two secondary graft failures were observed—one in a TCR haploidentical transplant and one in a MUD recipient, both salvaged by autologous stem cell back-up. The incidence of severe acute GVHD (grade III–IV) was 18%, lowest in the TCRαβ-depleted haploidentical cohort (12%) compared with MUD transplants (28%). Notably, no patient developed clinically significant chronic GVHD, and no GVHD-related mortality occurred. Infectious complications comprised bacterial (18%) and invasive fungal infections (12%), viral reactivations were frequent (CMV 45%, adenovirus 18%, EBV 3%) but uniformly manageable, with no associated deaths. Immune reconstitution was robust, with day-100 $CD4^+$ counts of 110/μL, 140/μL and 120/μL respectively in TCD, TCR and MUD transplants. Transplant-related mortality was 0%, overall survival reached 100%, and event-free survival was 100% in the TCD cohort, 50% in TCR cohort and 85% among MUD

recipients with median follow up of 441 days. All except two survivors achieved and continue to maintain complete transfusion independence.

Conclusions: This study shows that alternative donor HSCT, especially TCRαβ-depleted haploidentical and matched unrelated donor transplantation, achieves outcomes in thalassemia major comparable to matched sibling donor HSCT, even in resource-limited settings. Complete survival, near-universal engraftment, and absence of chronic GVHD highlight the effectiveness of modern graft-engineering with optimal supportive care. These robust real-world data strongly support wider adoption of alternative donor HSCT in transfusion-dependent β-thalassemia major patients to overcome donor availability limitations.

EXPERIENCE OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH *GATA2* MUTATION

*Liubov Ovsiannikova[1], **Larisa Kuzmina**[1], Vera Vasilieva[1], Olga Pokrovskaya[1], Olga Koroleva[1], Anastasia Pichugina[1], Alina Kokhno[1], Tatiana Obukhova[1], Elena Parovichnikova[1]*
[1]National Medical Research Center for Hematology Ministry of Health of Russia, Moscow, Russian Federation (the)

Background: The *GATA2* gene, located on the long arm of chromosome 3, follows an autosomal dominant inheritance pattern. *GATA2* deficiency is associated with immunodeficiency, cytopenias, severe infections, and a high risk of hematologic malignancies. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the only curative option. However, these patients pose a significant therapeutic challenge due to the high prevalence of comorbidities and infectious complications.

Methods: We retrospectively analyzed data from five patients diagnosed with myelodysplastic syndrome (MDS) and confirmed *GATA2* mutations. Clinical presentations were diverse and included prolonged trilineage cytopenia, isolated thrombocytopenia, non-tuberculous mycobacterial infection (*Mycobacterium avium*), interstitial lung disease, primary lymphedema, sensorineural hearing loss, clinodactyly, thrombotic events, renal abscess, and salpingo-oophoritis. Two patients had additional hematologic malignancies (CML and hepatosplenic T-cell lymphoma), and one developed secondary AML. Three patients exhibited high-risk cytogenetic abnormalities, specifically monosomy 7. Patient characteristics are summarized in Table 1.

Results: All patients underwent allo-HSCT; four received reduced-intensity conditioning, one reduced-toxicity conditioning. Donors included three haploidentical relatives (after genetic screening), one matched unrelated donor (MUD), and one partially matched unrelated donor (MMUD). All potential related donors underwent genetic screening for *GATA2* mutations. In

two cases, no pathogenic variants were detected, and the relatives were used as donors. In one case, the *GATA2* mutation was identified in both the patient's father and brother; consequently, they were excluded as donors, and an alternative donor source was utilized. In one case, related donors were excluded after identification of the familial *GATA2* mutation. Acute GVHD occurred in 2 patients, chronic GVHD in 3. One patient died due to septic shock at 11 months post-transplant. Four patients remain alive in remission with follow-up ranging from 1 to >10 years. Transplant outcomes are detailed in Table 1.

Table 1. Clinical characteristics of patients and outcomes of allo-HSCT.

Parameter	Patient №1 Ts, 27 y.o.	Patient №2 S, 45 y.o.	Patient №3 I, 27 y.o.	Patient №4 L, 41 y.o.	Patient №5 B, 19 y.o.
History	Since 2015	Since 1998	Since 2022	Since 2006	Since 2012
Clinical manifestations	Trilineage cytopenia	Trilineage cytopenia, mycobacterial infection	Recurrent infections	Lymphedema, hearing loss, clinodactyly, cytopenia, thromboses	Thrombocytopenia, left kidney abscess, salpingo-oophoritis
Family history	Father, brother – *GATA2* mutation	None	None	Grandmother – lymphedema, clinodactyly	None
Diagnosis	AML (transformed from MDS)	MDS	CML, MDS	MDS, hepatosplenic T-cell lymphoma	MDS
GATA2 mutation	Heterozygous, c.1187G>A, missense	-	Heterozygous, c.1168A>G, missense	-	-
Cytogenetics	Monosomy 7, trisomy 8	Tetrasomy 1, deletion 3	Monosomy 7	Trisomy 8	Monosomy 7
Conditioning / Donor	Flu180+Bu8 Haploidentical (mother)	Flu180+Bu8 Haploidentical (son)	Flu180+Bu8 Haploidentical (brother)	Flu150+Treo36 Matched unrelated donor (MUD)	FLAMSA-RIC Partially matched unrelated donor (MMUD)
GVHD	Chronic GVHD	Acute GVHD	Chronic GVHD	Chronic GVHD	Acute GVHD

Follow-up / Outcome	11 months Death (sepsis)	16 months Remission	1 year Remission	4 years Remission	>10 years Remission

Conclusions: *GATA2* mutations confer a high risk of hematologic malignancies, profound immunodeficiency, and life-threatening infectious complications throughout the disease course and during treatment. In patients presenting with a suggestive clinical phenotype, genetic testing for *GATA2* deficiency syndrome is strongly recommended. Allo-HSCT can be curative in *GATA2* deficiency, but requires careful donor selection, including genetic testing of related donors.

Disclosure: Nothing to declare.

A236

ALLOGENEIC HSCT WITH MYELOABLATIVE CONDITIONING IN SICKLE CELL DISEASE: A SINGLE-CENTER EXPERIENCE

Seda Öztürkmen[1], Sefika Akyol[1], Hayriye Daloglu[2], Burcu Akıncı[2], Suleimen Zhumatayev[2], Vedat Uygun[1], Gülsün Karasu[2], ***Akif Yesilipek***[1]
[1]Medicalpark Antalya Hospital, Antalya, Turkey, [2]Medikalpark Göztepe Hospital, Istanbul, Turkey

Background: Sickle cell disease (SCD) is associated with substantial morbidity, including recurrent vaso-occlusive crises, progressive organ damage, and reduced quality of life despite advances in supportive and disease-modifying therapies. Allogeneic hematopoietic stem cell transplantation (allo-HSCT) represents the only curative treatment option; however, transplant-related toxicity, graft failure, and graft-versus-host disease (GVHD) remain significant concerns. In recent years, reduced-toxicity conditioning regimens and improved GVHD prophylaxis strategies have enhanced the safety of allo-HSCT in children, underscoring the importance of real-world, single-center outcome data.

Methods: We performed a single-center, retrospective analysis of pediatric patients with SCD who underwent allo-HSCT between 2011 and 2025, evaluating clinical characteristics, transplant-related variables, and post-transplant outcomes.

Results: A total of 15 pediatric patients were included, of whom 9 (60%) were female. The median age at transplantation was 8.2 years (range, 1–20 years). Indications for transplantation primarily included transfusion dependency (60%) and recurrent painful vaso-occlusive crises (27%). Donors consisted of matched sibling donors in 8 patients (53.3%), matched unrelated donors in 3 patients, and related donors in 4 patients (2 matched related and 2 haploidentical). Bone marrow was the predominant stem cell source (n=10, 66.6%). At last follow-up, 12 patients (80%) remained disease-free, while graft rejection occurred in 3 patients. Only one had the chance to undergo second transplant which resulted in aplasia. Therefore, a backup transplant utilized to him. The median post-transplant follow-up was 40 months (range, 3–91 months). BU/Treo based myeloablative conditioning, also including

ATG, was used in all patients. For GVHD prophylaxis PTCy was given for haploidentical donors and the other patients received MTX+CsA or Tacrolimus. Grade II-IV acute GVHD occurred in 4 patients with gastrointestinal, cutaneous, or hepatic involvement, all of whom responded to intensified immunosuppressive therapy.No cGVHD was observed.

Conclusions: In this single-center pediatric cohort, using myeloablative conditioning, allo-HSCT demonstrated favorable long-term disease control with low transplant-related morbidity in children with SCD. The absence of chronic GVHD and the manageable incidence of acute GVHD highlight the feasibility and safety of allo-HSCT. Larger prospective studies are warranted to optimize conditioning strategies and donor selection to further improve outcomes.

Disclosure: None.

A238

SHOULD FRAILTY SCORES BE CONSIDERED WHEN ASSESSING ELIGIBILITY FOR ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION? THE EXPERIENCE OF THE SOUTH WALES BLOOD AND MARROW TRANSPLANT PROGRAMME

Emily Booth[1], Bronagh McGoldrick[1], Damith Dhanasekara Koralage[1], Mary Warren[1], Rey Consolacion[1], David Davies[1], Keith Wilson[1,2], ***Wendy Ingram***[1]
[1]University Hospital of Wales, Cardiff, United Kingdom of Great Britain and Northern Ireland (the), [2]Cardiff University School of Medicine, Cardiff, United Kingdom of Great Britain and Northern Ireland (the)

Background: Frailty and haematological malignancy both increase with age and increased frailty is associated with poorer health outcomes. All patients undergoing haematopoietic stem cell transplantation (HSCT) at the SWBMT Programme are assessed for frailty as part of prehabilitation. The aim of this study was to assess whether frailty predicted for outcome following allogeneic HSCT and whether it should be routinely incorporated into eligibility criteria.

Methods: 87 patients, undergoing allogeneic HSCT, for a variety of indications, between June 2022 and December 2024, were assessed prior to undergoing prehabilitation, using the clinical frailty scale (CFS) and short physical performance battery (SPPB) alongside traditional widely accepted and validated assessment methods, including HCT-comorbidity index (HCT-CI). Admission and discharge CFS and SPPB scores were also recorded.
We assessed HCT-CI scores of 0-2 v 3+, SPPB scores of ≤9 v 10+ and CFS of ≤3 v 4+, with the outcome measures length of stay (LOS), number of readmission days within one year of HSCT, overall survival, 1y relapse rate and 1y NRM.

Results: Our study confirmed the known statistically significant relationship between HCT-CI and LOS, with higher HCT-CI scores correlating to longer LOS (p=0.0314). There was no statistical difference seen according to CFS or SPPB scores, but those with higher admission

SPPB scores were more likely to have a longer stay (p=0.1901). For prehab scores this was a median of 24 days for SPPB 10+ versus 28 days for SPPB of ≤9.
14/87 (16%) patients relapsed within the first year. This was evenly distributed between HCT-CI scores of 3+ and 0-2. For the SPPB, 7/14 had a score of 10+, 6/14 a score of ≤9 and 1 was unrecorded. 5/14 were over the age of 60.
23/87 (26%) patients died within 1 year, 6 of these due to relapse. No difference was found between either NRM or OS and CFS or SPPB, possibly because of small patient numbers.
There was a trend towards discharge frailty scores predicting readmission within 1 year: 8.5 v 1 day for SPPB of ≤9 v 10+, respectively (p=NS).

N	**87 (%)**
Gender Male Female	 54 (62) 33 (38)
Age <60 60 and above	 48 (55) 39 (45)
Diagnosis AML (including tAML/sAML) MDS (including tMDS/sMDS) MF ALL CMML/sMPN CML (one with concurrent CLL) SAA Other- Histiocytic sarcoma (1), HL (1), NHL (2), CLL (1)	 40 (46) 13 (15) 9 (10) 8 (9) 7 (8) 2 (2) 2 (2) 6 (7)
Baseline SPPB 9 or below 10+ Missing data	 36 (41) 48 (55) 3 (3)
Baseline CFS 3 or below 4+ Missing data	 46 (53) 40 (46) 1 (1)
HCT-CI 0-2 3+	 48 (55) 39 (45)

Baseline patient characteristics are shown in the table.

Conclusions: Our data did not show any statistically significant association between prehab frailty measures and relapse, NRM or LOS. However, discharge SPPB may predict for risk of readmission within 1 year. Whilst our study was probably not large enough to show a significant correlation, it is also possible that SPPB and CFS are not sensitive enough as frailty measures in the allogeneic HSCT population. Note that the EBMT recommends use of the Electronic Frailty Index in MDS. We have since added the HCT frailty score and it will be interesting to compare this with existing measures prospectively in a larger dataset.

IS HLA MISMATCHING BECOMING A HISTORY IN THE ERA OF POST-TRANSPLANT CYCLOPHOSPHAMIDE?

*Derya Üstün Eroğlu[1], **Elcin Erdogan Yucel**[1], Aybuke Olgun[1], Zuleyha Can Erdi[1], Yazgulu Cansu Ozkan[1], Mehmet Dokumaci[1], Oktay Bilgir[1], Zehra Narlı Ozdemir[1]*
[1]Izmir City Hospital, Izmir, Turkey

Background: Post-transplant cyclophosphamide (PTCy) represents a paradigm shift in the prevention of graft-versus-host disease (GVHD) following allogeneic hematopoietic stem cell transplantation (HSCT). PTCy offers a unique mechanism to facilitate graft tolerance, mitigate GVHD, and preserve graft-versus-leukemia (GVL) effects. The beneficial effects of PTCy on GVHD appear to be independent of donor type, graft source, or conditioning regimen intensity. The aim of this study was to determine the effect of HLA mismatching on transplant outcomes in patients receiving PTCy.

Methods: We retrospectively analyzed 61 adult patients who underwent HSCT at our transplantation center between May 2024 and October. Patients who received PTCy as GVHD prophylaxis were included in the study. Stem cell source was peripheral blood (PBSCs). All patients received PTCy at 50 mg/kg/day on days +3 and +4, with cyclosporine on days +5 after transplant. In the haploidentical setting, mycophenolate mofetil (MMF) was combined with cyclosporine. The analysis assessed the impact of HLA mismatching on the period of PTCy using multivariable Cox regression and competing risks models supplemented with Kaplan-Meier survival estimates.

Results: Patients were grouped according to HLA matching status as 10/10 (n=30), 9/10 (n=20), and haploidentical (n=11). Median follow up time was 4.7 (2.2-20.5) months. Demographic features of the patients presented in Table 1. The underlying disease profile was predominantly acute myeloid leukemia (AML) in all groups (n=55). No significant difference was found between the groups in terms of conditioning regimen intensity, with myeloablative conditioning (MAC) being the most frequently used regimen. Donor-recipient age and the frequency of female-to-male transplants were also similar between the groups. The only variable differing significantly between HLA matching groups was the total

nucleated cell dose infused, which was higher in the haploidentical cohort (p=0.008) (Table 1).

No significant differences were observed in survival outcomes or the incidence of acute GVHD among the transplant groups. When 61 patients undergoing HSCT were stratified by HLA match status, progression-free survival (PFS), overall survival (OS), GVHD-free relapse-free survival (GRFS), and relapse-free survival (RFS) did not differ significantly ($p > 0.05$). According to donor HLA compatibility (9/10 matched, 10/10 matched, and haploidentical), median OS was 5.1, 4.2, and 4.2 months, respectively; median GRFS was 2.2, 2.4, and 2.4 months; median PFS was 5.1, 3.6, and 4.0 months; and median RFS was 2.6, 2.4, and 3.9 months, respectively.

In the entire cohort, 25 (41%) patients were administered ant thymocyte globulin (ATG) with PTCY. When patients who received ATG and those who did not were compared based on HLA mismatch status, no significant association was found between the occurrence of GVHD and relapse (p=0.78).

When patients were stratified by conditioning intensity (MAC vs RIC/NMA), no statistically significant differences were observed in PFS, OS, GVHD, GRFS, RFS, or non-relapse mortality (NRM) ($p > 0.05$; Figure 1). Similarly, the incidence of acute and chronic GVHD did not differ significantly between the groups ($p > 0.05$).

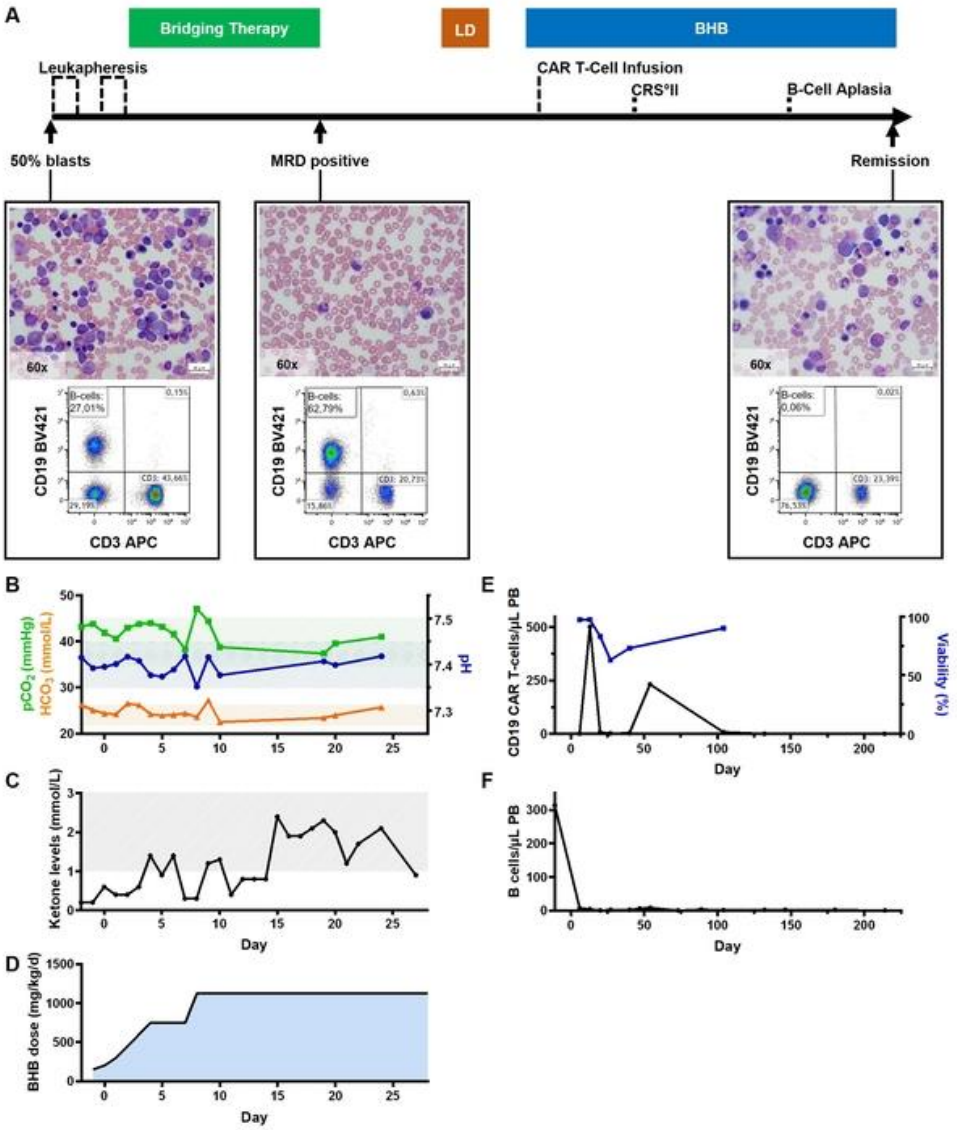
INDUCING KETOSIS WITH B-HYDROXYBUTYRATE SUPPLEMENTATION DURING CHIMERIC ANTIGEN RECEPTOR T CELL THERAPY IN RELAPSED/REFRACTORY INFANT ACUTE LYMPHOBLASTIC LEUKEMIA

Patrizia Lehr[1], *Rebekka Wiedenhöfer*[1], *Semjon Willier*[1], *Stefano Malvestiti*[1], *Sarah C. Grünert*[1], *Anke Schumann*[1], *Carsten Speckmann*[1], *Brigitte Strahm*[1], *Tobias Feuchtinger*[1]
[1]*Medical Center and Faculty of Medicine, University of Freiburg, Freiburg, Germany*

Background: *KMT2A*-rearranged acute lymphoblastic leukemia (ALL) is an aggressive subtype with poor prognosis despite intensive therapy, though outcomes have improved with CD19-directed chimeric antigen receptor (CAR) T-cell treatment. Metabolic modulation, particularly through β-hydroxybutyrate (BHB) supplementation, has been proposed as a strategy to enhance CAR T-cell efficacy, with murine studies showing that BHB augments CAR T-cell function and clinical data suggesting associations between elevated BHB levels and improved outcomes.

Methods: We report the case of *KMT2A*-rearranged infant leukemia with early isolated bone marrow relapse after hematopoietic stem cell transplantation. The patient subsequently received CAR T-cell therapy with tisagenlecleucel. We developed a strategy for managing ketosis with BHB supplementation, focusing on feasibility, dosing, monitoring, and safety in a pediatric setting. BHB was initiated on day -2 before CAR T-cell infusion and continued until day +28 (A). Ketone levels were measured in venous blood. Blood gas analyses, including acid-base status and electrolyte profiles, were performed daily during the first two weeks to assess potential metabolic complications of BHB supplementation. Following CAR T-cell administration, CAR T-cell expansion kinetics, CAR T-cell viability, B-cell count, and remission status were assessed.

Results: BHB supplementation was well tolerated and achieved target ketone levels on nearly half of treatment days (C+D). No supplementation-related adverse effects were observed. Blood gas analysis revealed no notable changes and serum creatinine levels remained within the normal range (B). CAR T-cells demonstrated robust expansion, peaking two weeks post-infusion with subsequent transient re-expansion. From day +132 onwards, CAR T-cells were no longer detectable in peripheral blood. Viability was initially high, declined over time, and showed a secondary peak (E). B-cell aplasia occurred rapidly after CAR T-cell infusion, with near-complete depletion by day +14 (F). Importantly, B-cell aplasia persisted despite undetectable circulating CAR T-cells, consistent with continued CAR T-cell activity. The patient remains in complete morphological and molecular remission with sustained full donor chimerism, as confirmed by bone marrow assessment at day +278 post CAR T-cell infusion. Same day peripheral blood analysis demonstrated ongoing B-cell aplasia.



Conclusions: This is the first reported case of BHB supplementation in a young child undergoing CAR T-cell therapy. Treatment was safe, feasible, and associated with favorable CAR T-cell kinetics and durable remission in an infant with very high-risk *KMT2A*-rearranged ALL. These observations may assist clinicians in considering BHB as a low-risk adjunct to CAR T-cell therapy for pediatric patients, with the potential to improve outcomes in high-risk cases.

OUTCOMES OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR PRIMARY IMMUNODEFICIENCY IN ADOLESCENTS AND YOUNG ADULTS: A SINGLE-CENTRE EXPERIENCE

Yazeed Bajuaifer[1], *Sarah Altayyari*[1], *Riad Elfakih*[1], *Rand Arnaout*[1], *Shaykhah Alotaibi*[1], *Ahmed BinSalman*[1], *Momen Nassani*[1], *Ahmed Abdrabou*[1], *Mostafa Saleh*[1], *Alfadil Adam*[1], *Leenh Ali*[1], *Manar Aleid*[1], *Chokri BenLamine*[1], *Samar Alfaqaawi*[1], *Shihab Ahmed*[1], *Marwa Nassar*[1], *Heba Madien*[1], *Nourah Alzaidy*[1], *Tusneem Elhassan*[1], *Marwan Shaheen*[1], *Omar Albanyan*[1], *Feras Alfraih*[1], *Ruah Alyamani*[1], *Ahmad Alnughmush*[1], *Saud Alhayli*[1], *Abdulwahab Albabtain*[1], *Abdullah Alamer*[1], *alfadel Alshaibani*[1], *Ahmad Alotaibi*[1], *Mansour Alfayez*[1], *Ayman Saad*[1], *Hanan Alkhaldi*[1], *Amr Hanbali*[1], *Ali Alahmari*[1], *Naeem Chaudhri*[1], *Walid Rasheed*[1], *Fahad Almohareb*[1], *Hazzaa Alzahrani*[1], *Mahmoud Aljurf*[1], *Syed Osman Ahmed*[1]
[1]*King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia*

Background: Primary immunodeficiencies (PID) represent a diverse group of inherited immune disorders that predispose affected individuals to severe infections, immune dysregulation, organ dysfunction, and premature mortality. Allogeneic hematopoietic stem cell transplantation (HSCT) offers a definitive curative strategy for many PID subtypes by restoring normal immune function. While outcomes of HSCT in pediatric populations are increasingly well characterised, data evaluating outcomes in adolescents and young adults remain limited.
This study presents a comprehensive single-centre analysis of survival, graft stability, immune reconstitution, infectious complications, and graft-versus-host disease (GVHD) in a consecutively transplanted cohort of young adult PID patients at King Faisal Specialist Hospital and Research Centre in Saudi Arabia

Methods: We retrospectively reviewed 21 patients with genetically or clinically defined PID who underwent allogeneic HSCT at our institution during the last two decades. The median age at transplant was 17 years (range 15-28). Underlying diagnoses where classified according to the International Union of Immunological Societies Expert Committee which included phagocytic/innate defects(n=10), combined immunodeficiency (n=10) and humoral/B-cell disorders (n=2). Donor sources included matched sibling donors (MSD, n=17), matched unrelated donors (MUD, n=2) and haploidentical donors (n=2). Stem cell source consisted of bone marrow (n=14) or peripheral blood stem cells (n=7). All patients received myeloablative conditioning regimens with Busulfan based regimen. Clinical outcomes assessed included overall survival (OS), acute and chronic GVHD, CMV viremia, need for IVIG post transplant, and donor chimerism.

Results: after a median follow up of 4.8 years, 20 out of 21 patients (95%) were alive, with a single transplant-related death. Cumulative incidence of Acute GVHD at 100 days was (39.8%), while cumulative incidence of chronic GVHD was (23.6%), all with mild to moderate severity and good responsiveness to immunosuppression. CMV viremia was documented in 47% of patients , with all episodes controlled using antiviral therapy without CMV-related mortality, 4 patients devloped invasive fungal infection and 2 patients had Veno-occlusive disease. During the finalassessment, 52% required immunoglobulin replacement at

a certain point of time. Donor chimerism showed full chimerism in 12 patients (57%) and mixed chimerism in 9 patients (43%). The single death was related to secondary graft failure and development of sever infection and ARDS. Kaplan-Meier survival curves demonstrated stable long-term OS following early post-transplant recovery.

Conclusions: Our single-centre experience shows that adolescents and young adults with PID can achieve HSCT outcomes comparable to pediatric populations, with 95% survival, acceptable GVHD rates, stable donor chimerism and immune reconstitution profiles similar to those reported in large pediatric cohorts.These findings support the effectiveness of HSCT as curative therapy in young adults with PID while emphasising the ongoing need for structured long-term follow-up to optimise immuno-recovery, manage infections, and monitor donor chimerism dynamics

Disclosure: I have no conflicts of interest to disclose

CD34⁺ CELL DOSE ABOVE 10 MILLION PER KILOGRAM ON THE OUTCOMES OF ALLOGENEIC STEM CELL TRANSPLANTATION WITH POST-TRANSPLANTATION CYCLOPHOSPHAMIDE

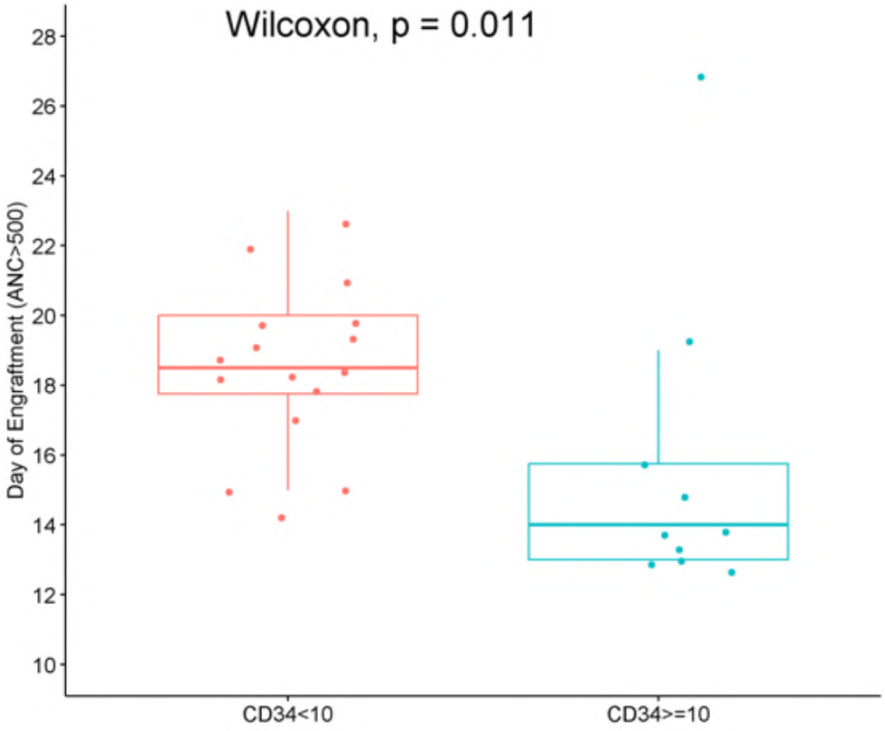
Lun-Wei Chiou[1], *Tran-Der Tan*[1], *Tzu-Ting Huang*[1]
[1]*Koo-Foundation Sun Yat-Sen Cancer Center, Taipei, Taiwan (Province of China)*

Background: For patients with high-risk malignant hematologic diseases or aplastic anemia, HLA-haploidentical related donors have become an acceptable stem cell source when matched sibling or unrelated donors are unavailable. Between October 2014 and March 2021, 26 patients underwent 27 haploidentical transplantations with post-transplant cyclophosphamide (PTCy) at Koo-Foundation Sun Yat-Sen Cancer Center. The objective of this study is to review our series and evaluate the impact of CD34+ stem cell doses greater than 10×10^6/kg on clinical outcomes in this cohort.

Methods: Retrospectively, we retrieved consecutive data from the hematopoietic stem cell transplantation database, reviewed medical charts, and made the analysis. We used a boxplot and the Wilcoxon rank-sum test to analyze the impact of $CD34^+$ dose above and below 10 million per kilogram on the median engraftment day. We divided cohorts into three groups based on disease risk at transplantation and used the Kaplan-Meier method to plot disease-free and overall survival curves for each group. We used a bar chart to record and grade graft-versus-host disease based on $CD34^+$ dose to analyze the association.

Results: Twenty-six patients, aged 7 to 64 years, were included. Thirteen were female. The cohort exhibited heterogeneous diagnoses, including AML (n=8), ALL (n=4), ATLL (n=1), HL (n=3), DLBCL (n=3), CLL with Richter's transformation (n=1), and sAA (n=6). At the time of transplantation, among the 20 patients with malignant diseases, 6 had active disease, 4 had minimal residual disease, and 10 were in complete remission (CR1–CR2). Six patients with sAA underwent a total of seven transplantations.

Survival ranged from 17 to 3,530 days. At 5 years, 70% of patients in CR1–CR2 and 100% of patients with sAA remained alive. Neutrophil engraftment was achieved in 96.3% of patients between days +13 and +27, and 88.8% reached platelet counts >20,000/μL with sustained transfusion independence between days +5 and +223. Median neutrophil engraftment occurred on day +14 for patients receiving CD34+ cell doses ≥10 × 10^6/kg and on day +18.5 for those receiving <10 × 10^6/kg (P=0.011).
The incidence of all-grade aGvHD was 70% and 68.8% in patients receiving CD34+ cell doses ≥10 × 10^6/kg and <10 × 10^6/kg, respectively. The incidence of cGvHD was 16.7% (n=6) and 42.8% (n=14) in the respective dose groups.



Conclusions: Haploidentical transplantation with PTCy for malignant hematologic diseases is a feasible therapeutic approach. In our cohort, remission status was the primary determinant of survival probability. A higher CD34+ cell dose (>10 × 10^6/kg) resulted in more rapid ANC engraftment—by approximately 4.5 days—compared with lower doses, without an associated increase in the incidence of aGvHD or cGvHD. The limitations of this study include its retrospective design and the relatively small sample size. Larger prospective studies will be required to validate these findings.

Disclosure: No conflict on interest

A245

OUTCOME OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANT IN ACUTE LEUKEMIAS IN ECUADOR

*Bella Maldonado-Guerrero[1], Julie Abifandi-Valverde[1], Mayhua Lam-Rodriguez[1], Brayan Flores-Reyes[1], **Luis Martillo-Maldonado**[1], Romina Muñoz-Pardo[1]*
[1]Hospital Solca Guayaquil, Guayaquil, Ecuador

Background: Allogeneic stem cell transplantation remains the most appropriate consolidation strategy and the only curative option for high-risk acute myeloid leukemia (AML) and acute lymphoblastic leukemias (ALL). Worldwide, most transplants are performed in North America and Europe; in Latin America, they are carried out in only 13 countries, with SOLCA Guayaquil being the only center accredited to perform them in Ecuador.

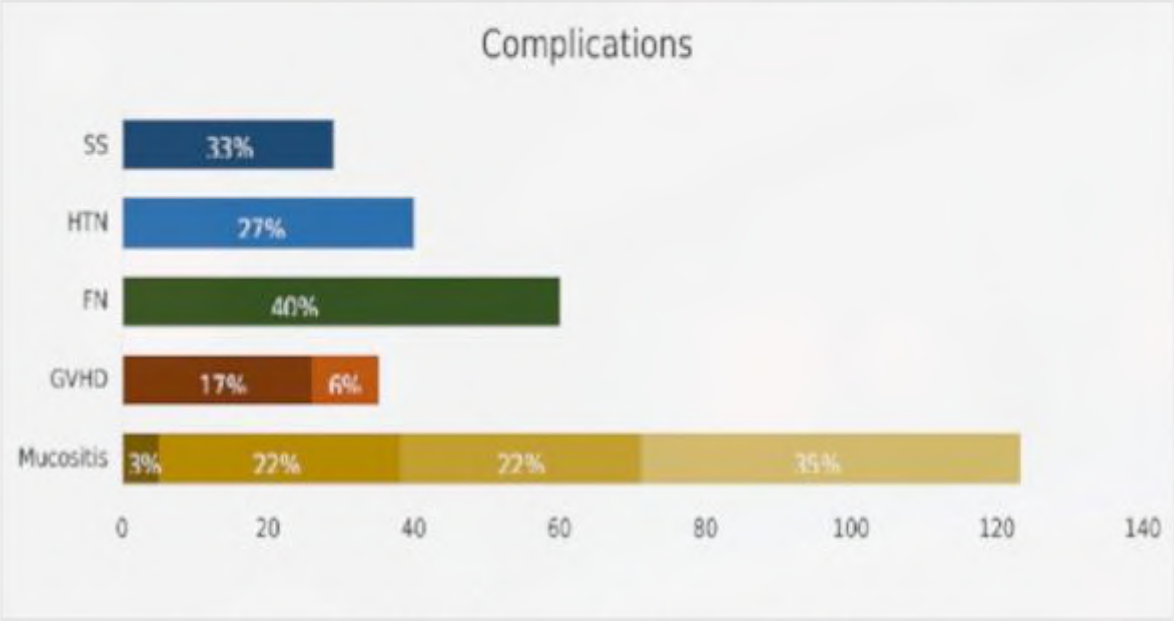
Methods: Retrospective and analytical study of patients treated between June 2006 and June 2025, evaluating the main clinical complications. Ten-year-disease-free survival was estimated using Kaplan-Meier within a 19-year observation window. Data analysis and visualization were performed using RStudio and Power BI.

Results:

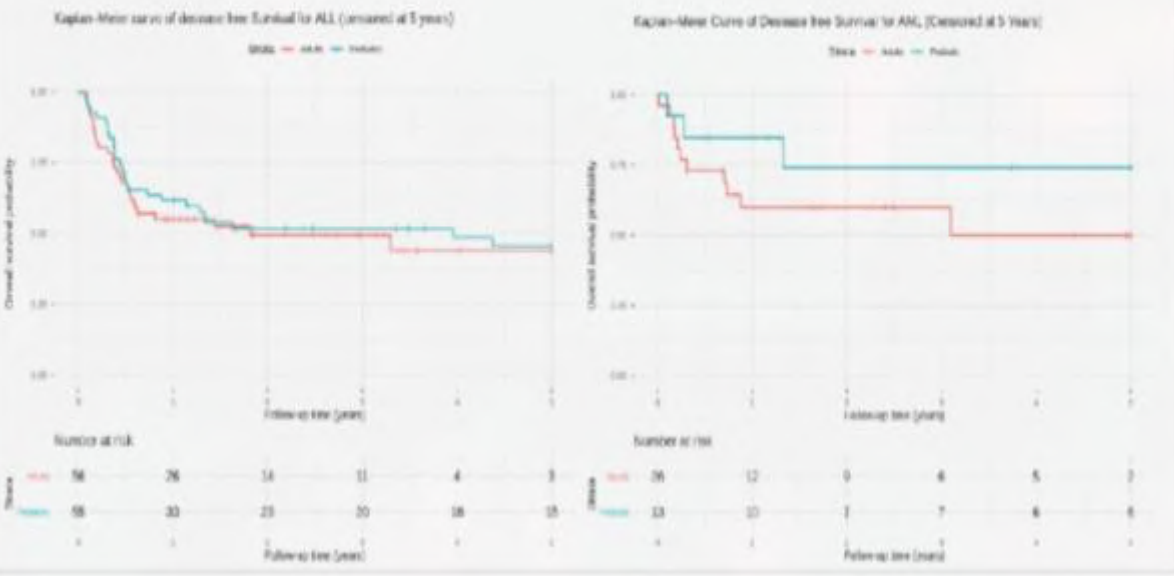
Figure 1. Complications related with Allogeneic HSCT and Disease Free Survival in Acute Leukemia

N= 150 patients

ALL 111: Pediatric 49,5% Adults 50,5%
AML 39 : Pediatric 33,3% Adults 66.7%



Kaplan–Meier Estimates of 5-Year Disease-Free Survival



We included 150 allogeneic transplant patients (111 ALL, 39 AML). All conditioned with Busulfan-Cyclophosphamide and given Cyclosporine-Methotrexate for graft vs host disease (GVHD) prophylaxis. Stem cell sources were bone marrow (5.3%), umbilical cord blood (9.3%), and peripheral blood (85.3%). The most frequent complications were mucositis, febrile neutropenia (FN), septic shock (SS), GVHD and calcineurin inhibitor induced-hypertension (HTN). The 5-year disease-free overall survival within 19-year follow-up was 49.50% for ALL and 61.5% for AML and was compared between pediatric and adult patients, as shown in Figure 1.
Mucositis occurred predominantly as Grade IV (35%). Markedly severe mucositis was associated with febrile episodes from an intestinal infectious source. Among 150 allogeneic transplant recipients with acute leukemia, febrile neutropenia occurred in 40% of patients, with 19.3% developing septic shock, while afebrile neutropenia occurred in 90 patients, with a shock rate of 20%. Most febrile episodes were non-infectious inflammatory events, whereas 1 in 5 afebrile patients developed severe infection. Fever was not a reliable discriminator of septic complications in this cohort. Graft-versus-host disease (GVHD) was observed in 23.3%; 17.3% were acute and 6% were chronic. No association was found between infectious febrile episodes and the occurrence of GVHD. Treatments available for GVHD management include calcineurin inhibitors (cyclosporine and tacrolimus), corticosteroids, and ruxolitinib. Additionally, 26.6% of patients receiving cyclosporine developed arterial hypertension during intravenous administration.

Conclusions: The 5-year disease-free survival in our 19-year cohort aligns with international benchmarks reported by EBMT and CIBMTR, confirming that our center's long-term outcomes are comparable to global standards. AML showed stronger disease control, while ALL demonstrated survival rates within expected ranges for allogeneic transplantation. Higher severity mucositis is a predisposing factor for intestinal infections. Septic shock occurred at similar rates in febrile and afebrile neutropenia, indicating that fever is not a reliable indicator of severe infection in post-transplant patients. A notable proportion of afebrile patients developed septic shock, reflecting profound immunosuppression and blunted inflammatory response, while nearly half of febrile episodes were non-infectious. These findings emphasize the need for early screening, biomarker-guided evaluation, and rapid initiation of sepsis management protocols regardless of fever. Continuous vigilance is essential to prevent delayed recognition of life-threatening infections. Although graft-versus-host disease represents a state of profound immune dysregulation, it was not associated with an increase of infectious complications. However, patients treated with ruxolitinib showed CMV reactivation. Arterial hypertension was exclusively associated with intravenous cyclosporine use, and occurred despite maintaining therapeutic serum cyclosporine levels.

EVALUATING THE ROLE OF ELTROMBOPAG IN POST-HEMATOPOIETIC STEM CELL TRANSPLANTATION PATIENTS WITH HEMATOLOGIC DISORDERS: A SYSTEMATIC REVIEW AND META-ANALYSIS

April Joy Ong[1], *Ana Margarita Natividad*[1], *Lynn Bonifacio*[1], *Teresita Dumagay*[1], *Anne Kristine Quero-Taggaoa*[1]
[1]*Philippine General Hospital, Manila City, Philippines (the)*

Background: Thrombocytopenia contributes to transfusion dependence, bleeding risk, and inferior survival after hematopoietic stem cell transplantation (HSCT). Eltrombopag, a thrombopoietin-receptor agonist, is increasingly used to enhance post-transplant platelet recovery.

Methods: A comprehensive search identified 577 citations from six databases with ten single-arm retrospective studies included in the analysis. Outcomes extracted included platelet recovery (≥50,000/μL), platelet transfusion independence, and time from eltrombopag initiation to response. Dichotomous outcomes (platelet recovery and platelet transfusion independence) were pooled as proportions and continuous outcomes (time from eltrombopag initiation to response) were pooled as means, with 95% CIs using a random-effects model. Subgroup analyses were conducted to compare platelet recovery between autologous and allogeneic HSCT.

Results:

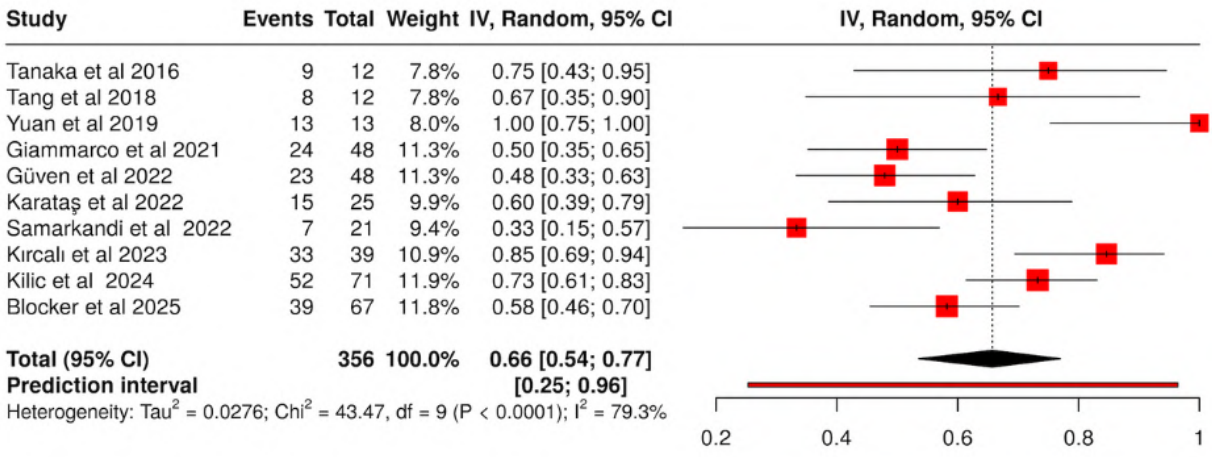

Figure 1. Forest plot of eltrombopag treatment outcomes following hematopoietic stem cell transplantation depicting pooled platelet recovery rate (≥50,000/μL) for all patients (n = 356).

Table 1. Summary of included studies reporting outcomes following eltrombopag treatment in post-hematopoietic stem cell transplantation patients.

Study (Year)	Platelet count recovery (≥50,000/μL)		Platelet Transfusion Independence		Time to Response (Platelet Recovery)		
	n	e	n	e	n	mean	SD
Tanaka et al (2016)	2	9	11	8	12	163.00	26.00
Tang et al (2018)	12	8	--	--	--	--	--
Yuan et al (2019)	13	13	13	8	13	29.25	9.75
Giammarco et al (2021)	48	24	--	--	48	33.00	9.50
Güven et al (2022)	48 (Auto 20; Allo 28)	23 (Auto 13; Allo 10)	--	--	48	60.00	47.70
Karataş et al (2022)	25 (Auto 15; Allo 10)	15 (Auto 10; Allo 5)	--	--	25	63.25	41.25
Samarkandi et al (2022)	21	7	16	12	21	107.75	83.75
Kırcalı et al (2023)	39	33	39	33	--	--	--
Kilic et al (2024)	71 (Auto 37; Allo 36)	52 (Auto 29; Allo 23)	--	--	73	32.00	42.00
Blocker et al (2025)	67	39	67	32	67	23.00	43.17

Across 356 total patients started on eltrombopag after hematopoietic stem cell transplantation, 66% (0.66; 95% CI 0.54-0.77) attained platelet recovery ≥50,000/μL for at least seven consecutive days without needing transfusion. Substantial heterogeneity was observed (I^2 = 79.3%, $p < 0.0001$), with individual study estimates ranging from 33% to 100%. The prediction interval (25%–96%) reflects variability in anticipated outcomes across

various clinical environments. In subgroup analyses involving three studies, the pooled platelet recovery rate was 0.69 (95% CI, 0.57–0.80) in autologous HSCT (82 patients) and 0.50 (95% CI, 0.32–0.69) in allogeneic HSCT (74 patients). Five studies including 146 patients contributed to the analysis of platelet transfusion independence, yielding a pooled proportion of 0.68 (95% CI, 0.50–0.83). Finally, eight cohorts comprising 307 patients were analyzed for time to platelet recovery, with a pooled mean of 61.7 days (95% CI, 41.4–82.0).

Conclusions: Eltrombopag treatment after hematopoietic stem cell transplantation is associated with a substantial rate of platelet recovery and transfusion independence in patients with thrombocytopenia. Two-thirds of patients reach platelet counts ≥50,000/μL without needing transfusions though notable variation occurs across different clinical contexts. There is substantial heterogeneity which is expected in retrospective, single-arm studies due to timing of platelet counts, disease severity, treatment protocols and center differences. Recovery rates are generally greater in autologous than in allogeneic HSCT recipients. Time to platelet recovery averages around two months but varies widely among patients. These findings support eltrombopag as an effective therapeutic option for post-transplant thrombocytopenia, while highlighting the need to consider patient and treatment heterogeneity when interpreting outcomes. Larger randomized trials are needed to confirm the magnitude of benefit.

TREATMENT OF RELAPSED/REFRACTORY HIGH-GRADE B-CELL LYMPHOMAS WITH POINT-OF-CARE MANUFACTURED ANTI-CD-MB-19.1 - CART-CELLS: A SINGLE CENTER, INTERIM ANALYSIS OF A PHASE 2 TRIAL FROM JORDAN

Khalid Halahleh[1], *Ahmad Abu-Khader*[1], *Husam Abu-Jazar*[1], *Mohammad Makoseh*[1], *Waleed Da'na*[1], *Rozan Al-Far*[1], *Ayat Taqash*[1], *Taima' Qabajeh*[1], *Mohammad Al-Sharairy*[1], *Saad Jaddoua*[1], *Hussam Al-Omari*[1], *Abdulraheem Yacoub*[2], *Mohammad Al-Rawashdeh*[1], *Alaa Abufara*[1], *Omar Shahin*[1], *Fatenah Ajlouni*[1], *Zaid Abdel Rahman*[1], *Maysa Al-Hussaini*[1], *Imad Treish*[1], *Hikmat Abdel-Razeq*[1,3], *Asem Mansour*[1]

Background: Anti-CD19 chimeric antigen receptor (CAR) T-cell therapy is the standard of care for patients with relapsed refractory high-grade B-cell lymphomas. However, industry-driven-CART-cells manufacturing complexity, financial toxicity, and manufacturing time represent barriers to widespread implementation. Study applicability, safety, and efficacy of a point-of-care manufacturing of autologous MB-19.1-CD19-directed CAR T-cell product, using lentiviral vector (Miltenyi-Biotec, Germany), were studied in a low-resourced country.

Methods: This is an interim analysis of a phase 2 trial, prospective single center, open label, single arm, single dose, optimal 2-stage Simon design, clinical trial. Patients aged >18-years-old with confirmed CD19+ve relapsed refractory diffuse large B-cell (DLBCL) and transformed follicular lymphomas (tFL), were included. Patients received a fresh single dose of MB-19.1-CD19-CART, will be followed for 12 months and evaluated for safety and efficacy. The primary endpoint was overall response rate (ORR), defined as complete response (CR) plus partial response (PR) within 3 months post-infusion. Secondary endpoints included duration of response, cumulative incidence of relapse-progression, CART-cell persistence, progression free survival (PFS) and overall survival (OS). Safety endpoints evaluated the incidence of cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Thirteen products were manufactured on site. Validation run data (n-3) demonstrated a successful anti-CD-MB-19.1 CART- cells production with robust transduction efficiency.

Results: As of December 5, 2025, 10 patients with high grade B-cell lymphoma relapsed or refractory to 2 lines of therapy were enrolled and 9 patients are included in this analysis. Among evaluable patients, 80% had DLBCL and 20% tFL to DLBCL, 70% received ≥ 3 lines of chemoimmunotherapy including, 60% had prior auto-SCT and none had prior CART therapy. The median age 43 yr (Interquartile range (IQR 41–58), and 50% male. Of subjects enrolled, all had progressive disease prior to apheresis, and none received bridging therapy prior to CART-cell infusion.
At a median follow-up of 148.5 days (IQR:108.75-238.25), the best ORR was 78%, with 56% of patients achieved CR and 22% achieved PR. The ORR at 3 months was 66.6%. Three patients progressed at a median of 31 day(range:30-91). The median duration of response was 77 days (range:28-180). The median PFS is 149 days (range:78–313 days) and all patients are alive at last encounter. There were no cases of manufacturing failure. MB-CD19.1-CART-cells peaked at a median of 13 days (range 12-14). CRS occurred in 22% and no patient had ICANS. No grade 3 CRS were observed. The median duration of grade 2 CRS was one day. One patient developed late pancytopenia fully recovered and has no serious sequalae.

Conclusions: In this pilot single institution study in a limited-resource setting, anti-MB-CD19.1-CART-cells were successfully manufactured. The construct demonstrated high objective responses despite high burden refractory diseases. Response rates were comparable to historic responses reported in pivotal trial using Tisagenlecleucel (JULIET trail, NCT02445248). Low incidence of immune toxicities were observed in our cohort. These promising results warrant a longer follow up and validation in a multicenter trial.

Clinical Trial Registry: NCT0271121

FEASIBILITY OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ELDERLY PATIENTS WITH MYELOID NEOPLASMS: SINGLE-CENTER EXPERIENCE

Natalia López Esteban[1], *Minia Grobas Sebio*[1], *Carol Herrera Hernández*[1], *María del Mar Perera Álvarez*[1], *Leslie González Pinedo*[1], *Jorge Gayoso Cruz*[1], *Melissa Karina Torres Ochando*[1], *Alejandro Morales Curbelo*[1], *Guillermo Rodríguez Rodríguez*[1], *Raquel García-Talavera Hernández*[1], *Amagoia Ruiz Martín*[1], *Concepción Sánchez Chamizo*[1], *Mónica Betancor Pérez*[1], *José Antonio Moreno García*[1], *Alfonso Naranjo Montero*[1], *Javier Ramírez Hurtado*[1], *María Teresa Gómez Casares*[1]
[1]*Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, Spain*

Background: Older adults have traditionally faced higher morbidity and mortality after allogeneic hematopoietic stem cell transplantation (allo-HSCT), which has limited its use in this age group. As transplant strategies have become more individualized, this therapy is increasingly offered to older patients. This shift underscores the need to better understand how advanced age affects clinical outcomes following allo-HSCT in patients with myeloid neoplasms.

Methods: We performed a retrospective observational study of patients aged ≥60 years with myeloid neoplasms who underwent their first allo-HSCT at a tertiary care center between January 2018 and May 2025. Outcomes assessed included overall survival (OS), relapse-free survival (RFS), non-relapse mortality (NRM), and graft-versus-host disease–free/relapse-free survival (GRFS), analyzed with Kaplan–Meier curves and compared with a cohort aged 40–59 years.

Results:

The study included 146 patients (55.5% aged 40-59; 45.5% aged ≥60), with a median age of 58 years (IQR 52 - 58) and balanced sex distribution. At transplant, 57.2% were in first complete remission. Donor types were: HLA-identical siblings (38.4%), haploidentical (43.2%), 10/10 matched unrelated (15.8%), and 9/10 matched unrelated (2.7%). Myeloablative conditioning (MAC) was used in 67.8% of the cohort and in 91.4% of patients aged 40-59. Additional characteristics are shown in Table 1. All patients received GVHD prophylaxis with post-transplant cyclophosphamide, tacrolimus, and mycophenolate.

With a median follow-up of 16.4 months (IQR 6.9 - 33.9), the overall cohort showed: OS of 70.2% (62.7 - 77.8) at 12 months and 59.4% (50.4 - 68.5) at 36 months; RFS of 63.9% (55.9 - 71.9) at 12 months and 51.3% (41.9 - 60.7) at 36 months; NRM of 23.5% (16.3 - 30.7) at 12 months and 27.4% (19.2 - 35.6) at 36 months; and GRFS of 56.4% (48.2 - 64.6) at 12 months and 39% (29.7 - 48.3) at 36 months.

When outcomes were compared by age group (Figure 1), OS was similar between patients aged 40–59 and those ≥60 (76.1% vs. 62.8%, log-rank=0.3). RFS (67.3% vs. 59.4%, log-rank=0.6) and GRFS (57.5% vs. 54.9%, log-rank=0.8) were also comparable. However, NRM was higher in the ≥60 group (33.1% vs. 15.5%, log-rank=0.04), driven mainly by infections (60.87%, 85.7% bacterial), followed by GVHD (17.3%). Within the older cohort,

NRM did not differ significantly by conditioning intensity (MAC 32% vs. RIC 35%, p=0.91). Among the patients aged ≥60, eight were ≥70 years old; in this subgroup, OS was 75% (45 - 100), RFS 75% (45 - 100), NMR 25% (0.0 - 55), and GRFS 72.9% (40.6 - 100).

Table 1. Clinical and demographic characteristics of patients with myeloid neoplasms undergoing allo-HSCT

		TOTAL n=146	40-59 years GROUP n=81 (55.5%)	≥60 years GROUP n=65 (44.5%)	*p*

	≥2, n (%)	3 (2.1%)	2 (2.5%)	1 (1.5%)	0.73
HCT-CI	*Intermediate risk (1-2), n (%)*	96 (67.6%)	57 (72.2%)	39 (61.9%)	0.19
	High risk (≥3), n (%)	46 (32.4%)	22 (27.8%)	24 (38.1%)	
Donor type	*HLA-identical sibling, n (%)*	56 (38.4%)	34 (42.0%)	22 (33.8%)	0.32
	Haploidentical, n (%)	63 (43.2%)	40 (49.4%)	23 (35.4%)	0.10

Table 1. Clinical and demographic characteristics of patients with myeloid neoplasms undergoing allo-HSCT

	MUD 10/10, n (%)	23 (15.8%)	5 (6.2%)	18 (27.7%)	0.00
	MMUD 9/10, n (%)	4 (2.7%)	2 (2.5%)	2 (3.1%)	0.82
Conditioning regimen	*MAC, n (%)*	99 (67.8%)	74 (91.4%)	25 (38.5%)	0.00
	RIC, n (%)	47 (32.2%)	7 (8.6%)	40 (61.5%)	

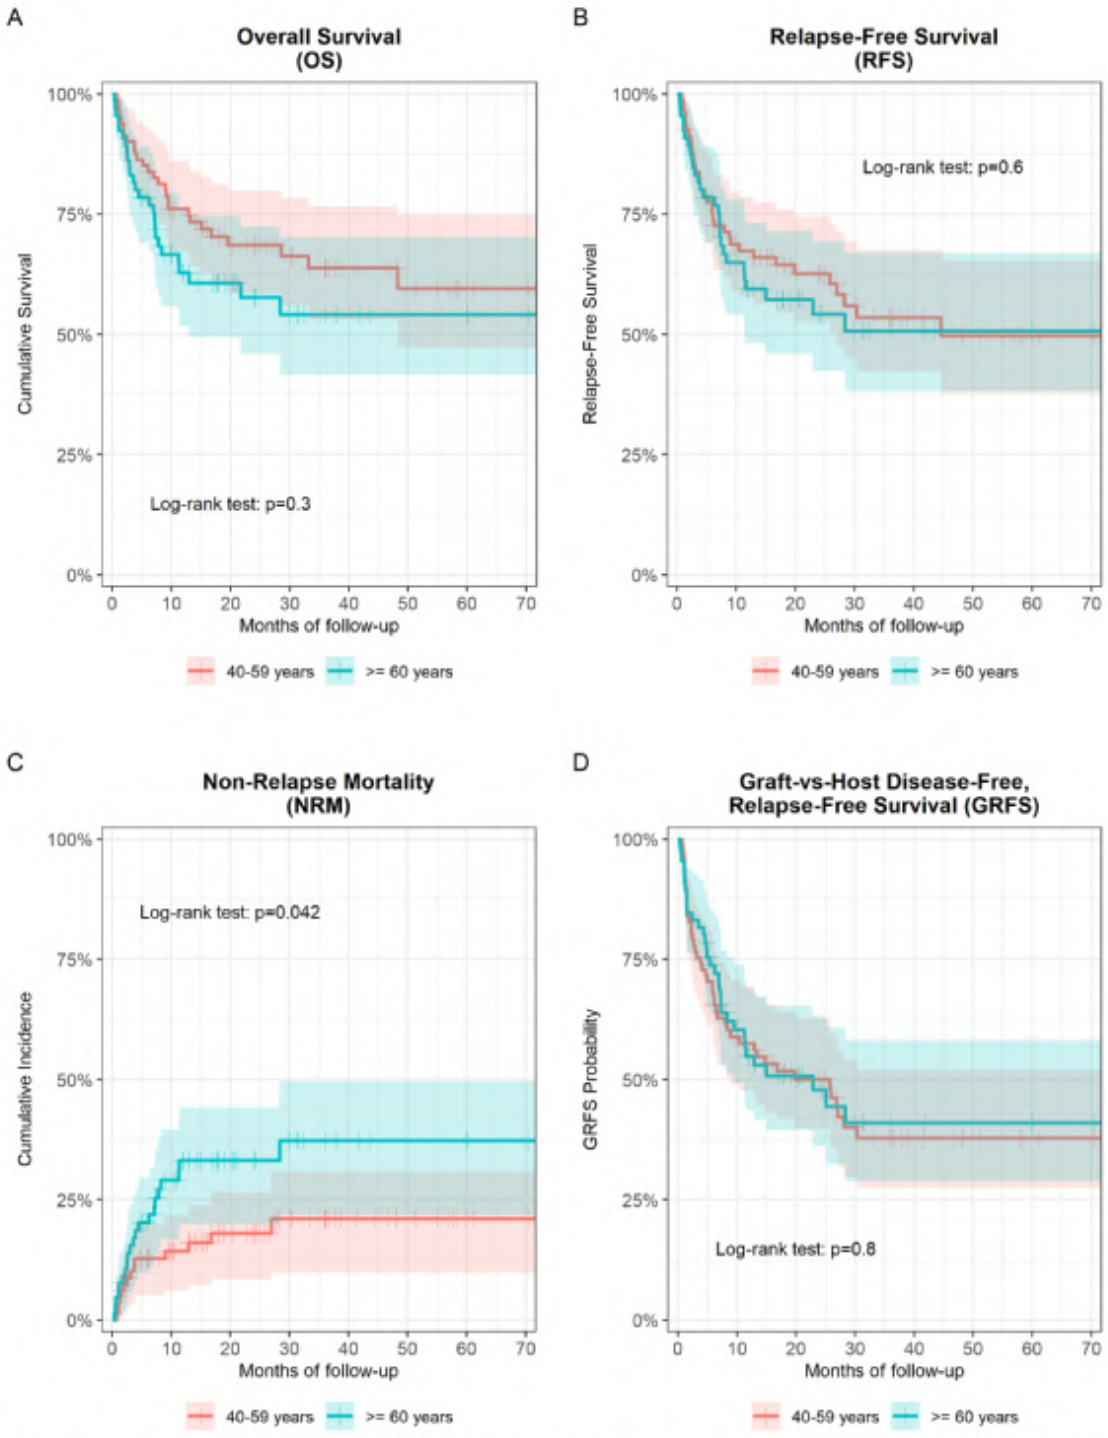

Figure 1. Impact of Age on Transplant Outcomes. Comparison of (A) Overall Survival (OS), (B) Relapse-Free Survival (RFS), (C) Non-Relapse Mortality (NRM), and (D) Graft-versus-Host Disease-Free, Relapse-Free Survival (GRFS) between patients aged 40-59 years (red) and >=60 years (blue).

Conclusions: Advanced age alone should not preclude allo-HSCT in patients with myeloid neoplasms. Data from patients aged ≥60 years, and particularly those ≥70 years, demonstrate that with appropriate selection, this approach is clinically feasible. Individualization of the conditioning regimen, prehabilitation, and specialized supportive care are key determinants for optimizing outcomes. Nevertheless, the risk of non-relapse mortality persists and requires a rigorous, case-by-case assessment.

OUTCOMES OF CORD BLOOD TRANSPLANTATION FOR AML-MR: PROGRESS AND REMAINING CHALLENGES

Shunsuke Nishino[1], *Hisashi Yamamoto*[1], *Mika Kuno*[1], *Otoya Watanabe*[1], *Kyosuke Ymaguchi*[2], *Kosei Kageyama*[2], *Daisuke Kaji*[1], *Yuki Taya*[2,1], *Aya Nishida*[1], *Shinsuke Takagi*[1], *Yuki Asano-Mori*[1], *Atsushi Wake*[2], *Go Yamamoto*[1], *Naoyuki Uchida*[1]
[1]*Toranomon Hospital, Minato-Ku, Tokyo, Japan,* [2]*Toranomon Hospital Kajigaya, Kawasaki, Kanagawa, Japan*

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is the only potentially curative option for AML-MR. Cord blood transplantation (CBT) offers rapid donor availability and has been used as an alternative donor source. However, concerns regarding non-relapse mortality after CBT have been raised, and prognostic factors as well as the optimal patient population for CBT in AML-MR remain poorly defined.

Methods: We retrospectively analyzed patients with AML-MR who underwent first single-unit CBT at our institution between 2010 and 2024, excluding those with an ECOG performance status (PS) ≥3 or those with AML-MR arising from antecedent MDS/MPN. Survival and competing-risk outcomes were analyzed using Kaplan–Meier and Fine–Gray methods. Prognostic factors were assessed using multivariable regression models.

Results: A total of 333 patients were included, with a median follow-up time of 62 months. 230 patients (69.1%) were male. The cohort included a substantial proportion of older patients, with a median age at CBT of 63 (range 19-79), and 275 (82.6%) patients were in non-remission status. The median infused CD34-positive cell dose was 0.84 $\times 10^5$/kg. Complex (≥3) and monosomal karyotype were observed in 117 (35.1%) and 103 (30.9%) patients, respectively; adverse cytogenetics were present in 151 patients (45.3%). Other baseline characteristics are shown in Table1.
The 3-year OS and LFS were 37.6% (95%CI: 32.3-43.0%) and 34.7% (29.5-40.0%). The 3-year CIR and NRM were 23.9% (95%CI: 19.4-28.8%) and 41.3% (95%CI: 35.9-46.7%), as shown in Figure1. Neutrophil engraftment was achieved in 85.0% of patients at day 28 and in 92.5% overall.

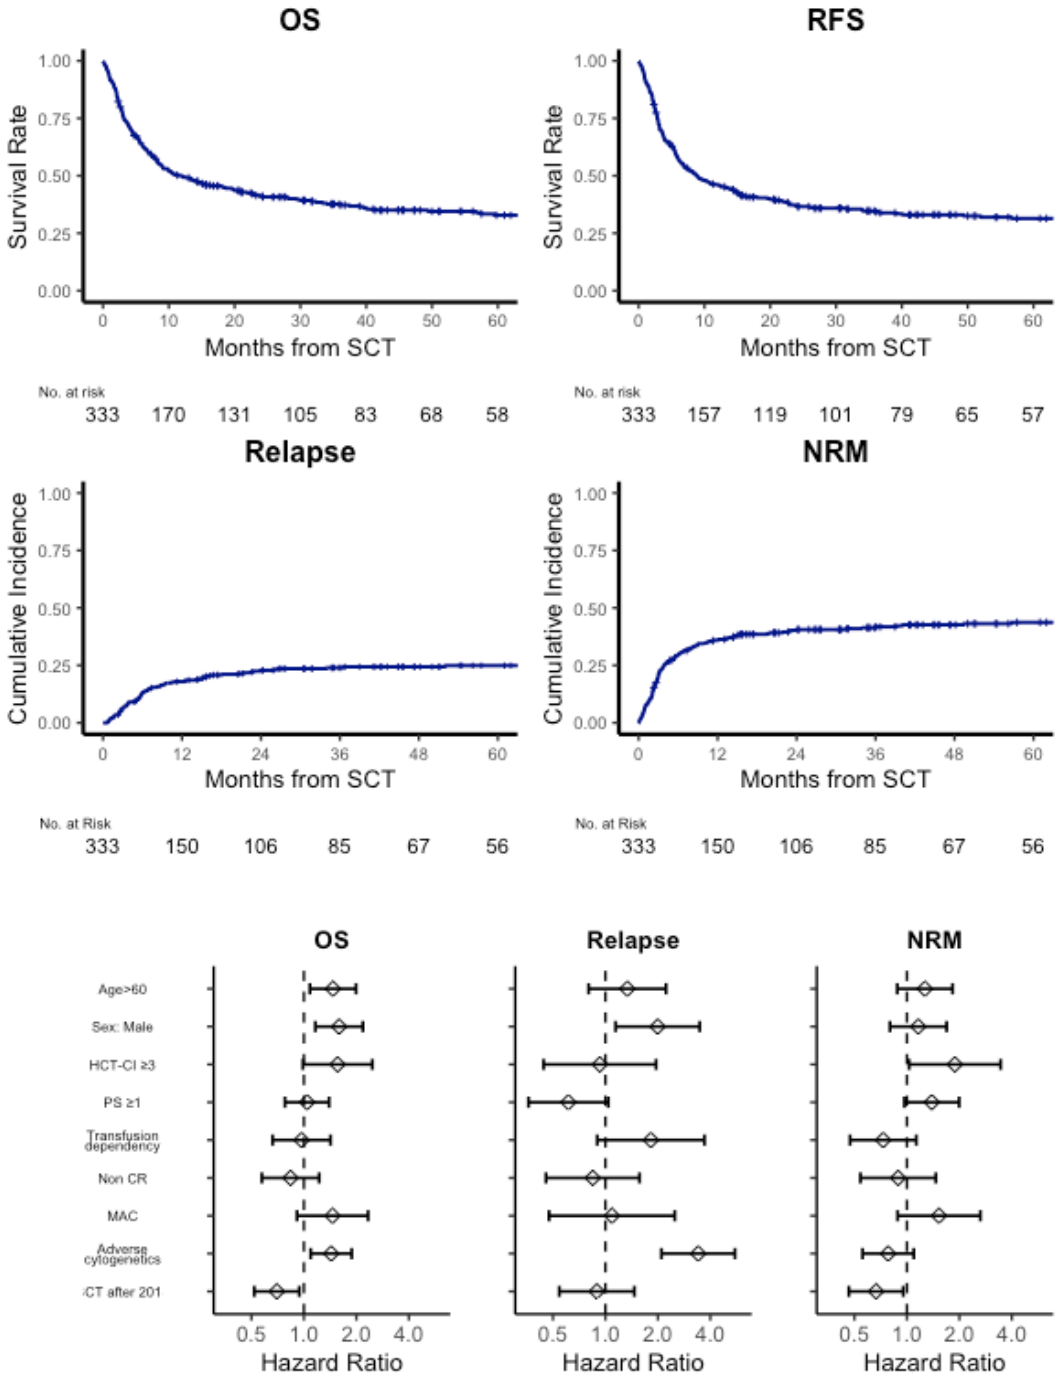
Characteristic	N = 333	Characteristic

Age (range, years)	63 (19-79)	Monosomal karyotype
<60	130 (39%)	Complex karyotype (≥3)
≥60	203 (61%)	Adverse cytogenetics
Sex		Disease Status
Female	103 (31%)	CR
Male	230 (69%)	Non CR
Neutropenia (<500)	198 (60%)	CMV antibody status in recipient
Transfusion dependency (RBC)	231 (69%)	HCT-CI
Transfusion dependency (PLT)	201 (60%)	0-2
ECOG Performance Status		≥3
0	51 (15%)	HLA mismatch
1	224 (67%)	≤1 mismatch
2	58 (17%)	≥2 mismatch
anti-HLA antibody	135 (41%)	
1Median (IQR); n (%)		

Univariate analysis showed age >60, male sex, transfusion dependency, non-remission status, impaired PS (≥1), adverse cytogenetics, transplant era were associated with inferior OS, and the same with LFS. For relapse, male sex, transfusion dependency, and adverse cytogenetics were significant, while age >60, PS≥1, high HCT-CI (≥3), transplant era were associated with NRM.
In multivariate Cox analysis, age>60 (HR 1.47, p=0.01), male sex (HR 1.59, p<0.01), adverse cytogenetics (HR 1.43, p<0.01), transplantation era (HR 0.70, p=0.02) were identified as independent prognostic factors with inferior OS. PS≥1 and non-remission status showed a trend toward an association with OS and LFS, although this did not reach statistical significance. For relapse, male sex (HR 1.99, p=0.01), adverse cytogenetics (HR 3.41, p<0.01) were independently associated, while PS≥1 and transplantation era were prognostic factors for NRM (HR 1.88 and 0.67, respectively).
Notably, a substantial reduction in NRM of more than 10 percentage points was observed in the more recent transplant era (2-year NRM, 46.3% vs 35.1%). In contrast, the relapse rate remained high in patients with adverse cytogenetic features, with a particularly high

incidence of early relapse, affecting 32.1% of patients within a year after CBT.

Figure.1 Transplant Outcomes and Multivariate analysis



Conclusions: CBT represents a viable option for allogeneic HSCT in patients with AML-MR, even in a clinically challenging population characterized by advanced age and a high proportion of non-remission status. While non-relapse mortality has substantially decreased over time, likely reflecting advances in transplant-related care, the high incidence of relapse in patients with adverse cytogenetic features remains a significant unmet challenge.

HAPLOIDENTICAL VERSUS FULLY MATCHED RELATED DONOR STEM CELL TRANSPLANTATION IN PEDIATRIC AND YOUNG ADULTS WITH SEVERE APLASTIC ANEMIA: A SINGLE-CENTER EXPERIENCE FROM A RESOURCE-LIMITED SETTING

Daniella Hodroj[1], *Elie Bechara*[1,2], *Samar Muwakkit*[1,2], *Hanadi Al Sayegh*[2], *Raphah Borghol*[1,2], *Dolly Noun*[1,2], *Miguel Abboud*[1,2]
[1]*Department of Pediatrics and Adolescent Medicine, Faculty of Medicine, American University of Beirut, Beirut, Lebanon,* [2]*Children's Cancer Institute, American University of Beirut Medical Center, Beirut, Lebanon*

Background:

In pediatric severe aplastic anemia, matched related donor transplantation is the preferred first-line treatment. In the absence of a matched related donor, immunosuppressive therapy is commonly used, while matched unrelated donor transplantation may be pursued when feasible. Given the financial and logistical barriers to matched unrelated donor transplantation in many regions, haploidentical transplantation with post-transplant cyclophosphamide (PTCy) has emerged as an accessible alternative, though pediatric data remain limited.

We present our single-center experience comparing haploidentical and fully matched related donor transplantation in children and young adults with severe aplastic anemia.

Methods: We retrospectively analyzed all pediatric patients and one young adult with SAA undergoing SCT from 2013 to 2025 at the American University of Beirut Medical Center. Outcomes included engraftment, chimerism, GvHD, complications, hospitalization, and early survival.

Results:

Fourteen patients were diagnosed with SAA, and one had DDX41-associated marrow failure. All but one were naïve to immunosuppressive therapy. The single patient previously treated with rabbit ATG and cyclosporine developed posterior reversible encephalopathy syndrome (PRES), which resolved with supportive management and treatment adjustment.

Sixteen transplants were performed in 15 patients (median age 7 years; range 3–20; males n=8). Eight patients received haploidentical related donor transplants, including one second transplant following delayed graft failure after matched-sibling SCT. Conditioning consisted of fludarabine (150 mg/m²), cyclophosphamide (29 mg/kg), antithymocyte globulin (2.5 mg/kg), and TBI (4 Gy) for haploidentical transplants, while fully matched related donor transplants received reduced-dose TBI. GVHD prophylaxis included a calcineurin inhibitor and methotrexate for matched related donors, and post-transplant cyclophosphamide with a calcineurin inhibitor and mycophenolate mofetil for haploidentical donors. T-cell–replete bone marrow was used in all cases.

The median infused $CD34^+$ cell dose was 4.93×10^6 cells/kg.

All 11 evaluable transplants achieved hematologic recovery (median neutrophil engraftment 15 days; platelet engraftment 17 days), with comparable engraftment between haploidentical and fully matched groups. Day +30 chimerism (n=12) demonstrated high donor fractions (median ~99%).

Acute GVHD occurred in two haploidentical recipients: one with hyperacute steroid-refractory gastrointestinal GVHD successfully treated with etanercept and ruxolitinib, and one with mild cutaneous GVHD versus trimethoprim-sulfamethoxazole hypersensitivity. No acute GVHD occurred in the fully matched group, and no chronic GVHD was observed.

Infectious complications included CMV viremia (n=2), EBV viremia (n=1), BK virus–associated cystitis (n=1), and isolated mild bacterial or viral infections. Median hospitalization duration was 43 days (range 28–136). All patients were alive at the last follow-up (median 22.6 months). Follow-up dates were available for 12 patients; duration data were incomplete for the others.

Conclusions: In pediatric patients with severe aplastic anemia, of whom only one patient had received prior IST**,** haploidentical stem cell transplantation using the Baltimore protocol achieved reliable engraftment, high donor chimerism, a comparable toxicity profile, and excellent early survival, comparable to outcomes observed with fully matched related donor transplantation.
Given the financial and logistical barriers to matched unrelated donor transplantation in many regions, haploidentical transplantation should be strongly considered as a curative and readily accessible alternative for children with severe aplastic anemia when a matched related donor is unavailable.

PROGNOSTIC FACTORS FOR CYTOKINE RELEASE SYNDROME (CRS) AND IMMUNE EFFECTOR CELL–ASSOCIATED NEUROTOXICITY SYNDROME (ICANS) AFTER CHIMERIC ANTIGEN RECEPTOR T-CELL (CAR-T) THERAPY: A SINGLE-CENTER EXPERIENCE

Aikaterini Benekou[1], *Eleni Siavou*[1], *Aikaterini Kolotsiou*[1], *Maria Dimitrakoudi*[1], *Eleni Lalou*[1], *Panagiota Petsa*[1], *Alexandros Machairas*[1], *Maria-Anna Papadopoulou*[1], *Maria Arapaki*[1], *John V. Asimakopoulos*[1], *Aikaterini Bitsani*[1], *Maria Dimou*[1], *Alexia Piperidou*[1], *Fotios Panitsas*[1], *Iliana Konstandinou*[1], *Marina Belia*[1], *Konstantinos Keramaris*[1], *Marina Siakantaris*[1], *Theodoros P. Vassilakopoulos*[1], *Maria K. Angelopoulou*[1]
[1]*National and Kapodistrian University of Athens/Laikon General Hospital, Athens, Greece*

Background: The present study aims to identify clinical and laboratory prognostic factors associated with the incidence and severity of CRS and ICANS following CAR-T therapy.

Methods: Fifty-one consecutive patients treated with CAR-T therapy for B-cell lymphomas between October 2022 and July 2025 were retrospectively analyzed. Patient characteristics

are summarized in the table. Grading and management of CRS and ICANS were performed according to EHA/EBMT guidelines. The appropriate non-parametric tests were applied for statistical analysis.

Results: A. For ICANS:

1. Performance status (PS) at referral and at lymphodepletion was associated with ICANS but not CRS. ICANS grade 2–4 occurred more frequently in patients with poor PS both at referral (PS 2–3: 55% vs 10%, p=0.004) and at lymphodepletion (PS 3–4: 63% vs 12%, p=0.004). Overall, PS>1 was associated with a higher risk of ICANS of any grade at referral (72% vs 13%, p=0.001) and at lymphodepletion (75% vs 16%, p=0.007).
2. Bulky disease at LDP was associated with higher rates of ICANS grade 2–4 (43% vs 11%, p=0.018), while only a non-significant trend was observed for CRS (CRS yes/no: 33% vs 12%, p=0.07).
3. C-reactive protein (CRP) levels on the day of CAR-T infusion were strongly associated with increased incidence and severity of ICANS. ICANS occurred in 8/16 patients with CRP >30 mg/L compared to 5/35 with CRP ≤30 mg/L (p=0.013). Similar results were observed using a CRP cutoff of 20 mg/L (ICANS yes vs no: 47% vs 12%, p=0.009). CRP levels >30 mg/L and >20 mg/L were also associated with a higher incidence of ICANS grade 2–4 (44% vs 9%, p=0.006 and 42% vs 6%, p=0.003, respectively).
4. Combined elevated CRP [(>20 mg/L), (*normal CRP (0-5 mg/L)]* and poor PS (>2) markedly increased the risk and severity of ICANS. ICANS occurred in 4/31 (13%) with CRP ≤20 mg/L and PS 0–2 (Group A), 3/13 (23%) with CRP >20 mg/L and/or PS 3–4 (Group B), and 6/7 (86%) with CRP >20 mg/L and PS 3–4 (Group C) (p=0.0001). ICANS grade 2–4 occurred in 6%, 23%, and 71% of Groups A–C, respectively (p=0.0001).

B. For CRS

1. Primary refractory disease was associated with higher rates of CRS grade 2–4 (10/17 vs 4/20, p=0.015).

C.Both for CRS and ICANS:

1. Ferritin levels at LDP were predictive of both toxicities. Patents with ferritin >650 ng/mL developed CRS grade 2–4 more frequently than those with lower levels (53% vs 25%, p=0.046) and also showed a higher incidence of ICANS (42% vs 15.6%, p=0.05).

Finally, ICANS grade 2–4 was associated with inferior overall survival. Two-year overall survival was 57% in patients with ICANS grade 0–1 versus 40% in those with ICANS grade 2–4 (p=0.05).

Patient's Characteristics	Number

[1]DLBCL: Diffuse Large B-cell lymphoma, [2]MCL: Mantle cell lymphoma	

Conclusions: Poor performance status, primary refractory disease, and bulky disease represent important clinical risk factors for CRS and ICANS following CAR-T therapy. Ferritin levels at lymphodepletion and CRP levels at infusion are significant predictive biomarkers for these severe toxicities, enabling early identification of patients at increased risk and potentially supporting pre-emptive management strategies.

WHEN COMBINING ATG WITH PTCY, HIGHER ATG EXPOSURE MAY RESULT IN HIGHER SURVIVAL

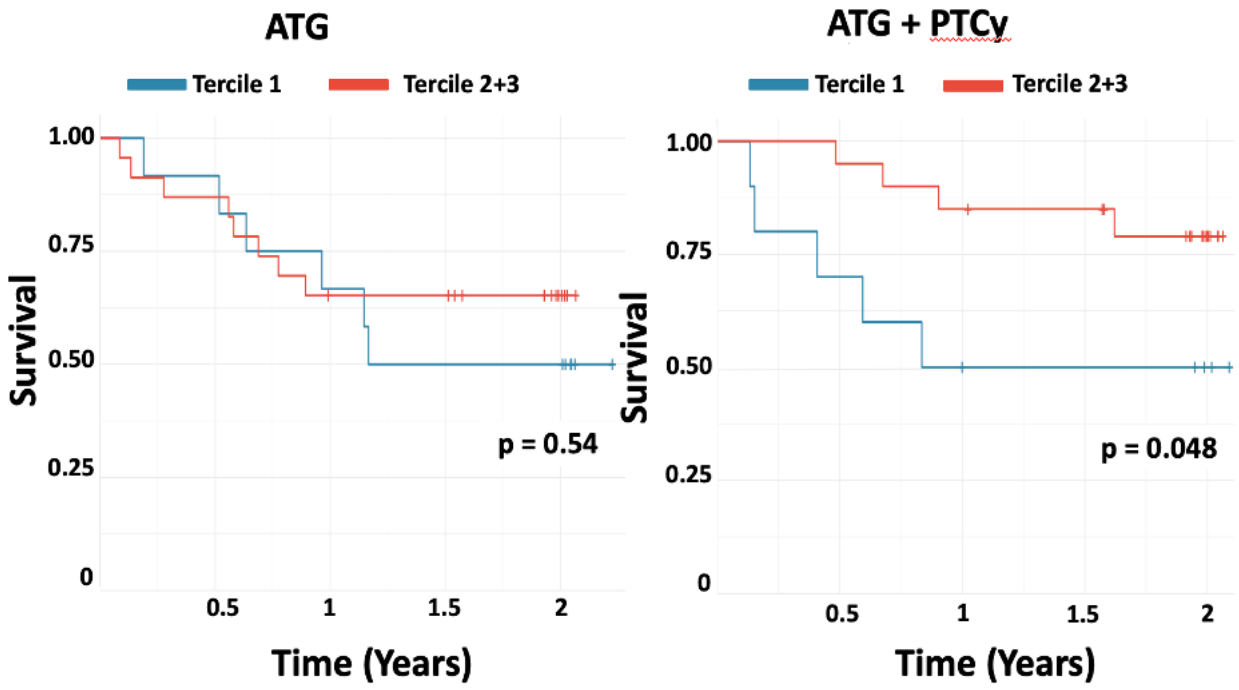
Hamid Ghazal[1], *Tristan Goncalves*[1], *Peter Li*[1], *Irwin Walker*[2], *Kristjan Paulson*[3], *Poonam Dharmani-Khan*[1], *Faisal Khan*[1], *Jan Storek*[1]

[1]University of Calgary, Calgary, Canada, [2]McMaster University, Hamilton, Canada, [3]CancerCare Manitoba, Winnipeg, Canada

Background: Anti-thymocyte globulin (ATG)-based GVHD prophylaxis as well as posttransplant cyclophosphamide (PTCy) based GVHD prophylaxis are commonly used because of their superiority to previously used GVHD prophylaxis (an antimetabolite and a calcineurin inhibitor). It is unclear whether the combination of ATG and PTCy in GVHD prophylaxis is even better. In a randomized study, ATG-based GVHD prophylaxis was compared to a combination of ATG and PTCy-based GVHD prophylaxis (Walker I.: ASH 2024 Abstract No. 3519, https://ash.confex.com/ash/2024/webprogram/Paper198798.html). Acute GVHD appeared to be reduced in the ATG+PTCy arm but, surprisingly, overall survival (OS) was not. Here we studied whether this surprising finding could be related to ATG exposure.

Methods: ATG was given as 0.5 mg/kg on day -2, 2.0 mg/kg on day -1, and 2.0 mg/kg on day +1 (total 4.5 mg/kg). PTCy was given as 50 mg/kg on day 3 and 4 (total 100 mg/kg). We studied 30 patients from the ATG arm and 35 patients from the ATG+PTCy arm, who consented to blood drawing for ATG pharmacokinetics (PK) (at the start and the end of each ATG infusion, before and after graft infusion, and on day 3, 7, 14, and 28 posttransplant). Serum concentration of ATG capable of binding to lymphocytes was measured using flow cytometry. A validated PK model estimated the AUC (surrogate for ATG exposure) for each patient. Patients were stratified into AUC terciles: T1 <40, T2 40-54, and T3 >54 U·day/L. Per preliminary analysis, in the ATG+PTCy arm, OS appeared higher for patients with T2 and T3 AUC than T1 AUC. Thus, for further analyses we used a combined group of patients with T2 and T3 AUC and compared their OS to the T1 AUC group, using Cox regression.

Results: In the ATG+PTCy arm, OS was higher in the T2+3 patients than the T1 patients (hazard ratio (HR)=3.4, p=0.048). In the ATG arm, no OS difference was observed between the T2+3 and the T1 patients.



Conclusions: Higher ATG exposure, which could be achieved by a higher than the 4.5 mg/kg ATG dose, appeared beneficial when combined with PTCy. We hypothesize that PTCy's attenuation of graft-versus-leukemia effect may increase reliance on ATG's direct antileukemic properties (Dabas et al 2019, DOI 10.1182/bloodadvances.2018030247) . Larger studies are needed to confirm these our findings.

IMPACT OF CORTICOSTEROID THERAPY ON CLINICAL OUTCOMES, TOXICITY, AND CAR T-CELL KINETICS IN PATIENTS TREATED WITH ACADEMIC ANTI-BCMA CAR T CELLS (HBI0101)

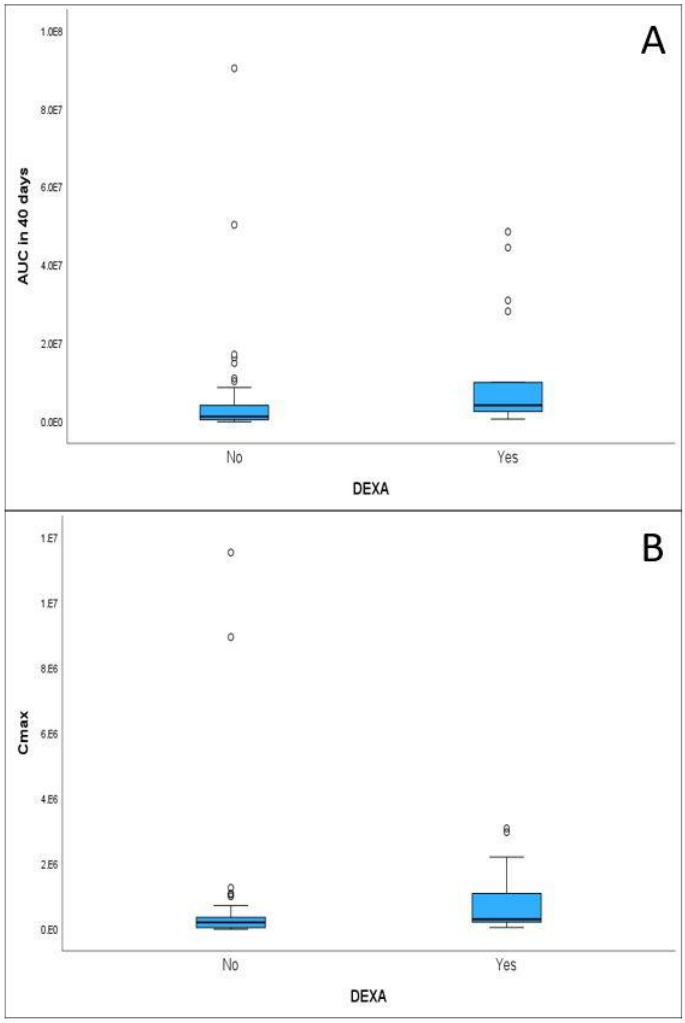
*Eyal Avigad[1], Nathalie Asherie[2], Batia Avni[2,1], Eyal Lebel[2,1], Shlomo Elias[1,2], Miri Assayag[2], Eran Zimran[2,1], Moshe E. Gatt[2,1], Polina Stepensky[2,1], **Sigal Grisariu**[2,1]*
[1]Hebrew University of Jerusalem, Jerusalem, Israel, [2]Hadassah University Hospital, Jerusalem, Israel

Background: Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) are the principal acute toxicities of CAR T-cell therapy. Corticosteroids are commonly used to treat higher-grade CRS and ICANS, yet concerns persist regarding potential negative effects on CAR T-cell expansion and durability. While these effects have been studied in commercial anti-CD19 CAR T products, data regarding anti-BCMA CAR T therapies, remain limited. This study evaluates the clinical, laboratory, and kinetic impact of corticosteroid exposure in patients treated with HBI0101, a locally manufactured academic anti-BCMA CAR T product.

Methods: This analysis included patients enrolled in the HBI0101 phase Ia/b clinical trial who received BCMA-targeted CAR T therapy. Patients were grouped according to corticosteroid exposure after infusion. Clinical outcomes, adverse events , response depth, progression-free survival (PFS), overall survival (OS), laboratory parameters, cytokine levels (IFN-γ, TNF-α, granzyme B), and CAR T-cell kinetics (40-day AUC - Area under the curve of CAR+ T cells concentrations, as a measure of CAR T overall expansion over a 40-days period and Cmax - Peak concentration of CAR+ T cells in the blood), were compared between groups. Statistical analyses included Mann–Whitney U tests, χ^2 tests, and Kaplan–Meier survival analyses.

Results: Eighty-four patients with relapsed/refractory multiple myeloma received BCMA-targeted CAR T therapy between October 2021 and March 2024; 17 (20.2%) received corticosteroids and 67 (79.8%) did not. Baseline characteristics were largely comparable, although steroid-treated patients were older (median 71 vs. 63 years; p=0.035) and had higher bone marrow plasma cell burden (≥10% in 70.6% vs. 36.5%; p=0.012).CAR T-cell expansion was greater in the steroid group, with higher 40-day AUC (median 4,231,953 vs. 1,318,310 cells/mL; p=0.007) and higher Cmax (median 307,433 vs. 209,899 cells/mL; p=0.016; Figure 1). Cytokine levels did not differ between groups.
CRS occurred in 95.2% of patients, with grade 3 CRS more frequent in the steroid group (64.7% vs. 6.0%; p<0.001), consistent with steroid indication. ICANS was uncommon (3.6%) but occurred more frequently among steroid-treated patients (17.6% vs. 0%; p=0.007). Infection rates were similar between groups, while febrile neutropenia was more frequent with steroid use (76.5% vs. 46.3%; p=0.026). Treatment responses are summarized in Table 1, with no significant differences between groups. Though steroid exposure was not associated with PFS (p=0.909), it was associated with borderline inferior OS (p=0.050, HR38.521, 95% CI 31.990-44.592). However, in a multivariable analysis for OS, only ECOG performance status > 0 retained statistical significance (p=0.038, HR 9.362, 95% CI 1.138 - 77.036), while steroid exposure did not (p=0.067).

Figure 1:



A:
Box plot comparing 40-days AUC (Area Under the Curve) CAR positive T cells/mL between the Corticosteroid and the control groups, with a statistically significant difference observed between the two groups (Mann-Whitney Test, p=0.007).

B:
Box plot comparing Cmax (Peak concentration) of CAR positive T cells/mL in the blood between the Corticosteroid and the control groups, with a statistically significant difference observed between the two groups (Mann-Whitney Test, p=0.016).

Table 1:
Best response by corticosteroid administration

Variable	Overall N=84	Corticosteroids		p-value[1]

[1]Best response, as defined in the International Myeloma Working Group (IMWG) consensus criteria for response and minimal residual disease assessment in multiple myeloma.
[2]Fisher-Freeman-Halton Exact Test

Conclusions: Among patients receiving the anti-BCMA CAR T product HBI0101, corticosteroid administration for CRS/ICANS did not negatively impact CAR T-cell expansion or depth of response. Although an association with inferior OS was observed in univariate analysis, this effect was attenuated and did not reach statistical significance in multivariable modeling. These findings support the safety of clinically indicated corticosteroid use in managing CAR T-related toxicities, while underscoring the need for larger cohorts to confirm these results and refine toxicity management strategies for anti-BCMA CAR T therapies.

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION POST–CAR-T THERAPY IN CHILDREN WITH PRE-B ACUTE LYMPHOBLASTIC LEUKAEMIA: NATIONAL POLISH EXPERIENCE

*Kacper Kozłowski[1], Paweł Marschollek[1], **Karolina Liszka**[1], Monika Mielcarek-Siedziuk[1], Jowita Frączkiewicz[1], Zuzanna Gamrot[1], Tomasz Jarmoliński[1], Anna Panasiuk[1], Igor Olejnik[1], Marek Ussowicz[1], Monika Richert-Przygońska[2], Magdalena Ćwiklińska[3], Jolanta Goździk[3], Jan Styczyński[2], Krzysztof Kałwak[1]*
[1]Wroclaw Medical University, Wrocław, Poland, [2]Nicolaus Copernicus University Torun, Toruń, Poland, [3]Jagiellonian University Medical College, Kraków, Poland

Background: CAR-T therapy represents an innovative treatment option for hematologic malignancies resistant to conventional therapies. However, in selected patients, hematopoietic stem cell transplantation (HSCT) may still be required following CAR-T therapy. The decision to proceed with HSCT depends on multiple factors, including relapse risk, biological and genetic characteristics of the malignancy, and the response to CAR-T therapy. A timely decision to perform HSCT may improve the likelihood of achieving long-term disease control.

Methods: Among 51 patients treated with CAR-T therapy in Poland, 12 children subsequently required allogeneic HSCT. HSCT procedures were performed at three pediatric centers: Wrocław, Bydgoszcz, and Kraków. We conducted a retrospective analysis that included demographic data, clinical history, CAR-T therapy characteristics, and details of the HSCT course. Seven children were treated for relapsed acute lymphoblastic leukemia (ALL), including one with a CD19-negative relapse. In one patient, the indication for HSCT was severe and prolonged hematologic toxicity after CAR-T therapy (ICAHT). One patient failed to achieve molecular remission, while in three children, CAR-T therapy served as a bridge to transplantation.
During the interval between CAR-T infusion and HSCT, two patients required a CD34+ stem cell boost.
The median time between CAR-T infusion and HSCT was 340 days (range, 64–908 days). Conditioning regimens included total body irradiation with etoposide in nine patients; treosulfan, fludarabine, and thiotepa in two patients; and fludarabine with cyclophosphamide in one patient.

Results: Post-transplant complications included one patient developing severe veno-occlusive disease, treated with defibrotide. Four children developed acute skin graft-versus-host disease (GVHD): three responded to steroid therapy, while one had steroid-resistant GVHD requiring etanercept. One child experienced graft rejection and required a second HSCT.
Two patients were treated with cidofovir for adenovirus reactivation, and one subsequently developed chronic bone marrow failure. No cases of chronic GVHD were observed.
The median duration of follow-up after HSCT was 8 months (range, 1-62 months). 1-year overall survival was 79%, while disease-free and event-free survival rates were 79% and 68%, respectively. Two patients died from disease recurrence, one at 5 months and the other at 8 months after the procedure.

Conclusions: Hematopoietic stem cell transplantation remains an important therapeutic strategy in selected patients following CAR-T therapy. The primary indication for HSCT in this setting is disease relapse; however, second CAR-T infusions are increasingly considered. Allogeneic HSCT after CAR-T is also recommended as remission consolidation in patients at very high risk of relapse—based on biological or genetic features—or in those who fail to achieve minimal residual disease (MRD) negativity after CAR-T therapy. In addition, severe or prolonged hematologic toxicity following CAR-T may necessitate HSCT. In these clinical scenarios, transplantation can provide more durable disease control and reduce the risk of subsequent relapse.

MULTICENTER PILOT CLINICAL TRIAL OF OLUTASIDENIB AS MAINTENANCE THERAPY AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION IN PATIENTS WITH AML/MDS CARRYING IDH1 MUTATIONS

Amandeep Salhotra[1], *Abhay Singh*[2], *Dongyun Yang*[1], *Brian Ball*[1], *Monzr Al Malki*[1], *Karamjeet Sandhu*[1], *Salman Otoukesh*[1], *Amanda Blackmon*[1], *Idoroenyi Amanam*[1], *Shukaib Arslan*[1], *Paul Koller*[1], *Ahmad Aribi*[1], *Ibrahim Aldoss*[1], *Haris Ali*[1], *Sunmin Park*[1], *Vinod Pullarkat*[1], *Andrew Artz*[1], *Anthony Stein*[1], *Eileen Smith*[1], *Guido Marcucci*[1], *Stephen Forman*[1], *Claudio Bernstein*[2], *Ryotaro Nakamura*[1]
[1]*City of Hope, Duarte, United States of America (the),* [2]*Cleveland Clinic, Cleveland, United States of America (the)*

Background: Somatic mutations in isocitrate dehydrogenase *(IDH1)* is seen in ~10% AML and 3-5% MDS patients. We and others have previously reported higher relapse with IDH mutation post allogeneic hematopoietic cell transplantation (alloHCT). Olutasidenb is a small molecule inhibitor of mutant *IDH1* (*mIDH1*) and has shown efficacy in phase 2 trial [ORR of 48% and response duration 26 months in patients who achieve Cr/CRh]. Here, we report on results of our multicenter pilot trial of Olutasidenib as maintenance after alloHCT in *IDH1* mutated AML/MDS patients (NCT06543381).

Methods: Patients were eligible if they were in complete remission (CR) on day +30 and had adequate marrow function. Olutasidenib was given at FDA approved dose of 150 mg twice daily between days +50-120 post-HCT for 2 years (Fig 1). The primary objective was to evaluate safety and tolerability, and secondary objectives were to assess survival outcomes. Sample size of 15 was determined based on modified rule of continuous monitoring for toxicity using Pocock-boundary with desired probability of early stopping of 0.75 if the unacceptable toxicity rate was ≥33%.

Results: Between 2024-2025, we enrolled 6 patients (n=5 AML; 83%) and MDS (n=1;16%) on study. The median age was 68 years (range:42-71) and majority of patients were Caucasian (83%). All patients with AML (n=5) were in CR1 pre HCT with majority (80%) being MRD negative. Based on ELN 2022, majority of AML patients had adverse risk (n=4; 80%), one patient was intermediate risk and MDS patient had IPSS high risk. Majority of patients received reduced intensity conditioning (n=5; 83%) and all patients received PBSC graft from 8/8 HLA matched donor (=4;66%) or 7/8 mismatched MUD (n=2;33%). GVHD prophylaxis was with post-transplant cyclophosphamide in majority of patients (n=5;83%) At the data cutoff of December 2025, 4 patients are currently on study with median follow-up of 140 days (range: 112-293). One pt died on day +131 (fungal pneumonia unrelated to study drug) and 1 withdrew on day +7. Median start time of protocol therapy is 119 days(range:77-138). All patients currently on treatment have completed >5 cycles of maintenance therapy and one patient has completed 12 maintenance cycles. We collected all grades of adverse effects (AEs) during the first 2 cycles, and grade ≥3 AEs for subsequent

cycles (Table 2). In the first 2 cycles, grade ≥3 AEs were mainly due to hematologic toxicity including: anemia (n=1), lymphopenia (n=1), dyspnea(n=1) and upper respiratory infection (n=1), one patient had grade 2 AE of URI. Most common grade 1 AEs included fatigue (n=2) and transaminitis (n=2), anemia, lymphopenia, nausea, diarrhea, and edema were other common AEs. Table 1 shows AEs for all cycles for the 5 patients treated on study. One patient passed away from fungal pneumonia (unrelated to study drug). No relapse of primary hematologic malignancy has been seen.

Conclusions: In conclusion, post-HCT maintenance therapy with Olutasidenib was safe and feasible with favorable survival outcomes in AML/MDS patients carrying *IDH1* mutations. No unusual toxicity or safety signal was noted in patients treated so far, the trial continues to accrue patients in multicenter setting.

A SINGLE CENTRE EXPERIENCE OF ALLOGENEIC STEM CELL TRANSPLANT IN PATIENTS OVER 70

Catharina Tao[1], *Faisal Basheer*[1], *Helen Bentley*[1], *Duncan Brian*[1], *Charles Crawley*[1], *Kushani Ediriwickrema*[1], *Martin Loader*[1], *Ram Malladi*[1], *Simon Richardson*[1], *Kiran Tawana*[1], *Ben Uttenthal*[1], *Chi Wong*[1], *Andrew King*[1]
[1]*Cambridge University Hospitals, Cambridge, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Incidence of haematological disorders increases with age. Yet use of allogeneic stem cell transplantation (alloSCT)—the only curative option for many such disorders—remains limited in elderly patients due to concerns about complications and comorbidity. Measures such as reduced-intensity conditioning regimens and improved supportive care have broadened eligibility, but outcome data in this age group remain scarce.

Methods: This retrospective single-centre study reviewed outcomes of patients aged ≥70 years undergoing alloSCT between 2015 and February 2024 at Addenbrookes Hospital (UK). Outcomes included: overall survival (OS), relapse-free survival (RFS), GVHD-free relapse-free survival (GRFS), relapse incidence, GVHD incidence/severity, chimerism, donor lymphocyte infusion (DLI) requirement, infection, and mortality incidence/cause.
Survival was estimated using Kaplan–Meier method. Cumulative incidences were calculated using competing-risks methods.

Results: Twenty-two patients (mean age 70.5, 72.7% male) were identified. Characteristics in Table 1. All received reduced-intensity conditioning (fludarabine/melphalan/alemtuzumab). 90.9% (20/22) had fully HLA-matched donors.
Median OS was 699.5 days. Survival at 1,2,3, and 5 years was 77.3%, 45.5%, 45.5%, and

39.8%, respectively. Median RFS was 667 days, with corresponding rates of 68.2%, 45.5%, 40.9%, and 35.8%. Median GRFS was 621.5 days. GRFS at 1,2,3, and 5 years was 63.6%, 45.5%, 40.9%, and 35.8%. (Figure 1)
Relapse occurred in 31.8% (7/22) patients. Median time to relapse was 203 days. Relapse incidence at 1 and 3 years was 18% and 27%. Survival probability 1-year post-relapse was 43%.
Acute GVHD occurred in 45.5% (10/22), with only one grade 3-4 case. Chronic GVHD affected 31.8% (9/22) including two severe cases, but no admission was required for either.
At analysis (June 2025), 13/22 patients had died. Transplant-related mortality (day-100 mortality) was 0%. 46.5% (6/13) of deaths were relapse-related. Incidence of relapse-related mortality was 9.1% at 1 year, 23% at 2 years, and 28% at 5 years. Incidence of non-relapse mortality was 14% at 1 year and 32% at 2 and 5 years, with infection as the leading cause contributing to 30.7% (4/13) of all deaths.
Clinically significant infections occurred in 86.4% (19/22) patients.
Complete whole-blood chimerism was achieved in all patients by day 30. Complete T-cell donor chimerism was 36.4% by day 30, decreasing to 31.8% by day 90. DLI was required in 45.5% (10/22) patients, for mixed chimerism (n=7), relapse (n=1), or both (n=2).

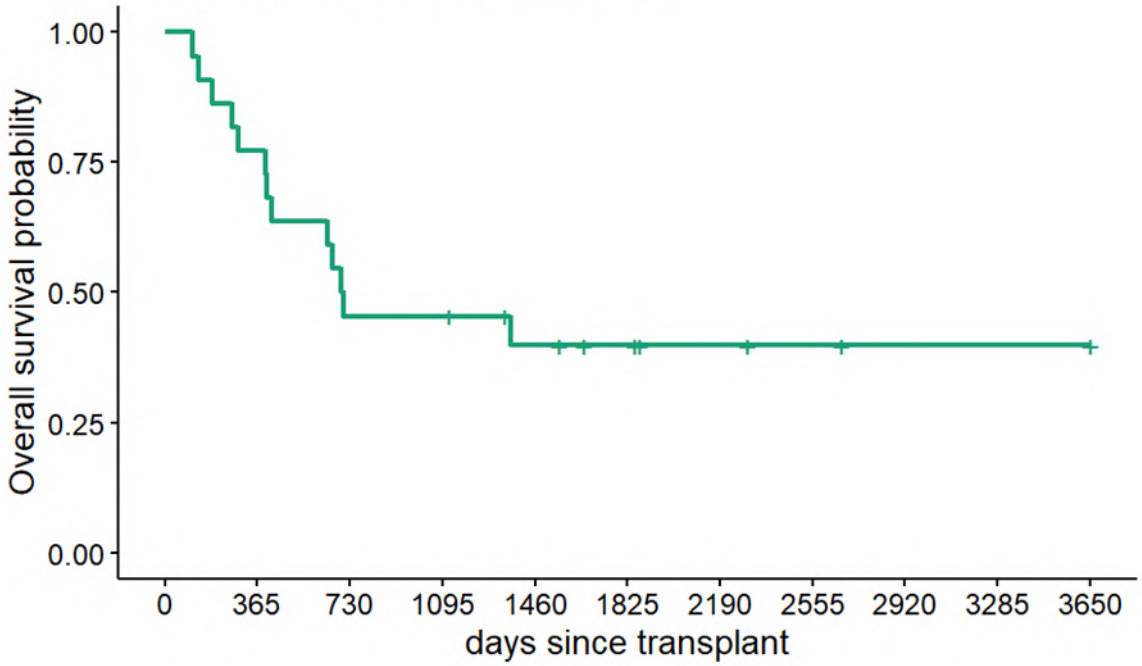
Table 1: Patient characteristics

Characteristic		**Number of patients**	**% of patients**
Diagnosis	MDS	7	31.8
	AML	13	59.1
	CML	1	4.6
	Diffuse large B-cell lymphoma	1	4.6
Donor type	VUD	20	90.9
	Sibling	2	9.1
HLA match	Full match	20	90.9
	9/10	2	9.1
HSCT-CI score	0	5	22.7
	1	7	31.8
	2	4	18.2
	3	2	9.1
	4	2	9.1

	5	2	9.1
ECOG	0	17	77.3
	1	5	22.7

Abbreviations: MDS, myelodysplastic syndromes; AML, acute myeloid leukaemia; CML, chronic myeloid leukaemia; DLBCL, diffuse large B-cell lymphoma; VUD, volunteer unrelated donor; HLA, human leukocyte antigen; HSCT-CI, Haematopoietic Cell Transplantation–Comorbidity Index; ECOG, Eastern Cooperative Oncology Group performance status

Figure 1: Overall Survival (OS)



Conclusions: AlloSCT in patients ≥70 years showed acceptable outcomes with good survival outcomes and zero transplant-related mortality. High rates of GVHD and infections highlight the need for improved post-transplant care, particularly in optimising GVHD prophylaxis/treatment and infection prevention.

LOW-LEVEL PRETRANSPLANT CMV DNAEMIA IS ALREADY A RISK FACTOR FOR POSTTRANSPLANT CMV INFECTION AFTER ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION

Catia Vieira Gomes[1], Manuel Schibler[1], Laurent Kaiser[1], Yves Chalandon[1], Stavroula Masouridi-Levrat[1], Christian Van Delden[1], ***Dionysios Neofytos***[1]*, Lena Royston[1]*
[1]*Université de Genève, Geneva, Switzerland*

Background: Clinically-significant CMV infections (csCMVi) still occur in allogeneic hematopoietic cell transplant recipients (allo-HCTr), even on letermovir prophylaxis. We recently reported that allo-HCTr with a positive pre-HCT CMV DNAemia were at higher risk of post-HCT csCMVi compared to allo-HCTr with undetectable CMV PCR (59.3% vs 26.3% at 180 days (d) post-HCT, respectively). Herein, we further explore the impact of pre-HCT CMV viral load (VL) on the incidence of post-HCT csCMVi and hematological outcomes.

Methods: This was a retrospective cohort study including consecutive adult allo-HCTr (16.11.2015-31.12.2023) with ≥1 CMV positive PCR (detectable (DT) or quantifiable (QT)) up to 90d prior to HCT. Plasma CMV PCR was performed with COBAS CMV test with limit of detection and quantification of 21 and 26 IU/mL, respectively, since 16.05.2018, and previously of 56 and 137 IU/mL, respectively. Since 01.05.2019, letermovir prophylaxis was administered to CMV-seropositive patients for 100d post-HCT. Pre-HCT CMV PCR was performed at pre-HCT consultation, HCT admission, day of HCT, and as clinically indicated. Post-HCT CMV PCR was performed weekly for 90d post-HCT and as clinically indicated thereafter. CsCMVi was defined as CMV PCR ≥ 500IU/mL during letermovir administration and ≥ 150 IU/mL without letermovir.

Results: Among 505 allo-HCT, a median of 3 CMV PCR tests (range 1-14) were performed within 90d pre-HCT. 63/505 allo-HCTr (12.5%) had ≥ 1 positive pre-HCT CMV PCR: 38/63 (60.3%) with DT PCRs and 25/63 (39.7%) ≥ 1 QT PCR. Among the latter, the median VL was 118 IU/mL (range: 38.2-95,600) and mean VL 4,221 IU/mL. Incidence of csCMVi at 180d post-HCT was similar between patients with DT (24/38, 63.2%) or QT (17/25, 68.0%, p=0.69) pre-HCT CMV DNAemia. Similarly, incidence of acute GvHD (60.5% vs 60.0%), relapse (50.0% vs 60.0%) and all-cause mortality (47.4% vs 44.0%) at 1-year post-HCT were similar between the 2 groups (all p > 0.05). There was no significant association between a higher pre-HCT CMV DNAemia and csCMVi, acute GvHD, relapse or death in logistic regressions.

Conclusions: Whereas pre-HCT CMV DNAemia was strongly associated with increased post-HCT csCMVi incidence, the magnitude of the VL is not associated with an increased risk. This suggests that any DT pre-HCT CMV DNAemia may represent an activity of CMV reservoir and could be considered as a relevant risk factor for csCMVi, regardless of the VL.

Disclosure: Nothing to declare.

ASSESSMENT OF COMPLEMENT PATHWAY DYNAMICS AFTER ALLOGENIC HEMATOPOIETIC CELL TRANSPLANT: RESULTS FROM A MONOCENTRIC LONGITUDINAL MONITORING PROGRAM

Camille Malbrun[1], *Mélissa Julien*[1], *Antoine-Adrien Demasi*[1], *Emilie Darche*[1], *Gabrielle Roth-Guepin*[1], *Caroline Bonmati*[1], *Céline Kicki*[1], *Arnaud Campidelli*[1], *Anne Béatrice Notarantonio*[1,2], *Maud D'Aveni*[1,2], *Caroline Jacquet*[1], *Pierre Feugier*[1,3], *Christine André-Botté*[1], *Maxime Cravat*[1], *Tshinguta Mbuyi*[1], *Marcelo De Carvalho-Bittencourt*[1], *Marie-Thérèse Rubio*[1,2], *Simona Pagliuca*[1,2]
[1]*CHRU Nancy, Vandoeuvre-Les-Nancy, France,* [2]*University of Lorraine IMOPA, Vandoeuvre-Les-Nancy, France,* [3]*INSERM U1256, Nancy, France*

Background: Systemic complement activation is a well-established pathophysiological mechanism involved in endothelial complications, particularly post-transplant microangiopathy (TMA), following allogeneic hematopoietic cell transplantation (allo-HCT). We previously demonstrated its impact on post-transplant outcomes in a prospective study involving patients who received a myeloablative conditioning (MAC) regimen (*Notarantonio et al. AJH 2024*). Here, we aimed to investigate the role of complement activation in the clinical course of a cohort of patients prospectively enrolled in a monitoring program between 2022 and 2024.

Methods: The cohort included patients who received either MAC or reduced-intensity conditioning (RIC) regimens. Complement monitoring was performed weekly from baseline through week 12 post-transplant, assessing CH50 activity and C3/C4 levels. Activation profiles were defined by a drop in one or more of these markers below the lower limit of normal.

Results:
A total of 125 patients were included in this study, with a male-to-female ratio of 2.3 and a median age of 59.4 years (interquartile range [IQR] 45.6–65.5). The cohort comprised 67 patients (54%) with acute myeloid leukemia, 13 (11%) acute lymphoblastic leukemia, 11 (8%) myelofibrosis, 6 (5%) other myeloproliferative neoplasms, 18 (14%) lymphoproliferative neoplasms or lymphoma, 9 (7%) myelodysplastic syndromes and 1 (1%) bone marrow failure. Donor types included matched related donors (n=20, 16%), matched unrelated donors (n=65, 53%), mismatched unrelated donors (n=24, 19%), and haploidentical donors (n=16, 12%). Most patients received grafts from mobilized peripheral blood (n=117, 94%), bone marrow (n=6, 5%) and umbilical cord blood (n=2, 1%). RIC regimens were mainly represented (n=107, 86%).

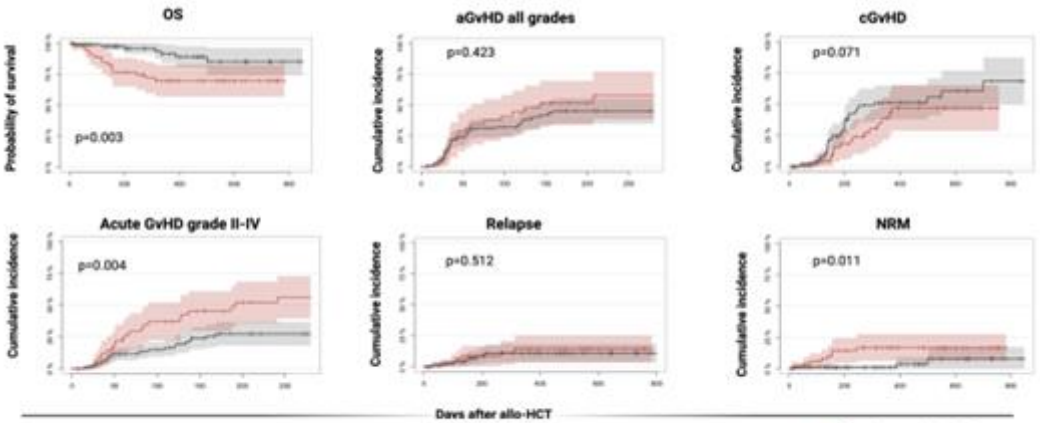

Figure 1. Different outcomes after allo-HCT in patients showing complement activation (red) or not (grey).

The complement profile at baseline showed that a substantial number of patients (n=20, 16%) exhibited isolated C3 activation, suggesting a possible selective activation of the alternative pathway prior to the initiation of the conditioning regimen. After allo-HCT, 52 patients (41%) developed a complement activation profile during follow-up between week 1 and 12. Among them, 16 patients had already exhibited an activated profile at baseline. We found that complement activation was associated with significantly worse overall survival (HR 3.84, 95% CI 1.55–9.49, p=0.0035) and higher non-relapse mortality (NRM, HR 5.44, 95% CI 1.49–20.16, p=0.0112), driven by an increased risk of grade II–IV acute graft-versus-host disease (GvHD) (HR 2.25, 95% CI 1.28–3.95, p=0.0046). The limited number of endothelial events (veno-occlusive disease [VOD] n=7, post-transplant TMA n=6, capillary leak syndrome n=1) precluded firm conclusions, although most affected patients exhibited complement activation. In the TMA group, 4 of 6 patients showed persistent, isolated C3 consumption suggestive of sustained alternative pathway activation. In the VOD group, 3 patients had isolated C3 decline and one showed global complement consumption consistent with systemic classical or lectin pathway activation.

Conclusions: These findings underscore the importance of monitoring complement activity after allo-HCT, since dynamic complement activation was associated with inferior survival and higher NRM, primarily driven by an increased risk of acute GvHD. Incorporating complement monitoring into routine post-transplant follow-up may help identify patients at risk and may open new avenues for the prevention of alloreactive complications.

HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION WITH POST-TRANSPLANT CYCLOPHOSPHAMIDE FOR MALIGNANT AND NON-MALIGNANT HEMATOLOGIC DISORDERS: A REAL-WORLD EXPERIENCE FROM QATAR

Afraa Fadul[1], *Amaal Gulied*[1], *Awni Alshurafa*[1], *Fatima Taloozy*[1], *Abdul Rashid Shah*[1], *Amna Gamil*[1], *Mohammed Abdulgayoom*[1], *Fabio Culurgioni*[1], *Wedad Saleem*[1], *Manal Yaghmour*[1], *Saloua Hmissi*[1], *Suparna Chandramouli*[1], *Nahrida Band*[1], *Suja Pillai*[1], *Medhat Askar*[1], *Honar Cherif*[1], *Javid Gaziev*[1], *Mohammad Bakr*[1]
[1]*Hamad Medical Corporation, Doha, Qatar*

Background: Haploidentical hematopoietic cell transplantation (Haplo-HCT) using post-transplant cyclophosphamide (PTCy) is a readily available alternative for patients without HLA-matched donors. This is an attractive approach in countries that lack donor registries and/or cannot afford the costs of an unrelated donor search. Accumulated experience shows that outcomes of haplo-HCT for hematological diseases are similar to those of matched related and unrelated transplants. We report our 5-years' experience of Haplo-HCT in hematologic malignancies and bone marrow failure syndromes at the National Center for Cancer Care and Research in Qatar.

Methods: Forty-three patients with a median age of 39 years (range 14–59) received haplo-HCT at our center. Majority with hematological malignancies; 28 (65.1%) with myeloid malignancies (AML, MDS, CML-BP), 11(25.6%) with lymphoid malignancies (ALL, NHL) and 4 (9.3%) with aplastic anemia and PNH. Donors were siblings in 69.8%. Donor-specific antibodies were negative in 38 (88.4%), while 5 (11.6%) were positive, 3 (7.0%) of whom required desensitization before transplant. At the time of transplantation, 38 patients of the hematological malignancy patients were in CR1/CR2, and 3 had relapsed/refractory disease. Most patients (90.7%) received a myeloablative conditioning (MAC) (90.7%), whereas 4 patients (9.3%) received a reduced-intensity conditioning (RIC). TBI-based conditioning with fludarabine 160 mg/m² and TBI 1200 cGy were administered to 30 patients (69.8%), whereas 13 patients (30.2%) received non-TBI conditioning. GVHD prophylaxis consisted of PTCy on days +3 and +4, CSA starting from day -1 and MMF from day +1. The median CD34 cell dose was 7.9 x 10^6/kg. Median CD34 dose 7.9 (range, 4.0–12.0), and the CD3 cell dose was 154.3 × 10^6/kg (range, 46.5-283.1).

Results: The median follow-up for surviving patients was 16 months (3 – 52 months). All patients engrafted, median chimerism at the time of engraftment was 99.8% (range, 95-100). The median time for neutrophil and platelets engraftment was 14 days (range, 11.0-42.0) and 18 days (range 9.0 -50), respectively. 2-year and 3-year OS: 90.2%, and OS: 84.2%, respectively (Figure 1). 2-year DFS and GRFS were 76.9% and 67.3%, respectively,

(Figures 2 and 3). The incidence of grade II-IV acute GVHD was 28%, (Figure 4). The 2 - year incidence of cGVHD (all grades) was 36.8% while the moderate to severe cGVHD was 23 % (Figures 5 and 6). 2-year CIR and NRM were 20.8% and 2.3% (Figure 7 and 8), respectively. The incidence of grade 1 and 2 CRS was 20.9%. Three patients (7%) had grade 3 CRS and required tocilizumab. Clinically significant CMV infection was significantly higher in patients who did not receive letermovir prophylaxis (92%) than in those who did (11.6%). One patient developed VOD that was treated with defibrotide. Three patients (7%) developed grade 3 BK-virus-associated hemorrhagic cystitis, and two developed TA-TMA.

Conclusions: Haplo-HCT with PTCy leads to excellent survival for patients who lack HLA-matched donors or access to an unrelated donor. Our results revealed universal engraftment, higher rates of disease-free survival and an improved graft-versus-host disease-free-relapse-free survival. Finally, in our cohort, both chemo and radiotherapy-based conditioning haploidentical cell transplantation resulted in low rates of relapse, non-relapse mortality and chronic GVHD.

OUTCOMES OF HAEMATOPOIETIC STEM CELL TRANSPLANTATION IN CHRONIC MYELOID LEUKEMIA IN TYROSINE KINASE INHIBITORS ERA: A SINGLE CENTRE STUDY FROM PAKISTAN

Mehreen Ali Khan[1], Jehanzeb Ur Rehman[1], Raheel Iftikhar[1], Maryam Khan[1], Yasir Abbas[1], Memoona Khan[1], Ammad Akram Chaudhary[1], Tariq Ghafoor[1], ***Bushra Ahsan***[2]
[1]*Armed Forces Bone Marrow Transplant Center, Rawalpindi, Pakistan,* [2]*Shaukat Khanum Memorial Hospital and research centre, Lahore, Pakistan*

Background: Chronic Myelogenous Leukemia (CML), a myeloproliferative stem cell cancer driven by the BCR-ABL1 gene, has seen a treatment revolution with tyrosine kinase inhibitors (TKIs). TKIs have enabled high survival rates in the chronic phase, superseding hematopoietic stem cell transplantation (HSCT) as the primary therapy. Nonetheless, factors such as TKI resistance, drug intolerance, the high expenses associated with ongoing treatment and molecular monitoring, and limited TKI access mean that HSCT continues to be an important option in resource-limited environments.

Methods: **Objectives:** To analyse OS, DFS and GRFS in CML patients undergoing allogeneic HSCT.
Methods: This retrospective study was carried out at AFBMTC from 1 Jan 2001 to 31 Aug 25. IRB approval was obtained and anonymized data was analyzed.

Results: A total of 104 CML patients underwent HSCT. The median age of patients was 27 years. (range: 5-50, IQR:21-34). 82 patients were males (76.6%) and 25 were females (23.3%). 72 patients in chronic phase (CP) underwent HSCT due to TKI resistance /intolerance, 19 were transplanted in accelerated phase and 16 in blast crises (BC). Out of BC, 7 patients had lymphoid BC and 9 had myeloid BC. There were 69 male and 38 female donors (median age:24). Myeloablative conditioning (MAC) (Bu, Cy with or without TG/ATG) was given to 103 patients and (Flu, Bu, TG/ATG) was given to 4 patients. Total body irradiation (TBI) was not given due to non-availability of TBI facility. CSA + MTX was the most common GVHD prophylaxis given to 106 patients who underwent fully HLA matched Allogeneic HSCT and PT/Cy was given to 1 patient who underwent haploidentical HSCT. Stem cell source was bone marrow harvest (BMH) in 40, peripheral blood stem cells (PBSC) in 64 and both BMH + PBSC in 3 patients. The median CD 34 dose was 3.94×10^6 /Kg and TNC dose was 3.79×10^8/Kg . Median days to neutrophil and platelets engraftment were +13 and

+18 post HSCT respectively. The most common infectious complication was neutropenic fever followed by hemorrhagic cystitis and gut toxicity. Acute GVHD was experienced in 27% patients and chronic GVHD was experienced in 30% patients. OS was 71.7%, DFS was 63% and GRFS was 37.4%.

Conclusions: Allogeneic hematopoietic stem cell transplantation (HSCT) remains a critical treatment for Chronic Myeloid Leukemia (CML) in low- and middle-income countries (LMICs), especially in cases of TKI resistance or advanced disease. While requiring a major initial investment and complex infrastructure, HSCT provides the possibility of a durable, treatment-free cure. This outcome can ultimately be more cost-effective than lifelong TKI therapy, offering significant long-term survival benefits for eligible patients in resource-limited settings.

ABT/CD19 DEPLETED HAPLOIDENTICAL STEM CELL TRANSPLANTATION IS A SAFE AND EFFECTIVE SALVAGE THERAPY IN HEAVILY PRETREATED RELAPSED/REFRACTORY PATIENTS WITH HODGKIN LYMPHOMA

Amelia Rinaldi[1], Sabrina Bonomini[1], Roberta Segreto[1], Benedetta Cambò[1], Maria Teresa Giaimo[1], Gabriella Sammarelli[1], Caterina Plenteda[1], Giannalisa Todaro[1], Ramona Linciano[1], Giovanni Roti[1], ***Lucia Prezioso***[1]
[1]*Hospital University of Parma, Parma, Italy*

Background: Hodgkin lymphoma (HL) represents only about 10% of all lymphomas, but has become a paradigm of successful cancer treatment, with cure rates now exceeding 80% in most patient populations. The prognosis of HL has dramatically improved over the past several decades through multiple therapeutic advances. Allogenic transplantation (HSCT) is now reserved only for a small number of patients who fail immunotherapy or experience early relapse. Due to the considerably high Transplant related mortality, above all GVHD, its role in HL has evolved considerably. In the last years haplo transplantation with PTCy has shown high efficacy, with a reported toxicity.

Methods: Ten patients, median age 27 years old (20-39) entered the study. Characteristics are shown in Tab 1. All but two patients had active disease at moment of transplantation. Median number of previous therapies was 6 (range 3-9). All but one patient has already received an autologous transplantation. One patient had received also an HSCT from matched unrelated donor. Only 2 patients were in CR (more than 2) at HSCT. Conditioning consisted of ATG 1,5 mg/kg from day -13 to day -10, Treosulfan 12gr/sqm from -9 to –7, Fludarabine 30mg/sqm from -6 to -2 and Thiotepa 5mg/Kg on days -5 and -4. Ten µg/kg G-CSF was used to mobilize PBPCs from one-haplotype mismatched donors (3 mothers, 5 brothers, 1 sister and 1 uncle; median age 45; range 21-62). T depletion was the only GVHD

prophylaxis. Any additional GVHD prophylaxis was used. Six patients had an unfavorable CMV sierology.

Results: Grafts contained a median of $10x10^6$/kg (range 6-17) CD34+cells, $9x10^6$ $CD3^+$Tcells/kg (range 2-21) with $4x10^4$/kg $\alpha\beta^+$T cells (range 1 – 7.5) and 9 $x10^6$ $\gamma\delta^+$Tcells/kg (range 2-20), $3x10^4$ B cells/kg(range 1,2-6.2) and $22.6x10^8$ $CD56^+$NKcells/kg (range 1-48). All patients engrafted. Median time to reach 500 neutrophils and 20.000 platelets was 12 days and 11 days, respectively. At a median follow up of 7.5 years (range 0.2-9.65) the overall survival was 80%. One patient died because of recurrent CMV reactivation in patient with an unfavorable sierology R POS/D NEG in pre letermovir era and the other one due to GVHD post Donor lymphocyte Infusion. No other cases of GVHD were seen. Interestingly, no relapses occurred. The most frequent infections were of viral origin, especially in the first 100 days post HSCT, but without leading to organ disease. CMV reactivation occurred, in 5 patients, with one experiencing organ disease, and EBV reactivation in three, that completely

responded to 2 cycles of Rituximab. No other long term life-threatening complications occurred. No patients have so far developed chronic GVHD.

Conclusions: Allogenic transplantation with ab T cell depletion is an effective and safe approach in relapsed/refractory Hodgkin lymphoma heavily pretreated, with a rapid donor hematopoietic engraftment and very promising outcome, with a very low transplant related mortality in patients heavily pretreated before HSCT.

FACTORS AFFECTING QUALITY OF BONE MARROW HARVESTING: AN ANALYSIS OF ANTHONY NOLAN DONORS FROM 2019-2024

*Ellouise Bishop[1], **Tania Dexter**[1], Diana Voiniciuc[1], Maram Ghiti[1], Angharad Pryce[1], Chloe Anthias[1]*
[1]Anthony Nolan, London, United Kingdom of Great Britain and Northern Ireland (the)

Background: Peripheral blood stem cell (PBSC) harvesting has changed the landscape of stem cell collection. However bone marrow harvesting (BMH) remains an important collection method. The total nucleated cell (TNC) dose administered is essential for successful engraftment with consensus of a minimum dose defined as $2x10^8$ cells/kg recipient body weight (RBW) and an "adequate" TNC dose 4 $x10^8$cells/kg RBW. Previous studies have shown higher infused TNC doses correlate with improved clinical outcomes including engraftment and overall survival .Factors impacting BMH yield include donor-recipient weight discrepancy and duration of harvest. We retrospectively examined procedural and donor variables at the Anthony Nolan unrelated donor registry in a contemporary donor cohort to confirm our previous findings and explore any additional factors influencing BMH yield.

Methods: 253 bone marrow donations from 2019-2024 were identified using our electronic database. Several variables were selected for analysis including:

- Collection centre
- Donor sex, age, weight, height, blood parameters (haemoglobin pre/post donation, platelets, ferritin)
- Patient weight and nucleated cells/kg ($x10^8$) requested
- Total Duration, TNC $x10^8$ Collected, TNC Density, CD3+, CD34+, Volume

Variables were analysed using the statsmodels package in python. A p value <0.05 was considered significant. All linear regressions are not adjusted.

Results:

Procedural/ Donor Factor	Categories	n	Outcome (unit)	Result	Statistical Test	Statistical Test result
Donor-recipient weight discrepancy *n=251 as patient weight unavailable in 2 cases	Donor heavier (>5kg)	199	Number of donors achieving adequate TNC yield (>4x10^8/kg)	127 (63%)	Fisher–Freeman–Halton exact test	p < 0.0001
	Weight matched (+/- 5kg)	22		1 (5%)		
	Patient heavier (>5kg)	30		1 (3%)		
Collection centre	5 collection centres	253	Average TNC yield (x10^8/kg RBW)	5.53	Kruskal-Wallis	H=10.336 p=0.035
	A	3		1.59		
	B	16		5.43		
	C	18		6.96		
	D	206		5.46		
	E	10		5.54		
Donor Age	> 40 years	9	Number of donors achieving adequate TNC yield (>4x10^8/kg)	0 (0%)	Fisher's test	p=0.001
	< 40 years	244		131 (54%)		
Duration of harvest	Minutes	253	Average TNC yield (x10^8/kg RBW)	Longer harvest duration associated with lower TNC yield	Linear regression	Coef = -0.063 p <0.001

52% BMHs collected an 'adequate' TNC yield > 4x10^8/kg. Donor-recipient weight discrepancy was strongly associated with the likelihood of achieving TNC > 4x10^8/kg RBW. 63% of donors heavier than their recipients achieved an adequate harvest compared with 5% and 3% of those who were a similar or lower weight respectively (p<0.0001).
Donors >40 collected significantly lower TNC dose than younger donors - median 4.4x10^8/kg

(95% CI: 3.85-4.97) vs 3.0x10^8/kg (95% CI: 1.83-3.29) (Mann Whitney U p=0.008). Small sample size is a limitation in other subcategory analyses. We found a significant difference in TNC yield between 2 collection centres, but one of the sites only performed 3 BMHs, so this should be cautiously interpreted.
Our data confirmed TNC yield per kg decreases as the duration of harvests increases, suggesting longer procedures lead to poorer efficiency harvests (Coef = -0.063, p< 0.001).

Conclusions: These findings support our previous analysis and that of others regarding the importance of the donor/recipient weight in achieving adequate BM harvest, as well as the impact of harvest duration. It also provides new insight to the impact of age in the efficacy of BMH donations in addition to other adverse outcomes from older donors.

Disclosure: Nothing to declare.

FOR CAR T CELL, SIZE DOES SEEM TO MATTER!

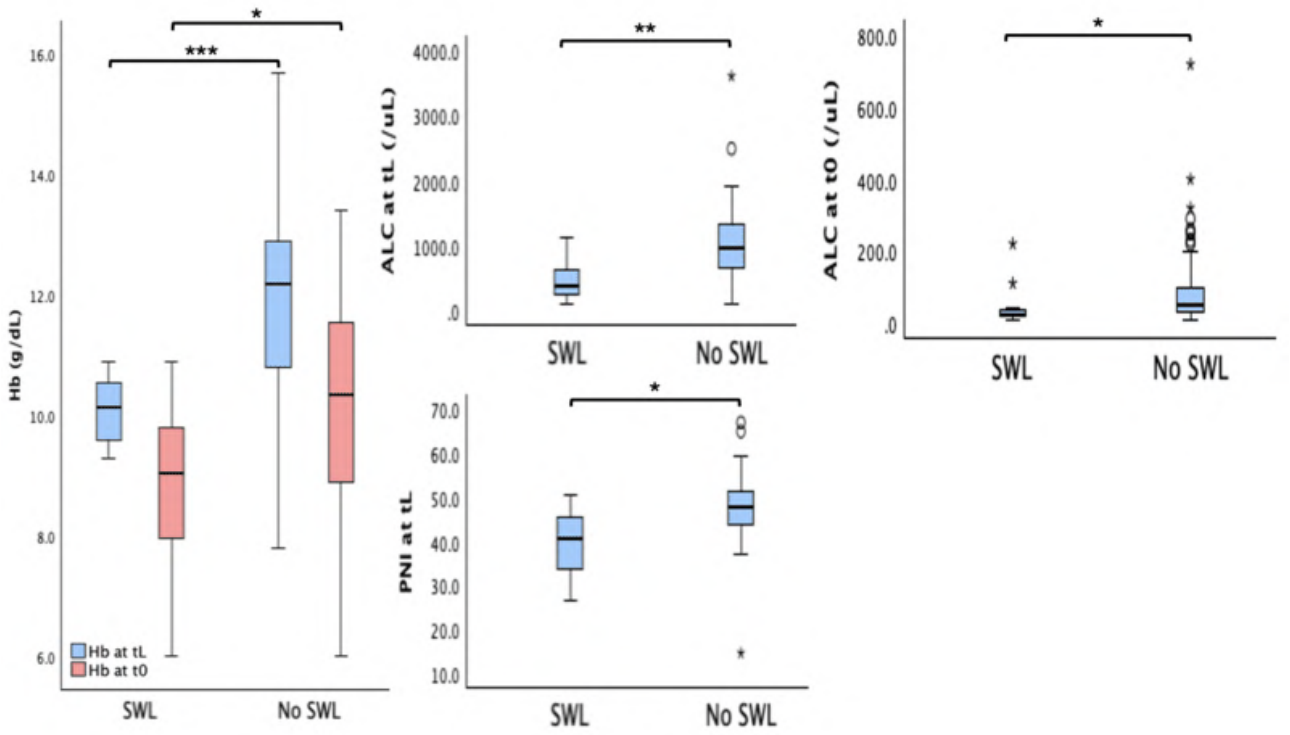
Leonardo Maia Moço[1], Ana Amarante[1], Ana Maria Hortas[2], Alice Fontoura Alves[1], Inês Clara[1], Gonçalo de Câmara Negalha[1], Paula Alves[1], Delfim Duarte[1], ***Susana Couto Irving***[1]*, Mário Mariz[1]*
[1]Instituto Português de Oncologia do Porto Francisco Gentil, E.P.E., Porto, Portugal, [2]Unidade Local de Saúde de Trás-os-Montes e Alto Douro, Vila Real, Portugal

Background: Chimeric antigen receptor (CAR) T-cell therapy has reshaped treatment of lymphoproliferative disorders. As with other T cell–based immunotherapies, nutritional status may influence outcomes. However, as a putative prognostic marker, its clinical significance remains unclear. This study aims to evaluate the impact of significant weight loss (SWL) prior to anti-CD19 CAR T-cell therapy on clinical outcomes and analytical markers of malnutrition.

Methods: This single-center retrospective cohort included adults treated with CAR T between 2019 and 2025. Key timepoints were the first CAR T evaluation (tC), apheresis (tA), pre-lymphodepletion (tL), and infusion (t0). SWL was defined as >5% weight loss, assessed between tC–tL (ΔC–L) and tA–tL (ΔA–L). The prognostic nutritional index (PNI) was calculated from serum albumin and absolute lymphocyte count (ALC). Endpoints included overall survival (OS), progression-free survival (PFS), duration of response (DoR), complete response (CR), overall response rate (ORR), plus laboratory differences by SWL. Associations were tested using chi-square/Fisher and Mann–Whitney/Student's t-test for univariate analysis, and Cox proportional hazards and logistic regression models for multivariate analysis.

Results: Ninety-eight patients (median age 57; male:female 1.4:1) were included, mostly with diffuse large B-cell lymphoma. Thirty patients had ≥3 prior treatment lines, and 76% were refractory to the last therapy. Within the prior month to infusion, 10% had been hospitalized and 11% had received anaerobe-spectrum antibiotics. Tisa-cel was the most frequently used product (61%), associated with lower neurotoxicity risk compared with axi-cel (OR 7.4). CR and ORR were 64% and 70%, respectively. Two-year OS, PFS, and DoR

were 56%, 71%, and 54% (median follow-up 7 months). Several analytical markers of malnutrition were associated with OS, PFS and DoR in univariate analysis; however, in multivariate models, only ALC at t0 and C-reactive protein at tL remained independent predictors of PFS (p=0.032; HR 1.01, 95% CI 1.001-1.020) and DoR (p=0.015; HR 1.005, 95% CI 1.001-1.010), respectively.
SWL occurred in 17% of patients during ΔC–L (median 81 days), and 14% during ΔA–L (median 46 days). SWL was not associated with baseline variables or clinical outcomes. Nonetheless, SWL in ΔC–L correlated with lower hemoglobin, ALC, and PNI at tL (p<0.001, 0.017, 0.049) and with lower hemoglobin at t0 (p=0.042). In ΔA–L, only ALC at t0 was reduced in the SWL group (p=0.019) (Figure 1). In multivariate analysis, no significant differences in laboratory parameters were observed between both groups.



Conclusions: Although not sustained in multivariate models, SWL showed a trend toward an association with adverse hematologic parameters, which in turn may constitute independent predictors of relapse. Nevertheless, the study stresses the pertinence of a more tailored multidisciplinary management for patients presenting with SWL at CAR T referral. Despite sample-size limitations, findings highlight the importance of systematic SWL awareness and the need for a targeted characterisation of nutritional status in CAR T programs.

Disclosure: Nothing to declare.

IMPACT OF SOCIODEMOGRAPHIC AND CLINICAL FACTORS ON ACCESS TO HEMATOPOIETIC STEM CELL TRANSPLANTATION IN ACUTE LYMPHOBLASTIC LEUKEMIA: A STUDY FROM MEXICO

Rosa Adriana Alvidrez-González[1], *Mistral Castellanos-Mares*[1], *Andrés Yesid Bonilla-Salcedo*[1], *Grecia Pamela Martínez-Vázquez*[1], *Victor Iván Salinas-Herrera*[1], *Vicky Margarita Moncada-Gardea*[1], *Irma Karen Pellon-Tellez*[1], *Victor Itai Urbalejo-Ceniceros*[1], *Luis Manuel Valero-Saldaña*[1]
[1]*Instituto Nacional de Cancerologia, Mexico City, Mexico*

Background:

Acute lymphoblastic leukemia (ALL) is one of the most aggressive hematologic malignancies in adults. Although survival has improved in high-income countries, substantial barriers persist in low- and middle-income settings such as Mexico, limiting timely diagnosis, treatment continuity, and access to highly specialized therapies. Allogeneic hematopoietic stem cell transplantation (HSCT) remains the most effective curative strategy for patients with high-risk, relapsed, or refractory ALL; however, indication for transplantation does not necessarily translate into access.

In Mexico, structural constraints including limited availability of specialized diagnostic tests, prolonged turnaround times, workforce shortages, and centralization of transplant centers contribute to delays that adversely affect outcomes. Additionally, social determinants such as socioeconomic status, travel distance, and indirect treatment costs further restrict access to HSCT in a disease characterized by rapid progression.

Methods: We conducted a retrospective, descriptive observational study of consecutive patients aged ≥16 years with confirmed B- or T-lineage ALL treated at the Instituto Nacional de Cancerología (INCan), Mexico, between January 1, 2018 and December 31, 2024.

Results:

Of 303 records reviewed, 261 adult patients with ALL were included. Median age was 32 years, and 50.6% were female. Most patients were <40 years old (68.6%). B-ALL accounted for 93.9%, and 82.8% were classified as high risk.

Socioeconomically, 36.0% of patients lived in poverty and 41.0% had low socioeconomic status; mean monthly household income was approximately USD 400. 48.7% patients originated with a median travel time of 3 hours. Most lived in urban areas (79.3%), and family support was present in 97.7%. Educational attainment was low, with only 17.6% completing higher education. Unemployment affected 52.5% of patients.

Overall, 237 patients (90.8%) had an indication for allogeneic HSCT, but only 58 (22.2%) underwent transplantation. Donor availability was identified in 47.9%. The most frequent reasons for not proceeding to HSCT were death prior to transplant (24.1%) and disease relapse (22.7%).

Among transplanted patients, haploidentical HSCT was the most common modality (55.2%), followed by matched related donor HSCT (39.7%). Myeloablative conditioning was used in 89.5% of cases. GvHD was the most frequent complication (61.3%).

Transplanted patients experienced prolonged pre-HSCT timelines, with a median of 160 days from diagnosis to transplant referral and 316 days from evaluation to HSCT, mainly driven by delays related to dentistry, psychology, and infectious disease assessments.
In multivariable analysis, marital status (OR 1.42, 95% CI 1.01–1.99; p=0.044) and lack of donor availability (OR 0.016, 95% CI 0.0035–0.076; p<0.001) were independently associated with failure to undergo HSCT. Median OS was longer in transplanted versus non-transplanted patients (35 vs 14 months; p=0.00037), with no OS difference between haploidentical and MRD HSCT (36 vs 36.5 months).

Characteristic	Overall (n=261)	No HSCT (n=203)	HSCT (n=58)	P value
Age at diagnosis	32(21-43)	33(21-44)	27(19-28)	0.040

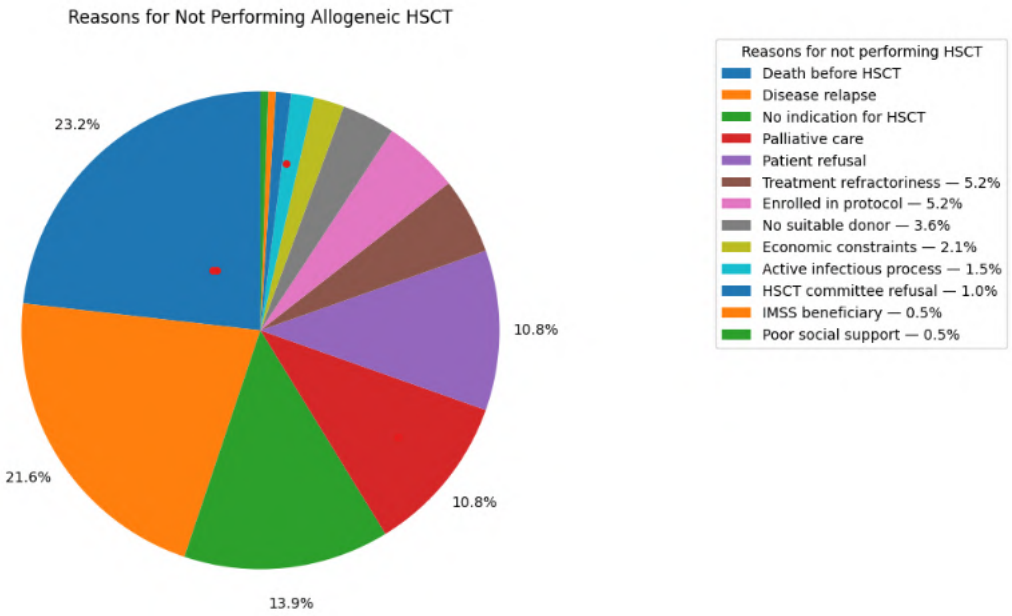
Table1. Baseline clinical and demographic characteristics of adult patients with LLA



Conclusions:

In adult patients with ALL in Mexico, a significant gap persists between transplant indication and access to allogeneic HSCT. Delayed referral and limited donor availability often related to restricted access to timely HLA typing, donor identification, and prolonged pre-transplant evaluation pathways are key determinants of HSCT access, particularly in rapidly progressive disease, beyond socioeconomic or geographic factors.

Disclosure: Nothing to declare.

SINGLE-CENTER RETROSPECTIVE CLINICAL STUDY ON THE CONDITIONING REGIMEN OF DECITABINE, THIOTEPA, BUSULFAN, AND FLUDARABINE (DTBF) COMBINED WITH ATG/PTCY FOR ALTERNATIVE DONOR TRANSPLANTATION IN MYELODYSPLASTIC NEOPLASMS

Shuanghui Yang[1], Lang Zou[1], Tao Su[1], Shujun Li[1], Jian Hu[1], Kaitai Yang[1], ***Yajing Xu***[1]*, Ling Nie[1]*
[1]Department of Hematology, Xiangya Hospital, Central South University, Changsha, China

Background: Allogeneic hematopoietic stem cell transplantation (allo - HSCT) is the only curative treatment for high-risk myelodysplastic neoplasms (MDS). Thiotepa has been

demonstrated favorable safety and efficacy in conditioning regimens for transplantation.However, no research data have been reported yet on the DTBF conditioning regimen combined with anti-thymocyte globulin (ATG)/post-transplantation cyclophosphamide (PTCy) in alternative donor HSCT for adult MDS. We conducted a retrospective single-center study focusing on adult MDS patients with DTBF conditioning regimen.

Methods: This study retrospectively analyzed a total of 11 adult MDS patients from October 2024 to August 2025. All patients provided written informed consent. The DTBF regimen consisted of decitabine (100 mg/m²), thiotepa (10 mg/kg), busulfan (9.6 mg/kg), and fludarabine (160 mg/m²). The GVHD prophylaxis regimen was based on ATG (7.5 mg/kg) combined with low-dose PTCy (29mg/kg), supplemented with cyclosporine, mycophenolate mofetil, and short-course methotrexate. All grafts were derived from donor peripheral blood stem cells.

Results: Among the 11 patients , the median age was 56 years (range: 24-65 years), and males accounted for 54.5% (6/11). All patients had an ECOG performance status of 0-1. Risk stratification included 3 cases of IPSS-M high risk and 8 cases of very high risk. Before transplantation, 27.3% (3/11) of patients achieved MRD negativity. One patient with MDS - biTP53 underwent a second transplantation due to primary graft failure after the first haploidentical transplantation. The second transplant succeeded involving 9/10 mismatched unrelated donor. Among the remaining 10 patients, 9 received haploidentical transplants, and 1 received 10/10 matched unrelated donor transplant. 10 patients achieved complete donor chimerism after HSCT. The median mononuclear cell dose was 9.56×10^8/kg (range: 7.12–15.03 × 10^8/kg), and the median $CD34^+$cell dose was 7.92×10^6/kg (range: 4.12–11.04 × 10^6/kg).The median time to neutrophil engraftment was 12 days (range: 11–14 days), and the median time to platelet engraftment was 13 days (range: 13–18 days).
As of December 12, 2025, the median follow - up duration was 242 days (range: 41–422 days). Six patients developed grade I acute GVHD.Two patients developed grade II acute GVHD (one with skin and gastrointestinal involvement due to self - discontinuation of immunosuppressive medication). Two patients developed chronic GVHD, one with moderate cGVHD and one with mild cGVHD. All GVHD were controlled well.
Other complications included infections in 9 cases(3 with pulmonary and 6 with intestinal), grade 3 oral mucositis in 3 cases, grade II hemorrhagic cystitis in 1 case, and renal impairment in 3 cases. All patients received letermovir for cytomegalovirus (CMV) infection prophylaxis. Among them, CMV reactivation occurred in 5 cases, and Epstein - Barr virus (EBV) reactivation occurred in 7 cases. One patient(MDS derived AML) relapsed after 5 months of HSCT . All patients remained alive at the time of reporting.

Characteristic	**DTBF (N=11)**	**Outcomes**	**DTBF (N=11)**
Median age, year (range)	56(24～65)	Neutrophil engraftment, day, median (range)	12(11～14)

Gender, *n* (%)		Platelet engraftment, day, median (range)	13(13～18)
Male/Female	6(54.5%)/5(45.5%)	Complete engraftment,n (%)	10(90.9%)
Disease subtype, n (%)		aGVHD, n (%)	
MDS-IB1	4(36.4%)	Grade I/ Grade II	6(54.5%)/2(18.2%)
MDS-IB2	4(36.4%)	Grade III-IV	0(0%)
MDS-LB	2(18.2%)	cGVHD, n (%)	
MDS-AML	1(9.0%)	Mild/Moderate/Severe	1(9.0%)/1(9.0%)/0(0%)
Risk stratification, n (%)		Invasion pulmonary mycosis	3(27.3%)
IPSS-M High risk/Very high risk	3(27.3%)/8(72.7%)	Oral mucositis	3(27.3%)
IPSS-R Intermediate risk/High risk/Very high risk	1(9.0%)/6(54.5%)/4(36.4%)	Sepsis	2(18.2%)
MRD at allo-HSCT, n (%)		Intestinal infection	6(54.5%)
Positive /Negative	8(72.7%)/3(27.3%)	Hemorrhagic cystitis	1(9.0%)
Donor source		Renal function impairment.	3(27.3%)
Haploidentical	10(83.3%)	Cytomegalovirus reactivation	5(45.5%)
Unrelated	2(16.7%)	EBV reactivation	7(63.6%)

Mononuclear cells, $\times 10^8$ /L, median (range)	9.56(7.12～15.03)	Relapse, n (%)	1(9.0%)
CD34+ cells, $\times 10^6$ /L, median (range)	7.92(4.12～11.04)	Death, n (%)	0(0%)

Conclusions: The preliminary data indicate that the DTBF + ATG/PTCy conditioning regimen demonstrates favorable efficacy and safety for alternative donor-HSCT in adult MDS patients.Future evaluations will involve expanding the patient cohort and extending the follow - up periods.

Disclosure: The authors declare no potential conflict of interest relevant to this article. This work was funded by the Hunan Provincial Natural Science Foundation of China（No. 2023JJ30928).

CONDITIONING MATTERS: A RETROSPECTIVE COMPARISON OF BUCY AND FLUBU IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

*Rosa Adriana Alvidrez-González[1], **Mistral Castellanos-Mares**[1], Andrés Yesid Bonilla-Salcedo[1], Grecia Pamela Martínez-Vázquez[1], Victor Iván Salinas-Herrera[1], Vicky Margarita Moncada-Gardea[1], Irma Karen Pellon-Tellez[1], Luis Manuel Valero-Saldaña[1]*
[1]Instituto Nacional de Cancerologia, Mexico City, Mexico

Background: BuCy has historically been used as a standard myeloablative conditioning regimen for allo-HSCT. FluBu has increasingly been adopted. Comparative outcome data between these regimens in real-world clinical practice remain limited.

Methods: This was a retrospective single-center study conducted at the National Cancer Institute, including 50 adult patients with a diagnosis of ALL or AML who underwent allo-HSCT.

Results:

A total of 50 patients were included, 25 conditioned with BuCy and 25 with FluBu. Patients in the BuCy group had a median age of 27 years (IQR 23–37), whereas those receiving FluBu were older (38 years, IQR 28–48; p=0.06). Male sex accounted for 48.0% of BuCy and 60.0% of FluBu patients (p=0.39). Diagnosis distribution was comparable, with ALL in 64.0% vs 56.0% and AML in 36.0% vs 44.0% of BuCy and FluBu patients, respectively (p=0.57).

Regarding conditioning intensity, MAC was more frequently used in the BuCy group (80.0%) compared with FluBu (56.0%), whereas RIC was more common in the FluBu group (44.0% vs 20.0%; p=0.07). Post-transplant relapse occurred in 12 patients overall, with a higher incidence in the BuCy group (28.0%) than in the FluBu group (20.0%), although this difference was not statistically significant (p=0.53). Transplant-related mortality at day +100 was identical in both cohorts (12.0% each; p=1.00).

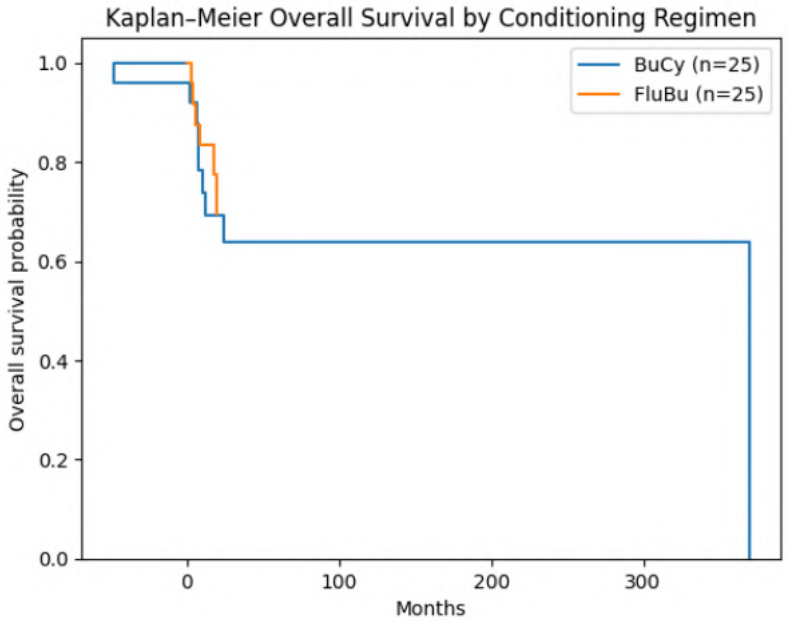
Early toxicities were analyzed by conditioning regimen and stratified by severity (≥ Grade II). Hepatic toxicity ≥ Grade II occurred exclusively in the FluBu group (16.7% vs 0%; p=0.04). Renal toxicity ≥ Grade II was uncommon and comparable between groups (4.0% vs 4.2%; p=1.00). Gastrointestinal toxicity ≥ Grade II occurred in 28.0% of BuCy and 20.8% of FluBu patients (p=0.54), while oral mucositis ≥ Grade II was frequent and similar in both cohorts (36.0% vs 37.5%; p=0.91). SOS was observed only in the BuCy group (8.0% vs 0%), without reaching statistical significance (p=0.15).

Median time to neutrophil engraftment was 13 days (IQR 10–13.5) in the BuCy group and 14 days (IQR 13.3–15.8) in the FluBu group (p=0.18). Median time to platelet engraftment was 15 days in both groups (BuCy IQR 11–17.5 vs FluBu IQR 14.3–16.8; p=0.74). Median hospital length of stay was 30 days (IQR 26–34) for BuCy and 29.5 days (IQR 29–31.8) for FluBu (p=0.81).

Overall mortality was 36.0% (9/25) in the BuCy group and 28.0% (7/25) in the FluBu group (p=0.55). FluBu was associated with fewer death events (25.0% vs 33.3%) and EFS tended to be higher compared with BuCy. Survival curves were comparable between conditioning regimens and between RIC and MAC approaches.

Variable	OS-HR(95% CI)	p value	EFS-HR(95% CI)	p value
Conditioning regimen (FluBu vs BuCy)	0.45 (0.10–2.01)	0.29	0.42 (0.12–1.49)	0.18
Conditioning intensity (RIC vs MAC)	0.33 (0.07–1.57)	0.16	0.60 (0.18–2.00)	0.40
Age	1.08 (0.99–1.18)	0.09	1.06 (0.99–1.15)	0.11
Sex (Female vs Male)	0.32 (0.08–1.35)	0.12	0.43 (0.12–1.48)	0.18
Diagnosis (ALL vs AML)	1.75 (0.41–7.46)	0.45	2.33 (0.65–8.36)	0.19

Table 1. Multivariable Cox proportional hazards analysis for OS and EFS



Conclusions: In this real-world cohort of patients with ALL and AML undergoing allo-HSCT, FluBu demonstrated comparable overall survival and a trend toward improved event-free survival compared with BuCy. Early transplant-related mortality, engraftment kinetics, and hospital length of stay were similar between regimens. These findings support FluBu as a safe and effective alternative to BuCy, although larger studies are needed to confirm potential differences in event-free survival.

MULTI-VIRUS SPECIFIC MEMORY T CELLS TARGETING CMV, BKV, AND EBV IN POST-HSCT VIRAL INFECTIONS

Seok-Goo Cho[1,2], *Nayoun Kim*[1,2], *Keon-Il Im*[1,2], *Junseok Lee*[1,2]
[1]*The Catholic University of Korea, Seoul, Korea (the Republic of)*, [2]*LucasBio, Seoul, Korea (the Republic of)*

Background: Reactivation of cytomegalovirus (CMV), BK virus (BKV), and Epstein–Barr virus (EBV) is a serious and potentially life-threatening complication following allogeneic hematopoietic stem cell transplantation (allo-HSCT). While antiviral therapies are available for CMV, no approved treatments exist for BKV or EBV, and current antiviral approaches are often limited by toxicity and drug resistance. Virus-specific T cell (VST) therapy represents a promising strategy to address these unmet clinical needs. Notably, our group has previously

established and clinically applied a SARS-CoV-2–specific VST platform, demonstrating complete resolution of COVID-19–associated pneumonia in immunocompromised patients with refractory disease, thereby providing a strong translational foundation for the development of multi-virus VSTs (Lee et al., *Clin Infect Dis*, 2025).

Methods: An off-the-shelf, partially HLA-matched, multi-virus-specific memory T cell platform targeting CMV, BKV, and EBV was established using peripheral blood mononuclear cells (PBMCs) from healthy donors. Virus-specific T cells were generated through peptide-based stimulation with immunodominant viral antigens, followed by ex vivo expansion. Product characterization focused on antigen-specific functional activity and safety. In vivo functional performance was evaluated in virus-relevant experimental models to support clinical translation. In parallel, this platform is currently being evaluated in an ongoing Phase I/II clinical trial enrolling allo-HSCT recipients with antiviral-refractory or -resistant viral infections.

Results: The final VST products demonstrated robust, multi-virus–specific functional activity, including antigen-specific IFN-γ and TNF-α secretion and cytotoxic responses, without evidence of alloreactivity. Across multiple virus-specific in vivo models, administration of VSTs resulted in effective target-specific control accompanied by sustained expansion and persistence of human T cells. Consistent antiviral activity was observed against CMV-, EBV-, and BKV-associated targets, along with enhanced infiltration of virus-reactive $CD8^+$ T cells at sites of viral challenge. Collectively, these findings demonstrate the functional potency and in vivo persistence of multi-virus-specific memory T cells, supporting their translational relevance for post-HSCT viral infections.

Conclusions: Our off-the-shelf, multi-virus-specific memory T cells demonstrate consistent functional activity and in vivo persistence against CMV, EBV, and BKV. Collectively, these findings support their potential as a clinically applicable immunotherapeutic strategy for managing viral complications following allo-HSCT and provide a foundation for ongoing clinical investigation in patients with antiviral-refractory or -resistant viral infections.

Clinical Trial Registry: This study was registered with the Clinical Research Information Service, Republic of Korea, as part of the World Health Organization (WHO) Registry Network (no. KCT0011031).

LONG-TERM OUTCOMES OF HAPLOIDENTICAL, MATCHED SIBLING, AND MATCHED UNRELATED DONOR HSCT IN 133 ELDERLY PATIENTS WITH HEMATOLOGIC MALIGNANCIES: A SINGLE-CENTER COMPARATIVE STUDY

Yanli Zhao[1,2], *Yanyan An*[1], *Yue Lu*[1,2], *Xingyu Cao*[1,2], *Jian-Ping Zhang*[1,2], *Zhijie Wei*[1,2], *Ruijuan Sun*[1,2], *Jiarui Zhou*[1,2], *Min Xiong*[1,2], *Deyan Liu*[1,2], *Jing Long*[3], *Peihua Lu*[1,2,3]

[1]Hebei Yanda Lu Daopei Hospital, Langfang, China, [2]Beijing Lu Daopei Hospital, Beijing, China, [3]Beijing Lu Daopei Institute of Hematology, Beijing, China

Background: In patients aged ≥60, allogeneic HSCT remains high-risk, with increased toxicity, NRM, and GVHD concerns. Yet evidence from large cohorts directly comparing donor platforms is limited. Robust comparison of haplo, MUD, and MSD outcomes in this population is therefore needed to inform optimal donor choice.

Methods: We retrospectively analyzed 133 patients aged ≥60 who underwent first allogeneic HSCT between December 2023 and January 2015, stratified by donor type into haploidentical (haplo, n=99), matched unrelated (URD, n=16), and matched sibling (MSD, n=18) groups. Clinical characteristics, engraftment kinetics, GVHD incidence, viral reactivation, relapse, transplant-related mortality (TRM), and long-term survival outcomes were compared across the three donor platforms.

Results: Among 133 elderly patients (≥60 years) undergoing first allo-HSCT, 99 received haploidentical, 16 URD, and 18 MSD grafts. Median age differed slightly across groups (haplo 63, URD 62, MSD 61 years, P = 0.010). Diagnosis distribution was similar (AML 60.9%, MDS 25.6%, ALL 7.5%,CMML 6%), and most patients were transplanted in CR1 (57.9%) or ≥CR2 (9.8%), with comparable pre-HSCT MFC-MRD positivity (~22%). Conditioning was predominantly BU-based (92.5%), and ATG use varied significantly by donor type (100% haplo and URD vs. 44.4% MSD, P < 0.001). Haplo-HSCT grafts were largely BM+PB (98%), URD grafts were 100% PB, and MSD BM+PB (66.7%) and PB (33%, P < 0.001). Haplo recipients received higher MNC doses (median 9.10 $\times 10^8$/kg) compared with URD (5.97 $\times 10^8$/kg) and MSD (7.20 $\times 10^8$/kg, P < 0.001), while $CD34^+$ and $CD3^+$ cell doses were similar. Median neutrophil (15–16 days) and platelet (13–15 days) engraftment times were comparable across groups.
Detailed prognostic results for different types of transplants see Table 1. With a median follow-up of 20.8 months across all transplant types, URD group demonstrated the best OS outcomes of 68.75%. This was followed by MSD (OS 55%;), while haplo transplants the lower rates (OS 46.96%). The 3-year CIR was not significantly different among the MSD, haplo, and URD groups. NRM was highest in the haplo group (44.20%). The incidences of Day 100 grade 2-4 and grade 3-4 aGVHD were 30.08% and 15.79%, respectively. The cumulative incidence of cGVHD was 11.71%. In the 90 CR patients, the MSD group had the highest 3-year OS(72.73%). The URD group showed intermediate outcomes(66.67%), and the haplo group had the lowest survival(53.90%). NRM was lowest in the MSD group and highest in the URD group for this cohort, while CIR remained low across all groups. Among the 43 NR patients, the URD group exhibited superior 2-year OS compared to the haplo and MSD groups. The CIR was 0% in the URD group, while the haplo group had the highest CIR. NRM was highest in the MSD group for NR patients.

ALEMTUZUMAB PROVIDES DURABLE DEPLETION OF CIRCULATING CAR-T CELLS IN A PATIENT WITH HYPOKINETIC MOVEMENT DISORDERS AFTER BCMA-TARGETING CAR-T CELL THERAPY

Lea Miebach[1], *Adrian Schwarzer*[1,2], *Uwe Grunwald*[1], *William Krüger*[1], *Jan Krönke*[1,3]
[1]*Universitätsmedizin Greifswald, Greifswald, Germany,* [2]*Hannover Medical School, Hannover, Germany,* [3]*Charité - Universitätsmedizin Berlin, Berlin, Germany*

Background: Movement and neurocognitive disorders (MNTs) are a rare but severe complication of BCMA-targeting CAR-T cell therapy (Cohen et al., Blood Cancer Journal (2022)). Thus far, "on-target/off-tumor" effects involving BCMA-expressing neurons and astrocytes in the basal ganglia have been discussed as the pathomechanism driving MNTs (Oekelen et al., Nature Medicine (2021)). Several studies have identified the massive expansion of CAR-T cells as a major risk factor in the development of MNTs. Therefore, effective treatment strategies to manage uncontrolled CAR-T cell expansion in these patients are urgently needed.

Methods: The patient, a 49-year-old male diagnosed with IgA lambda multiple myeloma in April 2024, received cilta-cel following three prior lines of therapy. Apart from cytokine release syndrome (CRS °II), which was successfully managed with tocilizumab and anakinra, the patient experienced no other adverse events in the first days following cilta-cel infusion. Nineteen days after CAR-T cell infusion, the patient presented with cranial nerve palsies and

a hypokinetic movement disorder displaying features of parkinsonism. Symptom onset was preceded by a massive expansion of circulating CAR-T cells, despite prophylactic administration of glucocorticoids. Based on previous reports, treatment attempts were made with cyclophosphamide, venetoclax, and ruxolitinib, complemented by intrathecal triple therapy after detection of CAR-T cells in the cerebrospinal fluid (CSF). Circulating CAR-T cells were characterized by multicolor flow cytometry at various time points throughout CAR-T expansion and disease progression. From day 26 onwards, the patient was treated with alemtuzumab intravenously and intrathecally following the identification of strong CD52 expression on both circulating and CSF CAR-T cells.

Results: CAR-T cell expansion in the peripheral blood peaked within the second week after cilta-cel infusion, reaching 40.000 CAR-T cells/µl. However, peak infiltration of the CSF occurred significantly later, on day 39 at a concentration of 157 CAR-T cells/µl, despite multiple cycles of intrathecal chemotherapy with dexamethasone, methotrexate and cytarabine. Longitudinal flow cytometric analysis revealed a dominance of $CD4^+$ CAR-T cells (CD4/CD8 ratio ~ 12) without evidence of clonal T-cell expansion as assessed by TRBC1 staining. Panel-sequencing of peripheral blood cells did not identify any mutations associated with clonal hematopoiesis. Strikingly, CAR-T cell expansion persisted despite multimodal chemotherapy. Flow cytometric analysis of potential immunotherapy targets revealed low expression of CD194 (mogalizumab) and CD30 (brentuximab vedotin) on circulating CAR-T cells, while strong expression of CD52 (alemtuzumab) was observed. Shortly after administration of alemtuzumab, a significant decline in CAR-T cells in the peripheral blood could be observed. Durable repression of CAR-T cells was achieved after four treatment cycles.

Conclusions: Non-ICANS neurotoxicities (NINTs), including MNTs are associated with uncontrolled expansion of CAR-T cells in the peripheral blood and CSF. In our case study, alemtuzumab successfully suppressed CAR-T cells in the peripheral blood and CSF after failure of systemic and intrathecal chemotherapy. Therefore, administration of alemtuzumab could be an effective rescue therapy for patients at risk of NINTs due to uncontrolled expansion of BCMA-targeting CAR T cells following cilta-cel therapy.

P008

IMPACT OF ATG DOSE ON OUTCOMES FOLLOWING MATCHED UNRELATED DONOR HEMATOPOIETIC STEM CELL TRANSPLANTATION: A RETROSPECTIVE COMPARISON OF 5 MG/KG VERSUS 10 MG/KG

Cheongin Yang[1], *Seong Hyun Jeong*[1], *Joon Seong Park*[1]
[1]*Ajou University Hospital, Suwon, Korea (the Republic of)*

Background: Anti-thymocyte globulin (ATG) is commonly used for graft-versus-host disease (GVHD) prophylaxis in matched unrelated donor (MUD) allogeneic hematopoietic stem cell transplantation (allo-HSCT). However, the optimal ATG dose remains controversial,

particularly regarding the balance between infection risk, GVHD prevention, and relapse control.

Methods: We retrospectively analyzed patients who underwent MUD allo-HSCT at Ajou University Hospital between 2014 and 2024, receiving a total of either 5 mg/kg or 10 mg/kg of rabbit anti-thymocyte globulin (ATG). Key clinical outcomes included 2-year overall survival (OS), relapse, acute and chronic GVHD, cytomegalovirus (CMV) reactivation, and infection events. Fisher's exact test was used to compare the incidence of these events between groups, while overall survival was analyzed using the Kaplan–Meier method.

Results: A total of 59 patients were included (5 mg group: n = 33; 10 mg group: n = 26). The most common underlying disease was acute myeloid leukemia (AML, 35.6%), followed by acute lymphoblastic leukemia (ALL, 22.0%) and myelodysplastic syndrome (MDS, 18.6%). The most frequently used GVHD prophylaxis regimen was cyclosporine combined with methotrexate (MTX), administered in 47 patients (79.7%). The incidence of relapse was comparable between groups (30.3% vs. 30.8%, p = 1.00). Acute GVHD occurred in 21.2% of the 5 mg group and 26.9% of the 10 mg group (p = 0.76), while chronic GVHD developed in 24.2% and 30.8%, respectively (p = 0.77). At 2 years after transplantation, the estimated overall survival was 62.6% in the 10 mg ATG group and 53.8% in the 5 mg ATG group (p = 0.41), with no statistically significant difference between the two groups. Notably, CMV reactivation was significantly more frequent in the 10 mg group (61.5% vs. 27.3%, p = 0.016). The incidence of infection events was slightly higher in the 10 mg group (73.1% vs. 66.7%, p = 0.78), though not statistically significant.

Conclusions: Although not statistically significant, the overall incidence of infection events tended to be lower in the 5 mg group compared with the 10 mg group. The 2-year overall survival did not differ significantly between the two groups. Our findings suggest that a total ATG dose of 5 mg/kg may reduce the risk of CMV reactivation without increasing the incidence of GVHD. These results support the potential feasibility of dose-reduced ATG in MUD transplantation settings, and prospective validation is warranted.
This abstract was previously presented at the 2025 ICBMT meeting. The current version includes updated 2-year overall survival data with extended follow-up.

P009

BONE MARROW TRANSPLANTATION IN TELOMERE BIOLOGY DISORDERS, THE EXPERIENCE OF PEDIATRIC BONE MARROW TRANSPLANT UNIT OF BRESCIA

Marianna Maffeis[1], *Stefano Rossi*[1], *Giulia Baresi*[1], *Marta Comini*[2], *Federica Bolda*[2], *Stefania Fontana*[2], *Elena Soncini*[1], *Arnalda Lanfranchi*[2], *Fulvio Porta*[1]
[1]*ASST Spedali Civili / Pediatric Oncohematology Unit and Pediatric Bone Marrow Transplant Center, Brescia, Italy,* [2]*ASST Spedali Civili / Stem Cell Laboratory, Section of Hematology and Blood Coagulation, Clinical Chemistry, Brescia, Italy*

Background: Telomere Biology Disorders (TBD) are a group of a rare hereditary diseases with the classic Dyskeratosis Congenita (DC) occurring predominantly in males and manifests clinically as the classic triad of reticulate hyperpigmentation, nail dystrophy and leukoplakia. These conditions are characterized by a predisposition to develop hematologic and non-hematologic malignancies, according to increased susceptibility of this subjects to chemo-radiation agents. Hematopoietic cell transplantation (HCT) represents the only possible cure for the hematologic features, though the risk of graft failure and toxicities are higher in this group of patients.

Methods: We report three recents cases of children affected by TBD. Patient A is a 5-years-old boy, affected with Revesz syndrome, treated with haploidentical HCT (TINF2 gene defect). Patient B is a 12-years-old girl (TERT gene defect), patient C is a 5-years-old girl (RTEL1 gene defect).

Results: Patient A presented bilinear pancytopenia and was candidated for allogenic hematopoietic stem cell transplantation and the father was selected as donor. Unfortunately during the work-up phase anti-HLA class I antibodies were detected (DSA HLA B27 1961 MFI, NDSA 1227-3336 MFI), for this reason he performed three plasma exchange sessions, infusion of Rituximab 375 mg/m2 and an infusion of high-dose IgEV. Conditioning therapy was: Alemtuzumab, Fludarabine Cyclophosphamide, TBI 200 cGy. Depleted TcR alpha/beta/CD19+ CD34+ 12.59 x10^6/kg, 0,612 x10^5/kg TcR alfabeta+. Unfortunately the patient developed a primary graft failure and second transplant was needed urgently. Second haploidentical transplant from a sibling donor with bone marrow stem cell collection was soon organized. During aplasia, the patient presented appendicitis, initially treated with broad-spectrum antibiotic therapy. Laparoscopic appendectomy was necessary on D-8. Antibiotic therapy was continued throughout the period, even during second conditioning started at D-5: ATG, fludarabine, TBI monofraction 200 cGy, Cyclophosphamide. Bone marrow stem cells were infused, 11.04 x10^6/kg. From D+10 patient showed an increased in white blood cells with clinical improvement and reduction of inflammation indices.
Patient B presented trilinear pancytopenia and bone marrow transplant was planned with the brother selected as donor. Conditioning regiment was: ATG, Fludarabine, Cyclophosphamide, TBI 200 cGy, Rituximab, GvHD prophylaxis with Tacrolimus and MMF. HPC-A: CD34+ 6,66 x 10^6/kg, CD3+ 30,52 x 10^6/kg. Platelet engraftment D+18, Neutrophil engraftment D+13.
Patient C presented a history of recurrent infections, trilinear cytopenia, hypogammaglobulinemia. Haploidentical transplant was performed using PBSC from his father (WBC 1.73x10^8cell/kg, CD34+ 14.19x10^6cell/kg, CD3+ 42.01 x 10^6 cell/kg). Unfortunately the patient developed a primary graft failure and second transplant was planned urgently using MUD donor 10/10, conditioning regimen: Alemtuzumab, Fludarabine, Cyclophosphamide, TBI200cGy, Rituximab 200 mg, GvHD with Tacrolimus. Platelet engraftment take D+14, neutrophil engraftment D+18.

Conclusions: Patients with TBD may benefit from allogenic HCT, though with higher risk of graft failure and toxicity. Multidisciplinary considerations must be taken into account to decide the best transplant strategy for this patients.

Clinical Trial Registry: N/A

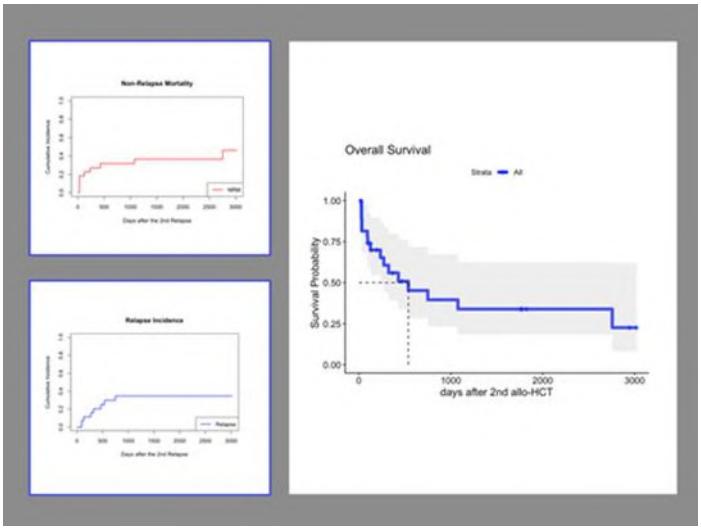
[1]*Bone Marrow Transplantation Unit, University General Hospital of Patras, Patras, Greece,* [2]*2nd Department of Internal Medicine, Hematology Unit, University General Hospital "Attikon, Athens, Greece,* [3]*Blood Center, University General Hospital of Patras, Patras, Greece,* [4]*Immunology Department, National Tissue Typing Center, General Hospital of Athens "G. Gennimatas", Athens, Greece*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) remains the only potentially curative approach for various hematologic malignancies, largely due to its graft-versus-leukemia effect. However, relapse after allo-HSCT continues to be the leading cause of treatment failure and is associated with extremely poor prognosis. Therapeutic options for post-transplant relapse include salvage chemotherapy, targeted agents, immunotherapy, donor lymphocyte infusions, and in carefully selected patients, a second allo-HSCT. Evidence on outcomes of second allo-HSCT remains limited. This study aimed to evaluate real-world outcomes of adult patients undergoing a second allo-HSCT in two transplant centers in Greece.

Methods: We conducted a retrospective analysis of consecutive patients with hematologic malignancies who underwent a second allo-HSCT for relapsed hematological malignancies, between October 2006 and June 2025 in two bone marrow transplantation centers in Greece. Demographic, clinical, disease-related, and transplant-related characteristics were extracted from institutional databases. Statistical analyses were performed with R software (R Development Core Team, Vienna, Austria) packages. Competing risk was taken into consideration when estimating the cumulative incidence rates of Graft vs Host Disease (GvHD), NRM and relapse rate.

Results: Twenty-seven patients were included (15 women, 12 men), with a median age of 38 years (range 20–66). Underlying diagnoses were acute myeloid leukemia (AML, n=14), acute lymphoblastic leukemia (ALL, n=8), myelodysplastic syndrome (MDS, n=4), and Hodgkin lymphoma (HL, n=1). The median time to relapse after the first allo-HSCT was 373 days (range 27–1215), and the median interval between the two transplants was 647 days (35–2583). At the time of the second allo-HSCT, 20 patients were in complete remission, 4 in partial remission, and 3 had refractory disease.
Donor type differed between the two procedures in all but one patient (26/27). For the second transplant, 3 patients received grafts from matched related donors, 19 from unrelated donors (11 WMUD, 8 MMUD), and 5 from haploidentical donors. Peripheral blood

stem cells were used in 24 cases, and bone marrow in 3. Engraftment was achieved in all but two patients who died early from transplant-related complications (on days +27 and +32). Median neutrophil recovery (WBC ≥1000/mm³) occurred on day 14 and median platelet engraftment (PLT≥20,000/mm³) on day 14.5.
The cumulative incidence of acute GvHD grades II-IV and III-IV at 100 days post 2nd allo-HSCT were 31% and 9%, respectively. The cumulative incidence of overall and severe chronic GvHD were 12.4% and 3.9%, respectively. OS at 12 and 24 months was 60.63% and 49%, respectively. Cumulative relapse incidence at 12 and 24 months was 26.73% and 37.51%, with median time to relapse of 199.5 days (160–448). NRM reached 22.59% at 12 months and 26.94% at 24 months.



Patients Characteristics			
Number of patients	27	Time to relapse (range)	373 (27-1215)
Median Age (range)	38 (20-66)	Time to 2nd allo (range)	647 (35-2583)
Sex – M/F	12/15		
Disease AML MDS HL B-ALL	 14 4 1 8	Donor Sibling WMUD MMUD Haplo	 3 11 8 5
Disease Stage before allo-HCT Refractory Disease Partial Response Complete Response	 3 4 20	Engraftment WBC≥1000/mmc, day (range) PLT≥ 20.000/mmc, day (range)	 +14 (8-20) +14.5 (8-134)

Conclusions: This real-world study demonstrates that a second allo-HSCT can offer meaningful long-term survival for selected patients with relapsed hematologic malignancies,

particularly those achieving remission before. Despite notable risks, including significant transplant-related mortality, outcomes compare favorably with other salvage strategies. These findings highlight the importance of careful patient selection, optimal timing of transplant, and tailored donor choice to maximize benefit while minimizing toxicity.

Disclosure: No conflict of interest to declare

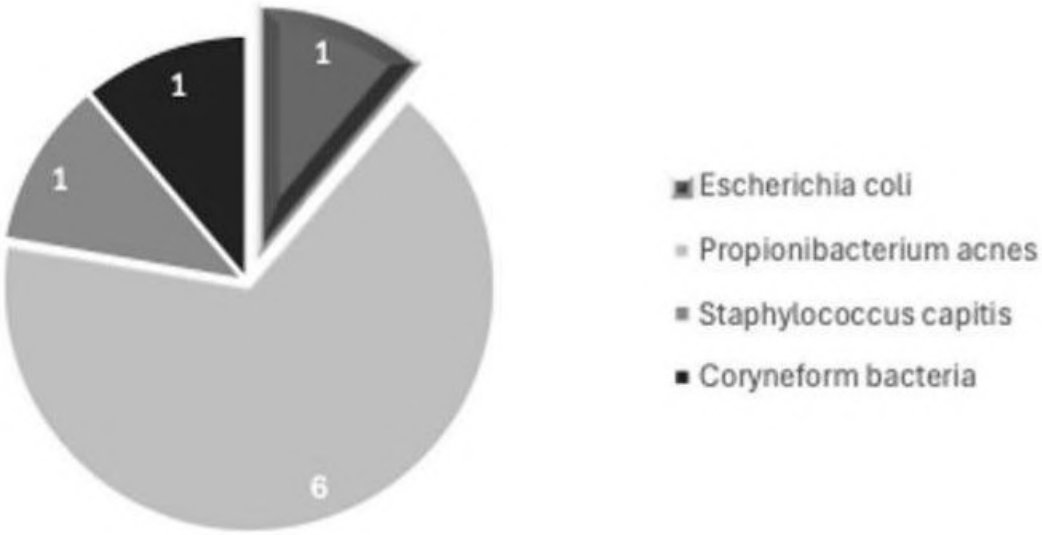
THE USEFULNESS OF CULTURING APHERESIS PRODUCTS IN HEMATOPOIETIC STEM CELL AUTOTRANSPLANTS

Guillermo J. Ruiz-Arguelles[1], *Lidia Joanna Alberto-Lopez*[1], *Max Robles-Nasta*[1], *Sofia Chavez-Martinez*[1], *Monica Daniela Salgado-Cabrera*[1], *Juan Carlos Olivares-Gazca*[1], *Guillermo J. Ruiz-Delgado*[2]
[1]*Centro Hematología y Medicina Interna, Clínica Ruiz, Puebla, Mexico,* [2]*Centro de Hematología y Medicina Interna, Clínica Ruiz, Puebla, Mexico*

Background: Bacterial cultures of apheresis products are mandated by FACT– JACIE standards as a safety measure in autologous hematopoietic stem cell transplantation (aHSCT), yet their clinical utility remains uncertain when fresh, noncryopreserved grafts are used.

Methods: We prospectively analyzed 629 apheresis products administered to 586 patients with multiple sclerosis or chronic inflammatory demyelinating polyneuropathy who underwent outpatient aHSCT between July 2021 and March 2025. Cultures were performed using the BACTEC system, and positive isolates underwent antimicrobial susceptibility testing.

Results: Bacterial contamination was identified in 8 products (1.3%). One culture yielded Escherichia coli within 24 hours, corresponding to a urinary tract infection and fatal sepsis in the donor; this product was discarded. The remaining seven cultures became positive 2–11 days after infusion and grew Cutibacterium acnes, Staphylococcus capitis, or Coryneform bacteria, all consistent with handling contaminants. None of the corresponding patients developed infectious complications within 28 days of follow-up.



Conclusions: Routine bacterial cultures provided clinically relevant information in only 1 of 629 cases, while most positive results represented contamination rather than true infection. Thus, the diagnostic yield of routine bacterial cultures in fresh, non-cryopreserved aHSCT grafts for autoimmune diseases is low, and their necessity should be reconsidered.

Disclosure: Nothing to declare.

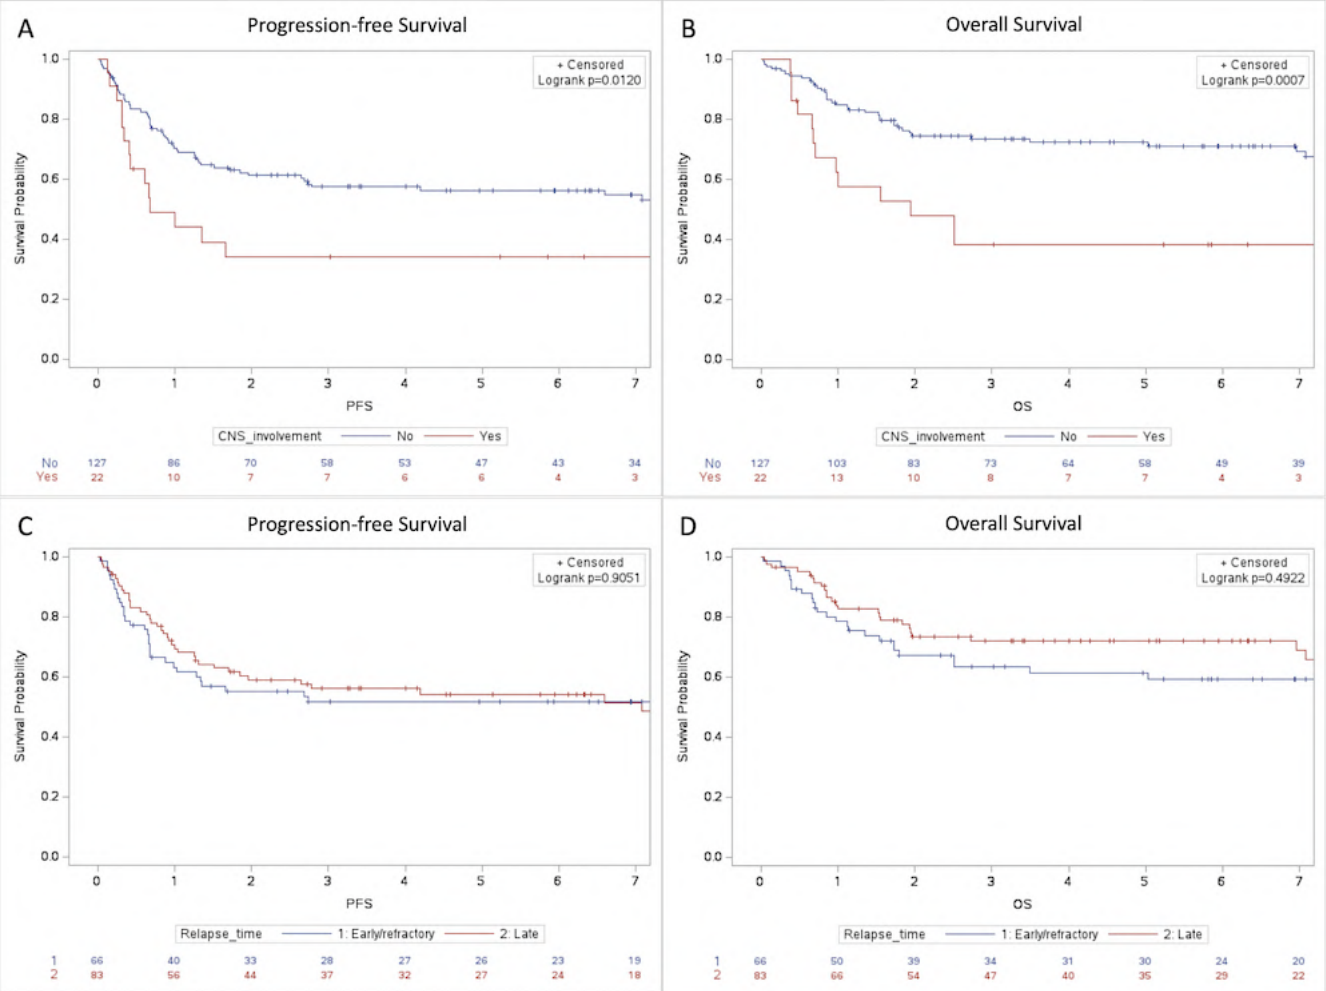
OUTCOME OF AUTOLOGOUS HAEMATOPOIETIC STEM CELL TRANSPLANT IN RELAPSE/REFRACTORY DIFFUSE LARGE B CELL LYMPHOMA: A MULTI-CENTRE RETROSPECTIVE COHORT STUDY

Xinxin Huang[1], *Victor Wei Teik Ling*[2], *Evelyn Aun*[2], *Pei Shin Teo*[2], *Jing Yuan Tan*[1], *Aloysius Yew Leng Ho*[1], *William Ying Khee Hwang*[1], *Francesca Lorraine Wei Inng Lim*[1], *Yunxin Chen*[1], *Chandramouli Nagarajan*[1], *Jeffrey Kim Siang Quek*[1], *Yeh Ching Linn*[1], *Hein Than*[1], *Yeow Tee Goh*[1], *Zhentang Lao*[1], *Esther Hian Li Chan*[2], *Liang Piu Koh*[2], *Lip Kun Tan*[2], *Edwin Thong*[2], *Michelle Poon*[2], *Lawrence Cheng Kiat Ng*[1]
[1]*Singapore General Hospital, Singapore, Singapore,* [2]*National University Hospital Singapore, Singapore, Singapore*

Background: Emerging novel treatments offer increasing therapeutic options for relapse/refractory diffuse large B cell lymphoma (R/R DLBCL). Despite this, intensive immunochemotherapy followed by autologous haematopoietic stem cell transplant (ASCT) consolidation remains an important treatment modality. This study examined the outcome of ASCT in R/R DLBCL and evaluated factors associated with the outcome.

Methods: R/R DLBCL cases that underwent second line immunochemotherapy followed by ASCT consolidation at Haematology Department, Singapore General Hospital and Division of Haematology, National University Hospital Singapore, between 2010 to 2024 were included. Demographics, disease characteristics and survival data were collected. Survival analyses were performed using Kaplan-Meier and Cox regression models.

Results:



149 R/R DLBCL cases were identified. Median follow up was 5.7 years (0.2 - 13.1 years). Average age was 53.6 years old at time of ASCT and 58.4% were male.
44.3% cases were early relapse (relapsed less than 1 year from end of first line treatment) or primary refractory, while the rest were late relapse. 14.8% (22 cases) of the cohort had central nervous system (CNS) involvement at relapse. Prior to ASCT, complete response was achieved in 73.4% of the cohort, partial response was achieved in 25.2%, and 2 cases (1.4%) were stable disease/progressive disease.
The overall 5-year progression-free survival (PFS) and overall survival (OS) post-ASCT were 53.1% [95%CI: 44.5 - 60.9] and 67.3% [95%CI: 58.8 - 74.4] respectively. 5-year non-

relapse mortality rate was 5.5% [95%CI: 2.6 – 10.1].
Between cases with and without CNS involvement, there was no significant difference in age, gender, relapse time, or pre-ASCT disease status, except in conditioning regimens (CNS involved group had more thiotepa-containing regimens: 81.8% vs. 4.7%, p<0.001). Compared with CNS non-involved group, CNS involved group had significantly inferior PFS (5-year PFS 34.2% vs. 56.3%, p = 0.01) and OS (5-year OS 38.6% vs. 72.5%, p < 0.001). The inferior PFS and OS of CNS involved group remained significant after adjusting for age, pre-ASCT disease status, and relapse time (PFS: HR 2.11 [95%CI 1.16 – 3.83], p = 0.01; OS: HR 2.74 [95%CI 1.44 – 5.21], p < 0.01). Between early relapse/primary refractory group and late relapse group, there was no significant difference in term of PFS and OS.

Conclusions: For R/R DLBCL that are chemo-sensitive, ASCT provides meaningful survival outcomes in both early relapse/primary refractory and late relapse cases. CNS involvement at relapse is associated with inferior survival post ASCT. Alternative salvaging treatments should be considered for this group.

Disclosure: Nothing to declare

P013

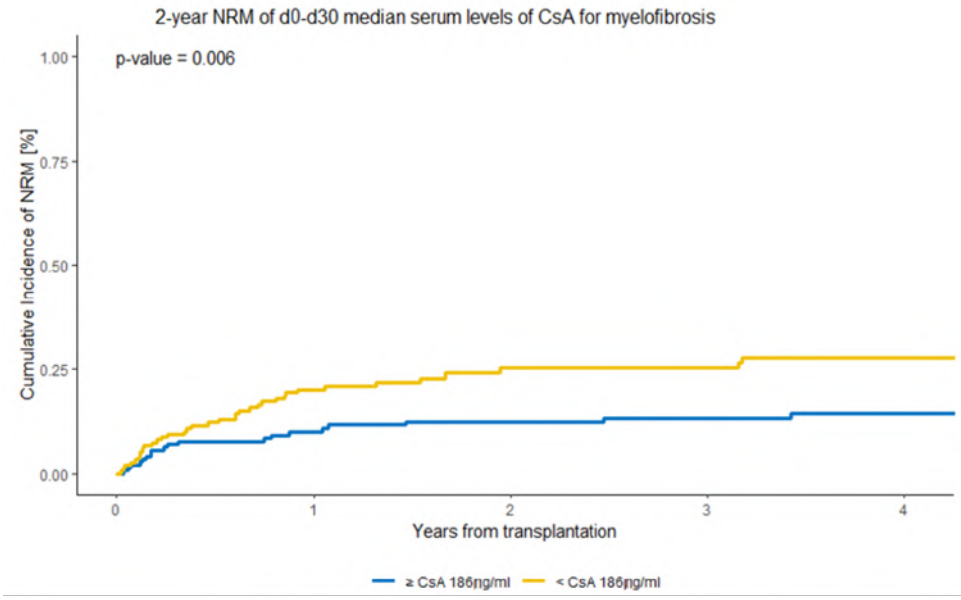
IMPACT OF CYCLOSPORINE A BLOOD LEVELS EARLY AFTER ALLOGENEIC STEM CELL TRANSPLANTATION FOR MYELOFIBROSIS ON OUTCOME

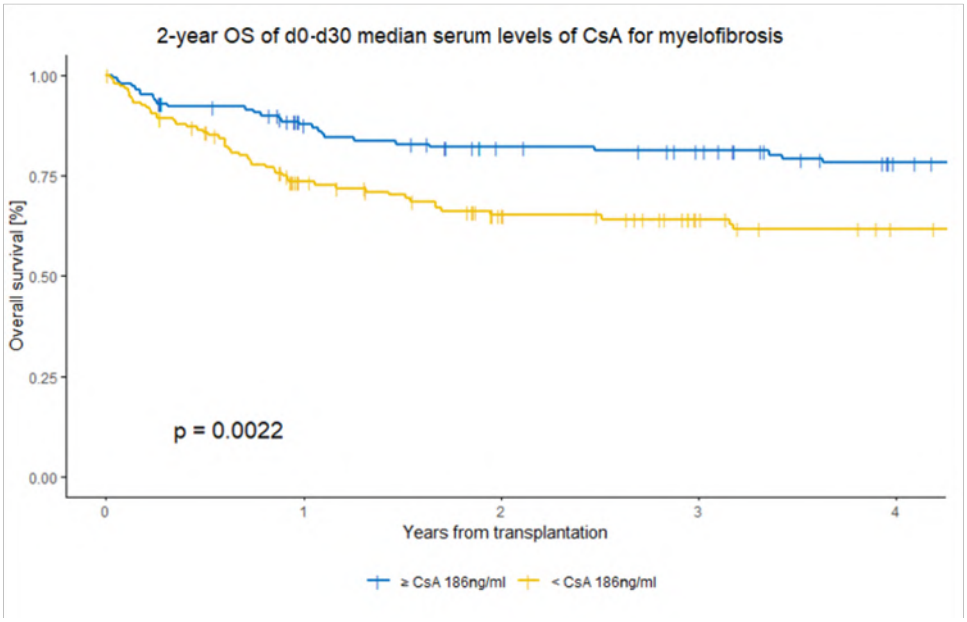
Max Wichmann[1], *Gunnar Weise*[1], *Rolf Krause*[1], *Mathias Schäfersküpper*[1], *Radwan Massoud*[1], *Catherina Lück*[1], *Ina Rudolph*[1], *Jochim Reinert*[1], *Maraike Harfmann*[1], *Sofia Oechsler*[1], *Jette Luedersen*[1], *Franziska Marquard*[1], *Gaby Zeck*[1], *Claudia Langebrake*[1], *Adrin Dadkhah*[1], *Nico Gagelmann*[1], *Evgeny Klyuchnikov*[1], *Silke Heidenreich*[1], *Nicolaus Kröger*[1], *Francis Ayuk*[1]
[1]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: In patients with myelofibrosis who undergo allogeneic stem cell transplantation (allo-HCT), the optimal level of post-transplant immunosuppression requires balancing between preventing graft-versus-host disease (GvHD) on the one hand and allowing graft-versus-malignancy effects as well as reducing drug toxicity on the other. The early days after transplantation may play a particularly decisive role in the development of GvHD. Therefore, we aimed to evaluate the association between early post-transplant Cyclosporine A (CSA) exposure and clinical outcomes following allo-HCT.

Methods: In this retrospective single-center study, we included patients with myelofibrosis who underwent allo-HCT between 2013 and 2025 at our clinic. Relevant patient characteristics, transplant-related variables, and CSA blood trough levels from day 0 to day 30 post-HCT were collected and median CSA blood level calculated. Patients were stratified into two groups above vs. below median level and compared regarding the cumulative incidence of non-relapse mortality (NRM), overall survival (OS), relapse and acute GvHD.

Results: The analysis included a total of 293 patients. The cumulative incidence of NRM at 2 years was significantly lower in patients above (12.4%) vs. below (25.2%) the median (p = 0.006; Figure 1). Consistently, overall survival at 2 years was higher in patients with CSA levels above the median (82.1%) compared with those below the median (65.2%; p = 0.002; Figure 1). The cumulative incidence for relapse was 11.2% and 15.5% for patients above and below the median, respectively (p = 0.77). Acute GvHD (grade 2 and higher) and severe acute GvHD (grade 3 and higher) on day 100 occurred more frequently in patients below (>°II: 39.4%, >°III 15.8%) vs. above (>°II: 25.9%, >°III 12.7%) the median (>II° p: 0.018; >III° p: 0.214). In univariate analysis, CSA levels below the median were associated with higher NRM (HR: 1.97, 95% CI 1.2-3.2, p = 0.008). Other factors significantly associated with NRM, were: Total body irradiation (TBI), Donor-type (matched related vs. other), recipient CMV serostatus, recipient age, and ECOG performance status. In multivariate analysis (n=133), CSA exposure above the median was not an independent predictor of NRM (HR 1.56, 95% CI 0.7-3.7, p = 0.32). Independent predictors of NRM were a high-risk MTSS score (HR 13.28, p = 0.027) and TBI (HR <0.001, p <0.001).





Conclusions: In this exploratory analysis, lower CSA exposure during the first 30 days after allo-HCT for myelofibrosis was associated with increased non-relapse mortality and inferior overall survival in the univariate analysis. These findings warrant further investigation in larger patient cohorts.

UTILITY OF IL-6, FERRITIN AND CRP LEVELS IN PREDICTING CAR T-CELL TOXICITIES IN PATIENTS TREATED WITH TISA-CEL FOR B CELL LYMPHOMA AND B-ALL

Hanan AlQudairy[1], *Riad El Fakih*[1], *Abdulrhman Zaitoun*[2], *Ali D AlAhmari*[1], *Yasmeen Tahaa*[2], *Reem Ahmad Awad*[1], *Farah Alhamdan*[2], *Zuheir Alkawi*[2], *Syed Abubakr Osman*[2], *Walid Rasheed*[1], *Mostafa Mohammed Saleh*[1], *Saud Alhayli*[1], *Alfadel Alshaibani*[1], *Abdulwahab Albabtain*[1], *Abdullah Alamer*[1], *Ayman Saad*[1], *Amr Alhanbali*[1], *Hanan Alkhaldi*[1], *Alfadil Adam*[1], *Feras Alfraih*[1], *Fahad Almohareb*[1], *Hadeel Samarkandi*[1], *Heba Madien*[1], *Sarah Alageel*[1], *Farhatullah Syed*[1], *Shaykhah Alotaibi*[1], *Hazzaa Alzahrani*[1], *Mahmoud Aljurf*[1], *Syed Osman Ahmed*[1]
[1]*King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia,* [2]*Alfaisal University, Riyadh, Saudi Arabia*

Background: Chimeric antigen receptor T cell (CAR-T) is a major breakthrough treatment for B cell malignancies. However, it is frequently associated with life threatening toxicities such as cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). Identifying proinflammatory markers that can predict at high-risk patients for sever toxicities is critical for patients monitoring and management.

Methods: A retrospective analysis was conducted on 45 patients who received tisagenlecleucel (Tisa-cel) (25 patients with B-cell lymphoma and 20 patients with B-cell acute lymphoblastic leukemia (B-ALL). Patient demographics and inflammatory biomarkers levels (IL-6, ferritin, and C-reactive protein (CRP)) were collected from pre-infusion Day −1 to Day +28 post-infusion. The incidence and grades of CRS and ICANS were collected. Peak concentration, area under the curve (AUC), and duration of biomarker elevation were assessed for each patient. Associations between biomarker features and toxicity severity were evaluated using Spearman correlation analysis.

Results: The median age was 48 years (IQR 36–60) and 22 years (IQR 18.5–26) for patients with lymphoma and B-ALL, respectively. CRS was observed in 88% of B-cell lymphoma patients (Grade 1: 56%, Grade 2: 20%, Grade 3: 4%, Grade 4: 8%) and in 95% of B-ALL patients (Grade 1: 70%, Grade 2: 25%, Grade ≥3: 0%). ICANS occurred in 24% of B-cell lymphoma patients (Grade 2: 4%, Grade 3: 20%) and in all B-ALL patients (Grade 1: 15%, Grade 2: 85%). IL-6 AUC showed a strong correlation with CRS severity in both B-cell lymphoma (Spearman ρ=0.67, P=0.00025) and B-ALL patients (Spearman ρ=−0.67, P=0.0011). IL-6 peak concentration was also significantly associated with CRS severity in both cohorts (B-cell lymphoma: Spearman ρ=0.57, P=0.0029; B-ALL: Spearman ρ=0.64, P=0.0023). In contrast, duration of IL-6 elevation demonstrated a significant association with

CRS severity in B-cell lymphoma patients (Spearman ρ=0.62, P=0.00093) but not in B-ALL patients (Spearman ρ=−0.35, P=0.13). Ferritin and CRP levels showed no significant association with CRS severity in either cohort. IL-6, ferritin, and CRP were not associated with ICANS occurrence or severity in B-cell lymphoma patients (P>0.2). However, in B-ALL patients, IL-6 AUC and IL-6 peak concentration were significantly associated with ICANS grade (P=0.018), while IL-6 elevation duration, ferritin, and CRP showed no significant associations.

Conclusions: IL-6, primarily AUC and peak concentration, is a reliable predictive marker for CAR-T toxicity severity and may be utilized for early identification of patients at risk for severe CAR-T toxicities, whereas ferritin and CRP provide limited utility. In B-ALL patients receiving Tisa-Cel, IL-6 AUC and peak concentrations also predict ICANS severity and may guide preemptive interventions. Further prospective studies are required to confirm these findings.

THE JOURNEY TO ALLOGENEIC STEM CELL TRANSPLANTATION OF PATIENTS TREATED WITH BCL2 INHIBITOR THERAPY IN MYELODYSPLASTIC SYNDROME AND ACUTE MYELOID LEUKEMIA IN MIDDLE INCOME COUNTRY

Gustavo Mesquita de Oliveira[1], Emanuelly Thays Muniz Figueiredo Silva Vasconcelos[1], Maria Laura Fontoura Chagas Rocha[1], Felipe de Menezes Cunha[1], Hercules Amorim Mota Segundo[1], ***Fernando Barroso Duarte***[1]
[1]*Universidade Federal do Ceará, Fortaleza, Brazil*

Background: Acute myeloid leukemia (AML) and high-risk myelodysplastic syndromes (MDS) disproportionately affect elderly and frail patients, particularly in low- and middle-income countries, where access to intensive chemotherapy, transplantation, and novel agents remains limited. The introduction of BCL2 inhibitors, especially venetoclax, combined with hypomethylating agents or low-dose cytarabine (LDAC), has expanded treatment options for patients deemed unfit for intensive therapy. This study aimed to describe the clinical characteristics, treatment patterns, and outcomes of patients with AML and high-risk MDS treated with venetoclax-based regimens in a public university hospital in Northeastern Brazil, with emphasis on barriers to allogeneic hematopoietic stem cell transplantation (allo-HSCT) in an middle-income country setting.

Methods: Retrospective, descriptive study including patients aged ≥18 years diagnosed with AML and high-risk MDS treated with a BCL2 inhibitor combination between January 2020 and October 2025.

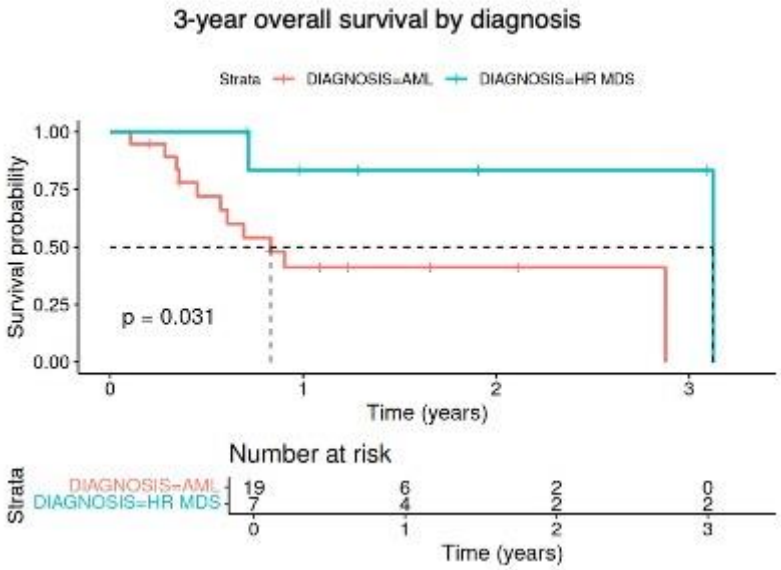
Results: Twenty-six patients were included (19 AML and 7 MDS), with a median age of 65 years (range: 37–81). Among AML cases, 57.9% were secondary, mostly evolving from prior MDS, reflecting delayed diagnosis and limited access to early disease-modifying therapies. Overall, 46.1% achieved complete remission and 3.8% partial remission, with a median time to best response of one treatment cycle. In AML, patients had a median overall survival of 304 days, whereas MDS patients had a median OS of 1141 days. Hematologic toxicity was universal, and febrile neutropenia occurred in 78.3% of patients. Despite many patients achieving remission, only three (11.5%) proceeded to allo-HSCT, all of them high-risk MDS patients. Major barriers to transplantation included advanced age, frailty, relapse and infectious complications.

Clinical and demographic characteristics

Characteristics	Cohort (N = 26)
Median age (range)	65 (37-81)
Female (%)	15 (57,6%)
AML (%) De novo Secondary	19 (73%) 8/19 (42,1%) 11/19 (57,9%)
Secondary AML (%) MDS CMML PV/PMF	 7/11 (63,6,%) 2/11 (18,2%) 2/11 (18,2%)
MDS (%) LB IB1 IB2	7 (27%) 2/7 (28,6%) 1/7 (14,3%) 4/7 (57,1%)
ECOG 0-1 2	 13/26 (50%) 13/26 (50%)
Risk stratification (AML) Favorable Intermediate Adverse	 1/19 (5,3%) 16/19 (84,2%) 2/19 (10,5%)
R-IPSS (MDS)	6 (5-10)
CBC at diagnosis Hemoglobin (g/dL)	7,01 (4,23-11,3) 1130 (50-40.960)

Clinical and demographic characteristics

Neutrophils (n/mm^3)	574 (0-300.675)
Blasts (n/mm^3)	35070 (14.330-383.000)
Platelets (n/mm^3)	



Conclusions: In this real-world middle-income country cohort, venetoclax-based regimens achieved response rates comparable to those reported in high-income countries. However, structural limitations, clinical frailty, treatment-related toxicities and relapse significantly restricted access to allo-HSCT, even among responding patients. These findings highlight the critical need to expand access to targeted therapies, optimize supportive care, and improve transplant referral pathways in public healthcare systems across low- and middle-income countries.

P019

OUTCOME OF HEMATOPOIETIC STEM CELL TRANSPLANTATION IN INFANT LEUKEMIA: A SINGLE-CENTER RETROSPECTIVE STUDY

Xiaoxi Lu[1], *Shengnan Su*[1], *Yiping Zhu*[1], *Dongjun Li*[1], *Yuan Ai*[1], *Shuwen Sun*[1], *Ju Gao*[1], *Ziting Xia*[1], *Hongye Cai*[1]
[1]*West China Second University Hospital, Sichuan University, Chengdu, China*

Background: Infant leukemia (IL) refers to leukemia diagnosed initially in patients under one year of age, with an extremely low incidence rate, and tends to present with aggressive clinical features and unique biology. The event-free survival of infants with leukemia is poor due to the vulnerability to complications and toxicity of the treatments and high relapse rate despite the use of intensive chemotherapy with or without hematopoietic stem cell transplantation. This study aims to evaluate the outcome and early complications of infants who underwent HSCT.

Methods: Infant leukemia (IL) refers to leukemia diagnosed initially in patients under one year of age, with an extremely low incidence rate, and tends to present with aggressive clinical features and unique biology. The event-free survival of infants with leukemia is poor due to the vulnerability to complications and toxicity of the treatments and high relapse rate despite the use of intensive chemotherapy with or without hematopoietic stem cell transplantation. This study aims to evaluate the outcome and early complications of infants who underwent HSCT.

Results: This study analyzed data from 32 infant leukemia who underwent HSCT. Patient and transplant characteristics are shown in Table 1. Nineteen males and thirteen females were enrolled, with a male-to-female ratio of 1.46:1. Median age at diagnosis was 8 (0, 12) months, and median age at transplantation was 15 (8, 49) months. There were 17(53%) infant acute lymphoblastic leukemia (IALL), 12(38%) infant acute myeloid leukemia (IAML), and 3(9%) infant mixed phenotype acute leukemia (IMPAL). MLL gene rearrangement occurs in 23 patients(72%). There were 23 CR1 patients(72%), 8 CR2 patients(25%), and 1 PR patient(3%). All of the 8 patients with CR2 achieved molecular remission in which 7 patients were treated with autologous CAR-T, including CD19 and CD19/CD22, and 1 patient was treated with Blinatumomab.All patients were treated with the MAC regimen, and with tacrolimus and low-dose MTX to prevent active GVHD. Donors included Cord Blood (n=19), Haploidentical (n=5), Matched Unrelated Donor (n=3), Matched Sibling Donor (n=3), and Mismatched Unrelated Donor (n=2). All patients achieved hematopoietic reconstitution. Median follow-up was 36 (2, 74) months. The overall survival (OS) during the follow-up period were 90.1%. The cumulative incidence relapse rate was 9.48%.The OS was 100% for MPAL group, 94% for ALL group, and 80% for AML group respectively(p=0.5%). The OS was 93% for patients with negative fusion genes prior to transplantation, compared to 0% for those with positive fusion genes ($p<0.001$).Three patients died due to relapse. Among them, one received second HSCT from father but relapse again after 3 month.The incidence rates of sepsis were 44%. Major complications included veno–occlusive disease (VOD) in 9% of patients which resolved by supportive measures and defibrotide.The incidence of grade II-IV acute GVHD was 31%, and the incidence of chronic GVHD was 15% respectively. 34% patients were diagnosed CMV viremia but only one patient suffered cytomegalovirus ophthalmia.

Conclusions: Infants with leukemia shows a low long-term survival. Hematopoietic stem cell transplantation is safe and effective in the treatment of infant leukemia. It is the most importance to make MRD negative before transplantation.

Disclosure: Nothing to declare.

P021

HEMATOPOIETIC STEM CELL TRANSPLANTATION IN APLASTIC ANAEMIA: EXPERIENCE FROM A TERTIARY CARE REFERRAL HOSPITAL

K.K Radhika[1]
[1]*Nizam's Instiute of Medical Sciences, Hyderabad, India*

Background: Aplastic anemia (AA) is associated with high morbidity and mortality, contributing significantly to both disease and economic burden. This study aimed to assess the clinical characteristics, survival rates, and treatment costs of patients who underwent hematopoietic stem cell transplantation (HSCT) for AA to support future research.

Methods: This retrospective study was conducted on patients who underwent HSCT for AA at a tertiary care referral hospital in India from January 2020 to June 2025. This study included patient demographic details, human leukocyte antigen (HLA) matching status, conditioning regimens, graft-versus-host disease (GVHD) prophylaxis, stem cell source and dose, transplant-related complications (infections, GVHD, and graft rejection or relapse), and survival outcomes. Transplant types comprised of matched sibling donor (MSD), matched unrelated donor (MUD), and haploidentical transplants. The stem cell dose ranged between 2.5×10^6 and 8.6×10^6 cells/kg body weight.

Results: A total of 29 patients with acquired AA who underwent HSCT were included in the study. The majority of patients (79.3%) were 18-40 years of age. Most patients (69.0%) were male, and 31.0% were female. Most patients (72.4%) presented with severe AA, whereas 27.6% had very severe AA. Paroxysmal nocturnal hemoglobinuria (PNH) clone was absent in most patients (69.0%), whereas 31.0% demonstrated a positive PNH clone. Hematopoietic cell transplantation Comorbidity Index score 0 was observed in 93% of patients. A majority of patients (83.0%) underwent transplantation with MSD, followed by haploidentical donors (10.0%) and MUD (7.0%). Sex-matched transplants were performed in 68.0% of patients, while 32.0% received transplants from sex-mismatched donors. 90.0% of patients received HLA-matched transplants, while only 10.0% received transplants from HLA-mismatched donors. Peripheral blood stem cells accounted for 79.0% of the stem cell harvest, followed by bone marrow stem cells (21.0%). First-line treatment was initiated in a significant proportion of patients (96.6%), while only 3.4% received second-line treatment. A triple combination of fludarabine, cyclophosphamide, and antithymocyte globulin (ATG) was administered in 79.0% of patients, whereas 17.0% received cyclophosphamide and ATG, and 3.0% received fludarabine and cyclophosphamide. Engraftment occurred on days 9-11 for MSD transplants and on days 18-21 for haploidentical transplants. Pre and peri-engraftment infections were the most common cause of mortality (44.0%), followed by graft rejection (22.0%), transfusion-related acute lung injury (11.0%), GVHD (11.0%), and life-threatening internal bleeding (11.0%). At 3 months, patient survival was 86.2%, while 1-year survival was 76.0%. The highest cost of allogenic bone marrow transplantation (BMT) was approximately 24.0 lakhs rupees, while the lowest cost was 7.2 lakhs rupees, indicating a wide range of expense, and all the transplants were covered under government sponsored schemes.

Conclusions: Allogeneic HSCT offers a curative option for AA, especially in younger patients with MSDs, with an overall survival rate of 76 % at 1 year at our institution**.** However, infection-related complications remain a major challenge, requiring enhanced supportive care. Government-sponsored allogenic BMT schemes are a boon for patients from low socioeconomic backgrounds.

Disclosure: Nothing to declare.

P022

A RARE CASE OF AUTOSOMAL DOMINANT OSTEOPETROSIS WITH CONCOMITANT CMML 1 TREATED WITH ALLOGENEIC HAEMATOPOIETIC STEM CELL TRANSPLANTATION

Jenny Miethke[1], *Carl Crodel*[1], *Ioannis Anagnostopoulos*[2], *Andreas Hochhaus*[1], *Inken Hilgendorf*[1]
[1]*University Hospital Jena, Jena, Germany,* [2]*University Würzburg, Würzburg, Germany*

Background: Osteopetrosis is a rare hereditary bone disorder with genetic and clinical heterogeneity. While allogeneic haematopoietic stem cell transplantation (allo-HSCT) is an established curative treatment for the severe autosomal recessive infantile form (ARO). Its use in patients with benign autosomal dominant osteopetrosis is rarely reported, as it is generally not recommended due to the typically mild clinical course and the increased risk of transplantation related complications with advancing age. We present a rare case of a young adult patient with ADO and concomitant chronic myelomonocytic leukaemia (CMML-1), both represent conditions potentially amenable to allogeneic haematopoietic stem cell transplantation.

Methods: A 33-year-old woman with confirmed diagnosis of ADO presented with leukocytosis, macrocytic anaemia, elevated LDH, hepatosplenomegaly, extramedullary haematopoiesis and EBV reactivation. A comprehensive diagnostic evaluation to exclude lymphoma, incorporating PET/CT imaging, bone marrow biopsy, and lymph node histopathology, ultimately revealed an MDS/MPN overlap consistent with CMML-1. Molecular analysis identified pathogenic *ASXL1* and *RUNX1*mutations, as well as a heterozygous *CLCN7* variant in Exon 11 associated with osteopetrosis. Due to intermediate 2 risk (CPSS Mol Score), the patient was referred for allo-HSCT.
She received reduced-intensity conditioning with treosulfan, fludarabine, and ATG, followed by peripheral blood stem cells from a 10/10 HLA-matched, unrelated donor. GvHD prophylaxis consisted of MMF/tacrolimus. Engraftment occurred on days +14 (neutrophilic), and +19 (platelet), while erythropoiesis was not yet self-sustaining. No acute graft-versus-host disease (GVHD) was observed by day +25.

Results: The patient tolerated allo-HSCT without major complications and demonstrated timely engraftment with dose-reduced conditioning. A gradual decline in risk of bone fracture and splenomegaly is anticipated.

Conclusions: This case highlights the feasibility of allo-HSCT in a young adult patient with ADO — an exceedingly rare scenario with limited published experience. Longer follow-up will be essential to assess long-term engraftment stability, GvHD risk, and osteopetrosis-related outcomes.

Disclosure: Nothing to declare.

P023

HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANT FOR JUVENILE MYELOMONOCYTIC LEUKAEMIA

Frances Yeap[1], *Poh Lin Tan*[1]
[1]*National University Hospital, Singapore, Singapore*

Background: Allogenic haematopoietic stem cell transplantation (HSCT) remains the only curative option for most children with Juvenile Myelomonocytic Leukaemia (JMML). While a subset of JMML patients with mainly germline CBL mutations can be long-term survivors with minimal therapy, the majority progress within a year if untreated. Predictors of aggressive JMML include age more than 2 at presentation, high Haemoglobin F levels, refractory thrombocytopenia and non CBL somatic gene mutations. We share our experience in managing this rare paediatric haematological malignancy using pre-transplant strategies for the 'best" disease control followed by haploidentical stem cell transplant with the "best" available donor and then post-transplant decitabine as a pre-emptive strategy to prevent relapse.

Methods: We transplanted 6 JMML patients over the last 10 years, with all >2 years old at diagnosis except 1 patient who was 1 month of age. One patient had previously received a matched sibling cord blood transplant but relapsed. All patients received chemotherapy consisting of Azacitidine, Cytarabine and etoposide prior to stem cell transplant. All patients received a peripheral blood haploidentical stem cell transplant with either parent as the donor. 5 out of the 6 patients (all PTPN11) underwent a splenectomy prior to HSCT. Choice of parent was predominantly dependent on gender (father preferred), or the parent with better NK alloreactivity. None of the patients had GVHD prophylaxis as these were all ex-vivo T cell depleted grafts using CD3/CD45 RA T- cell depletion technique. Transplant conditioning was Fludarabine Thiotepa and melphalan based, without radiation. 4 out of the 6 patients received Decitabine pre-emptive therapy, with a minimum of 6 cycles given monthly.

Results: All 6 patients are alive and remain in remission with a median follow-up of 6.6 years (range 1 year to 10.2 years) post HSCT. One out of the 6 patients required a second transplant as he failed to engraft the first time and his course was complicated by disease relapse and sepsis (klebsiella, sternotrophomonas maltophilia, disseminated mycobacterium). Five of the other patients all engrafted by D20 post HSCT and no patient had more than grade 2 acute graft versus host disease (aGVHD). Only 1 patient had chronic GVHD.

Patient	Age at transplant (y)/ Gender (M/F)	Genetics	Bone marrow blast % (time of transplant)	Haplo PBSCT conditioning	Engraftment	Complications	aGVHD	cGVHD	Outcome
1	8.4y/ M	PTPN11	49%	FluCyTTMel	100% Donor D+9	Engraftment fever, Infections (Adenovirus)	Grade 2 (skin/liver/gut)	Extensive (oral, skin, joins)	Alive
2	1.2y/ M	NRAS	Not done	FluTreoTTMel	100% Donor D+9	Engraftment fever, Infections (CMV reactivation)	Grade 2 (gut)	Nil	Alive
3	5.1y/ M	PTPN11	10%	FluTreoTTMel	98% Donor D+20	Engraftment fever, Infections (C.difficile, Mycobacterium abscessus, fortuitum)	Nil	Nil	Alive
4a	6.8/M	PTPN11	1.3%	FluBuTTMel	86% Donor D+10, 2% Donor D+18	Rejection, Infections (Klebsiella, Stenotrophomonas)	NA	NA	Rejection/Relapse
4b	6.9y/ M	PTPN11	27.5%	FluTreoTTMel	98% D+11	Infections (CMV reactivation, BK hemorrhagic cystitis, Stenotrophomonas,	Nil	Nil	Alive

						disseminated mycobacterium)			
5	7.2y/F	PTPN11	0.01%	FluTreoTTMel	96% Donor D+24	Engraftment fever, Infections (Ecoli)	Nil	Nil	Alive
6	3.4y/F	PTPN11	0.014%	FluTreoTTMel	98% Donor D+9	Engraftment fever	Nil	Nil	Alive

Conclusions: High risk PTPN11 JMML is associated with high morbidity and mortality. In our 6 patients, 5 had PTPN11 mutations and 1 infant with NRAS. These patients with PTPN11 mutations also had abnormal cytogenetics, high blast percentage, HbF (>10%) at diagnosis and also severe thrombocytopenia. Although there is no robust clinical evidence in using azacytidine in combination with chemotherapy in JMML, however it is efficacious in cytoreduction and generally safe as a bridging therapy prior to HSCT. In summary, haploidentical HSCT has proven to be effective in the long-term treatment of our group of high risk JMML by providing a source of stem cells quickly and allowing rapid engraftment and immune recovery. Together with post-transplant Decitabine, we have achieved 100% overall survival in this high risk group of patients. Splenectomy before HSCT has not shown to reduce relapse and as it may increase infection risks, its use remains unclear.

Clinical Trial Registry: NA

OPTIMIZING PAEDIATRIC LYMPHAPHERESIS: KEY FACTORS FOR SAFE AND EFFECTIVE PROCEDURES

Mercé Albert Bayo[1,2], *Andrea Espasa*[1], *Marina Rierola*[1,2], *Sofia Alonso*[1,2], *Shiomara Quiñones*[1], *Violeta Vidal*[1], *Julia Ayats*[2,3], *Mònica Linares*[2,4], *Maria Teresa Contijoch*[1,2], *David Gómez–Vives*[1,2], *Carmen Montanero*[1,2], *Juan Manuel Porras*[1,2], *Marc Vilches*[1,2], *Laura Alonso*[5], *Pablo Velasco*[5], *Cristina Díaz de Heredia*[5], *Verònica Pons*[1,2]
[1]*Blood and Tissue Bank of Catalonia – University Hospital Vall d'Hebron, Barcelona, Spain,* [2]*Transfusional Medicine Group – VHIR, Barcelona, Spain,* [3]*Blood and Tissue Bank of Catalonia – University Hospital Germans Trias i Pujol, Badalona, Spain,* [4]*Blood and Tissue Bank of Catalonia – Cell Therapy Service, Barcelona, Spain,* [5]*Department of Pediatric Hematology and Oncology – University Hospital Vall d'Hebron, Barcelona, Spain*

Background: Current literature provides limited details on technical and procedural approach to paediatric lymphapheresis with the Spectra Optia system, highlighting the need

for harmonized practices. Our aim is to describe our experience and share practical insights to help other centres optimise paediatric lymphapheresis safely.

Methods: We performed a retrospective study at a single paediatric centre (2019–2025) using the Spectra Optia® machine (Terumo BCT) with the cMNC programme. We analysed patient demographic characteristics, peripheral blood values, and lymphapheresis-related parameters. Results are reported as median [minimum–maximum].

Results: We analysed 26 lymphapheresis performed in 25 subjects (10 months-17 years), of whom 23 had B-cell acute lymphoblastic leukaemia and 2 were healthy lymphocyte donors. Patients aged 8 years or younger accounted for 52% of the cohort. Other baseline characteristics are shown in Table 1.
Central venous catheters (CVCs) were employed in 23 lymphaperesis, whereas peripheral venous access was used in 3 adolescent subjects (aged ≥ 12 years). CVCs were located in the jugular vein (left n=12, right n=9, non-available n=2). French (Fr) size and weight of the subjects were: Fr 6.5, n=2, 7.3 kg [7.3–7.3]; Fr 8, n=11, 27.0 kg [15.0–37.0], Fr 11.5 (n=10, 47.5 kg [21–61]).
Regarding machine set up, blood priming was required for 13 processes (50%) and collection preference remained stable across 10 procedures, while it was modified during lymphapheresis in the remaining 61.5% of cases. Other technical aspects are described in Table 1.
Acid Citrate Dextrose solution A (ACD-A) was used in 7 procedures (26.92%), and ACD-A+heparin in 19 (73.08%). Prophylactic calcium was given in 21 runs (80.8%), 1 subject experienced tingling and received calcium post-procedure. Procedures using ACD-A alone resulted in higher citrate infusion volumes (625 [518–1178] mL) compared to ACD-A+heparin (291 [105–772] mL). Citrate volumes positively correlated with patient's weight ($p<0.001$, $r=0.63$).
Maximum flow rate (mL/min) varied by CVC Fr: 10.8 (Fr 6.5), 45 (Fr 8), and 65 (Fr 11.5); and correlated with patient weight ($p<0.001$, $r=0.72$). Minimum and maximum ACD-A infusion rates were 0.4 and 1.1, with ACD-A ratios ranging 1:14–1:10 (ACD-A alone) and 1:28–1:16 (ACD-A+heparin).
Subjects had a 22.96% [2.90–69.88] of peripheral blood CD3+ lymphocytes and 630 cells/µL [60–2350]. This peripheral blood CD3+ cell count correlated with product CD3+ cell yield ($p<0.001$, $r=0.73$). Collection efficiency for CD3+ was 70.04% [29.87–107.5]. Lymphapheresis product was 11.54-fold (1.15–29.61) more concentrated than peripheral blood. Yields are shown in Table 1. Lymphaperesis caused drops in platelets counts (-29.73% [-62.07 – 1.00), while haematocrit and haemoglobin changes were not relevant.
Target criteria for CAR T-cells (1-1.5x10^9 $CD3^+$ T-cells) were met in 22/23 patients, although CAR T-cells could be manufactured in all cases. No serious side-effects associated with the lymphapheresis process were observed.

Table. 1	Parameter	Values
Subject Characteristics (N=25)	**Age** (years)	8.0 [0.83–17.00]

	Sex - Female / Male n (%)	10 (40%) / 15 (60%)
	Weight (Kg)	33.0 [7.30-64.0]
	Diagnosis (B-ALL / Healthy donor)	23 / 2
	Subjects undergoing T-cell lymphapheresis (Once / Twice)	23 / 2[a]
Patients Receiving CAR T cells (N=23)	**CAR-T infused / non-infused** (n patients)	22 / 1[b]
	Exitus within the 1st year after infusion (yes / no)	5 / 17[c]
Lymphapheresis Process Parameters (N=26)	**Patient's total blood volume** (mL)	2342 [660.6–4404]
	Time of the process (min)	242 [112–403]
	Total blood volume processed	3.12 [1.46–6.00]
	AC in the patient (mL)	434 [105–1178]
	Collection volume (mL)	203 [105–370]
	Total AC in lymphapheresis product (%)	10.22 [4.67–17.06]

	Maximum flow rate (mL/min)	38 [10–65]
Lymphapheresis Collection Yields (N=26)	**Total Nucleated Cells** (x 10^9)	5.53 [0.36–101.00]
	Mononuclear Cells (x 10^9 / %)	4.77 [0.32–99.95] / 95.54 [38–100]
	Lymphocytes (x 10^9 / %)	3.99 [0.24-32.12] / 69.67 [4.00-98.62]
	CD3+ Lymphocytes (x 10^9 / %)	3.15 [0.22-8.75] / 53.99 [3.5-92.9]

[a]A patient underwent a failed lymphapheresis due to venous access issues (excluded from this analysis). Another patient underwent 2 consecutive successful lymphapheresis to obtain a single product.
[b]The CAR-T was not infused because disease relapsed.
[c]Three patients have not yet reached one year since lymphapheresis but are currently alive.

Conclusions: Paediatric lymphapheresis is safe and effective even in very young and low-weight patients. Weight is crucial for selecting venous access and setting up the procedure. Our study outlines relevant aspects that may help optimise practice and guide future research, offering practical parameters for other centres, although further studies are needed.

P026

CLINICAL CHARACTERISTICS AND OUTCOMES OF HODGKIN LYMPHOMA PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION: A REAL-WORLD EXPERIENCE FROM A NATIONAL REFERRAL CENTER

Vicky Margarita Moncada Gadea[1], *Rosa Adriana Alvidrez-Gonzáles*[1], *Grecia Pamela Martínez Vázquez*[1], *Mistral Castellanos-Mares*[1], *Andres Yesid Bonilla-Salcedo*[1], *Victor Iván Salinas-Herrera*[1], *Irma karen Pellon-Tellez*[1], *Luis manuel Valero-Saldaña*[1]
[1]*Instituto Nacional de Cancerologia, Ciudad de Mexico, Mexico*

Background: High-dose chemotherapy followed by hematopoietic stem cell transplantation (HSCT) remains a cornerstone therapeutic strategy for patients with relapsed or refractory classical Hodgkin lymphoma (cHL). However, much of the evidence supporting transplant-based approaches originates from clinical trials conducted in highly selected populations, which limits their applicability to routine clinical practice. In Latin America, real-world data remain particularly scarce despite notable differences in epidemiology, access to healthcare, tumor burden at diagnosis, and availability of novel therapies. These factors highlight the need to generate context-specific evidence to better inform therapeutic decision-making in the region.

Methods: This was a retrospective, observational study including adult patients diagnosed with Hodgkin lymphoma who underwent HSCT between 2014 and 2024. Clinical, laboratory, and treatment-related variables were collected from institutional medical records. Outcomes of interest included overall survival (OS), progression-free survival (PFS), relapse, and transplant-related mortality. Survival curves were estimated using the Kaplan–Meier method. Statistical analysis was performed using SPSS version 2.2.

Results: A total of 73 patients were included, with a mean age at diagnosis of 27 years (range 18–62), and a predominance of males (60.3%). Most had good functional status (ECOG 0–1 in 93%) and low comorbidity burden (HCT-CI = 0 in 72.6%). At diagnosis, 69.9% presented with advanced-stage disease (Ann Arbor III–IV) and 79.5% had B symptoms. Extranodal involvement occurred in 49.3%, mainly in the mediastinum/lung and bone marrow. Nodular sclerosis was the predominant histological subtype (54.8%). The mean time from diagnosis to transplant was 30.3 months.
The most common frontline regimen was ABVD (79.5%); however, high rates of primary refractory disease (60.3%) and early relapse (<12 months) were observed (69.3%). Prior to transplant, 53.4% received brentuximab vedotin (BV) as bridging therapy, and 52.1% received BV as post-transplant consolidation, with an average of 10 total cycles.
Most patients underwent autologous transplantation (89.0%), with myeloablative conditioning in 91.8%. At day +100 post-transplant, 71.2% achieved complete metabolic response. During follow-up, 87.7% remained in complete remission. Five deaths (6.8%) were documented, mainly due to disease progression or leukemic transformation. With approximately 10 years of follow-up, the mean OS was 9.94 years (95% CI: 9.13–10.75), and the mean PFS was 9.18 years (95% CI: 8.33–10.03); the median was not reached for either outcome.

Conclusions:

Figure 1.

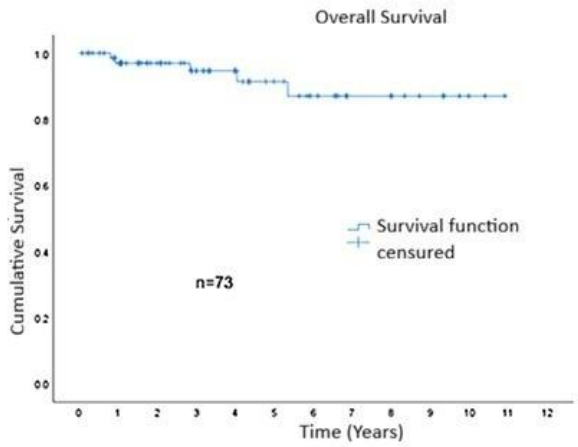

Figure 2.

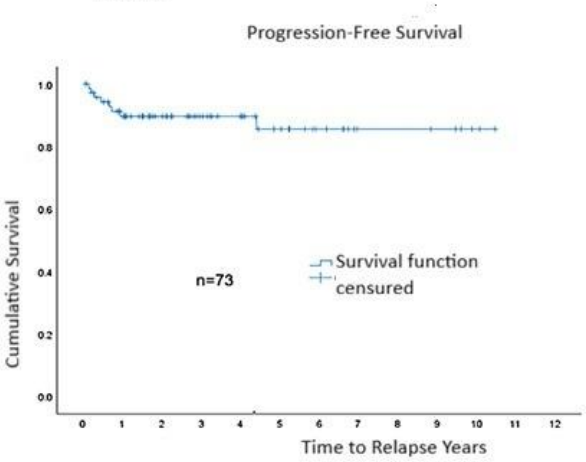

Despite a high proportion of advanced-stage disease, extranodal involvement, and early refractoriness, patients with Hodgkin lymphoma undergoing HSCT in this real-world cohort achieved highly favorable post-transplant outcomes. The incorporation of brentuximab vedotin as both bridging and consolidation therapy, along with appropriate patient selection, resulted in survival outcomes comparable to—or even superior to—those reported in international series. These findings reinforce the role of HSCT as an effective therapeutic strategy and underscore the importance of generating real-world evidence in Latin America'.

CD19 CAR-T THERAPY OUTCOMES IN OLDER ADULTS: A SINGLE-CENTER REAL-WORLD EXPERIENCE FROM ASIA

Lawrence Cheng Kiat Ng[1], *Kye Ling Wong*[1], *Nicole Ann Lim*[1], *Shin Yeu Ong*[1], *Chandramouli Nagarajan*[1], *Jeffrey Kim Siang Quek*[1], *Than Hein*[1], *Tertius Tansloan Tuy*[1], *William Ying Khee Hwang*[1], *Francesca Wei Inng Lim*[1], *Aloysius Yew Leng Ho*[1], *Yunxin Chen*[1]
[1]*Singapore General Hospital, Singapore, Singapore*

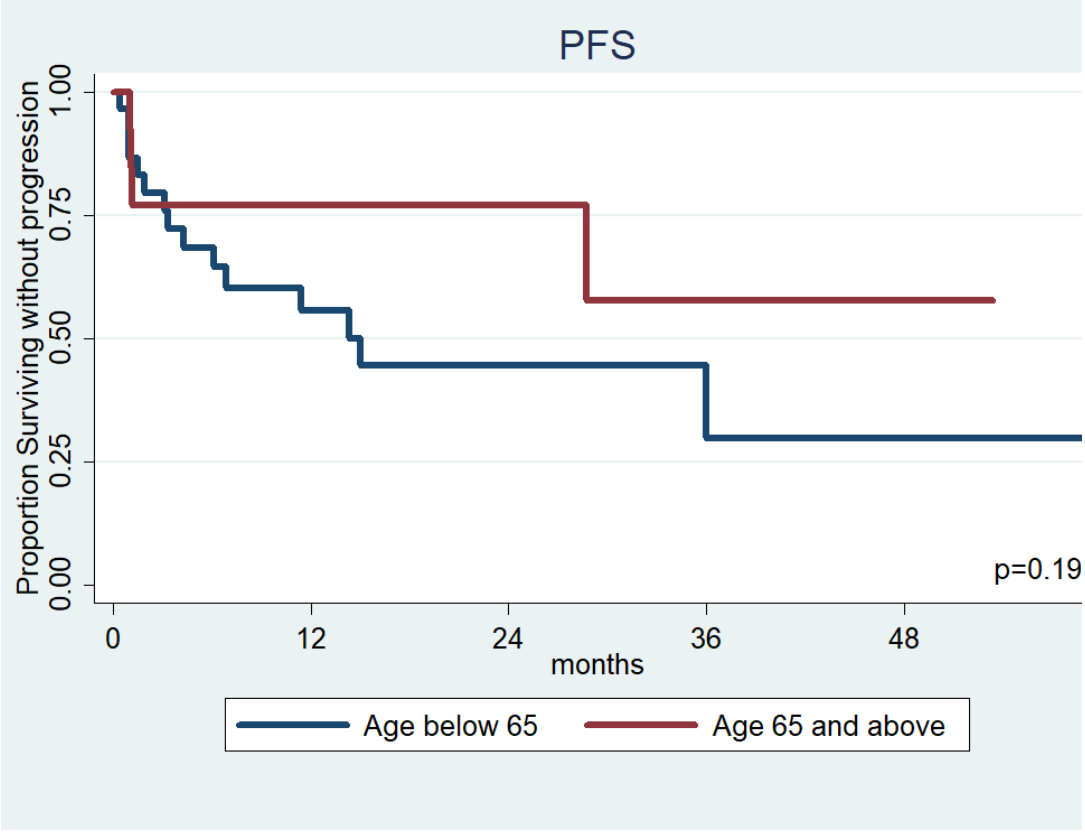
Background: CD19 CAR-T therapy shown promising results in patients with relapsed or refractory B-cell lymphoma, demonstrating durable responses and potential for cure. However, unique toxicities—including cytokine release syndrome (CRS), immune effector cell–associated neurotoxicity syndrome (ICANS), and an increased risk of infection—may limit its use in older adults. Several studies have highlighted the importance of geriatric and comorbidity assessments when managing CAR-T therapy in this population. In this retrospective study, we compared the outcomes of CAR-T therapy in patients aged 65 and older with those of patients younger than 65.

Methods: We retrospectively analyse data of patients underwent CD19 CAR-T therapy for lymphoma from the Singapore General Hospital CAR-T registry (2020-2025). Demographic data and CAR-T outcome from medical records were collected. Chi-squared and Fisher's exact two-sided tests were used to compare the categorical variables. Two-sided P-values of <0.05 were statistically significant. The survival probabilities, progression-free survival (PFS), and overall survival (OS) were calculated using the Kaplan-Meier estimator. Log-rank analysis was used to compare the different groups.

Results: A total of 43 patients were included in the analysis: 30 were aged <65 years, and 13 were aged ≥65 years. Baseline functional and comorbidity characteristics—including ECOG performance status, Karnofsky Performance Score (KPS), and Cumulative Illness Rating Scale (CIRS)—were similar between the two groups. All four mantle cell lymphoma patients who received Brexu-cel were age ≥65 years. The median number of prior lines of therapy was three in the younger cohort and two in the older cohort. Before CAR-T infusion, 67% of older adults and 69% of younger adults had stable or progressive disease.Regarding toxicities, there was a trend toward higher rates of ≥ grade 3 CRS and ICANS in younger adults compared with older adults (CRS: 10% vs 0%; ICANS: 23% vs 8%). Correspondingly, younger adults had a longer median hospitalization duration (22 days) than older adults (16 days). Grade ≥3 N-ICAHT occurred in 67% of younger adults and 46% of older adults, while ≥ grade 3 T-ICAHT was similar in both groups (31% vs 30%). Grade ≥3 infections occurred in 30% of younger adults and 46% of older adults. The 30-day readmission rates were similar between groups (13% vs 15%). Non-relapse mortality occurred in three younger adults (10%) and one older adult (8%).
With median follow-up of 12 months, younger adults had similar overall response (77%) and complete response (57%) rates compared with older adults (ORR 77%, CR 69%). The 12-month PFS were 55% in younger patients and 77% in older patients (p=0.19), whereas 12-months OS were 86% and 77% for younger adults and older adults, respectively (p=0.49).

Outcome of CAR-T		< 65-year-old (N=30)	%	≥ 65-year-old (N=13)	%	p-value
Median duration of hospitalization		22 days (16-53)		17 days (14-34)		
CRS	None	4	13	1		0.62
	Grade 1-2	23	77	12	92	
	Grade 3-4	3	10	0		
ICANS	None	18	60	10	77	0.60
	Grade 1-2	8	27	2	15	
	Grade 3-4	4	23	1	8	
No. of patients required anakinra		5	17	2	15	0.91

N-ICAHT	≥ Grade 3	20	67	6	46	0.21
T-ICAHT	≥ Grade 3	9	30	4	31	0.96
Infection (including CMV reactivation)	≥ Grade 3	9	30	6	46	0.31
Readmission within 30days		4	13	2	15	0.86



Conclusions: Patients with age 65 years and older experienced toxicity and efficacy outcomes comparable to those of younger patients, suggesting that age alone should not preclude access to CD19 CAR-T therapy. Geriatric assessment, comorbidity indices, and disease-burden biomarkers remain important considerations during patient selection. A prospective study incorporating geriatric assessment is currently underway at our institution to further elucidate the complex relationship between age-related risk and CAR-T outcomes.

DECEASED DONOR BONE MARROW TRANSPLANT: FIRST EVER HUMAN CASE REPORT OF SUCCESSFUL ENGRAFTMENT AFTER INFUSION OF A CRYOPRESERVED DECEASED DONOR BONE MARROW IN A PATIENT WITH AML

*Muneer Abidi[1], Josephine Emole[1], 3. Shatha Farhan[1], 4. Edward Peres[1], 5. Asif Alavi[1], 6. Nancy Mikulandric[1], 7. Klodiana Neme[1], Preethi Prasad[2], 9. Vicki Graves[2], Erik Woods[2], Scott Goebel[3], **Sagar Munjal**[2]*
[1]Henry Ford Cancer Center, Michigan, United States of America (the), [2]Ossium Health, San Fransisco, United States of America (the), [3]Indiana University of Indiana, Indianapolis, United States of America (the)

Background: Allogeneic hematopoietic cell transplantation (HCT) is a potentially curative therapy for a variety of hematologic diseases. Clinical data now confirm that T-cells contained within the donor graft exert a "graft- versus-malignancy" effect. Use of HLA-mismatched unrelated donors (MMUD) would greatly increase treatment options for all patients, but particularly for those who are ethnically diverse. Cryopreserved hematopoietic progenitor cell (HPC) marrow from deceased organ donors provides an "on-demand" HPC graft for patients without available living donors. Here we report the first human to be treated with unrelated, minimally manipulated allogeneic cryopreserved HPC marrow for hematopoietic reconstitution after reduced intensity conditioning. This marrow is processed through proprietary means from vertebral bodies of deceased organ donors.

Methods: A 68-year-old African American female patient with acute myeloid leukemia in CR1 was transplanted using cryopreserved HPC marrow from a cadaveric donor at Henry Ford Health, Detroit, MI. Prior to transplant the patient received fludarabine 30 mg/m^2 (Day -6 to Day -2), melphalan 140 mg/m^2 (Day -6) and TBI 2Gy in one fraction, as part of reduced intensity conditioning regimen. The transplant was approved by the local IRB. High resolution HLA matching between donor and recipient was 4/8. All organ function were reported to be in normal range and KPS score was 80%. Patient received 5.27x10^6 cryopreserved CD34$^+$ cells/kg. The infusion lasted for approximately 76 minutes. The HPC, marrow product infusion was uneventful. Graft-versus-host disease (GVHD) prophylaxis consisted of tacrolimus, mycophenolate mofetil and two doses of post-transplant cyclophosphamide (PTCy) at a dose of 50 mg/kg administered on Days +3 and +4.

Results: Neutrophil engraftment was reported on Day +16 (neutrophil count D+16- 570, D+17-1500, D+18-3690 cells/L) and platelet engraftment was reported on Day+ 21 (platelet count Day + 21-20,000, D+22-22,000, D+23-34,000 cells/L) post-transplant. Full blood donor chimerism was reported on Day +30. Bone marrow on Day +60 showed 100% donor chimerism.
Based on clinical suspicion, on Day +54 acute upper GI GVHD (Grade II, stage 1) was diagnosed. The acute GVHD is being treated with budesonide 3 mg by mouth daily and tacrolimus 2.5 mg twice daily, and her GVHD was well controlled. The patient subsequently

died on Day 282 from non-relapse causes, determined not to be related to HPC-marrow.

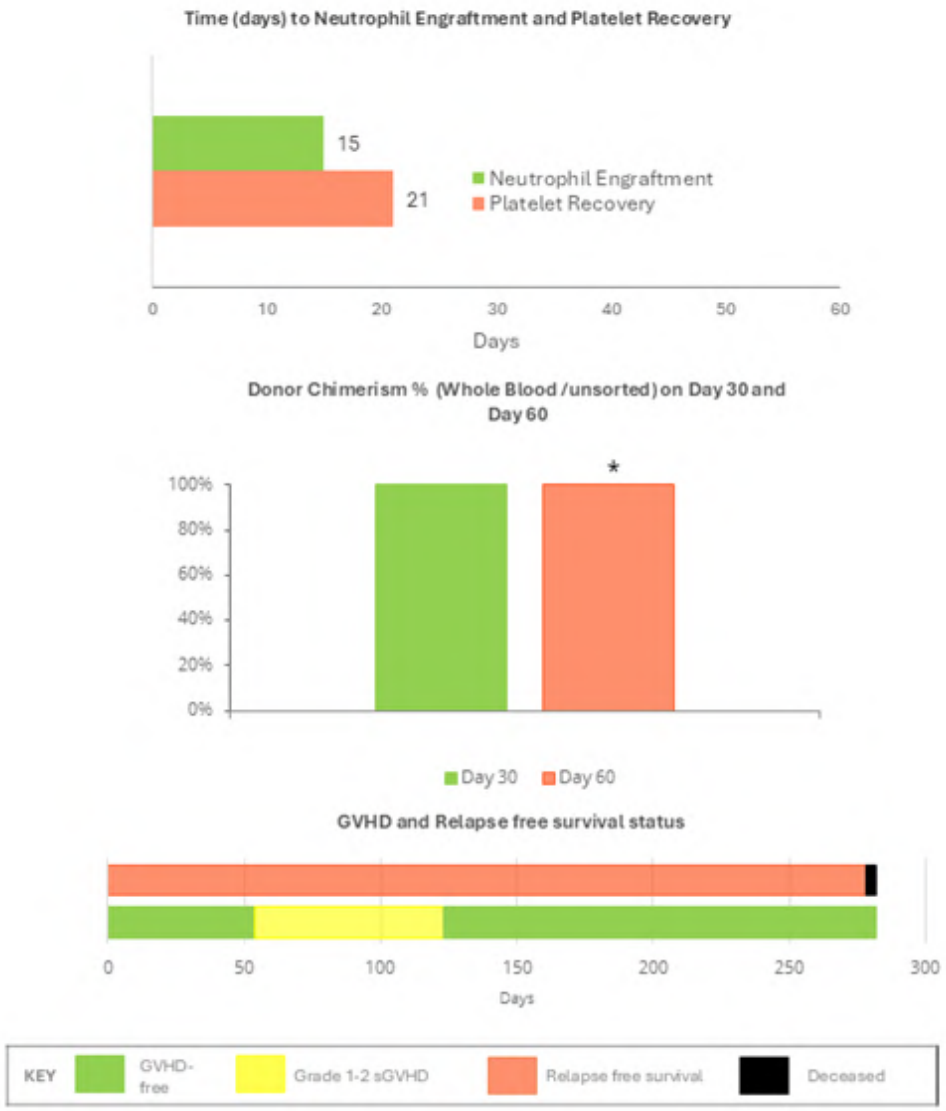

Fig 1: Patient safety journey, * Bone marrow chimerism

Conclusions: The successful engraftment in this case demonstrates the potential of cryopreserved HPC marrow from mismatched deceased organ donors as a viable option for HCT. HCT with a MMUD cryopreserved HPC marrow from a deceased organ donor can play a significant role in expanding access to HCT for patients who have unmet needs, and it can be made available "on demand". Clinical studies are currently being conducted to further evaluate the safety and effectiveness of a cryopreserved HPC marrow product.

P030

COMPARATIVE EFFECTIVENESS OF RATG, PTCY, AND CNI/MTX FOR GVHD PROPHYLAXIS IN MATCHED SIBLING AND UNRELATED DONOR TRANSPLANTATION

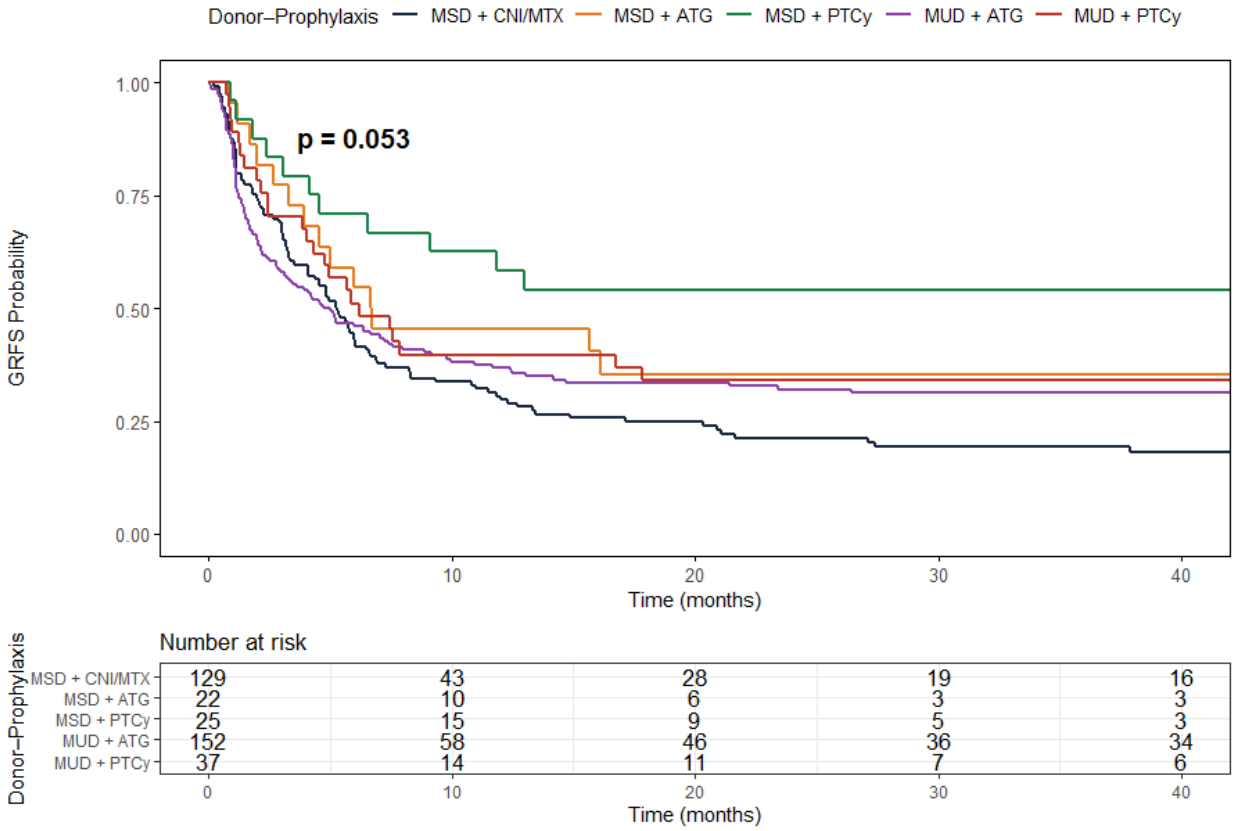
Gonzalo Bentolila[1], *Cristian Rodriguez*[2], *Jorge Arbelbide*[3], *Georgina Bendek*[4], *Gonzalo Ferini*[3], *Mercedes Garcia*[2], *Juliana Martinez Rolon*[1], *Ana Lisa Basquiera*[2]
[1]*Fundacion contra la Leucemia (FUNDALEU), Ciudad Autonoma de Buenos Aires, Argentina,* [2]*Hospital Privado Universitario de Córdoba-Instituto Universitario de Ciencias Biomédicas de Córdoba, Ciudad de Cordoba, Argentina,* [3]*Hospital Italiano, Ciudad Autonoma de Buenos Aires, Argentina,* [4]*Hospital Italiano, San Justo, Argentina*

Background: Graft-versus-host disease–free, relapse-free survival (GRFS) provides an integrated measure of post-transplant tolerance in hematologic malignant diseases. Although several GVHD-prophylaxis strategies are widely used, their comparative effectiveness across donor types remains uncertain. We aimed to determine whether CNI/MTX, PTCy, or rATG differentially influence GRFS and major transplant outcomes in matched sibling (MSD) and unrelated donors (MUD).

Methods: We conducted a multicenter cohort study of adults undergoing first allogeneic transplantation between 2017–2024 across three Argentine centers (n=365; median follow-up 44 months). Five donor–prophylaxis strategies were evaluated: MSD–CNI/MTX, MSD–rATG, MSD–PTCy, MUD–rATG, and MUD–PTCy. The primary endpoint was GRFS. Secondary endpoints included relapse, non-relapse mortality (NRM), acute and chronic GVHD, and the proportion of patients achieving ≥90 consecutive days free of systemic immunosuppression (IS-free ≥90d). Multivariable Cox and Fine–Gray models adjusted for age, DRI, HCT-CI, conditioning intensity, donor age/sex, graft source, and CD34 dose.

Results:

Marked heterogeneity was observed among MSD cohorts: MSD–ATG was enriched for myelofibrosis, MSD–PTCy included younger recipients with diverse malignancies, and MSD–CNI/MTX showed the broadest diagnostic distribution. Conversely, MUD–rATG and MUD–PTCy were clinically comparable.
GRFS did not differ significantly across strategies (log-rank p=0.053). MSD–PTCy was the only regimen independently associated with improved GRFS (HR 0.47 vs MSD–CNI/MTX). Age ≥60 years (HR 1.51) and high/very-high DRI (HR 1.43) were adverse predictors.
No prophylaxis strategy was independently associated with NRM in multivariable Fine–Gray models. Relapse differences across strategies were also non-significant, although MSD–CNI/MTX and MUD–PTCy exhibited numerically higher hazards. High/very-high DRI remained the only independent predictor of relapse (HR 1.59; p=0.035).
In a pooled comparison of rATG versus PTCy, ATG showed a non-significant trend toward higher NRM (HR 2.20; p=0.11) but was associated with significantly lower relapse (HR 0.53; p=0.03). In this subanalysis, relapse risk further increased among patients with high/very-high DRI (p=0.0013) and with HCT-CI ≥3 (p=0.0093).
Acute GVHD II–IV occurred in 16–38%, with no independent association with prophylaxis strategy or sex-match category. Moderate-to-severe chronic GVHD showed a non-significant reduction with MSD–PTCy (sHR 0.14; p=0.052) and MSD–rATG (sHR 0.20; p=0.11). Female donor grafts were strong independent predictors of moderate-to-severe cGVHD (female→female: sHR 2.81; p=0.018; female→male: sHR 2.68; p=0.014).
IS-free ≥90d was more frequent in MSD–PTCy and MSD–rATG (27–40%) compared with MSD–CNI/MTX and both MUD strategies (6–24%).



Conclusions: Profound baseline imbalance among MSD cohorts limits direct comparison of prophylaxis strategies and likely underlies the variability in GRFS, relapse, NRM, and IS-free outcomes. In contrast, the close clinical alignment of MUD–rATG and MUD–PTCy yielded virtually indistinguishable results across all endpoints, suggesting functional equivalence in unrelated donor transplantation. Across analyses, disease-risk level and comorbidity burden—not prophylaxis choice—were the dominant determinants of relapse and GVHD-related morbidity.

Disclosure: Nothing to declare for all authors.

P031

EFFICACY OF ROMIPLOSTIM ON HASTENING PLATELET COUNT RECOVERY IN POST-TRANSPLANT PATIENTS: A SINGLE-CENTER EXPERIENCE

N Kaushik[1], *Sanjukta S. Rao*[1], *Chaitanya H. Balakrishnan*[1], *Cecil R. Ross*[1], *Michael Pais*[1], *TV Ruthvik*[1], *B Madhupriya*[2], *Seetharam Anandram*[1], *Ganapathiearaman Ramakrishnan*[1]
[1]*St John's Medical College Hospital, Bengaluru, India,* [2]*Kempegowda Institute of Medical Sciences, Bengaluru, India*

Background: Prolonged thrombocytopenia following hematopoietic stem cell transplantation (HSCT) increases bleeding risk and healthcare burden. Romiplostim, a thrombopoietin receptor agonist, has shown potential in accelerating platelet recovery. However, data on its efficacy in the post-transplant setting remains limited. To evaluate the efficacy of romiplostim in shortening the duration of thrombocytopenia in patients undergoing peripheral blood stem cell transplantation.

Methods: We conducted a retrospective cohort study comparing 33 consecutive patients who received romiplostim (2-3 mcg/kg between D+5 to D+10) following HSCT at our center (March 2023–October 2025) with 23 historical controls transplanted prior to March 2023 without romiplostim. The cohort included 21 autologous and 12 allogenic transplants in cases, and 13 autologous and 10 allogenic in controls. We excluded patients at high risk of veno-occlusive disease. Primary endpoint was platelet engraftment (first of two consecutive platelet counts >20,000/μL, unsupported). Subgroup analyses were performed by disease category (plasma cell dyscrasia, lymphoma), conditioning intensity (MAC, RIC), and donor status (matched, haploidentical). Statistical analysis used Mann-Whitney U test with significance at $p<0.05$.

Results: Baseline characteristics were comparable between groups (age: 47.3±14.3 vs 43.1±12.9 years, p=0.261; male sex: 57.6% vs 69.6%, p=0.412). Median time to platelet engraftment was 11.5 days (IQR 11.0–13.2) in the romiplostim group versus 12.0 days (IQR 10.0–15.0) in controls (p=0.630). Mean engraftment time was 12.75±3.70 vs 13.17±4.00 days (mean difference: 0.42 days, 95% CI: -1.65 to 2.50). Subgroup analyses showed no significant differences in plasma cell dyscrasias (11.0±1.2 vs 10.4±2.0 days, p=0.328), lymphoma (13.5±2.4 vs 15.8±1.5 days, p=0.180), autologous (11.5±1.8 vs 12.1±3.1 days,

p=0.801), or allogenic transplants (15.2±5.1 vs 14.6±4.7 days, p=0.697). Notably, later engraftment (>14 days) occurred in 15.6% of romiplostim patients versus 30.4% of controls (OR=0.42, p=0.208).

Study Population Characteristics

Variable	Romiplostim (n=33)	Control (n=23)	p-Value	Test
Age (years)	47.3±14.3 / 49 (21-75)	43.1±12.9/45(19-67)	0.261	Mann-Whitney U
Sex (M/F)	19 (57.6%) / 14 (42.4%)	16(69.6%)/7(30.4%)	0.412	Fisher's Exact
Transplant Type	Auto:21(63.6%)/Allo:12(36.4%)	Auto:13(56.5%)/Allo:10(43.5%)	0.796	Chi-square
Plasma Cell Dyscrasia	17 (51.5%)	9 (39.1%)	----	----
Lymphoma	4 (12.1%)	4 (17.4%)	----	----
Other (AML/MDS/CML)	12 (36.4%)	10 (43.5%)	----	----
Conditioning (Allo only)	MAC: 7(58.3%)/RIC:5(41.7%)	MAC:3 (30.0%)/RIC:7(70.0%)	0.231	Fisher's Exact
Donor: Matched	5 (41.7%)	8 (80.0%)	---	-----
Donor: Haploidentical	7 (58.3%)	2 (20.0%)	---	-----

Age shown as Mean ± SD / Median (Range); Auto=Autologous, Allo=Allogenic, MAC=Myeloablative, RIC=Reduced Intensity

Conclusions: Romiplostim administration (2-3 mcg/kg, D+5 to D+10) did not significantly hasten platelet engraftment in this cohort. None of the patients experienced any adverse effects from romiplostim. However, amongst patients who had a later engraftment, there was a trend toward benefit from romiplostim. Given that romiplostim appears safe in the immediate post-transplant period, we propose larger, prospective ,randomized trials to assess its utility and define its role in this setting.

ANALYSIS OF GRAFT-VERSUS-HOST DISEASE–FREE, RELAPSE-FREE SURVIVAL (GRFS) IN ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR MYELOID MALIGNANCIES

Minia Grobas Sebio[1], *Natalia López Esteban*[1], *Carol Herrera Hernández*[1], *María del Mar Perera Álvarez*[1], *Leslie González Pinedo*[1], *Jorge Gayoso Cruz*[1], *Melissa Karina Torres Ochando*[1], *Alejandro Morales Curbelo*[1], *Concepción Sánchez Chamizo*[1], *Amagoia Ruiz Martín*[1], *Raquel García-Talavera Hernández*[1], *Guillermo Rodriguez Rodriguez*[1], *Mónica Betancor Pérez*[1], *José Antonio Moreno García*[1], *María Teresa Gómez Casares*[1]
[1]*HUGCDN, Las Palmas de Gran Canaria, Spain*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is a standard curative treatment for myeloid malignancies, although its effectiveness may be limited by relapse-related and treatment-associated morbidity and mortality. Severe graft-versus-host disease (GVHD) significantly impairs long-term quality of life in survivors, a dimension not adequately captured by overall survival (OS). In this context, graft-versus-host disease–free, relapse-free survival (GRFS), as a composite endpoint integrating treatment-related mortality, relapse, and severe GVHD, provides a comprehensive assessment of clinical benefit and a reliable criterion for risk estimation and long-term quality of life in transplant candidates. The aim of this study was to assess the clinical benefit of allo-HSCT using GRFS, thereby evaluating transplant success in terms of long-term quality of life.

Methods: A retrospective observational analysis was conducted in patients with myelodysplastic syndrome (MDS) and acute myeloid leukemia (AML) who underwent a first allo-HSCT at a tertiary-care center between January 2018 and May 2025. GRFS events were defined as grade ≥3 acute GVHD, severe chronic GVHD, disease relapse, or death from any cause. Descriptive statistics were summarized using measures of central tendency; risk associations were evaluated using the χ^2 test; and event-free survival was assessed using Kaplan–Meier methodology

Results:

Table 1: Cohort Characteristics

Sex	*Male n (%)*	80 (46.8%)	**Conditioning Regimen**	*Non-myeloablative n (%)*	47 (28%)
	Female n (%)	91 (53.2%)		*Myeloablative n (%)*	121 (72%)

Diagnosis	*AML n (%)*	116 (67.8%)	**EBMT Risk Score**	*Low n (%)*	104 (66.7%)
	MDS n (%)	55 (32.2%)		*Intermediate n (%)*	22 (14.1%)
Disease Status Pre-HSCT	*Persistent disease n (%)*	54 (32.9%)		*High n (%)*	30 (19.2%)
	Complete response n (%)	110 (67.1%)			
AML Disease Status Pre-HSCT	*First complete remission n (%)*	93 (90.3%)	**ECOG**	*0 n (%)*	130 (81.3%)
	Second or subsequent remission n (%)	10 (9.7%)			
Transplant Type	*HLA-identical related donor n (%)*	66 (38.6%)		*1 n (%)*	26 (16.2%)
	Matched unrelated donor (10/10) n (%)	27 (15.8%)		*≥ 2 n (%)*	4 (2.5%)
	Matched unrelated donor (9/10) *n (%)*	5 (2.9%)	**Karyotype**	*No complex (%)*	125 (87.4%)
	Haploidentical n (%)	73 (42.7%)		*Complex (%)*	18 (12.6%)
Stem Cell Source	*Peripheral blood n (%)*	169 (99.4%	**Transplant-related complications**	*Hemorrhagic cystitis n (%)*	18 (10.6%)
	Bone marrow	1 (0.6%)		*VOD n (%)*	13 (7.6%)

A total of 171 allo-HSCT recipients were analyzed; 67.8% had AML and 32.2% had MDS. The median follow-up was 18.2 months (IQR, 7.2–38.2). The median age was 56 years (19–73). Donor types included haploidentical (42.7%), HLA-identical related (38.6%), 10/10 matched unrelated donor (15.8%), and 9/10 matched unrelated donor (2.9%). All patients received GVHD prophylaxis with post-transplant cyclophosphamide, tacrolimus, and mycophenolate. Clinical and transplant characteristics are detailed in Table 1.

At the median follow-up, GRFS was 65.4%, with death representing the most frequent cause of GRFS failure (45.7%) (Figure 1). GRFS declined to 63.1% at 24 months, coinciding with a 6.3% absolute increase in relapse, and further decreased to 59.1% at 30 months; although death remained the most frequent cause of GRFS failure, this additional decline was associated with a 3.2% absolute increase in severe GVHD.
GRFS differed significantly between AML and MDS in the overall analysis ($p = 0.02$) (Figure 1); however, the marked differences in age distribution between both groups suggest a potential influence of age on GRFS outcomes.
In the overall cohort, at the median follow-up, GRFS was 70.6% in AML and 56.3% in MDS, with treatment-related mortality being the most prevalent event in both groups (38.2% and 54.1%, respectively). At 24 months, treatment-related mortality remained predominant in MDS (56%), whereas relapse increased in AML (35.1%). At 30 months, higher mortality persisted in MDS (55.5%), while relapse and severe GVHD were more frequent in AML (35.7% and 33.3%, respectively).

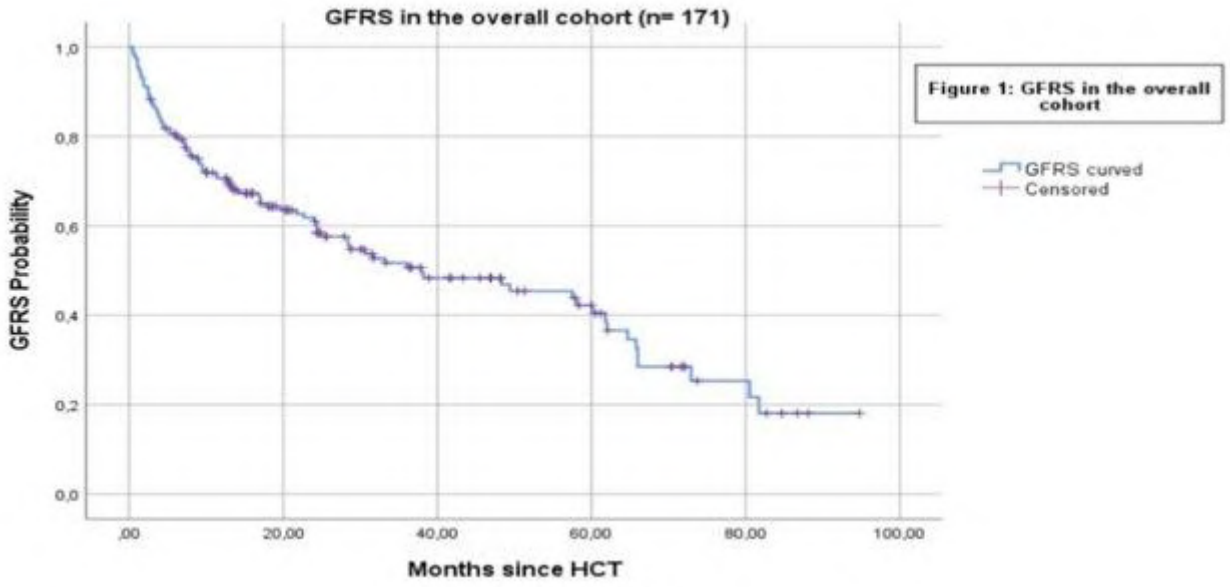

Figure 1: GFRS in the overall cohort

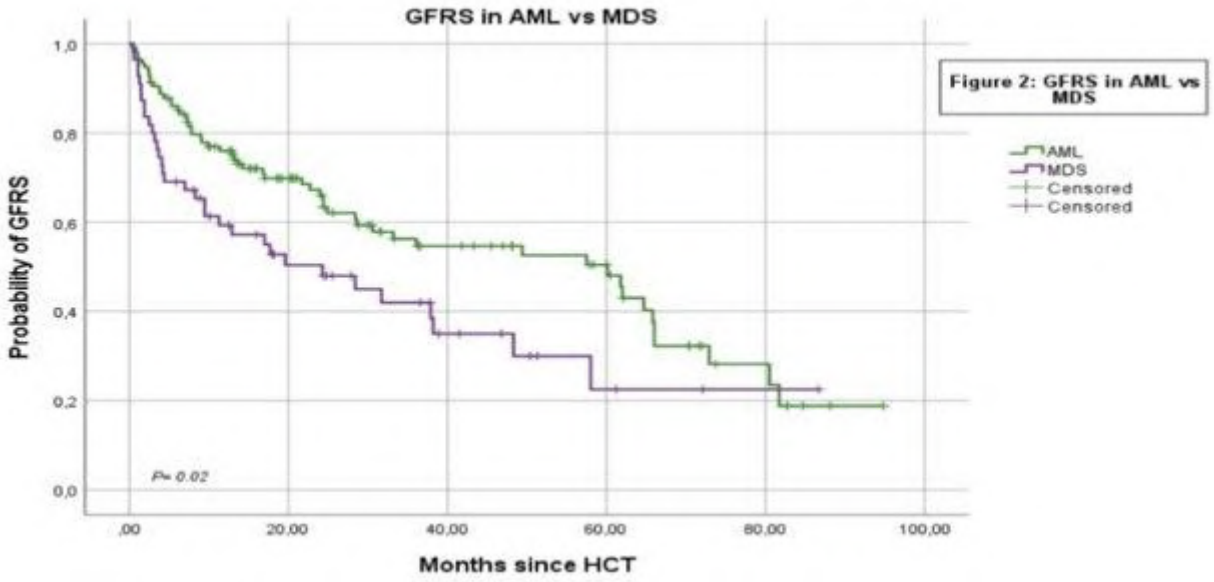

Figure 2: GFRS in AML vs MDS

Conclusions: GRFS declined progressively during follow-up, with treatment-related mortality remaining the leading cause of failure and an increasing late contribution of relapse and severe GVHD. Although overall GRFS differences between AML and MDS may be influenced by age, GRFS enabled an integrated assessment of post-transplant events, reaffirming its value as a clinically relevant endpoint in allo-HSCT.

Disclosure: Nothing to declare.

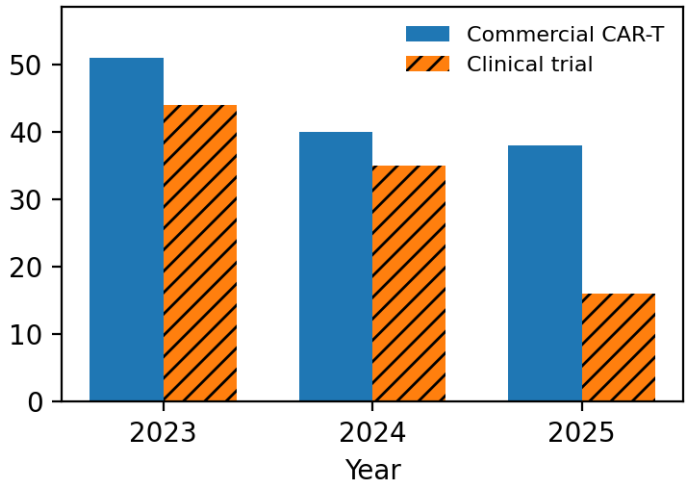
Dr. Negrín, Las palmas de gran Canaria, Spain,* [12]*Centro Vasco de Transfusión y Tejidos Humanos, Vitoria, Spain,* [13]*Hospital Infantil Universitario Niño Jesús, Madrid, Spain,* [14]*Hospital Universitario Central de Asturias, Oviedo, Spain,* [15]*Centro Regional de Hemodonación, Murcia, Spain,* [16]*Hospital Virgen del Rocio, Sevilla, Spain,* [17]*CTTC Málaga, Malaga, Spain,* [18]*Centro Hospitalario Ramón y Cajal, Madrid, Spain,* [19]*Centro Regional Transfusión Sanguínea de Granada, Granada, Spain,* [20]*Centro de Transfusión de la Comunidad Valenciana, Valencia, Spain*

Background: Cryopreserved leukapheresis has become an established option for modern CAR-T cell manufacturing, ensuring product stability and enabling flexible logistics without compromising clinical outcomes. In Spain, Kymriah® (tisagenlecleucel) and Novartis clinical-trial platforms mandate cryopreservation at hospital-based cell-processing laboratories. Despite its widespread use, national real-world data describing the magnitude and temporal evolution of this activity are lacking.

Methods: The Spanish Society for Blood Transfusion and Cellular Therapy (SETS) Working Group on Cellular Processing and Advanced Therapies conducted a nationwide survey assessing cryopreserved leukapheresis activity for both commercial (Kymriah®) and clinical-trial CAR-T manufacturing over the last three years. The study included all authorized cell-processing centers in Spain, ensuring comprehensive national coverage.

Results: Nineteen centers responded to the survey. Six centers reported no cryopreservation activity and were therefore excluded from **Figure 1**, which summarizes activity only from the 13 centers that confirmed performing cryopreserved leukapheresis. Among active centers, five performed cryopreservation exclusively for Kymriah®, while eight supported both commercial and clinical trial CAR-T programs. From 2023 to 2025, cryopreservation volumes decreased by 25**%** for commercial CAR-T manufacturing and by 64**%** for clinical-trial CAR-T manufacturing (**Figure 1**).



Conclusions: Cryopreserved leukapheresis represents a core competency of Spanish cell-processing laboratories and a critical component of CAR-T manufacturing logistics. The observed decline in activity may reflect the higher complete responses reported with alternative anti-CD19 CAR-T constructs compared with Kymriah® in aggressive B-cell non-Hodgkin lymphoma. The decline in clinical-trial cryopreservation activity may be partly explained by the completion of recruitment in Novartis lymphoma programs in 2024, together with a shift in ongoing Novartis CAR-T trials toward other indications (e.g., autoimmune diseases) that typically enroll smaller cohorts. This trend highlights evolving clinical practice, changes in CAR-T program dynamics, and the importance of continued national monitoring to appropriately adapt capacity and resource allocation.

Clinical Trial Registry: Not applicable

P036

PERICATHETER AND SYSTEMIC THROMBOSIS DURING CAR-T LYMPHOCYTAPHERESIS: INCIDENCE AND CLINICAL CORRELATES

*Ilaria Pansini[1,2], **Eugenio Galli**[2], Alessandro Corrente[1], Nicola Piccirillo[1,2], Marcello Viscovo[1,2], Stefan Hohaus[1,2], Patrizia Chiusolo[1,2], Federica Sorà[1,2], Simona Sica[1,2]*
[1]Università Cattolica del Sacro Cuore, Rome, Italy, [2]Fondazione Policlinico Universitario Agostino Gemelli, Rome, Italy

Background: Pericatheter thrombosis (PCT) is a recognised complication of large-bore venous catheters used for cell collection. An incidence of local thrombotic occlusion of approximately 1.8% has been described in literature for Mahurkar catheters used in peripheral blood stem cell collection. Despite these devices being widely used in chimeric

antigen receptor t (CAR-T) cell manufacturing, the incidence and determinants of PCT in this setting are still unclear. This study provides a real-world evaluation of PCT in patients undergoing lymphocytapheresis for CAR-T therapy. The aim is to characterise thrombotic events and explore potentially relevant clinical or procedural factors.

Methods: A retrospective, single-centre analysis was conducted on 158 adults evaluated for CAR-T therapy between September 2019 and October 2025. Of these patients, 62 who underwent lymphocytapheresis using a Mahurkar catheter were included in the analysis. The underlying diseases were large B-cell lymphoma (79.0%), mantle cell lymphoma (9.7%) and B-cell acute lymphoblastic leukaemia (11.3%). Clinical, laboratory, and procedural variables were collected at the time of catheter placement. Two predefined analytical strategies were employed: (1) comparison of patients with pericatheter thrombosis (PCT) versus all other patients (with or without thrombosis at distant sites); and (2) comparison of patients with any thrombotic event (PCT or distant thrombosis) versus those with no thrombosis. Continuous variables (age, platelet count, haemoglobin, white blood cell count, fibrinogen and D-dimer) were analysed using a Student's t-test, while categorical variables (sex, disease status, lactate dehydrogenase -LDH- level above or below the laboratory limit, Khorana score, anticoagulation, catheter site and procedural difficulty) were analysed using a chi-squared test or Fisher's exact test, as appropriate.

Results: PCT occurred in 5 out of 62 patients (8%). An additional 8 patients (13%) developed thrombosis at non-catheter sites, for a total of 13 thrombotic events (21%). No continuous variable was associated with PCT, although platelet count showed a borderline trend ($p = 0.061$). Procedural difficulty was more frequent in PCT cases (66% vs. 18%), though this was not statistically significant after Yates's correction. Sex, LDH, Khorana score, anticoagulation, disease status, catheter site and other laboratory parameters showed no association with PCT. In the overall thrombosis analysis, no clinical or laboratory variable reached statistical significance, with platelet count again demonstrating a borderline trend ($p = 0.098$).

Conclusions: The main finding of this study was that PCT during lymphocytapheresis for CAR-T manufacturing was more frequent than had been reported in historical series of Mahurkar catheters used for peripheral blood stem cell collection. Within the analysed population, no baseline clinical or laboratory variable was found to be associated with an increased risk of thrombosis. This suggests that CAR-T candidates undergoing lymphocytapheresis have a relatively homogeneous thrombotic risk profile. These observations highlight the need for comparative analyses with patients undergoing haematopoietic stem cell apheresis to determine whether the higher incidence observed reflects factors related to the procedure, the disease, or the population.

Disclosure: Nothing to declare.

P038

T-CELL ACUTE LYMPHOBLASTIC LEUKEMIA RELAPSE AFTER CAR-T THERAPY

Antonella Zanette[1,1], *Mariane Caleffi*[1], *Ana Luiza de Melo Rodrigues Teixeira Rodrigues Teixeira*[1], *Miriam Perlingeiro Beltrame*[1], *Afonso Pereira Leite Neto*[2], *Maria Luiza Lima Coelho Brito*[1]
[1]*Hospital Erastinho, Curitiba, Brazil,* [2]*Hospital das Clínicas Primavera, Campo Grande, Brazil*

Background: Tisagenlecleucel (formerly CTL019), an anti-CD19 chimericantigen receptor (CAR) T-cell therapy, is an establishedtreatment for pediatric patients with relapsed or refractory B-cell acute lymphoblastic leukemia (B-ALL). Although most studies demonstrate high remission rates following CAR-T cell infusion, long-term outcomes, including relapse patterns, are still being evaluated. Likewise, the role of hematopoietic stemcell transplantation (HSCT) after CAR-T therapy remains under investigation, with some studies suggesting improved survival when both strategies are combined.
Recently, an increasing number of secondary T-cell malignancies have been reported following CAR-T cell infusion, with an estimated incidence ranging from 0.03% to 0.1%.

Methods: We report the case of a patient with refractory ALL treated with CAR-T cell therapy. After disease relapse following the first CAR-T infusion, a second CAR-T was administered as a bridge to HSCT. Unfortunately, the patient subsequently developed T-cell acute lymphoblastic leukemia (T-ALL) after CAR-T therapy.

Results: A 16-year-old patient was diagnosed with B-ALL, with a normal karyotype, no central nervous system involvement, and no detectable molecular abnormalities. The disease was refractory to conventional chemotherapy. Prior to CAR-T therapy, the patient received multiple chemotherapy regimens, including RE-ALL (with a measurable residual disease [MRD] of 38.36% at the end of induction phase 2), cytarabine and etoposide, hyper-CVAD, and blinatumomab (post-treatment bone marrow MRD of 59.7% blasts). The final salvage regimen consisted of topotecan, which achieved the best disease control, with a pre-CAR-T MRD of 3.8%. The patient underwent lymphodepletion with fludarabine (120 mg/m²) and cyclophosphamide (1000 mg/m²), followed by the first CAR-T cell infusion. Post-infusion bone marrow evaluations were initially negative; however, three months after the infusion, the patient relapsed. The topotecan regimen was repeated, and a second CAR-T cell infusion was administered. On day +14 after the second CAR-T, blasts were detected by peripheral blood immunophenotyping. A new treatment regimen with vincristine and PEG-asparaginase was initiated, followed by three doses of inotuzumab. After inotuzumab, the patient achieved bone marrow remission and proceeded to HSCT. A haploidentical HSCT from his sister was performed on February 28, 2025, using a Cy-TBI conditioning regimen. Initial post-transplant bone marrow evaluation was negative; however, on day +100, the patient experienced another relapse, with MRD of 40.6% blasts of T-cell lineage.
Currently, six months after relapse, the patient remains on low-dose methotrexate and mercaptopurine, with no blastos on peripheral blood and stable clinical status.

Conclusions: Delays between CAR-T cell therapy indication and infusion may increase relapse risk, particularly in low- and middle-income countries. These data support the

integration of systematic relapse surveillance into post-CAR-T follow-up protocols. Ongoing vigilance by flow cytometry laboratories is crucial for the early identification of lineage switch, including the emergence of T-lineage blasts.

IMMUNE RECONSTITUTION AND INFECTIOUS COMPLICATIONS IN PATIENTS UNDERGOING CAR-T CELL THERAPY: A REAL-WORLD SINGLE-CENTER EXPERIENCE

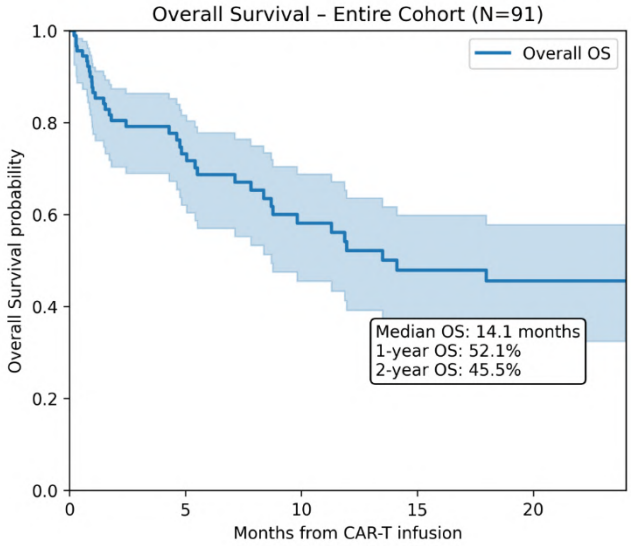
Virginia Naso[1], Filippo Antonio Canale[1], Giorgia Policastro[1], Gaetana Porto[1], Barbara Loteta[1], Andrea Rizzuto[1], Marta Pugliese[1], Erica Bilardi[1], Massimo Martino[1], ***Maria Caterina Mico'***[1]
[1]*Grande Ospedale Metropolitano Bianchi Melacrino Morelli, Reggio Calabria, Italy*

Background: Real-world data on overall survival (OS), non-relapse mortality (NRM), infections, and immune reconstitution after chimeric antigen receptor T-cell (CAR-T) therapy for lymphoma, multiple myeloma (MM), and acute lymphoblastic leukemia (ALL) remain limited, with most evidence from clinical trials. We present a single-center Italian experience with commercial CAR-T products in adults treated from 2020 to 2025, focusing on outcomes, early mortality, infections, and post-infusion immune deficits.

Methods: This retrospective observational , single center, study included 91 adults patients (median age 61 years; 73% male) affected by different hematologic malignancies: diffuse large B-cell lymphoma (DLBCL, 65%), mantle cell lymphoma (MCL, 11%), MM (14%), primary mediastinal B-cell lymphoma (PMBCL, 4%), follicular lymphoma (FL, 2%), and ALL (3%). The first patient with MM was treated only in November 11, 2024. The median follow-up time was 56.1 days in MM patients, 147 days in lymphoma patients, and 155 days in leukemia patients. Most patients (86%) had ECOG 1 performance status; 32% had prior autologous stem cell transplant (auto-SCT). Bridging therapy (62%) yielded complete response (4%), partial response (19%), stable disease (18%), or progression (45%). We assessed OS, NRM (1-Kaplan-Meier), cytokine release syndrome (CRS)/ Immune effector cell–associated neurotoxicity syndrome (ICANS), cytopenias, infections, IV Immunoglobulin (IG) use, readmissions, relapses (38%), and immune reconstitution ($CD4^+$ T cells >200/μL; $CD19^+$ B cells).

Results: Over follow-up, 37% of patients died, for: progression (19%), CRS (4%), viral infections (3%). CRS occurred in 37% (grade 1: 55%; grade 2: 28%; max grade 5: 4%); ICANS was rare (74% none; grade 5: 1%). Cytopenias persisted in 19% at day +30, declining to 3% at day +365. IVIG post CAR-T was needed in 25 %; 25% of patients required readmission. Median OS was 14.1 months (1-year: 52%; 2-year: ~40%) (figure 1); median disease-free survival, 6.1 months. NRM was 11% at day +100 (stable at 1 year), all early events occured in lymphoma (8/75) and ALL (1/3); none in MM (but the first MM patient was infused on November 2024) . Infections affected 27% (25/91 patients; 30 episodes), clustering early (24/30 within 3 months). Documented etiologies (9 cases, all

lymphoma): bacterial (4), viral (3), CMV (2). Immune recovery was delayed: $CD4^+$ >200/µL was documented in only 15% of lymphoma patients (median 180 days), none in MM/ALL; $CD19^+$ B-cell recovery was rare in the first year after infusion. Poor $CD4^+$ reconstitution trended with NRM in lymphoma (not significant); prior auto-SCT and bridging may contribute.



Conclusions: In this real-world cohort, CAR-T yielded median OS of 14.1 months with low early NRM (11%), mainly in lymphoma/ALL. Infections peaked in the first 3 months amid hypogammaglobulinemia and delayed reconstitution, defining a high-risk window. These data advocate structured early surveillance, serial immune monitoring (e.g., $CD4^+$ counts), and tailored support (IVIG, prophylaxis), especially for lymphoma/ALL. Prior therapies warrant further risk stratification.

OUTCOMES OF CD19 CAR T-CELL THERAPY IN DOWN SYNDROME–ASSOCIATED B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: A THREE-PATIENT CASE SERIES FROM A CENTER IN THE MIDDLE EAST

Nourah Alzaidy[1], *Marwa Nassar*[1], *Mostafa F. Mohammed Saleh*[1], *Ahmed Kotb Abdrabou*[1], *Chokri Benlamine*[1], *Momen Nassani*[1], *Heba Madien*[1], *Samar Alfaqwai*[1], *Hanan Alkhaldi*[1], *Ahmed Alotaibi*[1], *Mansour Alfayez*[1], *Omar Albanyan*[1], *Ali Alahmari*[1], *Ayman Saad*[1], *Mahmoud Aljurf*[1], *Hazza Alzahrani*[1], *Syed O. Ahmed*[1], *Amr Hanbali*[1]
[1]*Adult Hematology, Stem Cell Transplant and Cellular Therapy Department, Oncology Center, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia*

Background: Children and adolescents with Down syndrome–associated acute lymphoblastic leukemia (DS-ALL) have unique therapeutic challenges, including heightened chemotherapy toxicity, increased treatment-related morbidity, and higher relapse risk. Data on the safety and efficacy of CD19 CAR T-cell therapy in this population remain limited. From King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia, we report a three-patient DS-ALL case series treated with tisagenlecleucel (tisa-cel), focusing on toxicity profile, MRD kinetics, and early outcomes.

Methods: Case descriptions:
Case 1: A 15-year-old male with Down syndrome (DS) was diagnosed with B-cell precursor ALL in 2019 and treated with AALL0932, later escalated to AALL1131 for persistent MRD. He attained MRD negativity during interim maintenance and completed therapy in February 2022. He relapsed 27 months later with 50% marrow blasts and received ALL-1331 salvage therapy (anthracycline-free), achieving <1% blasts but residual MRD (0.2%). Following T-cell apheresis and vincristine/dexamethasone/6-MP bridging, pre–CAR T marrow showed morphologic remission with MRD 0.28%. He received tisa-cel on 14 October 2025 after Flu/Cy conditioning, with no CRS or ICANS. Day +30 marrow showed MRD negativity (0.01%) and persistent B-cell aplasia. He remains clinically stable.
Case 2: A 15-year-old male with DS and congenital heart disease achieved MRD-negative remission on AALL0232 but relapsed in June 2025 with 48% blasts. Two doses of inotuzumab ozogamicin induced morphologic remission with MRD 0.75%. His chemotherapy course was complicated by acute necrotizing pancreatitis, a transient LV thrombus requiring anticoagulation, and pacemaker dependence. Despite vincristine bridging, pre–CAR T marrow remained MRD positive (1.2%). He received tisa-cel on 21 October 2025 without CRS or ICANS. Day +26 lymphocyte analysis confirmed B-cell aplasia. Post CAR T bone marrow showed hypocellularity with trilineage regeneration and immunophenotypic findings negative for definite MRD.
Case 3: An 18-year-old male with DS was diagnosed with B-ALL in October 2021 and received an MTX-free AYA protocol due to intolerance risk, achieving CR by day 27 and MRD negativity (0.1%) post-consolidation. Blinatumomab was unavailable, and he proceeded to delayed intensification with reduced-dose doxorubicin. Pre–CAR T evaluation in May 2022 showed MRD negativity and no CNS disease. He received tisa-cel on 22 May 2022, developing grade 2 CRS requiring tocilizumab and one neutropenic fever episode. He remained in remission with persistent B-cell aplasia through 2023 but developed progressive renal dysfunction and hydroureteronephrosis. Lost to follow-up after December 2023, he was later reported deceased in September 2025, with no evidence of relapse during documented care.

Results: Across the three DS-ALL patients, CAR T-cell infusion was feasible with no ICANS and limited CRS (only one grade 2 event). All patients achieved MRD-negative remission after tisa-cel with sustained B-cell aplasia during follow-up. Toxicities were primarily non–CAR T related and related to comorbidities.

Conclusions: Tisagenlecleucel demonstrated favorable tolerability and effective disease control in DS-ALL patients, with low neurotoxicity and consistent MRD clearance. This series highlights CAR T-cell therapy as a viable option for DS-ALL, a population historically vulnerable to chemotherapy-related toxicity. Larger studies are needed to define long-term outcomes.

AN UNSUPERVISED APPROACH TO PREDICTING EARLY POST-TRANSPLANT FEVER IN ADULTS WITH ACUTE MYELOID LEUKEMIA UNDERGOING ALLOGENEIC STEM CELL TRANSPLANTATION USING ROUTINE LABORATORY AND CLINICAL PARAMETERS

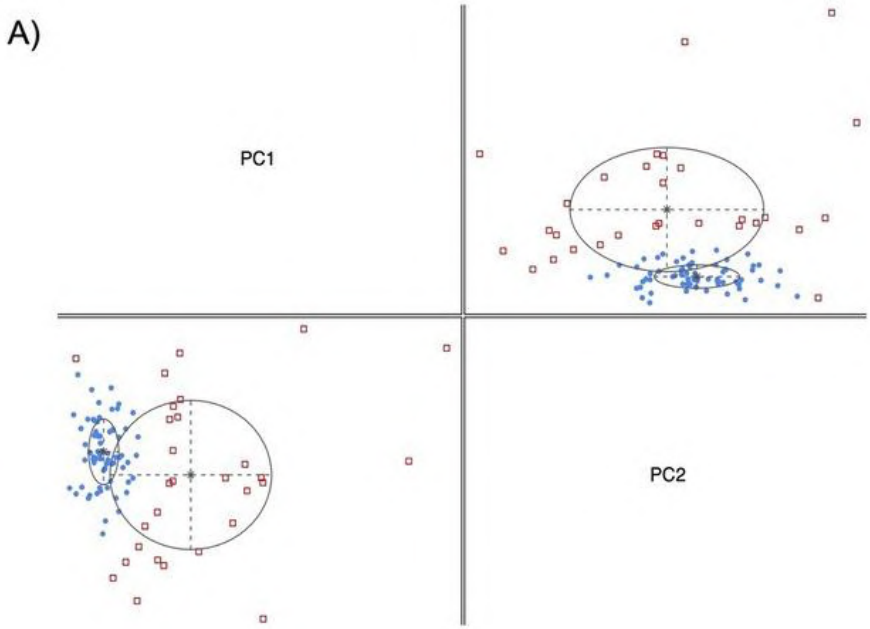
Jaromir Tomasik[1], *Kajetan Karaszewski*[1], *Agnieszka Tomaszewska*[1], *Piotr Boguradzki*[1], *Joanna Drozd-Sokołowska*[1], *Piotr Kacprzyk*[1], *Wiesław Wiktor Jędrzejczak*[1], *Grzegorz Basak*[1]
[1]*Medical University of Warsaw, Warsaw, Poland*

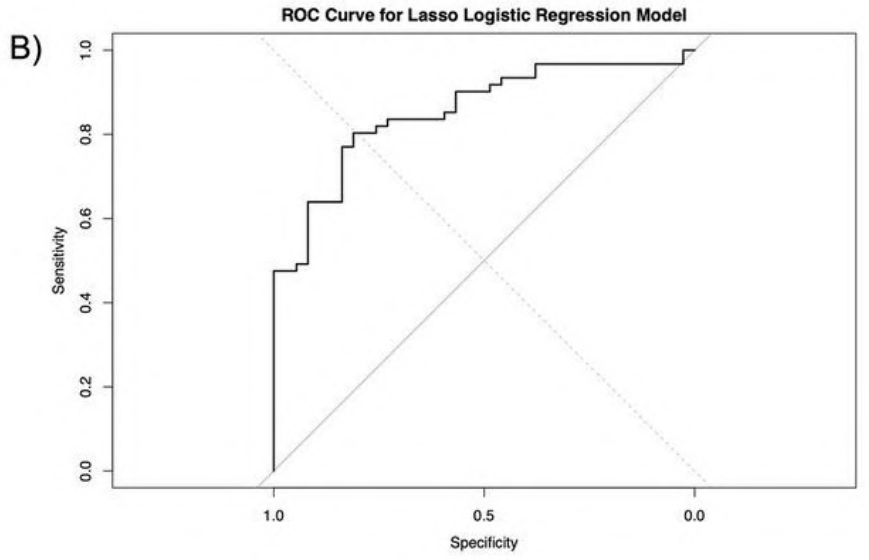
Background: Infections are among the leading causes of morbidity, ICU admission, and death after allogeneic stem cell transplantation (alloSCT) for acute myeloid leukemia (AML). Fever is a key sign of infection, but it also reflects non-infectious inflammation, while microbiological confirmation is often delayed. We hypothesized that an unsupervised, data-driven analysis of routine laboratory and clinical parameters could identify patients who will develop fever and help distinguish infectious from non-infectious causes of fever.

Methods: This study enrolled all adults with AML undergoing alloSCT treated in the years 2017-2024 in a single center (n=90). The primary outcome of interest was fever status in the post-transplant course: no fever (i); at least one episode of fever without microbiologically confirmed infection (ii), and fever with documented infection (iii). The observation window was day 0 to +30 after transplantation. For each patient, we extracted age and 37 routine clinical variables (vital signs, complete blood count, inflammatory markers, renal and liver function tests, glucose, and electrolytes) measured 2 days before fever onset (DAY-2) or the corresponding reference day in afebrile patients.
In the exploratory, unsupervised stage, we applied principal component analysis (PCA) for dimensionality reduction and to identify variables contributing most to overall variance. Model-based clustering (mclust) was applied in PCA space to find distinct clusters of patients. Subsequently, we checked the association of cluster allocation with the primary outcome. In the model-development stage, to obtain a clinically applicable prediction tool, we fitted a LASSO-penalized logistic regression model on non-transformed DAY-2 data. Model performance was assessed by receiver operating characteristic (ROC) analysis.

Results: Among the enrolled patients, the median age was 54 years, and 47% were male. Most patients received matched unrelated donor transplants (54%), followed by matched related donor (26%), mismatched unrelated donor (10%), and haploidentical (10%). Twenty-three percent of patients developed fever with documented infection, whereas 36% had microbiologically negative fevers. Remaining patients (41%) remained afebrile. Among these groups, we found no difference in transplant type distribution. Median time from alloSCT to fever onset was 9 days.
In the unsupervised phase, we found two separate clusters (Figure 1.A), one consisting of both afebrile and febrile patients, the second comprising exclusively fever-positive individuals

($p<0.05$). PCA-based clustering failed to discriminate patients based on fever origin. In the second phase, the final LASSO model retained five DAY-2 predictors: heart rate, C-reactive protein, neutrophil, monocyte, and platelet counts. The resulting logistic model showed good discrimination for subsequent fever, with an area under the ROC curve (AUC) of 0.85 (Figure 1.B). At the chosen decision threshold, sensitivity was 0.80, specificity 0.81, positive predictive value 0.88, and negative predictive value 0.71.





Conclusions: In this alloSCT AML cohort, multivariate analysis of routine laboratory and clinical data obtained two days before fever onset allowed accurate discrimination between patients with and without impending fever. However, discrimination between the cause at

DAY -2 was impossible. The presented approach could support closer surveillance, earlier blood culture ordering, and optimization of empirical antibiotics while awaiting microbiology results. However, these findings need validation in a larger, independent cohort before clinical application.

CLINICAL OUTCOMES FOLLOWING TREATMENT WITH CD19 CAR T-CELL THERAPY IN PATIENTS WITH DOWN SYNDROME-ASSOCIATED ALL: A SINGLE-INSTITUTION EXPERIENCE

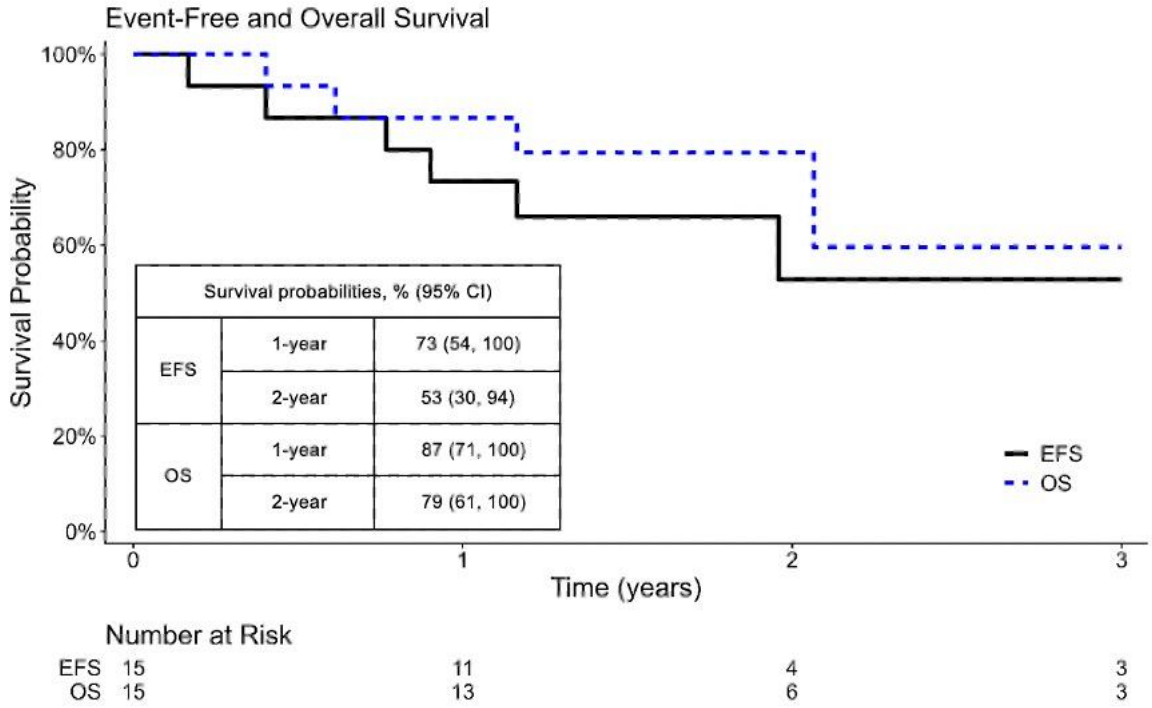
Brittany Ivory[1,2], *Chelsea Balian*[1], *Erica Ma*[1], *Veronica Terrones Hudson*[1], *Yueh-Yun Chi*[1,2], *Emily Hsieh*[1,2]
[1]*Children's Hospital Los Angeles, Los Angeles, United States of America (the),* [2]*Keck School of Medicine, University of Southern California, Los Angeles, United States of America (the)*

Background: Patients with relapsed or refractory Down syndrome-associated ALL (DS-ALL) have historically poor outcomes, including following hematopoietic stem cell transplant (HSCT). Early reports suggest promising results for DS-ALL patients treated with CD19 chimeric antigen receptor T-cell (CART) therapy, but published data remain limited.

Methods: This single-institution retrospective cohort study evaluated survival outcomes and treatment-related toxicities among pediatric and young adult patients (<26 years) with DS-ALL treated with CD19 CART therapy between 2017 and 2024 at a tertiary academic center. Demographic, disease, treatment, toxicity, and survival data were extracted from the electronic medical record. Survival was estimated using the Kaplan–Meier method, and response and toxicity outcomes were summarized descriptively.

Results:

Figure 1 Kaplan–Meier Estimates of Event-Free and Overall Survival



Fifteen patients receiving 22 CD19 CART infusions were included (median age 14 years; 53% female; 73% Hispanic/Latino; 80% publicly insured). Most patients had high-risk DS-ALL (73%, n = 11) and received CART therapy for first relapse (60%, n = 9). Disease burden at infusion was low, with 73% (n = 11) having M1 marrow status and 93% (n = 14) without CNS involvement. Overall rates of severe toxicity were also low. Cytokine release syndrome (CRS) occurred in 67% of patients (n = 10), with only one case of severe (grade 4) CRS. Immune effector cell–associated neurotoxicity syndrome (ICANS) occurred in 27% (n = 4), with one severe (grade 3) case. Both severe CRS and ICANS resolved with standard steroid and anti-cytokine therapies. Hematologic toxicity was common: 73% (n = 11) developed grade 3–4 cytopenias, with full hematologic recovery at a median of 20 days (range 6–151 days) post-infusion. Two patients experienced rare ocular toxicities, including retinal detachment, which resolved with treatment. All patients were minimal residual disease (MRD)–negative and without CNS disease at first post-CART assessment (21–40 days). Median duration of B-cell aplasia was 402 days (13 months). Seven patients (47%) experienced B-cell recovery, over half within 6 months (n = 4). Four patients (27%) relapsed following CART therapy (three CD19-positive; one unknown). Four patients (27%) underwent subsequent allogeneic HSCT due to early B-cell aplasia loss (n = 3) or relapse (n = 1); two died from transplant-related complications. Among four total deaths, two were due to disease relapse and two due to post-transplant complications. Median follow-up was 21

months (range 5–90). One-year overall survival (OS) and event-free survival (EFS) were 87% and 73%, respectively; two-year OS was 79% and EFS 53% (Figure 1).

Conclusions: CD19 CART therapy was efficacious and generally well tolerated in this DS-ALL cohort, with survival outcomes comparable to or exceeding those previously reported and substantially better than historical outcomes with chemotherapy alone in the relapsed setting. Rates of severe CRS and ICANS were lower than prior reports, likely reflecting low disease burden prior to infusion. Rare ocular toxicities were observed, highlighting potential population-specific toxicity considerations in DS-ALL. Allogeneic HSCT remained highly toxic and accounted for half of all deaths, underscoring persistent transplant-related risks in this population.

DEVELOPING PEDIATRIC ALLOGENIC STEM-CELL TRANSPLANTATION IN LOW-MIDDLE- INCOME COUNTRY: REPORT FROM MOROCCO

Maria El Kababri[1], *Mariame Lakhrissi*[1], *Amina Kili*[1], *Naoual El Ansari*[1], *Zineb Isfaoun*[1], *Kaoutar El Mourabit*[2], *Sara Bougar*[2], *Ouafae Atouf*[2], *Mohamed El khorassani*[1], *Asmaa Quessar*[3], *Laila Hessissen*[1]
[1]*Pediatric Hematology and Oncology Center, Mohammed V University, Rabat, Morocco,*
[2]*Transfusion, Immunology and Cell Therapy, Mohammed V University, Rabat, Morocco,*
[3]*Cheikh Zaid Fondation, Hematology and Transplant Unit, Rabat, Morocco*

Background: The implementation of allogeneic hematopoietic stem cell transplantation (allo-HSCT) in low and middle income countries is a challenge due to the problems of premises, human resources and the difficulty of access to drugs for transplant. We report the experience of the Pediatric Hematology and Oncology Center (CHOP) of Rabat (Morocco) since the initiation of the transplant program in 2020.

Methods: A retrospective analysis of all children who underwent allo-HSCT from June 2020 to October 2025 was done. Clinical characteristics, transplant procedures, and outcomes were analyzed.

Results: This descriptive study included 41 pediatric allo-HSCTs. The median age at transplantation was 5 years (9 months–17 years), with a male-to-female ratio of 1.4. Consanguinity was present in 45% of patients, including 75% first-degree consanguinity. The indications were
aplastic anemia (24 cases, including 11 Fanconi anemia), primary immunodeficiencies (7 cases), acute leukemias (7 cases), and thalassemia (3 cases).
Most donors were HLA-matched related donors (35 cases), while 6 transplants were haplo-identical. The source of stem cells was bone marrow (BM) in 39 cases and peripheral blood

(PB) in 2 cases. A total of 28 patients underwent myeloablative transplants and 13 had reduced intensity conditioning (Fanconi). Graft-versus-host disease (GVHD) prophylaxis consisted of cyclosporine plus methotrexate (22 cases), cyclosporine plus mycophenolate mofetil (13 cases), cyclosporine, MMF and post-transplant cyclophosphamide in haplo-identical transplants (6 cases). Median time to neutrophil and platelet engraftment was J19 ± 6 and J22 ± 5, respectively. Primary graft failure was observed in 2 cases and secondary graft rejection in 4 cases. At last follow-up, 33 of 41 patients were alive (80%). Day-100 mortality (TRM) was 4/41 (9,5%). Causes of death were graft versus host disease (GVHD)-1, Veno Occlusive Disease (VOD)-1, and septis-2. Four children died post-day-100 due to relapse (2), two patients had rejection (aplastic anemia-1, Fanconi-1). Acute cutaneous GVHD occurred in 5 patients, chronic cutaneous GVHD in 4, and digestive GVHD in one patient.

Conclusions: Pediatric allo-HSCT at the CHOP of Rabat achieves encouraging outcomes with acceptable toxicity, despite limited resources. The progressive implementation of haplo-identical transplantation significantly expands access to curative therapy and represents a major advance for pediatric transplantation in Morocco.

Disclosure: Nothing to declare.

P046

RARE EWSR1 REARRANGEMENT IN AML

Yannan Yuan[1], Jun Lu[1], ***Shaoyan Hu***[1]
[1]*Children's Hospital of Soochow University, Suzhou, China*

Background: EWSR1 rearrangements are known as hallmark drivers in sarcomas but remain exceedingly rare in acute myeloid leukemia (AML). We report the first documented case of pediatric AML harboring two novel concurrent fusions, EWSR1::HOXA10 and CALD1::MEF2C. Notably, the patient achieved favorable long-term survival following allogeneic hematopoietic stem cell transplantation (allo-HSCT).

Methods: A 5-year-old male presented with thrombocytopenia and fever and was diagnosed with AML-M7 based on MICM criteria. Bone marrow showed >90% cellularity with 52.5% blasts; flow cytometry revealed CD41/CD61/CD11b positivity. Cytogenetics showed a normal karyotype and negative FISH results. Targeted DNA-NGS identified mutations in *APC*, *NFE2L3*, and *EFL1*. Crucially, RNA-based NGS uncovered two in-frame fusion transcripts: an EWSR1 exon 7-to-HOXA10 exon 2 fusion, and a CALD1 exon 8-to-MEF2C exon 4 fusion, both validated by RT-PCR and Sanger sequencing.

Results: Considering the newly identified fusion genes, the patient underwent allo-HSCT from a matched related donor following induction chemotherapy. The transplantation procedure was uneventful, with no significant acute graft-versus-host disease (aGVHD). At last follow-up (9 months post-HSCT), the patient remains in complete morphological and molecular remission, with no evidence of minimal residual disease, demonstrating an excellent response.

Conclusions: This is the inaugural report of concurrent EWSR1::HOXA10 and CALD1::MEF2C fusions in AML. This case demonstrates the critical importance of molecular diagnostics in identifying rare fusion genes and confirms the efficacy of allogeneic hematopoietic stem cell transplantation (allo-HSCT), ultimately resulting in favorable clinical outcomes for the patient. These novel fusion genes may indicate potential therapeutic targets and warrant further investigation.

Disclosure: Nothing to declare.

P047

BETTER SURVIVAL FOLLOWING ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION IN ELDERLY (>65 YEARS OLD) AML PATIENTS - RESULTS OF AN INTERNATIONAL, TWO-CENTER ANALYSES

Karolina Bełdzińska-Gądek[1], *Krzysztof Pastuszak*[1,2], *Jan Mateusz Zaucha*[1], *Elizabeth Weiß*[3], *Johannes Lakner*[3], *Christa Unger*[3], *Frauke Theis*[3], *Charlotte Wagner*[3], *Jan Maciej Zaucha*[1], *Christian Junghanss*[3]
[1]*Medical University of Gdańsk, Gdańsk, Poland,* [2]*Gdańsk University of Technology, Gdańsk, Poland,* [3]*Rostock University Medical Center, Rostock, Germany*

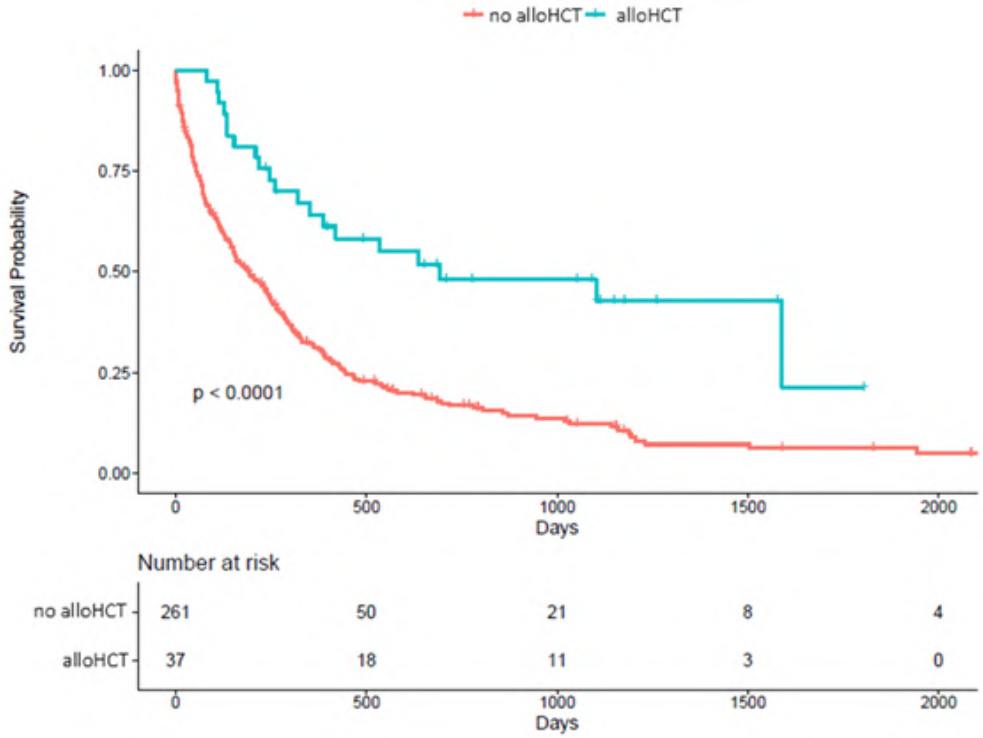
Background: Treatment of acute myeloid leukemia (AML) of elderly patients (>65 years) remains a challenge. Survival in this group is poor and most of the patients are ineligible for intensive treatment at the time of diagnosis. Data on elderly patients qualifying for allogeneic hematopoietic cell transplantation (alloHCT) as well as on the survival of this group of patients remains scarce. Herein, we present experience of Polish and German clinical centers in alloHCT of elderly patients diagnosed with AML.

Methods: In this double-center retrospective study we included 303 adult (>65 years old) patients diagnosed with AML, treated between 2018 and 2024 in the Department of Hematology and Transplantology of Medical University of Gdańsk, University Clinical Center, Poland and in the Department of Hematology, University Medical Centre, University of Rostock, Rostock, Germany. Inclusion criteria included age and AML as underlying disease. The performance status, data on demographics, ELN 2022 risk classification, treatment type and outcomes were evaluated. For the current analyses patients who underwent alloHCT were analyzed and the statistical analysis was performed. In survival analysis, Schoenfeld test was used to assess the proportionality of hazards. Variables which significantly affected survival in univariate Cox proportional hazards models were then considered in multivariate Cox HR analysis.

Results: In the analyzed group 37/303 (12%) patients underwent alloHCT procedure. The group included 21 (56.8%) male and 16 (43.2%) female patients. Median age of the group was 68 years (range 65-75)**.** Most of the patients in the analyzed group were below 70 years of age (n=26; 70%).
According to ELN 2022 AML risk classification, 5 patients (14%) were diagnosed with favorable, 14 patients (38%) with intermediate and 18 patients (49%) with adverse risk

AML. Twenty-six patients (70%) proceeded to alloHCT after completing first line treatment and 25 patients (67.6%) proceeded to alloHCT with complete remission. The median time of survival was 16.1 months (range 2.6-59.3). Seventeen out of 37 pts (46%) remain alive at the time of analysis with median time of follow-up of 2.9 years (range 0.6-4.9; alive pts). Undergoing allo-HCT was significantly associated with an increased probability of surviving 2 years after diagnosis (OR 4.99, 95% CI 1.28-19.50, p=0.0207). In both univariate and multivariate models alloHCT procedure was significantly associated with decreased hazard – HR 0.37, 95% CI 0.24-0.59, p<0.0001 and HR 0.55, 95% CI 0.32-0.97, p=0.0373 respectively. As expected, population that underwent alloHCT presented significantly (p <0.0001) better overall survival compared to the patients who did not undergo the procedure (Figure 1.)

Figure 1. Overall survival analysis comparing survival of elderly patients who underwent and did not undergo alloHCT. Survival was possible to assess in case of 298 patients.



Conclusions: Data on alloHCT among elderly patients remains scarce, hence more data is needed to ensure optimal treatment and care for this group of patients. This two-center analysis adds a new perspective to the treatment of elderly patients. The preliminary findings of the study support that alloHCT eligibility must be carefully evaluated in older individuals in order to identify eligible patients that might benefit from this potentially curative procedure.

Disclosure: Nothing to declare.

P048

BEYOND SUPPORTIVE CARE: ALLOGENEIC STEM CELL TRANSPLANTATION IN CHILDREN WITH FUCOSIDOSIS

*Sefika Akyol[1], Seda Öztürkmen[1], Hayriye Daloglu[2], Burcu Akıncı[2], Koray Yalcin[2], Suleimen Zhumatayev[2], Vedat Uygun[1], Gülsün Karasu[2], **Akif Yesilipek**[1]*
[1]Medicalpark Antalya Hospital, Antalya, Turkey, [2]Medikalpark Göztepe Hospital, Istanbul, Turkey

Background: Fucosidosis is a rare autosomal recessive lysosomal storage disorder caused by deficiency of α-L-fucosidase, leading to progressive accumulation of fucose-containing substrates in multiple organs. The disease presents with a broad clinical spectrum, including neurodevelopmental delay, recurrent infections, dysostosis multiplex, angiokeratomas, and progressive neurodegeneration, resulting in significant morbidity and early mortality. Currently, treatment is largely supportive, and no definitive disease-modifying medical therapy is available.
Allogeneic hematopoietic stem cell transplantation (allo-HSCT) represents a potential therapeutic strategy for selected lysosomal storage disorders by providing sustained donor-derived enzyme through cross-correction. However, due to the extreme rarity of fucosidosis, evidence regarding HSCT outcomes is limited to small case series, particularly in pediatric patients, and long-term neurological outcomes remain insufficiently characterized. Reporting real-world pediatric HSCT experiences is therefore essential to better define the role and feasibility of transplantation in this ultra-rare disease.

Methods: We performed a retrospective single-center analysis of pediatric patients with fucosidosis who underwent allo-HSCT. Diagnosis was established based on clinical findings, reduced α-L-fucosidase enzyme activity, and/or confirmatory molecular genetic testing. Collected data included demographic characteristics, disease phenotype, pre-transplant neurological and systemic involvement, transplant characteristics, engraftment status, graft-versus-host disease (GVHD), and post-transplant clinical outcomes.

Results: Three pediatric patients underwent allo-HSCT at a median age of 73 months (range: 10–110 months). Bone marrow was used as the stem cell source in all cases. Two transplants were from 10/10 and 9/10 matched-unrelated donors , and one was from a fully HLA-matched maternal donor. All patients received busulfan-based conditioning regimens combined with fludarabine, ATG, and thiotepa. One patient required a second allo-HSCT because of declining donor chimerism and increasing enzyme levels suggestive of graft rejection; defibrotide was administered due to pre-existing hepatic involvement.
Full donor chimerism and sustained engraftment were achieved in all patients. No acute or chronic GVHD was observed. One patient presented with advanced neurological involvement at the time of transplantation and demonstrated clinically meaningful post-transplant neurological improvement, including a marked reduction in dystonia and the emergence of social interaction, followed by sustained neurological stabilization. Of the remaining two patients, the youngest, transplanted at 10 months of age, exhibited mild developmental delay with inability to sit independently at baseline. The third patient had pre-transplant motor impairment with inability to ambulate, a history of seizures, and hearing impairment. All patients are alive and disease-free with stable graft function at a median follow-up of 75

months (range: 50–81 months). The summaries of the patients are available in Table 1.

Table 1. The summary of the cases

Case	Gender	Transplantation age (Months)	Donor	Follow-up time (Months)	The last chimerism	The last Enzyme level (nmol/h/mg protein) (76,7 +/- 29,4)	The last clinical findings
FO	M	110	MRD	75	64	67,9	Decrease in dystonia, no seizures, and partial head control
YEO	M	10	• 1. MUD • 2. 9/10 UD	81	100	92	Obeys commands, walks, and speaks 4-5 words
YD	M	74	MRD	50	99	53,4	Walking with support, trying to speak with nonsensical sounds

M: Male, MRD: Matched related donor, MUD: Matched unrelated donor, UD: Unrelated donor

Conclusions: Allo-HSCT is a feasible and safe disease-modifying treatment option for pediatric fucosidosis, providing durable engraftment and long-term disease-free survival. Neurological stabilization or improvement may be achievable even in patients with advanced disease. These findings support early referral and timely transplantation to optimize outcomes in this rare disorder.

Disclosure: None.

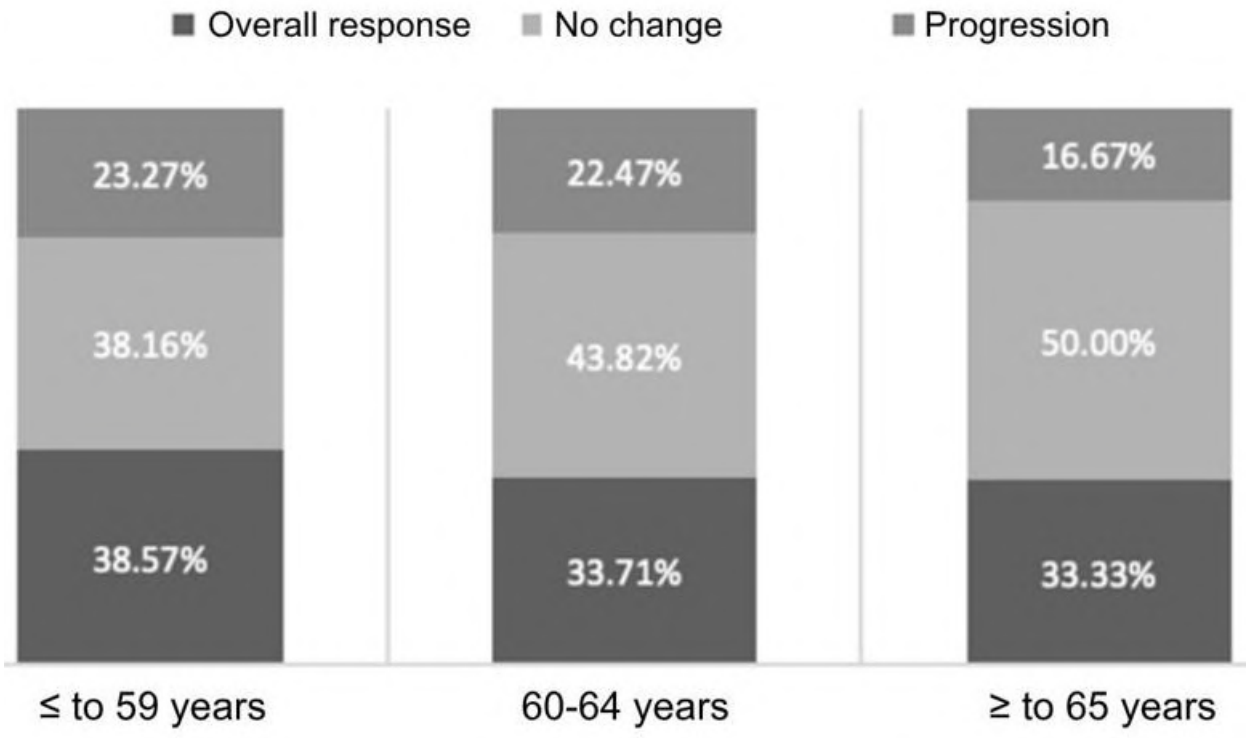
PATIENTS WITH MULTIPLE SCLEROSIS ABOVE AGE 60 HAVE NEUROLOGICAL RESPONSES TO AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTS SIMILAR TO YOUNGER INDIVIDUALS: A SINGLE-CENTER EXPERIENCE

Guillermo J. Ruiz Arguelles[1], *Miguel Angel Viveros Lugo*[1], *Lidia Joanna Alberto Lopez*[1], *Michelle Lavoignet Cisneros*[1], *Max Robles Nasta*[1], *Sofia Chavez Martinez*[1], *Monica Daniela Salgado Cabrera*[1], *Miguel Ángel Gómez Cabrera*[1], *Juan Carlos Olivares Gazca*[1], *Guillermo J. Ruiz Delgado*[1]
[1]*Centro Hematología y Medicina Interna, Clínica Ruiz, Puebla, Mexico*

Background: Multiple sclerosis (MS) is an autoimmune disease of the central nervous system characterized by inflammation, demyelination, and progressive neurodegeneration. Autologous hematopoietic stem cell transplantation (aHSCT) has emerged as a therapeutic option that eliminates autoreactive lymphocytes and reconstitutes the immune system. Patients older than 60 years have been reported to fare worse when given aHSCT for other diseases.

Methods: MS patients prospectively treated with aHSCT using the "Mexican Method" were analyzed. This protocol combines high-dose cyclophosphamide (200 mg/kg), rituximab 1 000 mg, filgrastim, and MESNA.

Results:



A total of 1 438 persons were accrued; 120 (8.3%) were ≥ 60 years. The positive response rate (PRR) for the cohort was 75.3% (IQR 72–78%), with 77.4% for RRMS, 72.7% for PPMS, and 74.7% for SPMS. By age, PRR was 75.2% (< 60 years) and 77.0% (≥ 60 years; p = 0.64). Subgroups 60–64 and ≥ 65 showed comparable PRR. Early complications occurred in 2.1% of patients < 60 and 5.8% of those ≥ 60 (p = 0.02).

Conclusions: Employing the "Mexican Method," PRR after aHSCT was 75.3%, with no significant difference between age groups. Although older patients had slightly more early complications, overall outcomes were similar, suggesting that age > 60 should not preclude aHSCT in MS.

Background: The current Italian guidelines for disposal of cryopreserved autologous stem cells (SCs) have been published over ten years ago (2014). Due to the rapidly evolving

landscape in hematopoietic stem cell transplantation and cellular therapy, a nationwide questionnaire was administered to the clinical Transplant Programs (TPs), to survey the practice of their Tissue Establishments (TEs) and lay the foundation for updating disposal guidelines. We report the most significant results.

Methods: An online survey, composed of two parts (autologous and allogeneic SCs and lymphocytes) was launched by *Gruppo Italiano per il Trapianto di Midollo Osseo, cellule staminali emopoietiche e terapia cellulare (GITMO)* and developed with the contribution of scientific societies in the field and the competent authorities. A total of 56 questions (34 for autologous and 22 for allogeneic setting, respectively) were administered to 87 TPs in January 2025 with the aim of assessing the centers' compliance to the 2014 guidelines throughout the year 2024 and the reasons of non compliance, if any. The survey results provide a basis to develop updated guidelines, taking into account not only the changing clinical landscape, but also the ethical and legal framework and the financial burden and logistics.

Results: A total of 69 out of 87 TPs (79%) replied by May 2025. Although 87% of centers declare to apply the 2014 guidelines for autologous SCs, only 62% of them apply all criteria. The policies of other centers vary due to a lack of specific regulation on this topic or the need of a signed informed consent from the patient Furthermore, 84% of respondents state that that their disposal policy is influenced by the availability of cold storage space. Increased storage demand for both autologous and allogeneic SCs and lymphocytes was documented (17% and 67% of centers, respectively), particularly regarding allogeneic products during the Covid-19 pandemic. However, only 57% of centers have a policy for the disposal of allogeneic products. Fifty-six percent of centers supports an update of 2014 guidelines, including: the application also to allogeneic products, a specific regulation and a standardized informed consent. Finally, over 60% of centers are available for releasing unused cryopreserved allogeneic hematopoietic stem cells for transplantation to other patients.

Conclusions: A nationwide survey on storage and disposal of autologous and allogeneic SCs and lymphocytes, covering the great majority of Transplant Programs in Italy, allowed to appreciate the extent of current application of 2014 guidelines and highlighted heterogeneity of duration of cryopreservation and graft disposal among centers. The questionnaire pointed out the need to update and improve the 2014 guidelines according to the rapidly evolving clinical landscape, ethical, legislation and logistical challenges.

SECOND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION FOR RELAPSED ACUTE LEUKEMIA AND MYELODYSPLASTIC SYNDROMES: A SINGLE-CENTER EXPERIENCE

Teresa Bedoya Palop[1], *Mireia Morgades De la Fe*[1], *María Josefa Jiménez Lorenzo*[1], *María Huguet Mas*[1], *Mercè Aren Jubany*[1], *Andreu Casas Medina*[1], *Alex Gimenez i Robert*[1], *Juan*

Manuel Sancho Cia[1], Anna Torrent Catarineu[1]
[1]Germans Trias i Pujol University Hospital. Catalan Institute of Oncology, Barcelona, Spain

Background: Relapse after allo-HSCT (allogeneic hematopoietic stem cell transplantation) remains the main barrier to cure in high-risk hematologic malignancies, including Acute Myeloid Leukemia (AML) and Myelodysplastic Syndromes (MDS), and is associated with an extremely poor prognosis. For selected patients, a second allo-HSCT (2nd-alloHSCT) may constitute the only potentially curative option; however, outcomes are highly variable , with high early non-relapse mortality (NRM) which ranges between 30-60% and long-term survival rarely surpassing 20–25% in most published cohorts. We present a single-center retrospective analysis evaluating the real-world outcomes of 2nd-alloHSCT in patients relapsing after a first alloHSCT.

Methods: We retrospectively analyzed data from patients with acute leukemia and MDS who underwent a 2nd-alloHSCT due to progression or relapse at our center between June 2002 and August 2024.

Results: The baseline characteristics of the included patients are summarized in **Table 1**. Despite the expected high-risk profile, the median overall survival (OS) after the second transplant was 6.3 months (95% CI, 2.1–24.4). OS probability at one and five years were 33% (95% CI, 14–55%) and 25% (95% CI, 8–48%), respectively **(Figure 1)**. The cumulative incidence of relapse (CIR) was 39% at one year and 46% at five years. NRM was 28% at both one and five years **(Figure 1)**. Eight patients relapsed after the 2nd HSCT, with an early median time to relapse of 2.9 months (range 0.6–12), 5 out of which had the same donor. As for the 10 patients who received the second allo-HSCT from a different donor, only 3 had a disease relapse. Five patients died due to transplant-related mortality: bilateral pneumonia (n=2), acute GVHD with septic shock (n=1), isolated acute GVHD (n=1) and veno-occlusive disease (n=1).

Table 1: Baseline Characteristics of the 2nd allo-HSCT Cohort (N=18).

Characteristic	Value
Age, median (range), years	45.5 (24 – 62)
Diagnosis, AML / ALL / MDS, n (%)	9 (50%) / 7 (39%) / 2 (11%)
Interval 1st-2nd HSCT, median, months	14.1 (range 3.4 – 64)
ECOG PS at 2nd HSCT (0 / 1 / 2), n=15	9 (60%) / 3 (20%) / 3 (20%)
Second Donor, Same / Different, n (%)	8 (44%) / 10 (56%)
Donor Type, Matched / Mismatched / Haplo	10 (55%) / 5 (28%) / 3 (17%)
Conditioning, MAC / RIC, n (%)	6 (33%) / 12 (67%)

Table 1: Baseline Characteristics of the 2nd allo-HSCT Cohort (N=18).

Stem Cell Source, Peripheral Blood, n	18 (100%)
GVHD Prophylaxis, CNI-based, n (%)	18 (100%)

Abbreviations: HSCT: Hematopoietic Stem Cell Transplantation; **AML:** Acute Myeloid Leukemia; **ALL:** Acute Lymphoblastic Leukemia; **MDS:** Myelodysplastic Syndrome; **ECOG PS:** Eastern Cooperative Oncology Group Performance Status; **MAC:** Myeloablative Conditioning; **RIC:** Reduced Intensity Conditioning; **GVHD:** Graft-versus-Host Disease; **CNI:** Calcineurin Inhibitor.

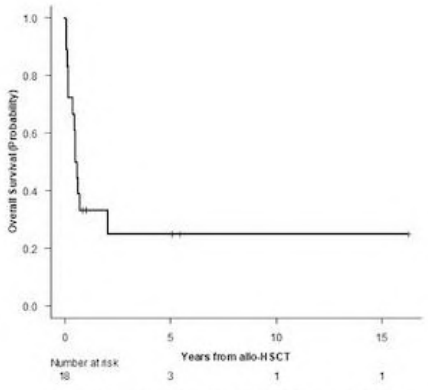

Figure 1. Overall survival after second allogeneic HSCT (N=18)

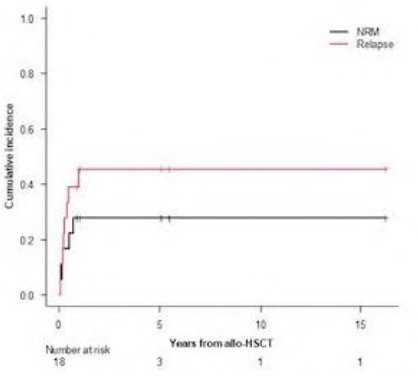

Figure 2. Cumulative incidence of relapse and non-relapse mortality after second allo-HSCT (N=18).

Conclusions: These results highlight the potential of second allo-HSCT as a salvage strategy, despite its poor results. Our data have certain limitations, such as the sample size and the heterogeneity of the procedures, which restrict the ability to identify prognostic factors or draw generalizable conclusions. Despite these constraints , this study underscores the importance of individualized evaluation when considering a second allo-HSCT and supports its use in carefully selected patients.

Disclosure: Nothing to declare

P052

IMPACT OF PRE-TRANSPLANT EVENTS ON THE FEASIBILITY OF ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

Sabrine Khirallah[1], Hatihem Cherif[1], Rihab Ouerghi[1], Insaf Ben Yaiche[1], Rimel Kanoun[1], Lamia Torjmane[1], Dorra Belloumi[1], Anna Chabaane[1], Tarek Ben Othman[1], ***Nour Ben Abdeljelil***[1]
[1]*National Bone Marrow Transplantation Center, Tunis, Tunisia*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) remain a potential curative therapy for a variety of malignant and non-malignant diseases. However, various events may hinder or delay its achievement and compromising its benefits. The aim of our study was to assess the impact of pre-transplant events on allo-HSCT feasibility and overall survival (OS).

Methods: Retrospective study conducted over a three-year period (2022–2024) at the National Bone Marrow Transplant Center in Tunisia (CNGMO). It included all patients referred for allo-HSCT and discussed during the bi-monthly transplant committee meetings. Patients' outcome was analyzed according to whether the transplant was ultimately performed as well as the factors responsible for delays or failure to proceed to transplantation. Since 2023, only patients with high-risk hematological malignancies have been eligible for haploidentical HSCT, in accordance with a standardized eligibility checklist established by the CNGMO transplant committee.

Results: Over the three-year study period, 278 patients were referred for allo-HSCT: 97 in 2022, 82 in 2023, and 99 in 2024, corresponding to an average of 93 referrals per year. Acute leukemia (AL) represented the predominant indication (68.5%), including acute myeloid leukemia (AML; n = 93, 33.5%) and acute lymphoblastic leukemia (ALL; n = 97, 35%). Overall, 120 patients (43%) proceeded to allo-HSCT, with a median age of 27 years (range 5–55). Pediatric patients accounted for 28% of the cohort, and the sex ratio was 0.9. Among 18 patients considered for haploidentical HSCT, only 3 underwent transplantation. Transplantation was carried out as initially scheduled in 89% of cases. A delay occurred in 13 patients (11%), mainly due to an infectious complications (n = 5), the need for pre-transplant disease reassessment (n = 4), or a logistical constraints (drug or radiotherapy unavailability, limited bed capacity, n = 4). The median duration of postponement was 30 days (range, 10–50 days). The median time from first presentation to actual allo-HSCT was 3 months (range, 1–12 months).
Among the 96 patients transplanted with malignant hematologic disease, 69 (72%) were in CR1, 24 (25%) in CR2, and 3 (3%) had refractory disease. Total body irradiation (TBI) was performed in 18.5% of patients with ALL. Post-transplant relapse occurred in 24 patients (20%), with a median time of 6 months (range, 1–34 months).
Allo-HSCT was not performed in 158 patients (57%): 48 in 2022, 53 in 2023, and 57 in 2024. The reasons for non-achievement of allo-HSCT are summarized in table 1.
The median overall survival (OS) was 89 months for transplanted patients, versus 36 months for non-transplanted patients ($P < 0.001$). At last follow-up, 76% of transplanted patients were alive, versus 41% of non-transplanted patients.

Table 1 : Reasons for non-achievement of the allo-HSCT

Reasons	N=158
Disease relapse	57 (36%)
Death prior to transplantation	10 (6%)
Signifiant patient comorbidities	13 (8%)
Refusal by either the donor or the recipient	3 (2%)
Age < 5 years or low body weight (referred to a pediatric transplant center)	5 (3%)
Reassessment resulting in withdrawal of the allo-HSCT indication	10 (6%)
logistic constraints	4 (3%)
Unavailability of essential Drugs (cyclosporine, chemotherapy…) or TBI	5 (3%)
Significant donor comorbidities	9 (7%)
For patients referred for haploidentical HSCT • Presence of donor-specific anti-HLA antibodies (DSA) • Rejected indication following committee review • Logistical constraints	15 (9%) 4 4 7
Excessive delay since the last therapy (no dose/intensity effect)	7 (4%)
Lack of feedback information after initial referral	20 (13%)

Conclusions: Pre-transplant events may hinder the completion of allo-HSCT and consequently have a negative impact on overall survival. Early recognition and proactive management of these factors are essential to improve transplant feasibility and patient outcomes.

Disclosure: Nothing to declare.

P053

FAVOURABLE SURVIVAL IN ALLOGENIC STEM CELL TRANSPLANT RECIPIENTS ADMITTED TO INTENSIVE CARE; 6-YEAR RETROSPECTIVE REVIEW FROM A UNIVERSITY HOSPITAL TRANSPLANT CENTRE IN THE UK

Behnaz Mobashwera[1], *Patricia Banda*[2], *Linda Jarvis*[3], *Christopher Dalley*[3], *Kim Orchard*[3], *Adrian Maraj*[3], *Deborah Richardson*[3], *Hwai Jing Hiew*[3], *Mariam Amer*[3]
[1]*Portsmouth Hospitals University NHS Trust, Portsmouth, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Addenbrooke's Hospital NHS Trust, Cambridge, United Kingdom of Great Britain and Northern Ireland (the),* [3]*University Hospital Southampton NHS Trust, Southampton, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Recipients of allogenic haematopoietic cell transplant (allo-HCT) are one of the most vulnerable groups of haematology patients during critical illness attributed to both severe immunocompromised state and treatment related toxicities. Historically allo-HCT patients have poor outcomes after Intensive care unit (ICU) admissions.
The aim was to evaluate the outcome of allo- HCT recipients admitted to ICU during the peri-transplant period in our centre. Primary outcome measured was 90-day mortality (defined as 90 days mortality from admission to ICU). Other outcomes measured included in-ICU, in hospital (defined as mortality within 90 days from any cause after admission and ICU step down) and 1-year mortality rates.

Methods: Between 1st January 2019 and 31st December 2024, patients who had allo-HCT requiring ICU admission during the peri-transplant period (period between the start of conditioning therapy up to day 100 post cell infusion) were included. Retrospective data were collected from electronic patients' record.

Results: During this period, 17 patients met the inclusion criteria with 23 ICU admissions between them. Three patients required multiple admissions. 294 patients received allo-HCT at our centre with incidence of ICU admission in the peri-transplant period at 5.7% (17/294). The median age was 49 years (range 17-67), 7/17 were female patients (41.1%) and 11/17 patients (64.7%) had high (score≥ 3) Haematopoietic Stem Cell Transplantation-Specific Comorbidity Index (HCT-CI) score. The most common indication for transplant was acute leukaemia 15/17 (88.2%) and 8/17 (47%) patients underwent myeloablative conditioning. The 90-day mortality of this cohort was 29.4% (5/17) which marginally increased to 35.2% (6/17) at one year. The in-ICU and in-hospital mortality rates were 23.5% (4/17) and 35.2% (6/17) respectively. The median length of ICU stay was 8 days (range 2-89). The median time to ICU admission from stem cell infusion was 15 days (range1-90 days). Comparing the in-ICU and 1-year mortality rates in our centre to national published data by Intensive Care National Audit and Research Centre (ICNARC) published in 2022 for non-haematological ICU admissions; 23.5% vs19-26.3% and 35.2% vs 26-28% respectively.
On reviewing baseline characteristics of the 90-day survival cohort to 90-day mortality cohort, no clear trend was noted except younger patients and more females in the latter,

though numbers are small for significance analysis. The median time to ICU admission from stem cell infusion was later in the 90-day mortality cohort at 22.5 days (range 14-75) compared to 15 days (range 1-90) which could be explained by less easily reversible cause of admission such as disease relapse. As expected, those in the 90-day mortality group all needed more than one organ support and the mortality rate was almost double in patients who required invasive mechanical ventilation.

Baseline demographic	**Overall N=17**	**90-day survival N=12**	**90-day mortality N=5**
Median age (range)	49 (17-67)	50.5 (17-67)	31 (19-66)
Age> 65	2 (11.7%)	1 (8.3%)	1 (20%)
Female	7 (41%)	4 (33.3%)	3 (60%)
HCT-CI score Low risk= 0 Intermediate risk= 1-2 High-risk= ≥ 3	 2 (11.7%) 4 (23.5%) 11 (64.7%)	 1 (8.3%) 3 (25%) 8 (66.6%)	 1 (20%) 1 (20%) 3 (60%)
Transplant indication ALL AML CML CMML	 8 (47.05%) 7 (41.1%) 1 (5.5%) 1 (5.5%)	 5 (41.6%) 5 (41.6%) 1 (8.33%) 1 (8.33%)	 3 (60%) 2 (40%) 0 0
Transplant conditioning Myeloablative RIC	 8 (47%) 9 (53%)	 5 (41.6%) 7 (58.3%)	 3 (60%) 2 (40%)
ICU characteristics	Overall episodes N=23	90-day survival N=18	90-day mortality N=5
Median time to ICU admission from stem cell infusion in days (range)	15 (1-90)	15 (1-90)	22.5 (14-75)
Reason for admission 1. Infection/sepsis 2. Mucositis / airway compromise 3. Posterior reversible	 12 (52.1%) 3 (13.0%) 2 (8.6%)	 11(61.1%) 2 (11.1%) 2 (11.1%)	 1(20%) 1(20%) 0

Baseline demographic	Overall N=17	90-day survival N=12	90-day mortality N=5
encephalopathy syndrome (PRESS) 4. Disease relapse 5. Graft-versus-Host Disease 6. Others (endothelial dysfunction, non-infective pulmonary pneumonitis, pulseless electrical activity)	2 (8.6%) 1 (4.34%) 3 (13.0%)	0 0 3 (16.6%)	2 (40%) 1 (20%) 0
Organ support Single Multi-organ support	12 (52.1%) 11 (47.8%)	12 (66.6%) 6 (33.3%)	0 5 (100%)
Invasive mechanical ventilation	6 (26.08%)	4 (22.2%)	2 (40%)

Conclusions: The overall incidence of ICU admission in our centre was low, compared to rates reported in literature (9-20%).This study highlighted overall comparable outcomes of this high-risk cohort from admission to critical care with non-haematological admissions. Additionally, we did not identify any risk factors that could predict survival; thus, we advocate for consideration of allo-HCT recipients for critical care admission regardless of their initial functional status.

G-CSF ADMINISTRATION AND CLINICAL OUTCOMES IN PATIENTS WITH RELAPSED/REFRACTORY B-CELL LYMPHOMAS TREATED WITH CAR-T CELLS: A MONOCENTRIC EXPERIENCE

Serafina Barbato[1], *Raffaella Iannotta*[1], *Sara Basile*[1], *Carlangela Causa*[1], *Gennaro Petricciuolo*[1], *Roberta Russo*[1], *Pierpaolo Santopadre*[1], *Alessandro Severino*[1], *Ilaria Cappuccio*[1], *Fabio Trastulli*[2], *Tiziana Izzo*[2], *Rossella Iula*[3], *Lucia Ammirati*[3], *Luca Pezzullo*[4], *Alessandro D'Ambrosio*[5], *Martina Di Palma*[5], *Davide Abagnale*[5], *Ferdinando Frigeri*[5], *Mario*

Annunziata[2], Catello Califano[3], Bianca Serio[4], Marco Picardi[1], Fabrizio Pane[1], Giorgia Battipaglia[1]
[1]Federico II University Hospital, Naples, Italy, [2]Hematology Unit, Cardarelli National Hospital, Naples, Italy, [3]Onco-Hematology Unit, Pagani Hospital A.Tortora, Pagani, Italy, [4]Hematology and Stem Cell Transplant Unit, San Giovanni di Dio e Ruggi d'Aragona University Hospital, Salerno, Italy, [5]Hematology Unit, Sant'Anna e San Sebastiano Hospital, Caserta, Italy

Background: Chimeric Antigen Receptor (CAR)-T cells are widely used to treat relapsed/refractory lymphoproliferative disorders, due to their high efficacy. However, hematological toxicity, such as severe neutropenia, frequently occurs. Granulocyte colony-stimulating factor (G-CSF) can be used to manage CAR-T related neutropenia, though concerns remain regarding its impact on toxicity, infection rates and duration of hospitalization. This study evaluates a single-center cohort of patients receiving G-CSF for neutropenia occurring early after infusion (≤30 days).

Methods: We retrospectively analyzed 45 patients treated with CAR-T [Axi-cel (n=29; 64%) or Tisa-cel (n=16; 36%)], between March 2022 and August 2025 for B-cell lymphoproliferative disorders.
G-CSF was administered when neutrophil levels were < 500/μL.

Results: Demographic characteristics are reported in the Table. The median age was 60 years (range 29-75). At the time of apheresis, most patients (80%) exhibited progressive disease. Seventy-one percent of patients (n=32) had received three or more prior lines of therapy. A bridging therapy before CAR-T infusion was required in 78% of cases. Thirty-five (78%) patients experienced severe neutropenia and needed G-CSF support, starting at a median of 4 days post-infusion (range 0-11) with a median duration of 4 days (range 1-124). Following CAR-T administration, cytokine release syndrome (CRS) was observed in 82% of patients, with a median onset of 3 (range 0-13) days and a median duration of 4 (range 1-26) days; only 2% were grade 3-4. Notably, CRS was observed in 89% (n=31) and 60% (n=6) cases of G-CSF and non-G-CSF-treated group, respectively.
Neurological toxicity occurred in 13% of cases, with 7% grade 3-4. Notably, the incidence of neurological toxicity affected only the G-CSF group [6 (17%) vs 0].
Median duration of hospitalization was similar in patients receiving or not G-CSF, being 19 (range 9-67) days in both cases.
Overall infections were documented in 11% of patients, occurring in 4 (sepsis n=1, urinary tract infection n=2, Sars-CoV-19 n=1) cases within the G-CSF group and 1 (sepsis n=1) case in the no-G-CSF.
We observed 6 (13%) deaths, with 5 (11%) attributed to disease progression. With a median follow-up of 17 months (95% CI, 11–20), the median progression-free survival (PFS) was 39 months (95% CI, 26–NR). The rate of PFS at 12 and 18 months was 76% and 72%, respectively. Median overall survival (OS) was not reached with estimated OS rates of 85% at12 and 18 months.

PNN< 500/µL Median time to PNN<µL, days (range) Use of G-CSF Median time to G-CSF, days (range) Median duration of G-CSF use, days (range)	35 (78) 4 (0-11) 35 (78) 4 (0-11) 4 (1-124)

Conclusions: Most patients undergoing CAR-T infusion experience neutropenia that can be managed with the use of G-CSF. Despite in our cohort CRS and neurological toxicity were more frequently registered in the G-CSF group, low numbers prevented us to make comparisons between groups. The potential effects of G-CSF in influencing CAR-T toxicities thus deserves further investigation, with several factors, including those inherent to disease and patient characteristics, which may have influenced post-infusion outcomes.

Disclosure: None.

P055

ROLE OF GILTERITINIB IN PREVENTING RELAPSE IN FLT3-MUTATED ACUTE MYELOID LEUKEMIA FOLLOWING ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANT: A REAL-WORLD COHORT STUDY

Laura Carral Fernandez[1], *Alejandro Luna de Abia*[1], *Anabelle Chinea Rodriguez*[1], *Adrian Sanchez-Tornero*[1], *Paula Guijarro Martinez*[1], *David Gomez Rocha*[1], *Laura Barbero del Olmo*[1], *Pilar Herrera Puente*[1], *Javier Lopez Jimenez*[1]
[1]*Instituto Ramón y Cajal de Investigación Sanitaria - IRYCIS, Madrid, Spain*

Background: FLT3 mutations are common in acute myeloid leukemia (AML) and are associated with high relapse rates, even after allogeneic hematopoietic cell transplantation (allo-HCT). Ongoing studies evaluate the efficacy of FLT3 inhibitors as maintenance therapy for relapse prevention following allo-HCT, seeking to establish the relationship with

measurable residual disease (MRD) in the peri-transplant period. Gilteritinib, a highly selective, next-generation FLT3 inhibitor, is functional against both internal tandem mutation (ITD) and tyrosine kinase domain (TKD) mutant forms. We assessed the response and safety of gilteritinib following allo-HCT in patients diagnosed with AML based on the peri-transplant status of MRD.

Methods: This is an observational, retrospective, single-centre study reviewing the medical records from December 2023 to November 2025 of patients diagnosed with AML undergoing post-transplant and gilteritinib use after allo-HCT. Data were collected on demographic characteristics, pre- and post-transplant reassessment by flow cytometry of measurable residual disease performed at months 1, 3, 6, 9, 12, 18, and 24, also monitoring NPM1 status in peripheral blood (PB) during this time, FLT3 mutation and association with NPM1 mutation at diagnosis, timing of drug initiation, dosage and adverse effects.

Results: A total of 8 patients (88% women), diagnosed with either FLT3-ITD (6/8) or FLT3-TKD (2/8) mutations, received gilteritinib (Table 1). They underwent transplantation in cytological remission with just 2 patients having positive MDR prior to allo-HCT, most of them receiving myeloablative conditioning regimens and the donors being haploidentical in most cases.

Patient # Sex	Mutations	ELN Risk	Age at transplant	Pre-HCT status	Conditioning	Donor	Initial dose	Time of initiation (month post-HCT)	Reason
Patient 1 Female	NPM1 FLT-TKD TP53	Adverse	26	Negative MRD	MAC	MUD	80mg *	3	Maintenance
Patient 2 Male	NPM1 FLT3-ITD	Intermediate	63	Negative MRD	RIC	MSD	80mg	3	Positive MRD post-HCT Mixed chimerism
Patient 3 Female	NPM1 FLT3-ITD	Intermediate	67	Positive MRD	RIC	Haploidentical	80mg	3	Positive MRD pre-HCT

Patient 4 Female	t(6;9)/DEK::NUP214 FLT3-ITD	Adverse	22	Aplasia	MAC	MUD	120mg*	1.5	Maintenance
Patient 5 Female	NPM1 FLT3-ITD	Intermediate	38	Negative MRD	MAC	Haploidentical	120mg*	6	Maintenance
Patient 6 Female	NPM1 FLT3-TKD	Intermediate	55	Negative MRD	MAC	Haploidentical	40mg	3	Maintenance
Patient 7 Female	NPM1 FLT3-ITD	Intermediate	32	Negative MRD	MAC	Haploidentical	80mg	3	Maintenance
Patient 8 Female	NPM1 FLT3-ITD	Intermediate	57	Positive MRD	MAC	Haploidentical	120mg*	6	Positive MRD pre-HCT

Table 1. Demographic and transplant characteristics. Underlined patients had positive MRD pre-HCT. RIC: reduced intensity conditioning. MAC: myeloablative conditioning. MUD: matched-unrelated donor. MSD: matched-sibling donor. * Marks patients requiring dose adjustment.

We present the evolution of each patient over time (Figure 1), from transplantation to the last follow-up (November 2025).

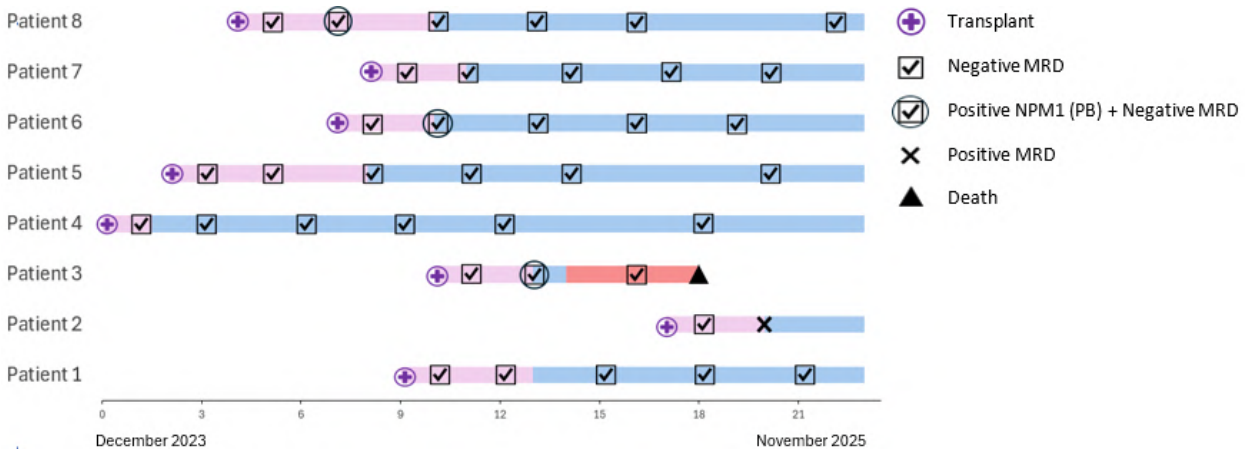

Figure 1. Representing follow-up (months) post-HCT until gilteritinib is initiated (pink segment) and evolution after (blue segment). It also shows drug discontinuation (red segment).

The median time to initiate gilteritinib was 90 days (IQR:45). Regarding its initial dose, 50% of the patients required adjustment due to adverse effects (3/4 suffered from moderate cytopenias, upholding acceptable counts after reducing 120mg to 80mg). The other patient experienced both papilledema and cytopenias, requiring a reduction in dosage from 80mg to 40mg. Other two had their dose reduced to 40mg due to hepatotoxicity with one subsequent discontinuation. This patient died from an undetermined infectious cause after a long hospital stay, with the possibility of an undocumented extramedullary relapse as well. Patient starting at 80mg did not need adjustment and other one with positive MRD at 3 months changed dose from 80mg to 120mg due to mixed chimerism.

Conclusions: Our study shows encouraging results in patients diagnosed with moderate to adverse risk FLT3-mutated AML with both positive and negative pre-transplant MRD treated with gilteritinib after allo-HCT with acceptable toxicity in most cases. The role of gilteritinib after allo-HCT warrants further investigation, as earlier initiation may prevent hematological relapse even in high-risk disease. Larger studies are needed to continue evaluating safety and efficacy of gilteritinib in this setting.

Disclosure: Nothing to declare.

AN EVOLVING LANDSCAPE – HOW CHANGING CONDITIONING REGIMES CAN IMPROVE MYELOFIBROSIS TRANSPLANT OUTCOMES

Tara Maisel[1], *Sarah Charrot*[2], *James Aries*[2], *Jeff Davies*[3], *James Cavenagh*[2], *John Gribben*[3], *Heather Oakervee*[2], *Paolo Gallipoli*[3]
[1]*Royal London Hospital, Barts Health NHS Trust, London, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Barts Health NHS Trust, London, United Kingdom of Great*

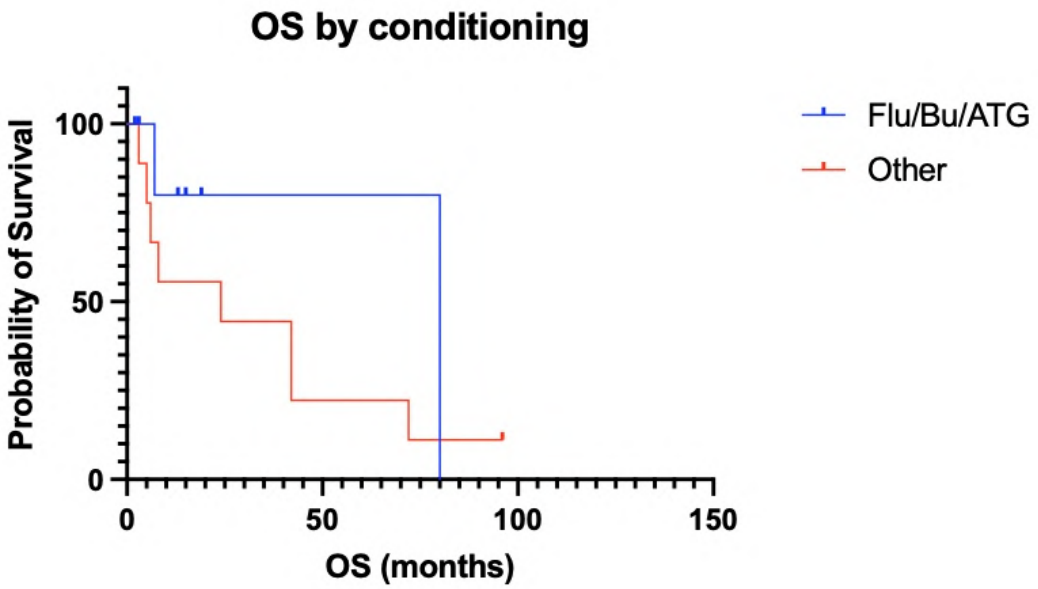
Britain and Northern Ireland (the), [3]Queens Marys University London, Barts Cancer Institute, London, United Kingdom of Great Britain and Northern Ireland (the)

Background: Allogeneic stem cell transplantation (allo-SCT) in myelofibrosis carries significant risks, and outcomes remain suboptimal, reported 5-year survival rates range from 40% to 60%. Despite this, it remains the only potentially curative option. Conditioning regimens vary widely across centres, and with increasing referrals to Barts Health NHS Trust, we aimed to review our outcomes to ensure the highest standard of care.

Methods: We reviewed our transplant data from 2010 to 2025, focusing on outcomes over time, particularly in relation to the introduction of new conditioning regimens. Patient demographics, diagnosis and transplant dates, conditioning regimen, treatment history, cytogenetics, molecular results, and donor type were reviewed. The primary outcome measured was overall survival (OS), secondary was event free survival (EFS).

Results: 16 patients underwent allo-SCT during this period. Seven received stem cells from matched sibling donors, eight from volunteer unrelated donors, and one from a haploidentical donor. 11 patients had primary myelofibrosis, four had secondary myelofibrosis and one had myelofibrosis transformed to AML. The average age at transplant was 55 years, with a male predominance.
Seven patients received Fludarabine/Busulphan/Antithymocyte globulin (Flu/Bu/ATG) conditioning (Fludarabine 30mg/m^2 for 5 days, Busulphan 3.2mg/kg for 2 days and rabbit ATG 2.5mg/kg for 2 days), seven received Fludarabine/Cyclophosphamide (Flu/Cy) (Fludarabine 25mg/m^2 for 5 days and Cyclophosphamide 1g/m^2 for 2 days), and two received Fludarabine/Melphalan (Flu/Mel) (Fludarabine 25mg/m^2 for 5 days and Melphalan 100mg/m^2 on one day). The haploidentical transplant received Fludarabine 30mg/m^2 for 5 days, Cyclophosphamide 14.5mg/kg for 2 days and TBI 200cGy with post-transplant Cyclophosphamide. From 2022, all transplants utilised Flu/Bu/ATG, with only one patient receiving this prior to 2022. In the Flu/Bu/ATG group two have died (29%) and five are alive (71%), compared to eight deaths (89%) and one alive (11%) in the other group.
Five patients had one prior treatment line, five had two, and six had more than two. Therapies included Ruxolitnib, Momelotinib, splenic irradiation and Hydroxycarbamide amongst others.
Cytogenetics were abnormal in four patients (two in each regimen group), normal in nine, and unknown in three. Molecular screening revealed JAK2 positivity in 10 patients, CALR in two, MPL in one and the remainder having a normal screen. Several patients had additional molecular abnormalities.
The median OS and EFS were 42 and 24 months, respectively. Stratifying by conditioning, patients receiving Flu/Bu/ATG had a median OS and EFS of 80 months, compared to 24 months (OS) and 6 months (EFS) for those treated with Flu/Cy or Flu/Mel.
Eight patients developed acute Graft versus host disease (GvHD) (four in each group), four progressed to chronic GvHD (two from each group). Acute GvHD was the cause of death for three patients (one from the Flu/Bu/ATG group and 2 from the other group). Other causes of death included pneumonia, AML and an acute illness. Four causes of death are unknown.

Graft failure occurred in four patients (25%).



Conclusions: Although limited by a small sample size, these findings indicate that the Flu/Bu/ATG conditioning regimen may be associated with improved outcomes. This supports its adoption as the preferred approach, in line with BSH guidelines.

VARIATIONS IN BLOOD TRANSFUSION PRACTICES AMONG SOUTH AFRICAN HAEMATOLOGY PROVIDERS: A SURVEY OF HAEMATO-ONCOLOGY AND HAEMATOPOIETIC STEM CELL TRANSPLANT PRESCRIBERS

Justin du Toit[1], *Adam Setzer*[1], *Estelle Verburgh*[2], *Vernon Johan Louw*[3]
[1]*University of the Witwatersrand, Johannesburg, South Africa,* [2]*University of Cape Town, Cape Town, South Africa,* [3]*University of Stellenbosch, Cape Town, South Africa*

Background: Haemato-oncology and haematopoietic stem cell transplant (HSCT) patients are highly transfusion-dependent. Variability in red blood cell (RBC) and platelet transfusion practices, as well as in requests for blood product modifications, may impact patient safety, resource use and costs.

Methods: We conducted a national cross-sectional survey using a 23-item REDCap® questionnaire distributed (July 2022 – June 2023) to clinicians who regularly prescribe RBCs and platelets for patients with haematological malignancies, HSCT and chronic haematological disorders. Eligible respondents included clinical haematologists, medical and paediatric oncologists, trainees, medical officers, internal medicine registrars and haematopathologists. Descriptive statistics and group comparisons were performed using χ^2 or Fisher's exact tests.

Results: Of 155 invitations, 79 responses were received (51%); 58 eligible, complete responses were analysed. Most clinicians across all groups reported using a restrictive RBC transfusion threshold of 6.0–6.9 g/dL. Clinical haematologists more often cited reduced cardiopulmonary reserve as a reason to transfuse additional RBC units, whereas "other" clinicians more frequently reported medico-legal concerns. Prophylactic platelet transfusion thresholds were broadly similar, but the "other" group was significantly more likely to transfuse more than one platelet unit per episode. Marked variation was observed in platelet thresholds for invasive procedures, with clinical haematologists tending to select guideline-concordant thresholds. Indications for irradiation of blood products also differed, with clinical haematologists more frequently requesting irradiation in accordance with current recommendations.

Conclusions: This national survey demonstrates substantial variation in transfusion thresholds and blood product modification practices among SA haematology providers. Targeted education, guideline implementation and audit-and-feedback strategies are needed to harmonise practice, enhance patient safety and support cost-effective use of blood products.

VIRUS-SPECIFIC T CELL THERAPY FOR POST-TRANSPLANT VIRAL INFECTIONS: ONE YEAR OF CLINICAL-GRADE MANUFACTURING EXPERIENCE

Rebecca Axelsson Robertson[1,2], *Peter Sahlstrom*[1,2], *Tina Thorberg*[1], *Pablo Giusti*[1], *Lyda Osorio*[1], *Teng Wang*[1,2], *Michael Uhlin*[1,2]
[1]*Karolinska University Hospital, Stockholm, Sweden,* [2]*Karolinska Institute, Stockholm, Sweden*

Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is associated with a prolonged period of immunosuppression, during which patients are at enhanced risk for viral infections, most commonly CMV, EBV, adeno- and BK- virus. A subset of patients does not respond adequately to conventional antiviral therapies, leaving limited treatment options. Virus-specific T cells (VSTs), manufactured under GMP conditions, offer a potential therapeutic alternative for these refractory infections.

Methods: Allogeneic donors—either the original HSCT donor or a haploidentical relative—were screened for circulating virus-specific T cells using a bispecific anti-CD45/IFN-γ antibody. A frequency of ≥0.05% virus-specific T cells was required to initiate manufacturing. Leukapheresis was performed to obtain suitable starting material. VSTs were produced using the closed, fully automated CliniMACS Prodigy system. Cells were stimulated with virus-specific peptide pools, and cells producing IFN-γ in response were identified by a bispecific detection antibody. A secondary magnetic bead–conjugated anti–IFN-γ antibody enabled enrichment of virus-specific T cells via magnetic separation.

Results: Four manufacturing processes were completed during the first year of GMP authorization for hospital exemption: one targeting CMV, one targeting BK virus, and two targeting both BK virus and adenovirus. Product quality and specificity was confirmed using flow cytometry. Donor starting material contained 0.04–0.13% virus-specific T cells, which were enriched to 5.8–68% in the final products. Final yields ranged from 90,000 to 1.1 million virus-specific T cells, with the highest output being for the CMV-specific product and the lowest for BK virus–specific products. Enrichment efficiency ranged from 100- to 1000-fold, consistently providing sufficient cell numbers for clinical infusion. All administrations went without incidents and no unexpected adverse events were detected. The clinical symptoms and/or viral load of the patients decreased post infusion.

Conclusions: The manufacturing process is robust, reproducible, and reliably yields adequate quantities of high-purity virus-specific T cells. All treated patients demonstrated reductions in symptoms and/or viral load following VST infusion, supporting the feasibility of this therapeutic approach.

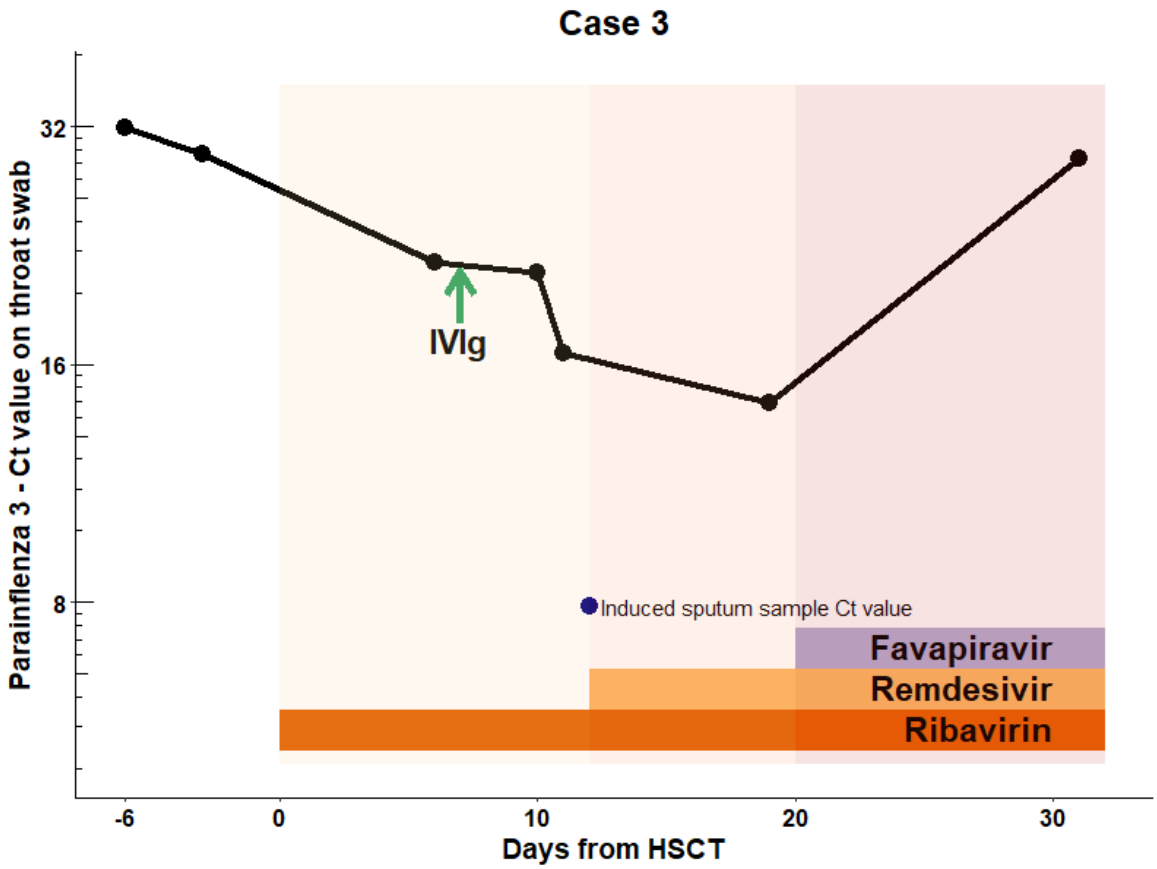
COMBINATION ANTIVIRAL TREATMENT IS EFFECTIVE IN TREATING PARAINFLUENZA 3INFECTION IN THE IMMEDIATE POST-TRANSPLANT SETTING, INCLUDING IN PATIENTS WITH IN-VIVO T-CELL DEPLETION

Antony Cousins[1], *Katharine Patrick*[1], *Samuel Harvey*[1], *Kathryn Edwards*[1], *Judith Breuer*[2], *Michael Ankcorn*[3]
[1]*Sheffield Children's Hospital, Sheffield, United Kingdom of Great Britain and Northern Ireland (the),* [2]*University College London, London, United Kingdom of Great Britain and Northern Ireland (the),* [3]*Sheffield Teaching Hospitals, Sheffield, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Infection of the respiratory tract with RNA-virus pathogens, including Parainfluenza, in the peri-transplant period is associated with high transplant-related mortality in paediatric allogeneic haematopoietic stem cell transplant (HSCT) (26.5% vs 7% (Ottaviano et al., 2020)). Despite high mortality in vulnerable patient groups, there are no licensed antivirals for human Parainfluenza infections.

Methods: We describe below a series of three cases in which combination antiviral treatment was used to treat Parainfluenza 3 infection in the peri-transplant period.

Results: **Case 1:** A 9-month-old male received a Fludarabine(160mg/m^2)/Treosulfan(36g/m^2)/Thiotepa(10mg/kg) (FTT)-Alemtuzumab (1g/kg) conditioned 12/12 HLA-Matched Unrelated Donor Bone Marrow HSCT for high-risk Infant Acute Lymphoblastic Leukaemia. At Day+5 post-stem cell infusion he developed fevers and recrudescence of Parainfluenza infection was found on throat swab. He developed a progressive oxygen requirement and respiratory distress due to parainfluenza lower respiratory tract infection (LRTI), with low Ct/high viral load PCR positivity on BAL and Chest CT changes. His condition deteriorated quickly such that by D+16 he required intubation and ventilation. Despite treatment with IVIg (intravenous immunoglobulin) at D+21, Nitazoxanide (D+24), Favipiravir (D+25), Ribavirin (D+26), and full supportive care, he died of respiratory failure at D+28.
Case 2: A 1-year-old female received an FTT-conditioned T-replete Unrelated Donor Umbilical Cord Blood HSCT for relapsed Acute Myeloid Leukaemia. At D+6 she developed fevers and was found to have recrudescence of Parainfluenza infection on throat swab. Her respiratory symptoms worsened on D+14 with tachypnoea, widespread crepitations/wheeze on auscultation, and perihilar changes on chest X-ray suggestive of LRTI. She was treated with IVIg (D+14), Ribavirin(D+14), and Remdesivir(D+15), with rapid complete resolution of symptoms, and rapid rise (i.e. decrease in viral load) in Parainfluenza Ct values on throat swabs.
Case 3: A 15-year-old female with severe aplastic anaemia and fungal pneumonia was admitted for a Fludarabine(150mg/m^2)/Cyclophosphamide(120mg/kg)-Alemtuzumab (0.3mg/kg) conditioned 12/12 HLA-Matched Sibling Bone Marrow HSCT. At D-6 she developed a transient oxygen requirement and was found to be Parainfluenza positive on throat swab, with significantly lower Ct value (high viral load) PCR positivity on a later induced sputum sample suggestive of LRTI. She was treated with Ribavirin (D+0) and IVIg (D+7) initially but deteriorated on D+12 and required non-invasive ventilation for progressive hypoxia. She was treated with addition of Remdesivir (D+12) and had resolution of symptoms over 96 hours. Favipiravir was added at D+20 to help viral clearance (graph below).



In these cases, Parainfluenza treatment was well tolerated. There were liver function test derangements in Case 1 (Bilirubin 46µmol/L, ALT 3x upper limit of normal (ULN), AST 5xULN) requiring dose interruption of Nitazoxanide/Favipiravir, but this was in the context of significant deterioration in clinical condition. No other toxicities were seen.

Conclusions: Combination therapy with Ribavirin, Remdesivir, Favipiravir, and/or Nitazoxonide, together with IVIg, can be effective in treating Parainfluenza LRTI in the immediate post-transplant period, including in children with *in-vivo* T-cell depletion. Our cases suggest that early combination treatment, prior to the need for invasive ventilation, may be most effective.
Controlled platform trials are necessary to further investigate the clinical efficacy of combination antivirals in this highly vulnerable population.

Disclosure: Nothing to declare

P060

GENETIC INSTABILITY IN BLOOM: A RARE CASE OF HEMATOPOIETIC STEM CELL TRANSPLANTATION

Angeliki Karagiannidou[1], *Konstantinos Gkirkas*[1], *Athina Samiotaki*[1], *Andrianna Diakoumi*[1], *Eleni Kalampoka*[1], *Ioanna Lazana*[1], *Chrysovalantou Chatzidimitriou*[1], *Ioannis Konstantellos*[1], *Panagiotis Tsirigotis*[1]
[1]*General University Hospital "ATTIKON", HSC Transplantation Unit, Chaidari, Greece*

Background: Bloom syndrome (BS) is a rare autosomal recessive disorder caused by pathogenic variants in the *BLM* gene (15q26). It is characterized by genomic instability and a significantly increased predisposition to cancer, including hematological malignancies. We report an adult patient newly diagnosed with acute myeloid leukemia (AML), referred for allogeneic hematopoietic stem cell transplantation (HSCT), who was subsequently found to harbor pathogenic *BLM* variants consistent with BS.

Methods: Peripheral blood (PB) cytogenetics was performed using standard G-banding. Next-generation sequencing (NGS) was conducted on an Illumina MiSeq platform using a panel of 193 genes associated with neoplastic diseases. Chimerism analysis in bone marrow (BM) and $CD3^+$ subsets was performed via amplification of nine short tandem repeat (STR) loci, followed by fragment analysis on a SeqStudio Genetic Analyzer (Thermo Fisher Scientific).

Results: A 37-year-old male was diagnosed with AML following BM aspiration and biopsy. PB cytogenetics demonstrated a highly complex karyotype: 43,XY,−5,−7,del(10)(q23),−13,add(18)(q21) and NGS revealed a TP53 mutation, c.818G>A p.(Arg273His). Upon referral to our BMT Unit for HSCT, clinical examination revealed short stature, microcephaly, and a narrow bird-like facies, raising suspicion for an underlying hereditary genomic disorder. NGS identified compound heterozygous *BLM* mutations—**c.772_773del p.(Leu258Glufs*7)** and **c.2015A>G p.(Gln672Arg)**—confirmed by Sanger sequencing. Family studies showed each parent carried one of the variants. With no matched related donor available, a fully matched (10/10) unrelated donor was selected. The patient received reduced-intensity conditioning consisted of Busilvex 45 mg × 8 doses, Thiotepa 5 mg/kg, and Fludarabine 125 mg/m², followed by infusion of 4.78×10^6 $CD34^+$ cells/kg. Neutrophil engraftment was achieved on Day 13.
Post-transplant chimerism on days 29, 62, 76, and 126 showed a progressive decrease in recipient-derived cells. However, on day 163, BM evaluation revealed morphological relapse. Chimerism demonstrated **46.57% recipient cells in BM** and **8.97% in the $CD3^+$ fraction**. STR analysis revealed **loss of one allele at loci D7S1517 and D11S554** in both BM and $CD3^+$ subsets (Figure). These abnormalities were absent in pre-transplant, pre-relapse, and germline samples, indicating an acquired somatic event. The apparent duplication of the remaining allele supported the presence of **copy-neutral loss of heterozygosity (cnLOH)**.

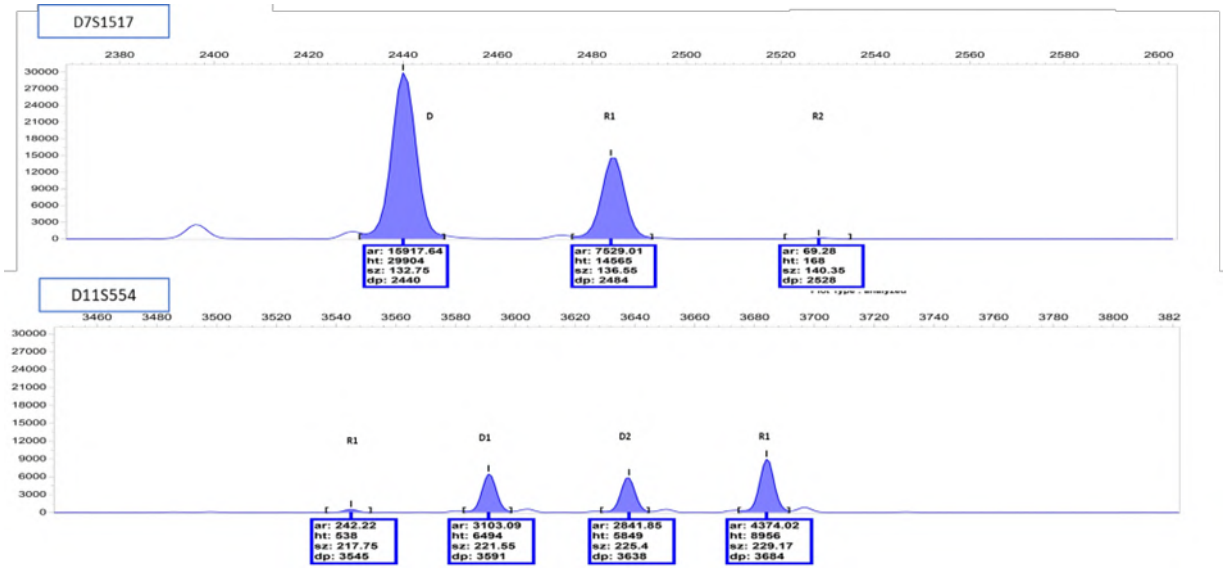


Figure: Post Transplant BM chimerism showing copy-neutral loss of heterozygosity

Post Transplantation Day	29	62	76	126	163
BM	2,75	2.9	-	-	46.57
CD3+	5,19	-	0.91	0,4	8.97

Table: Chimerism analysis post transplantation

Conclusions: This case illustrates AML development and post-HSCT relapse in an adult with previously unrecognized Bloom syndrome. The allelic pattern, at loci **7q31.32** (D7S1517) and 11p11–p12 (D11S554), in which the remaining allele appears duplicated, is consistent with cnLOH, rather than a simple deletion. Its absence in pre-transplant and germline samples represents a somatic event arising in the relapsed leukemic clone, independent of the monosomy 7 observed at diagnosis. Its presence in both BM and $CD3^+$ compartments suggests involvement of early hematopoietic progenitors. The 7q31 region is recurrently altered in myeloid malignancies and may harbor relevant tumor suppressor genes, while the significance of the 11p11–p12 alteration remains uncertain. BS-associated genomic instability likely contributed to these somatic rearrangements, emphasizing the value of high-resolution genomic profiling at relapse for prognosis and therapy guidance, particularly in patients with underlying chromosomal instability syndromes.

P061

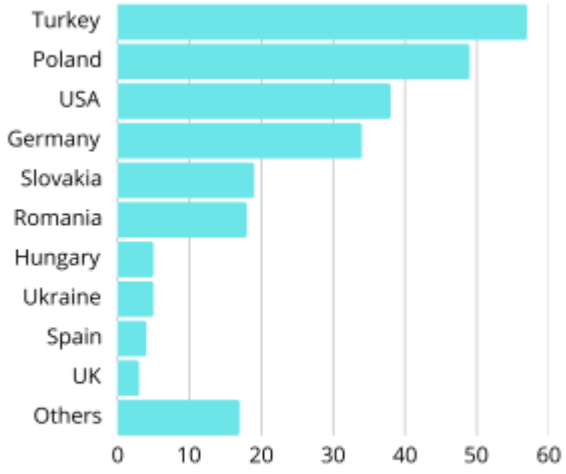
CLINICAL UTILIZATION OF CORD BLOOD UNITS IN THE FAMICORD GROUP

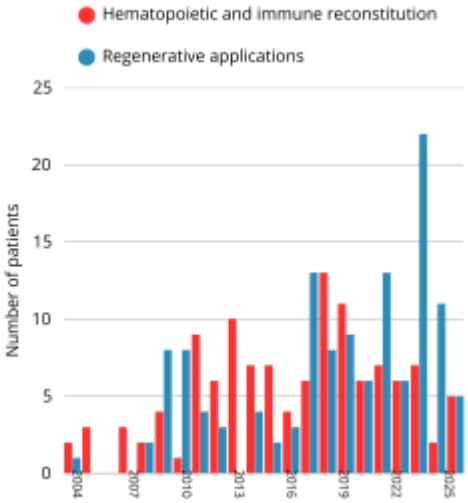
Tomasz Baran[1], *Dariusz Boruczkowski*[1], *Emilian Snarski*[1], *Tomasz Ołdak*[1], *Izabela Zdolińska-Malinowska*[1]
[1]*Polish Stem Cell Bank, FamiCord Group, Warsaw, Poland*

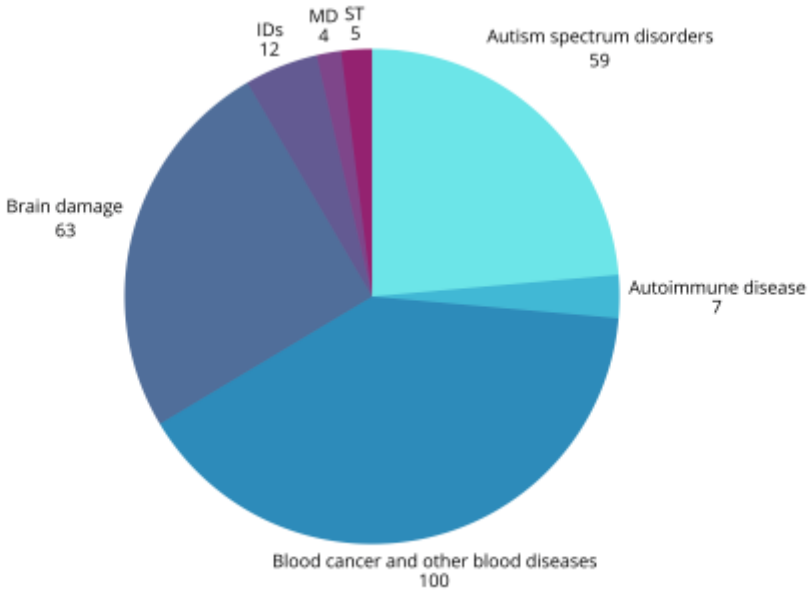
Background: Cord blood (CB) banking aims to enable clinical use of stored units. Three CB banking models exist: public, family, and hybrid. Although most CB transplantations use publicly banked units, CB stored in accredited family banks is also clinically applicable for autologous and related allogeneic use. The FamiCord Group is the largest cord blood bank in Europe, primarily focused on family banking while also offering hybrid and public models. This study reports CB unit releases from FamiCord-affiliated banks between 2004 and 2025.

Methods: Data were extracted from the FamiCord Group release database and analyzed using descriptive statistics.

Results: A total of 250 CB units were released: 120 (48.0%) autologous, 112 (44.8%) related allogeneic, and 17 (6.8%) unrelated allogeneic; relatedness was unspecified in one case. The most frequent indication was bone marrow reconstitution (BMR; n=100, 40%), followed by brain injuries (n=63, 25.2%), autism spectrum disorder (n=59, 23.6%), immunodeficiencies (n=12, 4.8%), solid tumors (n=5, 2.0%), and metabolic disorders (n=4, 1.6%). Eleven units (4.4%) were used in an autologous setting for standard hematological indications. CB units were released to clinics in 23 countries, most commonly Turkey, Poland, the USA, and Germany. Over time, CB releases increased for both hematological and regenerative applications, with greater growth in regenerative medicine.







Conclusions: Family cord blood banks represent a relevant source of CB units for transplantation and investigational regenerative therapies.

Clinical Trial Registry: Not applicable.

Disclosure: All of the authors are employed by the Polish Stem Cell Bank (FamiCord Group), Warsaw, Poland.

P063

EFFICACY AND SAFETY OF SHORT-COURSE BLINATUMOMAB FOR PEDIATRIC B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA WITH MOLECULAR RECURRENCE AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION

Chen Xinyu[1], Weng Chenyu[1], Lu Jun[1], ***Shaoyan Hu***[1]
[1]*Children's Hospital of Soochow University, Suzhou, China*

Background: Pediatric B-cell Acute Lymphoblastic Leukemia (B-ALL) patients who experienced hematopoietic stem cell transplantation (HSCT), including molecular recurrence, have a poor prognosis with conventional approaches. Molecular recurrence, defined as patients who had genetic markers and immunophenotypic characteristics before treatment, and after treatment, the results of FCM, fusion gene, and other tests turned from negative to positive and remained positive after re-examination, is a critical predictor of subsequent overt relapse and poor survival. Blinatumomab, a CD19/CD3 bispecific T cell engager, has demonstrated high remission rates and favorable tolerability as adjunctive therapy for relapsed pediatric B-ALL during chemotherapy. However, short-course Blinatumomab for post-HSCT molecular recurrence is scarce. This study aimed to evaluate its efficacy and safety.

Methods: Retrospective analysis of 4 pediatric B-ALL patients with post-HSCT molecular recurrence who received short-course Blinatumomab (dose escalated from 5 μg/m²/day to 15 μg/m²/day via continuous IV infusion, completed in approximately 14 days). Efficacy was assessed by FCM/fusion gene re-examination after Blinatumomab; adverse events (AEs) were graded by CTCAE v5.0.

Results: The types of transplantation in 4 pediatric patients were, respectively, 2 cases of haploid transplantation and 2 cases of fully matched transplantation from unrelated donors. Median time from HSCT to molecular relapse was 102.5 days (range: 65.5 - 299.0). Recurrence markers include the fusion genes KMT2A::AFF1, KMT2A::MLLT1, chr3::LMBR1L, and the mutated gene IL7R. After one course of treatment, 3 cases (75%) achieved complete molecular remission, and 1 case remained positive for the fusion gene (1 case). Median follow-up was 20 months, with a 100% overall survival (OS) rate and a 100% progression-free survival (PFS) rate. AEs included grade 1 cytokine release syndrome (CRS) (2 cases), elevated transaminases (1 case), and elevated brain natriuretic peptide (BNP) (1 case), all of which were effectively controlled by supportive treatment. No grade of graft-versus-host disease (GVHD) was observed in any of 4 pediatric patients during and after the treatment of blinatumomab.

Conclusions: Short-course blinatumomab therapy exhibits favorable efficacy and safety in the treatment of post-transplant molecular relapse of B-cell acute lymphoblastic leukemia (B-ALL). It prevents disease progression and reduces the rate of secondary hematopoietic stem cell transplantation, while the long-term efficacy and safety still require verification by large-scale clinical studies.

Disclosure: Nothing to declare.

P065

OUTCOME OF ALLOGENEIC STEM CELL TRANSPLANTATION IN ACUTE MYELOID LEUKEMIA AND MYELODYSPLASTIC SYNDROMES: EXPERIENCE FROM A TERTIARY CENTER IN SAUDI ARABIA

Wael Alanazi[1], *Mousa J. Alhaddad*[1], *Faisal H. Alharbi*[1], *Abdullah S. Almusalam*[1], *Abdulmalik H. Alabdulqader*[1], *Talal K. Alafif*[1], *Omar Albanyan*[1]
[1]*King Fahad Specialist Hospital, Dammam, Saudi Arabia*

Background: Acute myeloid leukemia (AML) and myelodysplastic syndromes (MDS) are characterized with significant mortality rates and poor clinical outcomes. Allogenic stem cell transplantation (AlloSCT) offers potential cure for AML and MDS . However, it carries significant risks of morbidity and mortality. Disease relapse, Graft Versus Host Disease (GVHD) and transplant related mortality (TRM) are potential risks to affect AlloSCT outcomes. This study aimed to report AlloSCT outcomes in AML and MDS at King Fahad specialist Hospital – Dammam (KFSH-D).

Methods: We retrospectively chart reviewed patients with myelodysplastic syndrome (MDS), acute myeloid leukemia (AML), myeloid sarcoma, and chronic myeloid leukemia (CML) with myeloid blast crisis who underwent AlloSCT at KFSHD between 2011 and 2023. We set Endpoints included graft-versus-host disease (GVHD), disease relapse, three-year survival, and overall survival (OS) rates.

Results: The study included 61 patients with a mean age at diagnosis of 37.95 ± 12.1 years. The majority were male (55.74%), and all were of Saudi nationality. AML was present in 91.80% of patients. Cytogenetic analysis revealed abnormalities in 50.83% of patients. Molecular testing showed NPM1 positivity in 9.84% and FLT3-ITD positivity in 34.42% of patients. The mean time to platelet and neutrophil engraftment were 13.88 ± 4.57 and 18.35 ± 4.78 days, respectively. Seventeen patients (27.87%) developed acute GVHD, and 37 patients (60.66%) developed chronic GVHD. Nineteen patients (31.15%) experienced relapse. The 100-day and two-year overall survival rate were 88.52% and 59.02% respectfully. Those who died relapsed more than the survivors (51.61% vs 10.0%, p-value < 0.01).

Conclusions: AlloSCT is a potentially curative therapeutic options for AML and MDS, yet it is associated with significant mortality rates. Our study revealed overall survival comparable to what has been reported in the literature but with significant rates of acute and chronic GVHD. Hence, improving GVHD prophylaxis protocols may reduce such risks.
We demonstrate the outcomes of AlloSCT at KFSH-D, highlighting the importance of careful patient selection and monitoring to improve survival rates and minimize complications.

Disclosure: No conflict of interest.

OUTCOMES OF THIRD ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION AMONG HEMATOLOGICAL MALIGNANCY PATIENTS RELAPSE POST SECOND ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION

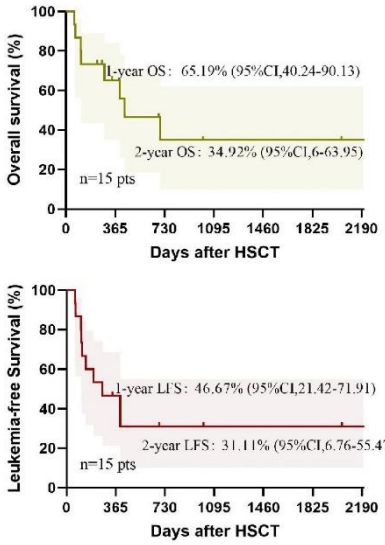
Song Xue[1], *Wei Ma*[2], *Zi-jie Wei*[2], *Min Xiong*[2], *Xing-yu Cao*[2]
[1]*Beijing Lu Daopei Hospital, Beijing, China,* [2]*Hebei Yanda Lu Daopei Hospital, Langfang, China*

Background: Relapsed hematological malignancy after allogeneic hematopoietic stem cell transplantation (allo-HSCT1) is associated with poor prognosis. A subset of patients can achieve durable remission through a second allo-HSCT (allo-HSCT2). However, a substantial number (30%) of patients experience relapse after allo-HSCT2, and there are limited therapeutic options for these patients. In select patients, a third allo-HSCT (allo-HSCT3) can be administered. Given the substantial risks involved in undergoing allo-HSCT3 , such procedures are infrequently attempted . Consequently, the benefits of allo-HSCT3 remains uncertain.

Methods: We performed a retrospective analysis of patient outcomes for individuals with hematological malignancies who underwent allo-HSCT3 due to either hematological/extramedullary relapse or persistent disease, as indicated by flow cytometry minimal residual disease positivity (FCM-MRD+) or the presence of a fusion gene, following a allo-HSCT2. This study was conducted at Beijing Lu Daopei Hospital and Hebei Yanda Lu Daopei Hospital, covering the period from 2015 to 2024. Patients who had previously undergone autologous hematopoietic stem cell transplantation prior to allo-HSCT3 or who received allo-HSCT following primary graft failure were excluded from the analysis.

Results: Following rigorous screening, 15 patients (6 males, 9 females) were included, with a median age of 15 years (range 1–42) at allo-HSCT1. Diagnoses were AML (n=9), B-ALL (n=3), T-ALL (n=1), MPAL (n=1), and MDS (n=1). All underwent allo-HSCT1 in CR from a haploidentical (HID, n=10), matched sibling (MSD, n=2), matched unrelated (MUD, n=2), or umbilical cord blood (UCB, n=1) donor, following BU/CY-based conditioning. Median time to relapse after allo-HSCT1 was 397 days (range 49–2201).After salvage therapy, 13 patients received allo-HSCT2 in CR, with donor changed in 11 cases. Conditioning was TBI-based (n=11) or BU-based (n=4). Median relapse time after allo-HSCT2 was 265 days (range 60–1913).Before the allo-HSCT3, patients received various salvage regimens. At allo-HSCT3, 9 were in CR and 6 were not. Donor was changed in 11 patients. Conditioning was myeloablative (MAC, n=7) or reduced-intensity (RIC, n=8). Median infused cell doses were 11.37×10^8/kg MNC (range 4.62–16.66) and 7×10^6/kg $CD34^+$ cells (range 2.8–7.37). All engrafted: median neutrophil recovery 15 days (9–21), platelet recovery 20.5 days (12–77). Complications included acute/chronic GVHD (n=11), CMV reactivation (n=10), and EBV reactivation (n=2).With a median follow-up of 340 days (range 63–2261) until July 7, 2025, 7 patients (46.7%) were alive and 8 (53.3%) had died-mainly from relapse (n=3) or infection (n=3), with 2 early deaths from infection within 100 days. Median LFS was 268 days, with 1- and 2-year rates of 46.7% and 31.1%, respectively. Median OS was 436 days,

with 1- and 2-year OS of 65.2% and 34.9%. Two patients remained disease-free >5 years.



Conclusions: Relapse of hematological malignancies after allo-HSCT remains a major therapeutic challenge. In this retrospective analysis,allo-HSCT3 enabled long-term LFS in a considerable proportion of patients, despite its inherent difficulties. While selection bias cannot be ruled out, the favorable outcomes may be partly due to the younger age of our cohort. These findings suggest that allo-HSCT3 can be a potentially curative option for selected patient populations.

HEMATOPOIETIC STEM CELL TRANSPLANTATION IN PATIENTS WITH LI-FRAUMENI SYNDROME AND HEMATOLOGIC MALIGNANCIES: A SINGLE-CENTER EXPERIENCE

Maria Ilyushina[1], *Anna Kazakova*[1], *Larisa Shelikhova*[1], *Maria Klimentova*[1], *Michael Maschan*[1]
[1]*Dmitry Rogachev National Medical Research Centre for Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation (the)*

Background: Li-Fraumeni syndrome is a major hereditary cancer predisposition syndrome. Hematologic malignancies account for about 4% of cases, mainly represented by acute lymphoblastic leukemia (ALL) with hypoploid karyotypes and secondary myelodysplastic syndromes (MDS). The lack of clear guidelines for both diagnosis and treatment, as well as

the genetic basis of the disease, creates significant challenges in selecting the optimal therapy and conditioning regimens prior to HSCT.

Methods: Four cases of Li-Fraumeni syndrome treated at a single center are presented. The patients underwent transplantation in 2024 and 2025.
Patient C, 17 years old; B-ALL, treated since 2022. Treated per a combined chemo-immunotherapy protocol. MRD detected at end of therapy; auto-CAR T given before HSCT, achieving a 3-month remission. Pre-HSCT MRI showed a right iliac bone lesion. Conditioning — see Table 1.
Patient K, 14; B-ALL since 2023. Intermediate risk. Oct 2024: very early isolated marrow relapse. ALL-REZ 2016: after FLAM blasts 45%; inotuzumab—blasts 15%; then blinatumomab: MRD 0.778%, blasts 6%. Pre-HSCT blasts up to 15%. Conditioning—see Table 1.
Patient P, 17. History: embryonal rhabdomyosarcoma of the left gluteal region, pT1N0M0 (May 2009); periosteal sarcoma of the left femur (Aug 2020). Diagnosis: MDS with excess blasts; treated since 2024. From Oct 2024: venetoclax plus low-dose decitabine. After repeat cycles, marrow blasts and MRD increased; decision for HSCT with split conditioning (Table 1).
Patient K2, 14: B-ALL (CNS-0) diagnosed 01/2023. Treated per ALL IC-BFM 2002 then LBL-2018 (high risk). MRD-negative remission on 17 Apr 2023; completed Protocols M and II; maintenance from Sep 2023.
On 14 Jun 2024: very early isolated marrow relapse. ALL-Rez 2016: FLAM block → remission; from 22 Jul 2024 blinatumomab; end of block: blasts <5%, MRD 0%. Conditioning—see Table 1.

Table 1 summarizes the patients' characteristics and main treatment phase.

	Diagnosis	Genetic	Status of disease before HSCT	Conditiotion	HSCT (D, BM|PBS	Preventive therapie GVHD

Results: All patients received myeloablative conditioning. Engraftment was achieved in all cases; donor chimerism and remission were confirmed on day +30. The HSCT procedures were completed without serious complications. Three of four patients relapsed. Two underwent a second HSCT.

Conclusions: Our observation indicates good tolerability of myeloablative conditioning.Overall, patients with Li-Fraumeni syndrome are at high risk for malignant tumors but rarely develop hematologic malignancies. Consequently, there are no cohort studies, and isolated case reports do not allow for reliable conclusions about prognosis and the risks associated with myeloablative conditioning regimens.

LATE-ONSET DONOR-DERIVED PDGFR-B–REARRANGED EOSINOPHILIC NEOPLASM FOLLOWING HAPLOIDENTICAL ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN A SECONDARY ACUTE MYELOID LEUKEMIA

Francien Bonifacia Lumauag[1], *Maria Fe Alvarez*[1]
[1]*St. Luke's Medical Center, Taguig, Philippines (the)*

Background: Donor-derived hematologic neoplasms are rare complications of allogeneic hematopoietic stem cell transplantation (allo-HSCT) and may present diagnostic challenges, particularly when manifesting as late-onset eosinophilia. Distinguishing clonal donor-derived disease from reactive eosinophilia or disease relapse is essential, as donor-derived neoplasms have distinct biological behavior and therapeutic implications. We report a case of late-onset donor-derived platelet-derived growth factor receptor beta (PDGFR-β)–rearranged eosinophilic neoplasm following haploidentical allo-HSCT for secondary acute myeloid leukemia (AML).

Methods: Clinical, laboratory, cytogenetic, and molecular data were retrospectively reviewed. Serial complete blood counts, bone marrow examinations, next-generation sequencing (NGS), and short tandem repeat (STR) chimerism analyses were evaluated. Fluorescence in situ hybridization (FISH) for hypereosinophilic syndrome–associated

rearrangements was performed following the development of persistent eosinophilia in the late post-transplant period.

Results: A 60-year-old female with high-risk myelodysplastic syndrome that transformed to AML achieved complete remission after induction chemotherapy with idarubicin, cytarabine, and venetoclax, followed by consolidation therapy. Pre-transplant NGS identified FLT3, IDH2, and KMT2A (MLL) mutations, with no PDGFR-β rearrangement detected, excluding pre-existing PDGFR-β–driven disease in the recipient. She subsequently underwent haploidentical allo-HSCT using her son as donor. The donor had normal baseline blood counts and no eosinophilia prior to stem cell collection.
Post-transplant bone marrow examinations demonstrated sustained morphologic and flow cytometric remission, and repeat NGS showed no pathogenic mutations. At Day +243 post-HSCT, the patient developed persistent eosinophilia, initially attributed to graft-versus-host disease or drug-related causes. Given its persistence, further molecular evaluation was pursued. FISH analysis revealed a PDGFR-β rearrangement, establishing a diagnosis of a clonal eosinophilic neoplasm. STR chimerism analysis performed after the onset of eosinophilia demonstrated 100% donor engraftment, confirming donor origin of hematopoiesis.
The late timing of presentation, absence of PDGFR-β rearrangement prior to transplant, normal donor hematologic parameters, and complete donor chimerism supported classification as a **l**ate-onset donor-derived myeloid/lymphoid neoplasm with eosinophilia, consistent with post-engraftment expansion of a previously occult donor clone.

Conclusions: This case represents a rare example of late-onset donor-derived PDGFR-β–rearranged eosinophilic neoplasm following haploidentical allo-HSCT. Clinically silent donor clones may exist despite normal donor blood counts and can expand after engraftment under altered immune and hematopoietic conditions. Persistent eosinophilia occurring beyond six months post-transplant warrants molecular evaluation for clonal disorders, even in the presence of complete donor chimerism and sustained remission, to ensure accurate diagnosis and enable timely targeted therapy.

A SINGLE CENTRE EXPERIENCE OF ALLOGENEIC STEM CELL TRANSPLANTATION IN PATIENTS WITH DDX41-MUTATED MDS AND AML

Catharina Tao[1], *Martin Loader*[1], *Faisal Basheer*[1], *Helen Bentley*[1], *Duncan Brian*[1], *Louise Corbett*[1], *Claire Cowling*[1], *Charles Crawley*[1], *Kushani Ediriwickrema*[1], *Zoe Edwards*[1], *Jo Hall*[1], *Ram Malladi*[1], *Kiran Tawana*[1], *Simon Richardson*[1], *Ben Uttenthal*[1], *Francisca Vasconcelos*[1], *Chi Wong*[1], *Andrew King*[1]
[1]*Cambridge University Hospitals, Cambridge, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Germline pathogenic variants in *DDX41* represent the most common genetic predisposition to myeloid malignancies, accounting for approximately 3% of cases. Despite this however, the prognostic implications of DDX41 mutations remains unclear and data on outcomes following allogeneic stem cell transplantation (alloSCT) remain limited.

Methods: This retrospective single-centre study reviewed outcomes of patients with DDX41 mutated MDS or AML undergoing allo(SCT) at our institution between 2019-2024. Outcomes included: overall survival (OS), relapse-free survival (RFS), GVHD-free relapse-free survival (GRFS), relapse incidence, GVHD incidence/severity, chimerism, donor lymphocyte infusion (DLI) requirement, infection, and mortality incidence/cause.
Survival was estimated using Kaplan–Meier method. Cumulative incidences were calculated using competing-risks methods.

Results: 8 patients with a presumed or confirmed germline pathogenic *DDX41* mutation were identified. 7 carried a second likely somatic mutation. 7 had AML (all ELN-2022 adverse risk). 1 had MDS (IPSS-R 3.5).
7 patients were male and the median age at transplant was 65.5 years (IQR 62.5-68.25). 7 patients received Fludarabine/Melphalan/Alemtuzumab (FMC) conditioning and 1 received Thiotepa/Busulfan/Fludarabine/ATG (miniTBF). In all cases a fully matched volunteer unrelated donor was used. (Further characteristics Table 1)
Median follow-up was 1040.5 days. Median OS was 307.5 days. Median RFS was 306 days. Median GRFS was 116.5 days. (Figure 1)
At follow up (24/11/2025), 5 (62.5%) of patients had died. Transplant-related (day 100) mortality was 12.5% (1/8) (Failure to engraft). Relapse-related mortality was 12.5% (1/8). Non-relapse mortality was 37.5% (3/8), due to infection. Cumulative incidence of death was 13% (95% CI 0.48%–44%) at day 180 and 63% (95% CI 18–88%) at one year.
1 patient experienced relapsed disease, at day 148 post-transplant. This patient survived 53 days post-relapse.
Acute GVHD occurred in 3 (37.5%) patients with no Grade III/IV disease. Chronic GVHD occurred in 3 (37.5%) patients (two severe, one moderate), with cumulative incidence of 13% (95%CI: 0.43%–45%) at day 180 and 38% (95%CIL: 6.1%–71%) at one year.
All patients reached complete whole-blood donor chimerism (≥95%) by day 30. 3 (37.5%) achieved complete T-cell chimerism. At day 100, whole-blood chimerism remained complete in 6/7 assessable patients, and complete T-cell chimerism in 2/7. Two patients required DLI both for mixed chimerism and both experienced post-DLI acute GVHD (stage 1 and stage 2 skin).
All patients experienced clinically significant infections post-transplant. Infection directly caused 3 deaths and contributed to two others. Median time to first infection was 134 days (IQR 54.25–359.5). The cumulative incidence of any infection was 63% (95%CI: 18–88%) at day 180 and 75% (95%CI: 23–94%) at one year.

HSCT-CI Score	Number of Patients
0	3
1	0

2	2
3	2

Table 1 - Further patient characteristics

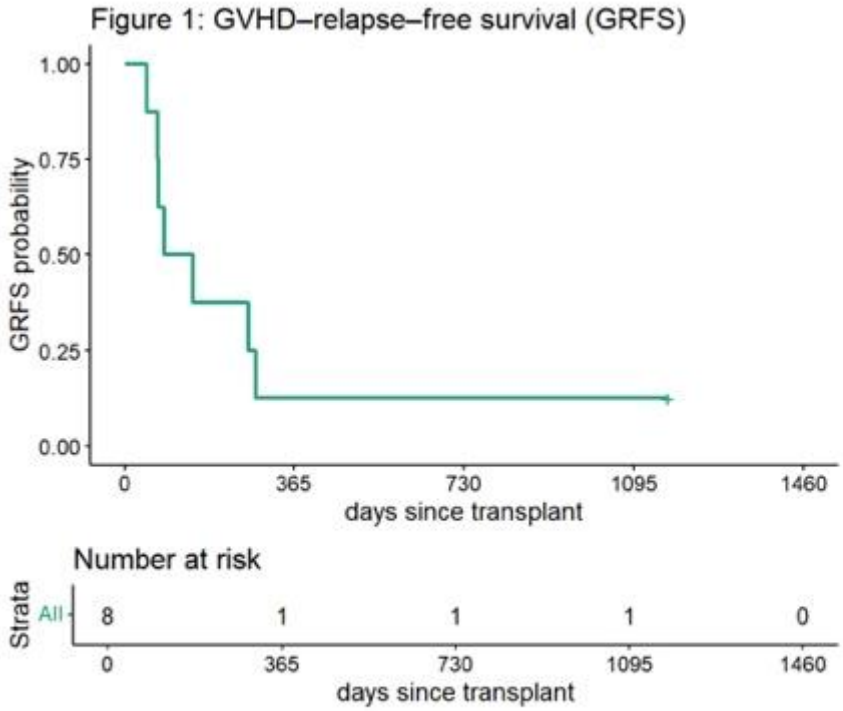

Figure 1: GVHD-relapse-free survival (GRFS) after alloSCT estimated using the Kaplan-Meier method.

Conclusions: AlloSCT for patients with germline DDX41 mutations is feasible but associated with substantial non-relapse mortality and high rates of both GVHD and infection. Further studies are required to optimise management strategies and supportive care for this genetically distinct patient population.

P072

SUCCESSFUL IMPLEMENTATION OF CAR-T CELL THERAPY AT THE ONCOLOGY INSTITUTE IN WARSAW

*Joanna Romejko-Jarosinska[1], **Lukasz Targonski**[1], Katarzyna Domanska-Czyz[1], Marcin Szymański[1], Beata Ostrowska[1], Ewa Paszkiewicz-Kozik[1], Monika Swierkowska[1], Agnieszka Druzd-Sitek[1], Anna Dabrowska-Iwanicka[1], Robert Konecki[1], Anna Borawska[1], Ewa Mroz-Zycińska[1], Leszek Czernik[1], Joanna Tajer[1], Tomasz Maleszyk[1], Katarzyna Szczesniak[1],*

Martyna Kotarska[1], Jan Walewski[1]
[1]National Research Institute of Oncology, Warszawa, Poland

Background: CAR-T therapy has become the standard treatment for patients with refractory diffuse large B-cell lymphoma (DLBCL) and refractory mantle cell lymphoma (MCL). We present here our initial experience with CAR-T therapy implementation over the past year at our center – tolerability and safety.

Methods: We collected data from 14 consecutive patients (5 with MCL and 9 with DLBCL) who underwent the CAR-T procedure between August 2024 and November 2025 at our center. Cyclophosphamide and fludarabine were administered on days 5-3, followed by the CAR-T cell drug infusion Yescarta (DLBCL) or Tecartus (MCL), depending on the diagnosis.

Results: Median age was 59 years, with a range of 31-71 years. The number of lines of therapy for MCL patients ranged from 3 to 5. All MCL patients were treated with the R-CHOP/RDHAP regimen with autotransplantation consolidation, followed by ibrutinib (n=3) or acalabrutinib (n=2) in subsequent lines. In the case of DLBCL, all patients received the RCHOP/Pola-RCHP regimen as first-line therapy. Two patients received CAR-T therapy as second-line therapy, and the remaining (n=6) as third-line or subsequent lines. The median time from leukapheresis to CAR-T cell administration was 35 days (range: 28-103). Ten patients received bridging therapy before CAR-T therapy, Pola-BR or R-GEMOX chemotherapy for DLBCL, and R-bendamustine for MCL. Cytokine release syndrome (CRS) occurred in 10 patients (71%) after CAR-T cell administration, with grade above 3 in only one patient (7%). The duration of CRS ranged from 2 to 10 days with a median of 2 days. Three patients required tocilizumab. Immuno-Effector Cell-Associated Neurotoxicity Syndrome (ICANS) occurred in 8 patients (57%), in 2 patients above grade 3 (14%), lasting from 1 to 10 days with a median of 2 days. Two patients received four doses of Anakinra. Haematological toxicity occurred in all patients: grade 3/4 neutropenia occurred from day 0 to 7 and lasted from 1 to 12 days with a median of 7 days. One patient developed anaemia requiring RBC transfusion, four patients had grade 3 thrombocytopenia, and one had grade 4 thrombocytopenia. Two patients experienced vomiting and general weakness. None of the patients developed confirmed infections. One patient died due to progressive grade 4 CRS. Following the CAR-T procedure, lymphoma progression occurred in four patients, two of them died due to progressive disease. Ten patients are alive, 8 in complete remission (4 with MCL and 4 with DLBCL) and 2 patients with DLBCL are treated with bispecific antibodies.

Conclusions: CAR-T therapy appears to be a safe and tolerable procedure despite the occurrence of profound neutropenia and the development of CRS and ICAN syndromes. Severe CRS and ICANS occurred in less than 15% of patients.

Disclosure: No disclosures.

P073

LASER DOPPLER-BASED MICROCIRCULATORY MONITORING AS AN EARLY PREDICTOR OF POOR VENOUS FLOW DURING LEUKAPHERESIS

Ryu Yanagisawa[1], *Saori Konno*[1], *Rui Murahashi*[2], *Ryo Matsuoka*[2], *Daichi Matsui*[2], *Tomoki Kamiyama*[2], *Manjiro Yamanaka*[1], *Kazuki Horiuchi*[1], *Shin-ichiro Fujiwara*[2]
[1]*Shinshu University Hospital, Matsumoto, Japan,* [2]*Jichi Medical University Hospital, Shimotsuke, Japan*

Background: Reliable venous access and stable blood flow are essential for the efficient collection of hematopoietic progenitor cells or lymphocytes for cellular therapy. Poor venous blood flow during leukapheresis remains a common procedural challenge that can compromise collection efficiency, prolong procedure time, and exacerbate patient burden. Moreover, robust predictive markers enabling early intervention are lacking.

Methods: We retrospectively analyzed 146 leukapheresis procedures (79 in patients with hematologic malignancies and 67 in healthy donors) at two institutions. Continuous peripheral microcirculatory blood flow was monitored using laser Doppler flowmetry during leukapheresis. The incidence, timing, and risk factors for poor venous flow were assessed, and hemodynamic parameters at onset were examined to determine whether microcirculatory changes precede clinically apparent flow deterioration.

Results: Poor venous blood flow during apheresis occurred in 23 of 79 individuals (29.1%) in the hematologic malignancy group and 18 of 67 individuals (26.9%) in the healthy donor group, with median onset times of 23 minutes (range, 0–165 minutes) and 21.5 minutes (range, 0–65 minutes), respectively. In patients, poor venous flow was independently predicted by multiple myeloma, lower baseline microcirculatory flow, and higher pulse amplitude. In healthy donors, older age was a notable predictor. A decline in peripheral blood flow preceded the onset of poor venous flow, while systemic blood pressure and pulse rate remained stable, indicating that microcirculatory changes may serve as an early and sensitive physiologic marker of impending flow deterioration.

Conclusions: Real-time peripheral blood flow monitoring using laser Doppler flowmetry may provide a sensitive early-warning signal for impending poor venous flow during leukapheresis. Incorporating baseline microcirculatory parameters into preprocedural risk assessment may help identify high-risk patients—particularly those with hematologic malignancies—and also support proactive strategies to optimize leukapheresis management. This physiological monitoring approach has the potential to improve the safety and efficiency of stem cell and cellular therapy product collection in clinical transplantation settings.

Disclosure: Nothing to declare.

P074

THE ILLUSION OF DEFEAT: PSEUDO-PROGRESSION FOLLOWING DUAL CD19/CD22 CAR-T THERAPY IN REFRACTORY DLBCL

Sundar Shewale[1], *Mihir Das*[1], *Kasturi Sengupta*[2], *Arunava Halder*[1], *Joydeep Chakrabartty*[3]
[1]*HCG Cancer Hospital, Kolkata, India,* [2]*AMRI Hospital, Mukundapur, Kolkata, India,* [3]*HCG Cancer Hospital, Kolkata, Kolkata, India*

Background: CAR-T cell therapy has revolutionized the management of relapsed or refractory B-cell lymphomas. While immune-mediated toxicities such as cytokine release syndrome (CRS) and immune effector cell–associated neurotoxicity syndrome (ICANS) are well recognized, pseudoprogression remains a rare and underreported phenomenon. This transient immune-driven flare can mimic disease progression, creating diagnostic uncertainty and management dilemmas.

Methods: A 69-year-old male with relapsed/refractory diffuse large B-cell lymphoma (DLBCL) with secondary CNS involvement which had initially been treated with multiple lines of chemotherapy, including RCHOP, R-HyperCVAD with eventual disease relapse involving the CNS and leptomeninges, The patient achieved partial remission after Zanubritinib R-ICE therapy. Patients admitted for CAR-T therapy (targeting CD19 and CD22). After lymphodepletion with fludarabine and cyclophosphamide, CAR-T cells were infused at a dose of 5.77×10^6/kg.

Results: The immediate post-infusion course was uneventful, with Grade1 cytokine release syndrome (CRS) and no neurotoxicity. On follow-up at three months, PET-CT demonstrated new hypermetabolic lesions in the liver and bone, raising concern for disease relapse. However, the patient remained asymptomatic. Bone marrow biopsy revealed absence of B cells and no clonal lymphoma. GeneXpert for tuberculosis was negative. Surpisingly Fibroblast Activation Protein Inhibitor (FAPI) scan done showed no activity.
Patient had no clinical symptoms, no B cell in bone marrow and persistent CAR-T presence, the findings were interpreted as immune-mediated pseudo-progression, likely due to CAR-T–induced inflammatory changes rather than true relapse. Over subsequent PET scan, the lesions regressed spontaneously without any intervention, confirming pseudo-progression. Next generation sequencing from peripheral blood of patient and daughter reveals DDX41 mutation suspecting possible predisposition of lymhphoma. A FAPI

Conclusions: This case underscores the importance of distinguishing true relapse from pseudo-progression following CAR-T therapy. Recognizing this phenomenon can prevent unnecessary and salvage treatments. Emerging imaging modalities such as FAPI PET may assist in differentiating inflammatory responses from residual disease, but their role remains investigational and requires further validation in larger studies. FAPI imaging may act as a complementary tool to FDG PET CT when metabolic flare creates diagnostic uncertainty.

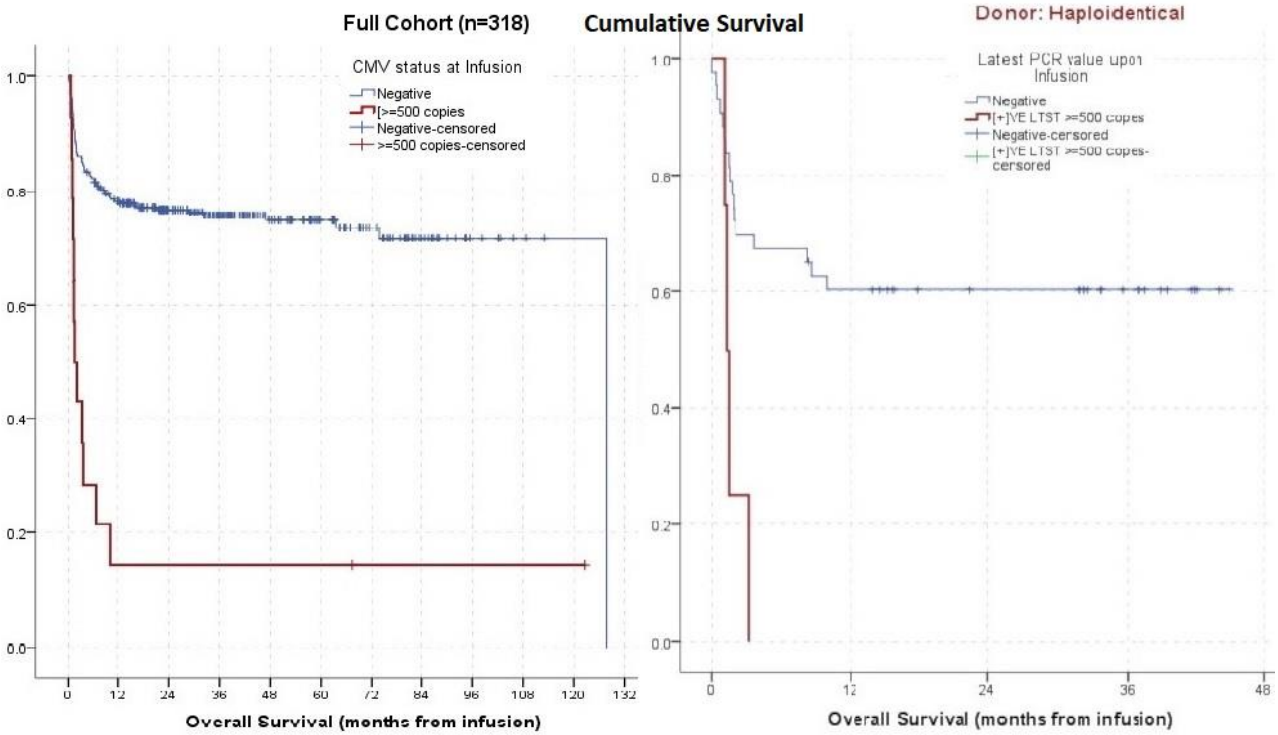
IMPACT OF REFRACTORY PRE-TRANSPLANT CYTOMEGALOVIRUS INFECTIONS ON SURVIVAL IN CHILDREN UNDERGOING STEM CELL TRANSPLANT FOR PRIMARY IMMUNODEFICIENCY DISORDERS

Fatema Al-Hashem[1], *Hawazen AlSaedi*[1], *Rafat Jafri*[1], *Khawar Siddiqui*[1], *Saadiya Khan*[1], *Abdullah Al-Jefri*[1], *Awatif AlAnazi*[1], *Mouhab Ayas*[1], *Ibrahim Ghemlas*[1], *Reem Mohammed*[1], *Hamoud Al Mousa*[1], *Ali Al-Ahmari*[1]
[1]*King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia*

Background: Harbouring a cytomegalovirus (CMV) infection in pre- transplant period has been associated with a negative effect on transplant outcome due to increased risk of graft failure and infections. However, knowledge about its impact on overall survival (OS) in pediatric population with primary immunodeficiency disorders (PIDs) in Saudi Arabia is still limited.

Methods: We retrospectively analyzed all transplant naïve pediatric patients (age at transplant ≤14 years), transplanted for PIDs, from January 2013 to June 2023. Presence of > 500 copies by PCR before infusion of stem cells was considered as positive CMV infection. Patients were included if they had a positive infection, refractory to antiviral treatment, whereas patients who were positive but responded to therapy and had < 500 copies were excluded. Kaplan-Meier curves were drawn for survival analyses by using SPSS Version 20.0 software.

Results:



318 transplants were considered analyzable. Median age at transplant was 0.9 years (0.5 months to 14 years). 56.3% were males. Severe combined immune deficiency (SCID) and combined immune deficiency (CID) were present in 145 (45.6%) patients, with other disease categories also contributing to the cohort (Table 1). Stem cell sources were bone marrow (80.8%), peripheral blood stem cell (9.1%) and cord blood (10.1%) respectively. 70.8% had myeloablative, 2.2% reduced and 27% had no conditioning. 65.1% had full matched, 14.8% haploidentical, 10.1% cord blood, 7.5% matched-unrelated and 2.5% mismatched donors. At infusion, fourteen (4.4%) patients were CMV seropositive.
At a median follow-up of 38.2 months and a mortality rate of 27.7%, the cumulative probability of 5-year overall survival (OS) was 72.1%, with an OS of 74.8% was observed among seronegative recipients, compared to 14.3% in seropositive recipients, which was statistically significant (P<0.001). Further, subgroup analysis showed a better cumulative probability of 5-year overall survival in seronegative patients in conditioned and non-conditioned cohorts and the same was true for fully matched and haploidentical recipients (P<0.001) with no seropositive haploidentical recipient survived (Figure1).
In the subgroup of recipients transplanted from cord blood, no statistically significant difference was seen in cord blood CMV positive and negative recipients.

Conclusions: Our results showed that a refractory pre transplant CMV infection impacts the survival of patients, especially for the recipients of haploidentical bone marrow transplants. Adaptive immune with Cytotoxic T-Lymphocytes (CTL) may be used to treat such patients to improve outcomes.

Disclosure: Nothing to declare.

P076

INCIDENCE AND CHARACTERISTICS OF EXTREMELY RARE COMPLICATIONS OF POST ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION: A BICENTRIC SAUDI ARABIAN EXPERIENCE

Shad Ahmed[1], *Amr Nassar*[1], *Khaled Altayyeb*[1], *Hala Ahmed*[1], *Bander Alharbi*[1], *Hasan Aljasem*[1], *Abdulaziz AlTuwajiri*[1], *Moyaed Alhamdan*[1], *Rania Krichen*[1], *Fahad Almohareb*[2], *Sultan Alotaibi*[1]
[1]*Prince Sultan Military Medical City, Riyadh, Saudi Arabia,* [2]*King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is an established therapeutic modality in Saudi Arabia, with extensive programs at major tertiary care centres. As the total number of HSCT has steadily increased in recent years, many complications have become more frequent despite improvement in supportive care. While common complications are well-documented, data on extremely rare complications with reported incidences below 1% are relatively low, particularly within the Middle Eastern population. This study details the occurrence of several such rare events at two major tertiary care canters in Riyadh.

Methods: We conducted a retrospective analysis of allo-HSCT recipients transplanted at KFSH&RC and PSMMC in Riyadh from January 2018 to October 2025. We specifically identified cases of pre-defined extremely rare complications as below, mostly these rare complication is ignored and possibly underdiagnose. Patient data regarding baseline characteristics, transplant specifics, time to complication onset, clinical management, and outcomes were abstracted and reviewed.

Results: Out of a total of approximately more than 200 allo-HSCTs performed at both centres during this period we identified a series of rare complications:

- **Post-transplant erythrocytosis:** 5 cases
- **Donor cell leukemia (DCL):** 2 cases
- **Scrotal swelling (non-infectious etiology):** 2 cases
- **Autoimmune disease (new onset):** 2 cases
- **Thoracic air leak syndrome (TALS):** 1 case
- **Arrhythmia/cardiac toxicity (severe):** 1 case
- **Hemophagocytic lymphohistiocytosis (HLH):** 1 case
- **CNS-post transplant lymphoproliferative disorder (**PTLD): 1 case
- **Pulmonary veno-occlusive disease (PVOD): 1 case**

Complication	Number of Cases	Primary Diagnosis	Early <90 /Late >90	Management & Outcome

Post-transplant erythrocytosis	7	4 SAA, 1 AML, 2 DLBCL	Late	Conventional Rx, all resolved; no driver mutation
Donor Cell Leukemia (DCL)	2	AML	Late	Treated with allo-HSCT from different donor
Scrotal swelling (non-infectious)	2	Sickle cell disease	Early	Supportive care, resolved
Autoimmune disease (new onset)	2	ALL	Late	Referred to Rheumatology/Immunology
Thoracic Air Leak Syndrome (TALS)	1	MDS	Late	Standard care, high mortality
Arrhythmia/cardiac toxicity (severe)	1	AML	Early	Patient passed away
HLH	1	AML	Late	Patient passed away
CNS-PTLD	1	Non-Hodgkin's Lymphoma	Early	Resolved with treatment
PVOD	1	AML	Early	Resolved with treatment

The incidences of DCL (~0.1% globally) and TALS are exceptionally low, aligning with international literature reporting them primarily in case studies. The DCL cases presented as late complications, while the TALS case occurred in the context of severe pulmonary cGVHD.

Conclusions: Our single-region, bi-centric experience highlights the spectrum of ultra-rare complications following allo-HSCT. The occurrence of a cluster of these infrequent events, particularly DCL and TALS which carry high morbidity and mortality, emphasizes the need for long-term, specialized follow-up care for transplant survivors. Continuous data sharing through national and international registries (such as the EBMT) is crucial for better understanding, risk stratification, and developing evidence-based guidelines for managing these rare, devastating post-transplant sequelae in the Saudi Arabian context. Introduction of less toxic conditioning regimen allowed the expansion of HSCT to more fragile elderly recipients.

Disclosure: I don't have any disclosure or any conflict of interest.

P077

CHALLENGES IN PERFORMING HAPLOIDENTICAL HEMATOPOIETIC STEM CELL TRANSPLANTATION IN RESOURCE-LIMITED COUNTRIES EXPERIENCE OF THE BONE MARROW TRANSPLANTATION CENTER IN TUNISIA

Haithem Cherif[1], Rihab Ouerghi[1], Sabrine Khirallah[1], Insaf Ben Yaiche[1], Dorra Belloumi[1], Rimmel Yosra Kanoun[1], Lamia Torjemane[1], Anna Chaabane[1], Tarek Ben Othman[1], ***Nour Ben Abdejlil***[1]
[1]*The Bone Marrow Transplantation Center, Tunis, Tunisia*

Background: In Tunisia, haplo-Hematopoietic Stem Cell Transplantation (haplo-HSCT) has been progressively implemented since 2021 to overcome HLA-matched sibling donors (MSD) unavailability.
A standardized eligibility checklist was established by the transplant committee of our center for patients with hematological malignancies since 2023. The objective of this study was to describe our experience with haplo-HSCT and to highlight the challenges associated with its implementation in resource-limited countries.

Methods: We conducted a retrospective, descriptive study over a 3-year period (2023–2025), including all patients with hematological malignancies referred for haplo-HSCT at the National Bone Marrow Transplantation Center in Tunisia, the unique center in the country.
All patients were hospitalized in rooms with laminar flow, with a capacity of only eight cabins.
Given local constraints, haplo-HSCT was indicated for children aged over 10 years and for adults aged under 40 years with high-risk AML, ALL, MDS, Hodgkin and non-Hodgkin lymphoma.
Conditioning regimens were mainly based on thiotepa, busulfan and fludarabine (TBF). GVHD prophylaxis consisted of cyclosporine, mycophenolate mofetil, and post-transplant cyclophosphamide. Stem cell sources included either bone marrow or peripheral blood stem cells.

Results: Thirty-One patients were referred for haplo-HSCT, of whom only 9 ultimately underwent haplo-HSCT. Among the 22 patients who did not receive transplantation, 8 had highly positive DSA (excluded due to the unavailability of desensitization protocols.), 4 had their transplant indication rejected after committee review, 2 patients relapsed before transplantation, 5 could not be transplanted due to logistical constraints, and 3 patients are currently scheduled for future haplo-HSCT. Among transplanted patients, the underlying disease included 2 cases of ALL, 3 of AML,1 MDS-EB2, and 3 Hodgkin lymphoma.
The median age was 18 years (range 10-40). Before transplant, five patients were in first complete remission, and three patients were in second complete remission.
The conditioning regimen was thiotepa/busulfan-based in five patients, TBI-based in two patients and other regimens in 2 patients. Median duration of hospitalization was 40 days (range 32-150).
Acute GVHD occurred in 8 patients, mainly with gastrointestinal involvement.One patient developed refractory grade IV acute GVHD and received three lines of therapy: corticosteroids, ruxolitinib, and infliximab.

Three patients developed chronic GVH, all with cutaneous involvement. One refractory case responded to ibrutinib.
Six patients experienced CMV reactivation, all of whom had previously developed acute GVHD.
Six Patients developed hemorrhagic cystitis due to BK virus.
The non-relapse mortality (NRM) rate was 33% with a median of 3 months (range, 3–5 months), due to severe infectious complications (n=2) and refractory acute GVHD (n=1). No patients experienced disease relapse.After a median follow-up of 4 months (range 3-60 months), all surviving transplanted patients were in complete remission. Among non-transplanted patients, the median follow-up was 14 months, and five patients died due to disease relapse.

Conclusions: Our experience demonstrated a high-risk of acute GVHD and viral infections, as well as early NRM, probably due to the intensive pre-transplant therapy and advanced disease status. Expanding haplo-HSCT to a larger patient population remains challenging in resource-limited settings.

USE OF ORAL AZACITIDINE AS BRIDGING THERAPY TO ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION (ALLO-HSCT): A SINGLE TRANSPLANT PROGRAM EXPERIENCE

Angela Carobene[1], *Serena Marotta*[1], *Maria Celentano*[1], *Stefania Leone*[1], *Ilaria Migliaccio*[1], *Mariangela Pedata*[1], *Cira Riccardi*[1], *Cristina Luise*[1], *Selenia Vitiello*[2], *Claudio Falco*[3], *Roberta Penta*[4], *Maria Salzano*[1], *Valentina Oliva*[1], *Alessandra Picardi*[1,5]
[1]*Stem Cell Transplant Program, AORN Cardarelli, Napoli, Italy,* [2]*Hematology Unit, AORN Cardarelli, Napoli, Italy,* [3]*Unit of Trasfusional Medicine, SIMT, AORN Cardarelli, Napoli, Italy,* [4]*U.O.S.D. Banca Regionale di Sangue di Cordone Ombelicale (BaSCO), Manipolazione Cellulare ed Immunogenetica, Napoli, Italy,* [5]*Biomedicine and Prevention Department of Tor Vergata University, Rome, Italy*

Background: Allo-HSCT remains the only curative option for patients with intermediate or high-risk AML. However, clinical issues related to the patient or the donor often delay the transplant procedure, increasing the relapse risk. Since the quality of CR and the timing of allo-HSCT are critical for transplant outcomes, identifying a standardized bridging therapy during delays in the allo-HSCT pathway is essential. We report the experience of a single adult Transplant Program in evaluating the efficacy and safety of oral azacitidine as bridging therapy, between last consolidation and allo-HSCT, for AML in CR.

Methods: From July 2024 to October 2025, 11 patients with intermediate/high-risk AML, according to ELN 2022, received oral azacitidine as bridging therapy during allo-HSCT delays. Inclusion criteria for oral azacitidine bridging therapy were: diagnosis of AML in hematological CR (including FLT3 mutations), off therapy for more than 2 months after

second consolidation, temporary donor unavailability or patient-related clinical issues. The median age was 48 years (range 29–67), with 6 males and 5 females. Oral azacitidine was administered at a dose of 300 mg/day for 14 consecutive days per cycle.
Nine allo-HSCTs were performed using matched related, matched and mismatched unrelated donors in 1, 5, and 3 cases, respectively. All patients received PBSC as the stem cell source, while intermediate and low-intensity conditioning regimens were administered in 5 and 4 cases, respectively.

Results: In our experience, the unrelated donor's unavailability or ineligibility represent the major cause of allo-HSCT delay, corresponding to 15% for year and 64% in the present series (table 1). In this cohort, 7 (64%), 2 (18%), and 2 (18%) patients received 1, 2 or more than 2 cycles of oral azacitidine**,** 6/11 (54%) patients received oral azacitidine in MRD-positive CR and 5/11 (45%) were FLT3 mutated. During bridging therapy, one patient lost transplant eligibility due to an increased frailty and continued oral azacitidine until relapse, while another patient is still awaiting donor availability. Ruling out one patient who loss eligibility to transplant, 10 of 11 (91%) were evaluable for efficacy: 9 of 10 (90%) underwent allo-HSCT in hematological CR, of whom 4 of 9 (44%) were MRD-negative. Overall, all patients MRD negative before bridge therapy, mainteined MRD negativity until allo-HSCT. The median time between oral azacitidine starting and allo-HSCT was 2.9 months (95% CI: 2.36–3.43). Moreover, no grade ≥2 adverse events related to oral azacitidine (CTCAE criteria) occurred in the 11 patients. With a median follow-up of 15.13 months (IC

13.03-17.22) months, DFS and OS after allo-HSCT were 77.8% and 90.9%, respectively.

Table 1: Cause of Bridging Therapy

Patient Id/UPN	Cause of bridging therapy Donor/Patient	Days between last CHT and allo-HSCT*	N of oral Azacitidine cycles
1/229.1	Temporary Unavailability/IFI	111	1
2/237.1	Multiple donors' unavailbility /-	92	1
3/NA	- /E. coli spondylodiscitis, IFI	*567	7
4/242.1	Temporary Unavailability/-	109	1
5/249.1	Temporary Unavailability/-	106	1
6/250.1	Temporary Unavailability/-	330	1
7/263,1	-/IFI	138	2
8/267,1	First unrelated donor ineligibility/-	181	2
9/274,1	-/Fungal skin infection	135	1
10/in progress	No donors identification/-	*158	4
11/278.1	-/IFI	118	1

Legend: Id= Identification; UPN= Unique patient number; Invasive Fungal Infection; NA= Not Applicable; * days to last follow up

Conclusions: Oral azacitidine as bridging therapy to allo-HSCT in patients with intermediate/high-risk AML is feasible and seems effective in maintaining hematological and molecular CR, including FLT3 mutated cases. Futhermore, in our cohort, no patients did not undergo allo-HSCT due to azacitidine related adverse events. Although our experience is limited to a small series, these data are encouraging for the use of oral azacitidine as bridging therapy in case of allo-HSCT delay.

MITIGATING RISK FACTORS FOR PROLONGED HOSPITALIZATION IN PEDIATRIC PATIENTS UNDERGOING HEMATOPOIETIC STEM CELL TRANSPLANTATION: A SINGLE-CENTER QUALITY IMPROVEMENT STUDY IN SAUDI ARABIA

Waad Alghamdi[1], *Ibraheem Abosoudah*[2], *Wasil Jastaniah*[2], *Mohamed Bayoumy*[2], *Amal Alseraihy*[2], *Hassan Altrabolsi*[2]
[1]*King Faisal Hospital and Research Center, Jeddah, Saudi Arabia,* [2]*KFSHRC, Jeddah, Saudi Arabia*

Background: Few studies evaluated the risk factors for prolonged hospitalization in pediatric hematopoietic stem cell transplantation (HSCT) recipients, who typically require six weeks of hospitalization. We aimed to reduce the average length of stay (LOS) in pediatric HSCT recipients by 5% from baseline, by identifying factors associated with LOS using the IACT Method.

Methods: One hundred and fifty pediatric patients were included in our study, with an age of 0.5–14 years, potential factors influencing the LOS were identified using a patient flow sheet, Pareto chart and questionnaire-based voting in the preimplementation period. In the implementation phase, interventions including increasing team awareness of early discharge readiness, based on a new discharge criteria, and ensuring medication/nutrition requirements with the aid of home health care were implemented.

Results: Prolonged hospital stay was defined as >21 and >35 days for autologous and allogeneic HSCT respectively, prolonged hospitalization was observed in 35 (39%) patients in the preimplementation group and 13 (22%) patients in the postimplementation group. The need for intravenous medication/nutrition (P 0.001), cytomegalovirus infection (P 0.001), hemorrhagic cystitis (P 0.003), graft-versus-host disease (P 0.007), neutrophil/platelet engraftment at >30 days (P 0.001), and pediatric intensive care unit admission (P 0.001) were significantly associated with prolonged hospitalization. In the postimplementation period, the need for intravenous medication/nutrition remained a significant risk factor for prolonged hospitalization (P 0.001).

Conclusions: Reducing the average LOS from 36 to 25 days was associated with an estimated total cost reduction of 4 356 000 SR (1 159 831 USD) for the study period September 2022 to December 2023. Our findings highlight that implementing tools to mitigate risk factors for prolonged hospitalization in pediatric HSCT recipients is essential for optimizing patient care, improve bed occupancy and healthcare resource utilization.

Clinical Trial Registry: Not applicable.

ALLOGENEIC TRANSPLANT JOURNEY THROUGH THREE MALIGNANCIES: A 75-YEAR-OLD PATIENT DEFYING THE ODDS

*Zehra Akşit Bozkina[1], Denis Sabriye Bozer[1], **Ajda GÜNEŞ**[1], Nur Soyer[1], FİLİZ Vural[1]*
[1]Department of Hematology, Ege University Faculty of Medicine Hospital, İzmir, Turkey

Background:

Recent advancements in hematopoietic stem cell transplantation (HSCT) have significantly increased long-term survival among transplant recipients.[1] However, a major late complication following allogeneic HSCT is the development of secondary malignancies.[2] Post-transplant lymphoproliferative disorders (PTLDs) associated with Epstein–Barr virus (EBV) reactivation are frequently donor-derived and typically emerge at a median of 2–4 months post-transplant.[3]

Methods: We present a case of a patient who developed acute myeloid leukemia (AML) on a background of myelofibrosis, achieved remission after chemotherapy, and was diagnosed with minimally invasive pulmonary adenocarcinoma during pre-transplant workup. After undergoing a successful HSCT, she subsequently developed EBV-positive diffuse large B-cell lymphoma (DLBCL) in the setting of post-transplant immunodeficiency, and currently remains in remission with appropriate therapy.

Results:

A 75-year-old woman was diagnosed with AML after lymphomonocytosis was detected. Bone marrow biopsy revealed 20% CD34-positive precursors and t(8;21) in 84% of cells. She was treated with azacitidine (7 days) and venetoclax (400 mg daily). After four cycles, blasts were cleared, although reticulin fibrosis (grade 3) with focal collagen deposition indicated myelofibrosis. During HSCT preparation from a matched male sibling donor, chest imaging identified a ground-glass nodule suggestive of adenocarcinoma. Right upper lobe wedge resection confirmed minimally invasive ROS1-positive adenocarcinoma (0.8 cm, 0.5 cm invasive) with negative margins. Multidisciplinary review recommended surveillance at three-month intervals. A total dose of 6.5×10^6 cells per kilogram was infused following Flu/Treo/ATG conditioning. Target cyclosporine levels could not be maintained; therefore, tacrolimus was initiated for GVHD prophylaxis. Bone marrow was normocellular, and complete donor chimerism was achieved by month one. CMV reactivation accompanied by diarrhea occurred on day 47 and was treated with ganciclovir. Due to persistent diarrhea, colonoscopy was performed at the end of month two, initially under suspicion of gastrointestinal GVHD. Unexpectedly, biopsy demonstrated EBV-positive DLBCL without histological evidence of GVHD. Immunosuppression was tapered. PET/CT demonstrated multiple FDG-avid lymph nodes and hypermetabolic nodules in both lungs. Biopsy was deferred due to cytopenia, and the patient received one cycle of rituximab followed by two cycles of R-mini-CHOP. Previously hypermetabolic lymph nodes demonstrated complete metabolic response (Deauville 1–2). Due to the development of profound neutropenia following chemotherapy, it was decided to continue the remaining treatment with rituximab monotherapy. The oncology department recommended follow-up at three-month intervals for the pulmonary malignancy. At the sixth month post-transplant, the patient remains in remission for all malignancies.

Conclusions: Donor cell–derived leukemia/lymphoma (DCL) represents an exceptionally rare complication of allogeneic HSCT. Azacitidine exerts antitumor activity by inhibiting DNMT1, thereby restoring tumor-suppressor gene expression. Real-world observations regarding azacitidine–venetoclax treatment have not shown an increased incidence of solid tumors; accordingly, the pulmonary adenocarcinoma in this case was interpreted as a synchronous malignancy rather than treatment-related. The successful outcomes, sustained remission, and ongoing survival of this elderly patient with three distinct primary malignancies underscore the clinical and academic relevance of this case.

P083

HARNESSING GRAFT-VERSUS-LEUKEMIA ALLOREACTIVITY TO TREAT MULTI-REFRACTORY ACUTE LYMPHOBLASTIC LEUKEMIA AFTER ALLOGENEIC HSCT

Amanda Campbell[1], ***Rajinder Bajwa***[1]
[1]*Nationwide Childrens Hospital, Columbus, United States of America (the)*

Background: Relapsed or refractory (R/R) acute lymphoblastic leukemia (ALL) after hematopoietic stem cell transplantation (HSCT) remains a major unmet need in pediatric transplant medicine. Children who relapse early after HSCT, develop extramedullary disease, or progress after exposure to both CD19- and CD22-directed CAR-T cell therapies have profoundly poor outcomes. Strategies that intentionally amplify graft-versus-leukemia (GvL) alloreactivity—such as donor lymphocyte infusion (DLI), cytokine priming, or other immunomodulatory approaches—are conceptually appealing but underexplored in heavily pretreated pediatric patients. We report a unique case of a child with pre-B cell ALL who experienced six total relapses, including relapses after two HSCTs and two CAR-T products, who ultimately achieved durable remission through deliberate augmentation of GvL using haploidentical DLI combined with interferon-alpha (IFN-α).

Methods: A retrospective review of the patient's disease course from diagnosis in December 2017 through late 2025 was performed. Data collected included disease characteristics, MRD kinetics, relapse chronology, prior cytotoxic and immune-based therapies, and transplant-related complications. Major interventions evaluated included CD19 and CD22 CAR-T cell therapies, a matched unrelated donor HSCT, and a maternal haploidentical HSCT. Particular attention was given to the rationale, timing, and outcomes of combining inotuzumab ozogamicin with haplo-DLI and IFN-α. Longitudinal assessment focused on the depth and durability of remission, immune-mediated toxicities, and the evolution of acute and chronic GvHD.

Results: The patient experienced six relapses, reflecting an exceptionally aggressive and treatment-refractory disease course. Early events included an extramedullary relapse shortly after induction and a CNS relapse with destructive intracranial chloromas following the first HSCT on 6/15/2018. Marrow relapse after CD19 CAR-T and another relapse after CD22 CAR-

T prompted a second HSCT—a maternal haploidentical transplant—on 4/21/2020. Despite this, an early fifth relapse was detected at day +100. Inotuzumab ozogamicin administered prior to haplo-DLI, followed by IFN-α, triggered a brisk alloreactive response resulting in severe steroid-refractory acute GvHD (SRaGvHD) involving the skin, GI tract, and liver. This immune activation was associated with a potent GvL effect, leading to a deep antileukemic response and achievement of clonoSEQ-negative complete remission (CR) by October 2020. The patient subsequently stabilized and was successfully weaned off all immunosuppression by 2022. A sixth molecular relapse occurred in 2023. Repeat haplo-DLI again led to recurrent SRaGvHD and induced deep molecular remission, demonstrating persistent GvL sensitivity. The patient subsequently developed severe chronic SR-GvHD requiring prolonged therapy with MSCs, ruxolitinib, belumosudil, and axatilimab. Despite chronic GvHD with joint contractures, decreased range of motion, and ongoing treatment with belumosudil and axatilimab, he has remained a full-time university student throughout his therapy, demonstrating remarkable functional resilience. As of late 2025, he remains in sustained NGS-negative remission

Conclusions: This case demonstrates that intentionally harnessed GvL—via haploidentical DLI augmented with IFN-α—can produce deep, durable remission in profoundly multi-refractory pediatric ALL. Although associated with significant acute and chronic GvHD, coordinated multidisciplinary management enabled control of both leukemia and immune dysregulation. These findings support further evaluation of cytokine-enhanced DLI strategies as a salvage modality for high-risk pediatric patients who relapse despite HSCT and advanced cellular therapies.

Disclosure: I have no conflict of interest

P084

ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION IN THE TREATMENT OF SEVERE APLASTIC ANEMIA IN ADULTS: EXPERIENCE OF THE REPUBLIC OF BELARUS

Tatsiana Talako[1], *Yuri Strongin*[1], *Oksana Nechay*[1], *Alena Dziuba*[1], *Oksana Morozova*[1], *Viktoriya Hrynevich*[1], *Victoria Smolnikova*[1], *Hanna Melnikovich*[1], *Aliaksandr Avadok*[1], *Nataly Milanovich*[1], *Anatoly Uss*[1], *Katsiaryna Yanusheuskaya*[1], *Tatiana Lebedeva*[1]
[1]*Minsk Scientific and Practical Center for Surgery, Transplantology and Hematology, Minsk, Belarus*

Background: Transplantation options for severe aplastic anemia (SAA) in adult patients include "upfront" or "delayed" allogeneic hematopoietic stem cell transplantation (alloHCT) after failed immunosuppressive therapy. AlloHSCT from matched sibling donor (MSD) remains the best option for patients at the age of 40 years or younger without significant comorbidities.

Methods: The study included 48 patients with SAA who underwent alloHSCT from 1995 to 2024 in our clinic. Median age of the participants was 25.5 (21.0-30.0) years, 23 of them

were male (48%). Paroxysmal nocturnal hemoglobinuria (PNH) clone was detected with flow cytometry in 6 patients at median level of 1.7 (0.3-5.7)%, 1 patient had PNH clone at 70.4%. Donor-specific antibodies were revealed in 2 patients. The patients were divided into subgroups according the treatment regimen (Table 1). ABO incompatibility was detected in group B in 6 donor-recipient pairs, in group C – in 2 pairs.

Table 1. Patients with SAA treated with alloHSCT from 1996 to 2024 depending on conditioning regimen

Characteristics	Group A (n=27)	Group B (n=16)	Group C (n=5)
Time of alloHSCT	Feb 1995 – Jan 2016	Aug 2016 – May 2024	Feb 2022 – Oct 2024
Median age, y.o.	23.0 (20.0-29.5)	27.5 (20.5-30.8)	26.0 (23.0-27.0)
Male, n	16	5	2
Median time to alloHSCT, months	3.0 (2.0-6.3)	6.6 (3.1-9.8)	7.0 (6.3-52.0)
Donor type: MSD, n Matched unrelated donor (MUD), n Mismatched unrelated donor (MMUD), n	27	8 8	3 2
Conditioning regimen, total dose	Cyclophosphamide (Cy), 200 mg/kg, anti-thymocyte globulin (ATG)*	Cyclophosphamide, 100 mg/kg, Fludarabine (Flu), 100 mg/m^2, ATG*	Cyclophosphamide, 120 mg/kg, Fludarabine, 150 mg/m^2, ATG*
Graft-versus-host disease (GvHD) prophylaxis	Cyclosporin A (CsA), methylprednisolone	CsA, methylprednisolone	MUD - CsA, methylprednisolone, MMUD - CsA, methylprednisolone, micophenolate mofetil

*- dosage depends on the manufacturer (brand) of ATG

Results: By Jan 1st 2025, 39 patients (81.3%) remained alive: 1 patient experienced autologous reconstitution after alloHSCT with complete hematopoiesis. The causes of death in group A were infectious complications (n=2), acute GvHD (n=1), graft rejection (n=1), chronic GvHD (n=1), in group B - infectious complications (n=3). Transplant-related

mortality (TRM) rate was 7.4% in group A and 6.2% in group B. Overall survival rate and 5-year survival in group A was 81.5% and 85.5% and did not differ significantly from group B: 80.8% and 80.8% (p=0,741). In group C 1 patient died because of Covid-19, TRM rate – 0%. PNH clone disappeared in 4 patients after alloHSCT, in 2 patients PNH clone still presents (<1%).

Conclusions: In the absence of MSD alloHSCT from an unrelated donor (matched or mismatched) is an effective and feasible option for patients with SAA. Flu/Cy/ATG and Cy/ATG conditioning regimens were associated with comparable survival rates.

Disclosure: Nothing to declare.

P085

FACTORS ASSOCIATED WITH OVERALL SURVIVAL AND DISEASE-FREE SURVIVAL IN ADULTS WITH ACUTE MYELOID LEUKEMIA AFTER ALLOGENEIC HEMATOPOIETIC STEM CELL TRANSPLANTATION AT A CENTER IN COLOMBIA

David Reyes-Villamizar[1], Manuel Rosales[2,3], Maria Luna-Gonzalez[1,3], Luis A. Salazar[1,3], Angela M. Peña[3,2], Miguel Ochoa-Vera[1], Carlos Orozco-Oviedo[2,3], Mario Arenas-Mantilla[2,3], Katherinee Morales-Chacón[2,3], Maria G. Velasquez-Oliver[1], ***Claudia Sossa-Melo***[1,2]
[1]*Universidad Autonoma de Bucaramanga, Bucaramanga, Colombia,* [2]*Fundación Oftalmológica de Santander, Floridablanca, Colombia,* [3]*Programa para el Tratamiento de Enfermedades Hemato-Oncológicas de Santander PROTHEOS, Floridablanca, Colombia*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) is the main curative treatment option for adults with intermediate and adverse risk acute myeloid leukemia (AML). Real-world outcome data after allo-HSCT from low- and middle-income countries remain limited. The aim of this study was to explore factors associated with overall survival (OS) and disease-free survival (DFS) in a cohort of adults with AML in Colombia.

Methods: We conducted a retrospective study of adults with AML who underwent allo-HSCT between 2013 and 2024 at a single center in Colombia. Overall survival (OS) was defined as the time from transplantation to death from any cause or censoring at last follow-up, and disease-free survival (DFS) as the time from transplantation to relapse. OS and DFS were estimated at 100 days, 1 year, and 5 years using the Kaplan–Meier method. Associations between clinical variables and OS and DFS were evaluated using univariate Cox proportional hazards models.

Results: A total of 47 adults with AML undergoing allo-HSCT were included. Fifty-one percent were male, with a median age of 45 years (range, 18–65). At transplantation, 53.1% had adverse-risk disease, 89.4% were in first complete remission, 17% had an ECOG performance status of 1, and 25.5% had a high comorbidity burden (HCT-CI score ≥3). HLA-identical donors were used in 65.9% of cases, myeloablative conditioning in 51.1%, and peripheral blood as the stem cell source in 97.8%. Acute and chronic graft-versus-host

disease occurred in 61.7% and 57.4% of patients, respectively.
The median follow-up was 44.6 months. One patient died within the first one hundred days; by 1 year, eleven patients (23.4%) had died, and by 5 years, seventeen patients (36.1%) had died. Estimated OS was 97.8% (95%CI 85.8-99.7) at 100 days, 78.7% (95%CI 64.0-87.9) at 1 year, and 58.0% (95%CI 40.3-72.1) at 5 years. The leading cause of death was transplant-related mortality (52.9%), with half of these deaths due to infectious causes. Among the remaining deaths, 17.6% were attributable to disease relapse.
Relapses occurred in 5 patients (10.6%), including 2 events within the first year and 1 event within the first one hundred days. Estimated DSF was 97.8% at one hundred days, 95.6% (95%CI 83.5-98.8) at 1 year, and 87.8% (95%CI 73.1-94.7) at 5 years. In univariate Cox analysis, an ECOG performance status of 1 at the time of transplantation was associated with worse OS at both 1 year (HR 8.19, p = 0.001) and 5 years (HR 4.34, p = 0.007); additionally, relapse was associated with increased mortality (HR 4.79, p = 0.004). No characteristic showed a statistically significant association with DFS.

Characteristics		Overall Survival				Desease-Free Survival			
		1 year % (95%CI)	5 year % (95%CI)	HR (95%CI)	P-value	1 year % (95%CI)	5 year % (95%CI)	HR (95%CI)	P-value
MRC Cytogenetic risk	Intermediate	86 (63.4 - 95.3)	57.5 (31.3 - 76.7)	1.12 (0.43 - 2.92)	0.80	100	89.4 (64 - 97.2)	1.48 (0.24 - 8.87)	0.66
	Adverse	72 (50 - 85.5)	58.1 (33.2 - 76.6)			91.6 (70.4 - 97.8)	86.5 (63.5 - 95.5)

	No	88.9 (62.4 - 97.1)	57.8 (28.1 - 78.9)			88.8 (62.4 - 97.1)	77.7 (51.1 - 91)		

Chronic GVHD	Yes	-	62.6 (39.7 - 78.9)	0.66 (0.25 - 1.72)	0.39	-	96.1 (75.6 - 99.4)	0.16 (0.01 - 1.47)	0.10
	No	-	50.9 (21.5 - 74.4)			-	76 (47.7 - 90.3)		

Conclusions: In this cohort, OS after allo-HSCT was comparable to that reported by large registries from high-income countries, with impaired functional status at the time of allo-HSCT and post-transplant relapses identified as the main determinants of mortality. Relapses rates were low and the small number of patients with ECOG 1 may have led to an overestimation of HR; however, the association remained statistically significant. These findings support the feasibility of achieving competitive outcomes in resource-limited settings resource-limited settings.

AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION IN HODGKIN LYMPHOMA: A 16-YEAR SINGLE-CENTER EXPERIENCE FROM EHU 1ST NOVEMBER OF ORAN, ALGERIA

Amal Bendimerad[1], *Soraya Benichou*[1], *Nawel Bounoua*[1], *Badra Enta Soltan*[1], *Nabil Yafour*[1]
[1]*Université Oran, Oran, Algeria*

Background: Autologous hematopoietic stem cell transplantation (ASCT) remains a cornerstone therapeutic intensification strategy in the treatment of relapsed or refractory Hodgkin lymphoma (R/R HL).
The objective of this study was to evaluate the efficacy and safety of ASCT in patients with HL treated at the Hematology Department of EHU 1er Novembre, Oran, Algeria.

Methods: This was a single-center retrospective study conducted over a 16-year period, including patients with HL. ASCT was administered as first-line consolidation therapy in 53 patients with advanced-stage disease (stage III–IV) and in 102 patients with relapsed or refractory R/R HL.
$CD34^+$ hematopoietic stem cells were mobilized using granulocyte colony-stimulating factor (G-CSF) alone (filgrastim or lenograstim) at a dose of 15 µg/kg/day for 5 days, or in combination with plerixafor in cases of mobilization failure. Stem cells were collected by cytapheresis. Graft was stored at +4 °C for 6 days. Cryopreservation of graft with liquid nitrogen freezing at −196 °C was introduced to our center in 2022. Conditioning regimens: CBV (2009–2010), BEAM (2010–2016), Benda-EAM (2015–2016), and EAM (2016–July 2025). The EAM regimen included a total dose of etoposide 800 mg/m², cytarabine 8 g/m², and melphalan 140 mg/m². All patients received Granulocyte colony-stimulating factor (G-

CSF) from day + 5 until neutrophil recovery (absolute neutrophil count > 0.5 G/L. Data of assessment was 31 November 2025.

Results: A total of 155 patients with HL were included between June 2009 and 31 July 2025. The median age was 26 years (range, 14–55 years), with a male-to-female ratio of 0.93 (75 males and 80 females).
Conditioning regimens included CBV in 15 patients (9.6%), BEAM in 45 patients (29%), Benda-EAM in 5 patients (3.2%), and EAM in 90 patients (58%). The median time to neutrophil engraftment was 14 days (range, 8–39 days), and platelet recovery (> 20 G/L) was 13 days (range, 3–42 days). The median number of red blood cell concentrates transfused was 3 (range, 1–5), and the median number of platelet concentrates transfused was 3 (range, 1–9).
At day 100 post-transplant, the TRM was 4.51% (7 patients). With a median follow-up of 5 years, the relapse rate was 16.7% (26 patients) and the OS was 83%. The median PFS and OS were 53 months and 65 months, respectively.

Conclusions: ASCT is a safe and effective treatment for patients with Hodgkin lymphoma. Using predominantly fresh grafts, the procedure showed low treatment-related mortality, rapid hematologic recovery, high remission rates, and durable long-term outcomes.

Disclosure: The authors declare no conflict of interest related to this study.

EXPERIENCE OF MISMATCHED UNRELATED DONOR TRANSPLANTS WITH PTCY BASED GVHD PROPHYLAXIS IN BENIGN HEMATOLOGICAL DISORDERS

Akanksha Garg[1], *Nidhi Jain*[1], *Rajan Yadav*[2]
[1]*Zydus Cancer Hospital, Ahmedabad, India,* [2]*Gujarat Cancer and Research Institute, Ahmedabad, India*

Background: Allogeneic hematopoietic stem cell transplantation (allo-HSCT) from mismatched unrelated donors (MMUD) is an option for patients with benign hematological disorders (e.g., aplastic anemia, hemoglobinopathies, inherited bone marrow failure syndromes and inborn errors of immunity) who lack matched sibling donors. Post-transplant cyclophosphamide (PTCy) is increasingly used to prevent graft-versus-host disease (GVHD) in mismatched donor settings, but data specifically in benign hematologic disorders are limited.

Methods: We present a retrospective analysis of 3 consecutive patients with benign hematological disorders who received MMUD allo-HSCT with PTCy-based GVHD prophylaxis at our transplant centre. Primary endpoints: neutrophil and platelet engraftment, cumulative incidence of grade II-IV acute GVHD, moderate–severe chronic GVHD, TRM, and OS at 1 year. Secondary endpoints: graft failure, infections, organ toxicities, and hematologic response.

Results: We performed a total of 3 MMUD in 2 patients with Dyskeratosis congenita (DKC) and one Wiskott Aldrich Syndrome (WAS) aged 49 years, 19 years and 18 months respectively. All 3 patients had HLA A mismatch.The child with WAS had 8/10 match with both the mismatches at HLA A locus and the two cases of DKC had single HLA A mismatch. The details of the 3 cases have been mentioned in table 1. All the 3 patients are alive and well with the median follow up duration of 30 months. None of the 3 cases developed any GVHD and immunosuppression could be tapered by Day 150 in all three.

Conclusions: PTCy-based GVHD prophylaxis appears to be a feasible strategy for MMUD allo-HSCT in benign hematological disorders, with acceptable rates of severe GVHD and transplant-related mortality in our cohort. Larger multi-center studies or prospective trials are needed to confirm these findings.

RISK FACTORS FOR RECURRENT CYTOMEGALOVIRUS INFECTION IN HEMATOPOIETIC STEM CELL AND SOLID ORGAN TRANSPLANT RECIPIENTS: A SCOPING REVIEW

Wenjian Mo[1], Jingyi Wu[2], Tingting Wang[2], ***Shunqing Wang***[1]
[1]Department of Hematology, Guangzhou First People's Hospital, South China University of Technology, Guangzhou, China, [2]Medical Affairs, Takeda (China) International Trading Company, Shanghai, China

Background: Recurrent cytomegalovirus (CMV) infection, characterized by the reappearance of detectable CMV DNA following initial viral clearance, is a frequent complication in transplant recipients. It not only increases the risk of end-organ disease and graft rejection but may also contribute to delayed immune reconstitution, heightened susceptibility to other opportunistic infections, and elevated mortality. Early identification of high-risk patients is essential for reducing complications and improving long-term outcomes. This study aimed to identify risk factors associated with recurrent CMV infection in hematopoietic stem cell transplantation (HSCT) and solid organ transplantation (SOT) recipients.

Methods: Following the PRISMA-ScR framework for scoping reviews, a systematic search for literature on risk factors for refractory CMV infection after transplantation was conducted in eight databases including PubMed, EMBASE, the Cochrane Library, Web of Science, CNKI, Wanfang, VIP and CBM (2010-2023). Two reviewers independently extracted data and assessed the risk of bias using the QUIPS tool.

Results: A total of 10 studies were included (HSCT: 5 studies including 331 patients; SOT: 5 studies including 217 patients). A total of 21 risk factors (9 HSCT-specific risk factors and 12 SOT-specific risk factors) for recurrent CMV were identified. The HSCT-specific risk factors for recurrent CMV included 5 host-related [graft-versus-host disease; recipient with higher age; diagnosis with acute myeloid leukemia/myelodysplastic syndrome; diagnosis with

hematological malignancies; progressing to a refractory state after CMV infection]; 3 transplantation-related factors [CMV serological status of donor$^{(-)}$ and recipient$^{(+)}$ / donor$^{(+)}$ and recipient$^{(+)}$ (vs recipient$^{(-)}$); donor type (cord blood vs. non-cord blood, mismatched family vs matched sibling donor, haploidentical blood and marrow transplant vs matched sibling donor, mismatched donor vs matched donor); post-transplantation high-dose steroids use (>=1 mg/kg)]; and 1 viral-related factors [CMV-specific CD8^{+} TcM at day 30 >=0.032 μL (vs. <0.032)]. Moreover, the SOT-specific risk factors for recurrent CMV included 5 host-related factors [chronic kidney disease (CKD); NFKB1 ins/ins genotype (vs ins/del-del/del); pneumonia; organ rejection within 3 months post-transplantation; decreased in absolute lymphocyte count]; 4 transplantation-related factors [CMV serological status of donor$^{(+)}$ and recipient$^{(-)}$ (vs others); delayed graft function; lung transplant (vs. non-lung); using of antilymphocyte therapy]; and 3 virus-related factors [baseline CMV miRNA detection-UL22A-5p; CMV clearance half-life > 3 days (vs < 3 days); higher peak viral load].

Transplant type	Factor category	Factors	Number of recurrent reference
Haematology transplant (n = 5)	Host-related factors	acute or chronic GVHD, any grade (yes vs. no)	1
		aGVHD (grade II-IV vs. grade 0-I)	2
		aGVHD (yes vs. no)	1
		Antilymphocyte therapy (yes vs. no)	1
		Diagnosis-AML/MDS (yes vs. no)	1
		Hematological malignancies (yes vs. no)	1
		Recipient age	1
		Response to treatment (refractory vs. not refractory)	1
	Transplantation-related factors	CMV serostatus (D-/R+ vs. R-)	1
		CMV serostatus (D+/R+ vs. R-)	1
		Donor type (cord blood vs. non-cord blood)	1
		Donor type (HBMT vs. MSD)	1
		Donor type (mismatched family vs. MSD)	1
		Donor type (mismatched vs. matched)	2
		Treatment with high-dose steroids after day 100 (≥1 mg/kg) (with vs. without)	1
	Viral-related factors	CMV-specific CD8+ TcM at day 30 (μL) (<0.032 vs. ≥0.032)	1
Organ transplant (n = 5)	Host-related factors	CKD (yes vs. no)	1
		NFKB1 genotype (ins/ins vs. ins/del-del/del)	1
		Pneumonia (yes vs. no)	1
		Rejection within 3 mo prior (yes vs. no)	1
		Decrease in ALC	1
	Transplantation-related factors	CMV serostatus (D+/R- vs. others)	1
		Delayed graft (days)	1
		Transplant type (lung vs. non-lung)	1
	Viral-related factors	Baseline CMV miRNA detection-UL22A-5p (yes vs. no)	1
		Viral load half-life, days (>3 vs. <3)	1
		Higher peak viral load	1

Figure 1. Hot map of risk factors for recurrent CMV infection.
Notes: The numbers in the hot map indicate the number of articles corresponding to the factors.
Abbreviations: aGVHD, acute graft-versus-host disease; ALC: absolute lymphocyte count; AML: acute myeloid leukemia; CMV: cytomegalovirus; CKD: chronic kidney disease; HBMT: haploidentical blood and marrow transplant; MDS: myelodysplastic syndrome; MSD: matched sibling donor.

Conclusions: This review identified the spectrum of host-, transplantation-, and virus-related risk factors for recurrent CMV in HSCT and SOT recipients, respectively. Early identification of these high-risk populations allows for optimized antiviral strategies, such as the selection of appropriate therapy and the extension of treatment duration, which may reduce the risk of recurrence, associated complications, ultimately improving long-term patient outcomes.

Disclosure: Jingyi Wu and Tingting Wang are employees of Takeda (China) International Trading Co., Ltd. The authors declare that there were no commercial or financial relationships that could be interpreted as potential conflicts of interest in the conduct of this study.

HAPLO-CORD HCT: SAVE THE SIBLING!

Sundar Shewale[1], *Akash Bhojgaria*[1], *Rajeev Agarwal*[2], *Prosanto Kumar Chowdhury*[3], *Mihir Das*[1], *Kasturi Sengupta*[4], *Joydeep Chakrabartty*[1]
[1]*HCG Cancer Hospital, Kolkata, India,* [2]*Renew Healthcare, Kolkata, India,* [3]*Cordlife Sciences India Pvt. Ltd., Kolkata, India,* [4]*AMRI Hospital, Mukundapur, Kolkata, India*

Background: Transfusion dependent thalassemia is a disorder for which allogeneic hematopoietic stem-cell transplantation (HSCT) remains the principal curative therapy. Lack of matched donors limits its broader application. Haploidentical transplant has its own risks of GVHD, and treatment related mortality. The Haplo-Cord transplant is unique method of transplantation which combines haploidentical peripheral-blood stem cells from one donor with cord-blood stem cells from other which may offer rapid engraftment, lower GVHD, and improved immune recovery. We report the successful use of HaploCord HSCT in a 7-year-old male with E Beta thalassemia treated under the *Save the Sibling (STS)* program.

Methods: Patient was older child with transfusion dependency, severe iron load and no sibling. Concept of combined HaploCord transplant was planned with mother as haplo donor and cord from sibling. Under Save The Sibling program which is collaboration between the fertility centre Renew Healthcare, the cord blood bank "Cord life", and the specialty hospital HCG Cancer Centre bone marrow transplantation was planned. A disease-free, HLA-matched sibling is conceived through IVF with preimplantation genetic diagnosis (PGD) in the STS program. Cord Blood Stem Cells collection, transportation, processing, testing, cryopreservation done by Cord life Sciences ,India. Patients received pre-transplant immunosuppression protocol for 6 weeks. Pharmacologic immunosuppression (PTIS) with fludarabine (30mg/m2), dexamethasone (25mg/m2), and azathioprine (1mg/kg), were given. Hydroxyurea (20mg/kg) was given to reduce host erythropoiesis. Hyper transfusion, dual iron chelators Deferoxamine, Deferiprone were used to reduce severe iron overload. Myeloablative conditioning with Fludarabine (25/mg2), Thiotepa (8mg/kg), GVHD prophylaxis with ATG (4.5mg/kg), PTCY, Tacrolimus (later switched to sirolimus) MMF and ruxolitinib were used. Defibrotide prophylaxis was initiated due to a high pre-transplant VOD risk score. Haplo graft cell dose was 11.66 × 10^6 cells/kg infused on Day+0 while Cord graft dose was 1.136 × 10^6 cells/kg ($CD34^+$ 50.2/µL) infused on Day+1.

Results: Patient had Grade 2 CRS responded to tocilizumab. Grad 2 mucositis managed with supportive care. Myeloid engraftment occurred on day +15 and platelet engraftment on day +21. The patient had moderate transaminitis with suspected GVHD responded to steroids. At discharge the patient was afebrile, transfusion-independent, and clinically stable. At Day 30 chimerism was 100% donor 1(mother). At Day 45 T cell chimerism is showing 95% Donor 1 (mother), 5% Donor 2 (cord) suggesting gradual rise in cord component.

Conclusions: Haplo-Cord HSCT provides a viable curative option for transfusion-dependent thalassemia when a matched donor is unavailable. This case demonstrates successful engraftment, manageable toxicity, and complete hematologic recovery with tailored prophylaxis and multidisciplinary care. By merging two graft sources, Haplo-Cord transplantation under *Save the Sibling(STS)* program embodies science and safety to deliver a lasting cure.

A CASE OF RESOLVED SEVERE HEMATOLOGICAL TOXICITY AFTER ANTI-BCMA CAR-T THERAPY FOR MULTIPLE MYELOMA

Mikhail Uss[1], *Ekaterina Drozhko-Metelskaya*[1], *Tatyana Shman*[1], *Alexander Meleshko*[2], *Dmitry Lutskovich*[2], *Tamara Vasileva*[1], *Anna Startseva*[1], *Anatoly Uss*[1]
[1]*Minsk Scientific and Practical Center for Surgery, Transplantology and Hematology, Minsk, Belarus,* [2]*Republican Scientific and Practical Center for Pediatric Oncology, Hematology and Immunology, Borovlyany Village, Belarus*

Background: CAR-T therapy leads to a rapid and durable response in most patients with hematological malignancies, but could be associated with unique toxicities such as cytokine release syndrome (CRS), immune effector cell-associated neurotoxicity (ICANS), and hemophagocytic lymphohistiocytosis (HLH). However, the most common severe adverse events are hematological toxicities associated with immune effector cells (ICAHT), including transfusion dependence and decreased quality of patients life.

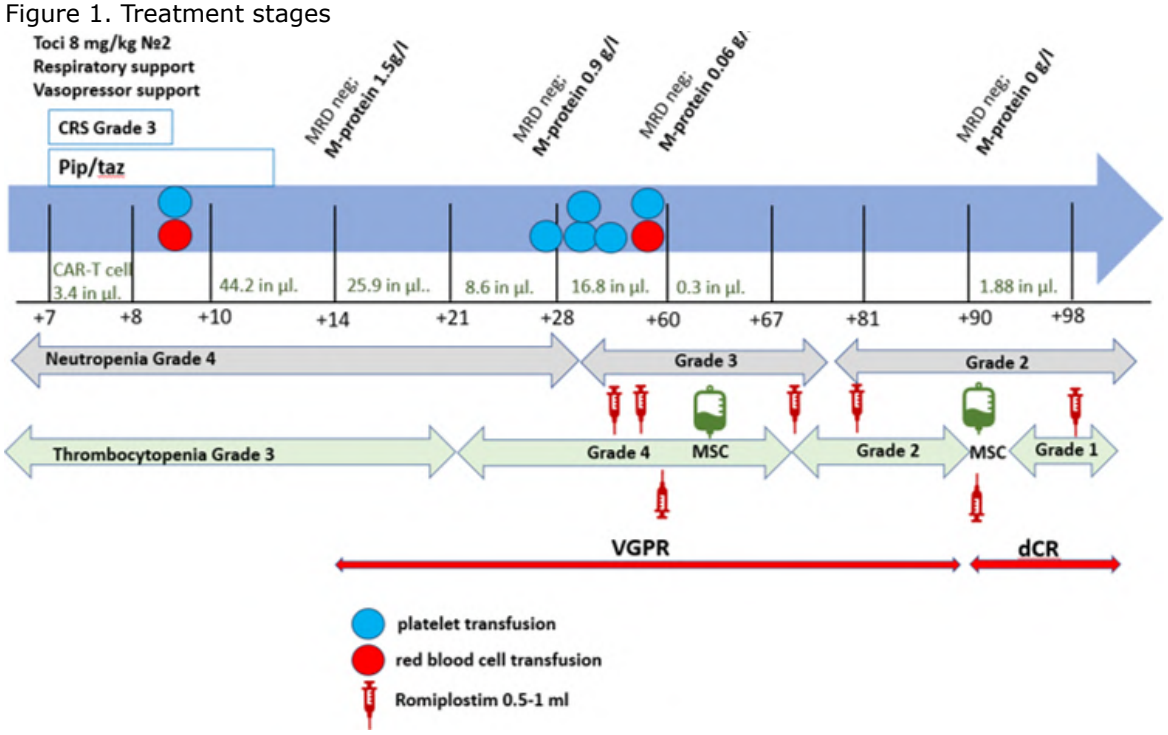
Methods: A 65-year-old woman with relapse/refractory multiple myeloma underwent anti-BCMA CAR-T cell therapy with a locally produced cell product. The study protocol was approved by the local ethics committee (No. 9 from 10/04/2024). Lymphodepleting therapy consisted of fludarabine 30 mg x m^2 and cyclophosphamide 300 mg x m^2 for three consecutive days.The CAR-T cell dose was 1.27 cells x 10^6/kg of patient body weight, the ratio of CD4+ to CD8+ cells was 1.15. Response to treatment was assessed according to the IMWG criteria, severity of adverse events according to CTCAEv5.

Table 1. Clinical characteristics of the patient.

Characteristics	Meaning
DS stage	IIA
ISS stage	II
Lines of therapy	10
Auto HSCT	non-mobilizer
Refractory	double
ECOG	2
CAR-HEMATOTOX score	3
M-protein	13.2 g/l
MRD in bone marrow	negative

Results: By day 14 after infusion, the patient had achieved a MRD negative very good partial response, by day 90 deep, complete response. Grade 3 CRS was detected on day 7, which required 2-fold administration of Tocilizumab at a dose of 8 mg/kg, vasopressor support, and respiratory support. There was no evidence of ICANS or HLH.
From day 3, severe neutropenia (Grade 4) was detected, from day 7 - grade 2 thrombocytopenia with progression to grade 4 from day 21 with the need for transfusion support. Three episodes of infection were verified within 90 days after the start of therapy, including CMV infection, acute respiratory infection, and purulent conjunctivitis with no need for hospitalization. From day 40 after CAR-T administration, Romiplostim therapy was prescribed at dose of 0.5-1 ml weekly; from day 60, mesenchymal stromal stem cells were administered at a dose of 1 million cells per kg monthly with administration of PEG-CSF when the neutrophil level is less than 0.5×10^9.
Currently (day + 140) hematological toxicity has completely resolved, patient in deep complete response and ECOG status - 1 continues outpatient observation with prophylactic administration of human immunoglobulin at a dose of 0.2-0.4 g/kg per month antibacterial and antiviral prophylactic therapy.

Figure 1. Treatment stages



Conclusions: Despite achieving deep durable responses in multiple myeloma, CAR-T therapy may be associated with severe and prolonged hematological toxicity requiring complex and long-term therapy.

Disclosure: Nothing to declare"

P091

JUVENILE MYELOMONOCYTIC LEUKEMIA WITH THERAPY-RELATED AML: A COMPLEX CASE OF MULTIPLE HAPLOIDENTICAL TRANSPLANTS AND CHRONIC GVHD

Esraa Abdelhakem[1], *Abdul Hakim Al Rawas*[1], *Amr Abdalla*[2], *Buthaina Al Musalhi*[1], *Yasser Wali*[1], *Nawal Al-Mashaikhi*[1]
[1]*Sultan Qaboos University Hospital, Muscat, Oman,* [2]*National Cancer Institute, Cairo University, Cairo, Egypt*

Background: Juvenile myelomonocytic leukemia (JMML) is a rare, aggressive hematopoietic disorder of early childhood. Allogeneic hematopoietic stem cell transplantation (HSCT) remains the only curative therapy in refractory cases. However, relapse, graft rejection, and treatment-related complications—including secondary malignancy—continue to present major challenges.

Methods: A 5-year-old boy was diagnosed with juvenile myelomonocytic leukemia (JMML) in 2017, according to the WHO 2016 criteria. He was referred abroad for hematopoietic stem cell transplantation (HSCT). The first transplant was performed on 03/08/2017, using his mother as the donor, with a conditioning regimen consisting of Treosulfan, Melphalan, Cyclophosphamide, and antithymocyte globulin (ATG). Peripheral blood stem cells, processed with α/β T-cell and CD19 depletion, were infused. However, graft rejection occurred on day +18, mediated by persistent anti-HLA-DRB1*04:04 antibodies. A second haploidentical HSCT was subsequently performed on 13/09/2017, using his father as the donor. Pre-transplant interventions included plasmapheresis and bortezomib to reduce donor-specific antibodies. Conditioning consisted of Fludarabine, Cyclophosphamide, Thiotepa, total body irradiation (TBI), and ATG, followed by infusion of an α/β T-cell and CD19-depleted peripheral blood stem cell graft. Engraftment was successful with achievement of full donor chimerism. The post-transplant course was further complicated by acute gut GVHD, treated with methylprednisolone, and renal impairment requiring supportive care. Bone marrow assessment on day +74 confirmed complete remission, and patient was transferred to our center.

Twenty-two months post-transplant, the child developed therapy-related acute myeloid leukemia (t-AML) with newly developed monosomy 7, while maintaining 100% donor chimerism. He received salvage chemotherapy with two cycles of FLA-IDA and subsequently achieved remission. This was followed by a third allogeneic HSCT from his uncle using a T-cell–replete graft on 07/01/2020. Conditioning included fludarabine, busulfan, and cyclophosphamide. GVHD prophylaxis consisted of post-transplant cyclophosphamide, tacrolimus, and mycophenolate. Engraftment was achieved by day +12. This was complicated by steroid-refractory acute GVHD of the skin and eyes, managed with Etanercept, narrow-band UV phototherapy, imatinib, and ruxolitinib, with partial response.

Results: The child remains in morphological and cytogenetic remission. Immunosuppression has been discontinued since August 2022, although chronic skin and ocular graft-versus-host disease (GvHD) sequelae persist. Despite these complications, his overall functional status remains good, with ongoing school attendance and continued follow-up support for learning difficulties.

Conclusions: This case illustrates the clinical complexity associated with JMML, particularly when compounded by graft failure, donor-specific antibodies, and the later emergence of therapy-related AML. The development of t-AML with monosomy 7, two years after HSCT, represents a rare but well-recognized complication. The decision to proceed with a third allogeneic transplant was complex and carried a high risk of mortality and morbidity.
A T-cell–replete graft was selected to optimize the graft-versus-leukemia effect, an especially important strategy in the presence of high-risk cytogenetic features such as monosomy 7. Although the patient subsequently developed severe steroid-refractory GVHD, multimodal immunomodulation—including ruxolitinib, etanercept, imatinib, and narrow-band UV phototherapy—achieved adequate control without major infectious complications. Narrow-band UV phototherapy contributed to partial improvement of cutaneous GVHD and enabled steroid tapering, supporting its recognized role as a safe and effective adjuvant treatment modality.

THE ROLE OF APHERESIS PLATELETS IN SUPPORTIVE THERAPY FOR PATIENTS AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION - CASE REPORT

Marina Sekulic[1], *Adrijana Djurisic*[1]
[1]*Institut for Blood Transfusion of Montenegro, Podgorica, Montenegro*

Background: Hematopoietic stem cell transplantation (HSCT) is a key therapeutic approach for patients with malignant hematologic diseases such as acute and chronic leukemias, myelodysplastic syndrome, and relapsed lymphomas, as well as for non-malignant disorders including aplastic anemia, hemoglobinopathies, congenital marrow failure, and primary immunodeficiencies.
The procedure restores normal hematopoiesis after high-dose chemotherapy and/or radiation.
A major post-transplant complication is **severe thrombocytopenia**, which requires transfusion support to prevent bleeding. Among platelet products, **apheresis platelets** (collected from a single donor via cell separator) are preferred over pooled platelet concentrates due to their higher platelet yield, lower risk of infectious transmission, and reduced alloimmunization potential. Donor screening (HBsAg, anti-HCV, anti-HIV 1+2, syphilis, CMV) and microbiological testing ensure product safety.

Methods: Two patients undergoing autologous hematopoietic stem cell transplantation (auto-HSCT) were monitored for hematologic recovery and transfusion support. The first patient received high-dose melphalan conditioning, followed by stem cell reinfusion on February 17, 2025; the second, diagnosed with multiple myeloma, underwent auto-HSCT on April 11, 2025. Post-transplant cytopenia and aplasia were managed with granulocyte-colony stimulating factor (G-CSF) and apheresis platelet transfusions. Daily platelet, leukocyte, and neutrophil counts were recorded to assess recovery kinetics and transfusion efficacy. Patients were discharged after hematologic stabilization and continued outpatient follow-up with scheduled laboratory evaluations.

Results: In both patients, the expected post-conditioning **cytopenic phase** occurred.
Case I: Platelet counts progressively decreased from 132×10^9/L (18.02) to a nadir of 12×10^9/L (28.02). Multiple apheresis platelet transfusions between 25.02 and 05.03 stabilized the counts, which subsequently rose to 42×10^9/L by 25.03.
Case II: Platelet decline began on 17.04 (50×10^9/L) with nadir values around $19–22\times10^9$/L (19–21.04). Three consecutive apheresis transfusions were administered during this period, resulting in gradual hematologic improvement. Platelet counts increased to 109×10^9/L by 28.04 and normalized (>150×10^9/L) by mid-May.
No transfusion reactions or clinical evidence of refractoriness were observed. Both patients demonstrated satisfactory recovery of leukocyte and neutrophil counts with G-CSF support.

Conclusions: Post-transplantation recovery of hematological parameters was accompanied by pronounced thrombocytopenia, which was effectively managed through the use of apheresis platelet transfusions. Their high efficacy, safety profile, and good tolerance make apheresis platelets the standard of supportive therapy for immunosuppressed patients following hematopoietic stem cell transplantation. Continuous monitoring of the therapeutic response showed no evidence of platelet refractoriness. In both presented cases, apheresis platelets successfully controlled thrombocytopenia and contributed to stable hematologic recovery, further confirming their essential role in post-transplant supportive care.

ALLOGENEIC STEM CELL TRANSPLANT WITH PERIPHERAL BLOOD SOURCE AS FRONTLINE THERAPY: A SINGLE CENTRE EXPERIENCE

*Antonio García Sánchez[1], **Guillermo Ramos Moreno**[1], Adolfo Jesús Sáez Marín[1], José María Sánchez Pina[1], Joaquín Martínez López[1], María Calbacho Robles[1]*
[1]Hospital Universitario 12 de Octubre, Madrid, Spain

Background: Allogeneic haematopoietic stem cell transplantation [allo-HCT] represents a potentially curative therapeutic strategy for patients diagnosed with acquired aplastic anaemia [AAA], being considered the first-line treatment of choice in individuals under 40 years of age with a suitable donor. Traditionally, the use of progenitor cells obtained from the bone marrow of an HLA-identical sibling donor has been prioritised in order to minimise the risk of graft-versus-host disease [GvHD] and graft rejection [GR]. However, the introduction of post-transplant cyclophosphamide [PTCy] has enabled the development of alternative platforms, which have shown apparently favourable initial outcomes in small retrospective studies and reports.

Methods: In this report, we describe our centre's clinical experience in the frontline treatment of four patients undergoing a first allo-HCT for AAA between 2022 and 2025, applying transplant platforms based on the use of peripheral blood haematopoietic stem cells, a conditioning regimen including in vivo T-depletion with equine antithymocyte globulin [ATG], and PTCy.

Results: Patient and transplant characteristics are displayed in **Table 1.**

Table 1. Patient and transplant characteristics

	Recipient 1	Recipient 2	Recipient 3	Recipient 4
Age at allo-HCT time (years)	27.4	19.0	40.8	35.8
Gender	Female	Male	Female	Male

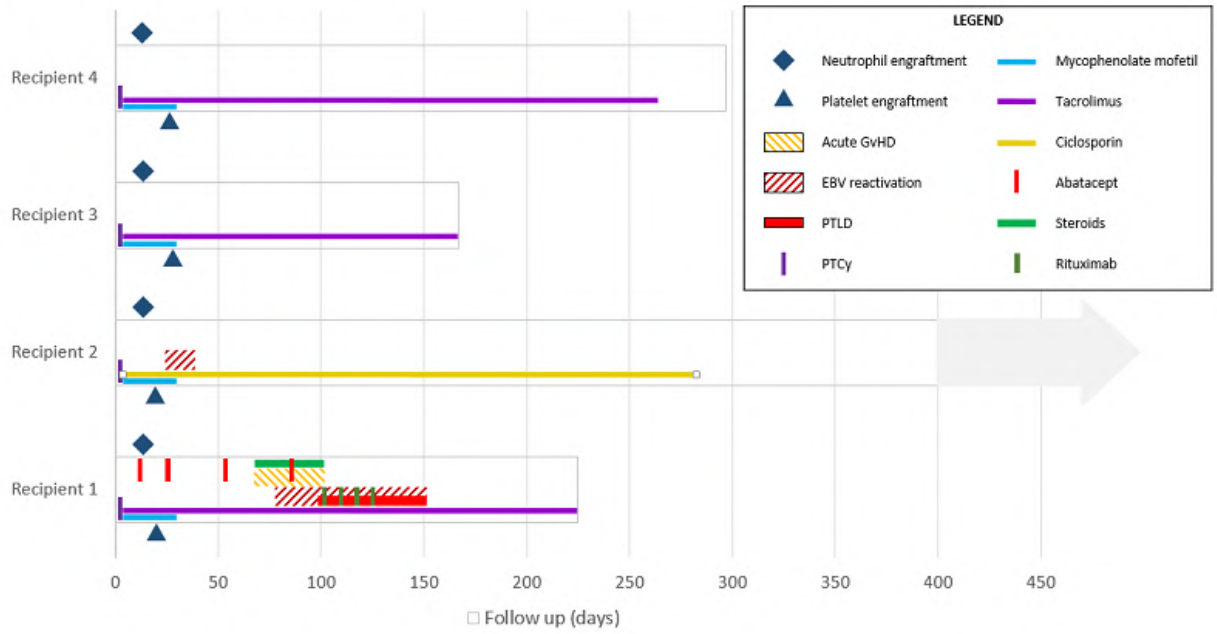
Time from diagnosis to allo-HCT (months)	3.5	2.3	1.3	1.8
Stem cell source	Peripheral blood	Peripheral blood	Peripheral blood	Peripheral blood
Donor type	HLA-mismatched unrelated	HLA-identical sibling	HLA-matched unrelated	HLA-identical sibling
ABO status (donor / recipient)	0 / A	B / B	0 / A	A / A
IgG CMV status (donor / recipient)	Negative / Negative	Negative / Negative	Positive / Positive	Positive / Positive
Conditioning intensity	Reduced intensity	Myeloablative	Reduced intensity	Reduced intensity
Conditioning scheme	Fludarabine Cyclophosphamide Equine ATG	Fludarabine Cyclophosphamide Equine ATG	Fludarabine Cyclophosphamide Equine ATG	Fludarabine Cyclophosphamide Equine ATG
GvHD prophylaxis	PTCy Tacrolimus MMF Abatacept	PTCy Ciclosporin MMF	PTCy Tacrolimus MMF	PTCy Tacrolimus MMF
Anti-infective prophylaxis	Acyclovir Posaconazole Trimethoprim-sulfamethoxazole	Acyclovir Fluconazole Trimethoprim-sulfamethoxazole	Acyclovir Isavuconazole Trimethoprim-sulfamethoxazole Letermovir	Acyclovir Isavuconazole Trimethoprim-sulfamethoxazole Letermovir
Time to neutrophil and platelet engraftment (days / days)	17 / 20	15 / 19	17 / 31	15 / 27
VOD	No	No	No	No
Acute GvHD	Yes (day +69, skin grade 3)	No	No	No
PTLD	Yes (day +98)	No	No	No
Graft failure	No	No	No	No

Follow up (months)	7.4	37.5	5.5	9.8

Allo-HCT: allogeneic haematopoietic stem cell transplantation; ATG: antithymocyte globulin; GvHD: graft-versus-host disease; PTCy: post-transplant cyclophosphamide; MMF: mycophenolate mofetil; CMV: cytomegalovirus; VOD: veno-occlusive disease; PTLD: postrasplant limphoproliferative disease.

Median age at allo-HCT was 31.6 years (interquartile range (IQR), 21.1-39.6), with no gender predominance. Median time from diagnosis to allo-HCT was 2.1 months (IQR, 1.4-3.2). The stem cell source was peripheral blood. The majority (75%) underwent HLA-identical allo-HCT, while two cases (50%) received transplants from unrelated donors, including one (25%) from a mismatched unrelated donor. The greater number (75%) were administered reduced-intensity conditioning [RIC] using fludarabine combined with cyclophosphamide and equine ATG. All patients received GvHD prophylaxis consisting of PTCy, a calcineurin inhibitor and mycophenolate mofetil [MMF]. One patient additionally underwent abatacept owing to an HLA-mismatched unrelated donor.
Median follow-up was 8.6 months (IQR, 6.0-30.6). Median time of neutrophil and platelet engraftment was 16.0 days (IQR, 15.0-17.0) and 23.5 days (IQR, 19.3-30.0), respectively. One patient who underwent RIC allo-HCT from an HLA-mismatched unrelated donor developed grade 3 acute cutaneous GvHD on day +69 (overall grade 2 acute GvHD), showing favourable evolution under systemic corticosteroid therapy until complete resolution within 5 weeks. This patient also developed an Epstein–Barr virus (EBV) reactivation, associated with post-transplant lymphoproliferative disease (PTLD), which was diagnosed on day +98. She was treated with a reduction in immunosuppression and a course of rituximab, with a favourable response (**Image 1**).

Image 1. Patient management and evolution after allogeneic haematopoietic stem cell transplantation



No cases of veno-occlusive disease [VOD] or graft failure were recorded. No further clinically relevant viral reactivations nor significant bacterial or fungal infections were documented. All patients were alive at the end of follow-up.

Conclusions: The results of our centre's clinical experience are consistent with the evidence to date in this field. The use of PTCy may facilitate the adoption of alternative transplant platforms and peripheral blood progenitors when performing allo-HCT in patients with AAA, while maintaining a low incidence of VOD, severe GvHD and graft failure. Careful immunosuppression management appears essential to balance the reduction in GvHD/GR incidence with the risks of infections and viral reactivations, including EBV reactivation and the development of PTLD. Further, larger-scale, prospective studies with extended follow-up are required to provide more robust scientific evidence in this area.

Disclosure: Nothing to declare.

P094

FLAG-VENETOCLAX-ENASIDENIB SALVAGE FOR 7+3 FAILURE

Kevin Sese[1], *Jan Miko Aaron Baybay*[1], *Francisco Lopez*[1]
[1]*St Luke's Medical Center-Global City, Taguig, Philippines (the)*

Background: Acute Myeloid Leukaemia with Myelodysplasia-Related Changes (AML-MRC) represents a high-risk subtype characterized by chemo-refractoriness and poor overall survival. Standard induction regimens, such as "7+3" combined with B-cell lymphoma 2

(BCL-2) inhibitors like venetoclax, have improved outcomes but do not guarantee remission in all patients. In cases of primary induction failure, the patient is often left clinically fragile, making standard myeloablative conditioning (MAC) for hematopoietic stem cell transplantation (HSCT) prohibitively toxic. This study highlights the utility of Next-Generation Sequencing (NGS) in identifying actionable mutations for salvage therapy and the strategic advantage of Reduced-Intensity/Non-Myeloablative (NMA) conditioning to bridge high-risk patients to curative transplant.

Methods: We report the case of a 49-year-old female presenting with anaemia. Bone marrow biopsy (BMB) and NGS confirmed a diagnosis of AML-MRC with high-risk mutations, including RUNX1, SRSF2, ASXL1, and IDH2. The patient underwent standard induction with the "7+3" regimen (Cytarabine/Idarubicin) plus venetoclax. Following treatment failure, a salvage protocol was designed based on NGS findings. The patient subsequently underwent an HLA-matched sibling allogeneic HSCT utilizing an NMA conditioning regimen.

Results: Despite initial intensive induction with "7+3" and venetoclax, the patient experienced primary treatment failure, with a post-induction BMB showing persistent disease (53.8% blasts) and pancytopenia. NGS identified IDH2 mutation (0.55% VAF). Consequently, a salvage regimen comprising FLAG (Fludarabine, Cytarabine, G-CSF), venetoclax, and the IDH2-inhibitor enasidenib (100 mg daily) was initiated. This targeted approach successfully cleared the marrow, resulting in a no detectable blasts by flow cytometry. Given the patient's extensive prior cytotoxic exposure and induction failure, an NMA conditioning regimen was utilized to minimize transplant-related mortality while relying on the graft-versus-leukaemia (GVL) effect. Thirty-two days post-allogeneic stem cell transplant, she achieved 100% donor chimerism on short tandem repeat (STR) analysis and remains clinically well.

Conclusions: This case demonstrates that NGS is indispensable in the management of refractory AML-MRC, specifically for identifying targets like IDH2 when standard venetoclax-based induction fails. The addition of enasidenib to FLAG-based salvage provided a crucial bridge to transplant. Furthermore, for patients who have failed intensive induction, NMA conditioning offers a viable, reduced-toxicity platform for allogeneic HSCT, allowing for successful engraftment and survival in a resource-limited setting.

CLINICAL IMPACT OF HLA-C*04:09 RECLASSIFICATION FROM NULL TO LOW-EXPRESSION ALLELE: A CASE AFTER APPARENTLY 10/10 MATCHED ALLOGENEIC HSCT

Rodrigo Gil Manso[1,2], *Franciso Javier Gil Etayo*[1,1,3], *Antonio Costa*[1,2], *Juan López-Pérez*[1,2], *Sara Marcos Asensio*[1,2], *Almudena Navarro*[1,2], *Pilar Terradillos Sánchez*[1,2], *Isabel Jiménez Hernaz*[1,2], *Ariadna Vicente Parra*[1,2], *Ana Balanzategui Echevarría*[1,2], *Nuria Calzada Nieto*[1,2], *Estefanía Pérez López*[1,2], *Mónica Cabrero Calvo*[1,2], *Alejandro Avendaño Pita*[1,2], *Ana García Bacelar*[1,2], *Almudena Cabero Martínez*[1,2], *Ana África Martín López*[1,2], *Lourdes Vázquez*

López[1,2], Mónica Baile González[1,2], Jenifer Alonso Rodríguez[1,2], Carmen Gilabert Gutiérrez[1,2], Fermín Sánchez-Guijo[1,2,4], Lucía López-Corral[1,2,4], Amalia Tejeda Velarde[1,2]
[1]Hospital Universitario de Salamanca, Salamanca, Spain, [2]Instituto de Investigación Biomédica de Salamanca (IBSAL), Salamanca, Spain, [3]Centro de Investigación del Cáncer (CIC, CSIC), Salamanca, Spain, [4]Centro de Investigación Biomédica en Red del Cáncer (CIBERONC), Madrid, Spain

Background: HLA-C*04:09N has historically been classified as a null allele, implying lack of cell-surface expression and absence of involvement in T-cell alloreactivity. However, recent functional analyses have demonstrated low but detectable expression levels, alongside evidence of peptide-dependent T-cell activation. These findings led to its reclassification as C*04:09L in December 2024. This update carries potential implications for donor selection in allogeneic hematopoietic stem cell transplantation (allo-HSCT), where clinical significance of nule alleles has been questioned. We report a case illustrating the potential clinical consequences of this reclassification, involving a patient with C*04:09N (currently classified as C*04:09L) who received a transplant from a donor initially considered 10/10 matched and subsequently developed severe GVHD, relapse and death.

Methods: A retrospective review of the patient's clinical history and transplant course was performed, including HLA typing, donor selection criteria, and post-transplant outcomes. In parallel, a focused review of the literature was conducted to evaluate current evidence on the expression and clinical relevance of HLA-C*04:09 and its recent reclassification from a null to a low-expression allele.

Results: A 66-year-old man with primary myelofibrosis harboring a JAK2 V617F mutation was referred for allo-HSCT. An unrelated female donor aged 56 years was selected. Both donor and patient were CMV seronegative, with minor ABO incompatibility and a permissive HLA-DPB1 mismatch. HLA typing classified the donor as C*02:02,-, and the patient as C02:02*,* *C*04:09N, with the case considered fully matched based on the null designation of C*04:09N. Conditioning consisted of reduced-intensity fludarabine and busulfan, followed by infusion of peripheral blood $CD34^+$ cells. GVHD prophylaxis included tacrolimus, sirolimus, and mycophenolate mofetil.
The early post-transplant course was notable only for expected oral mucositis. Neutrophil engraftment occurred on day +23 and platelet engraftment on day +29. At day +100, the patient achieved complete hematologic and molecular remission with full donor chimerism in bone marrow. On day +151, he developed grade 3 overlap acute/chronic GVHD, involving skin, mucosa, and joints, which responded partially to high-dose corticosteroids and adjustment of tacrolimus/sirolimus. Subsequently, he developed polyserositis attributed to an atypical form of chronic GVHD, requiring restarting systemic corticosteroids. His clinical course was further complicated by a vertebral fracture and two episodes of nosocomial pneumonia. On day +293, bone marrow evaluation revealed 3% blasts and 3% recipient chimerism, raising concern for disease relapse. By day +302, he experienced recurrent inflammatory serositis, and progression to secondary acute myeloid leukemia was confirmed on day +310. Given progressive clinical deterioration, recurrent infection, and leukemic transformation, therapeutic limitations were applied, and the patient died on day +316 post-transplant.

Conclusions: This case illustrates the clinical relevance of the reclassified low-expression allele C*04:09L, which may represent a functionally significant HLA mismatch rather than a null allele. Donor selection algorithms that rely on outdated allele expression data may inadvertently classify such transplants as fully matched, potentially increasing the risk of alloreactivity, GVHD, and adverse outcomes. Continued integration of updated immunogenetic knowledge into routine donor selection is essential to prevent misclassification and optimize allo-HSCT safety.

P096

SUCCESSFUL MANAGEMENT OF POST-TRANSPLANT AML RELAPSE WITH SALVAGE CHEMOTHERAPY AND DONOR LYMPHOCYTE INFUSION

Hakan Goker[1], *Alkim Yolcu*[1], *Haluk Demiroglu*[1]
[1]*Hacettepe University Hospital, Ankara, Turkey*

Background: Acute myeloid leukemia (AML) is the most common reason for allogeneic hematopoietic stem cell transplantation (HSCT) in adults. Allogeneic HCT is primarily used to treat intermediate- and high-risk AML due to its potential for long-term survival. Relapse after allogeneic HCT is the leading cause of treatment failure post-transplantation and occurs in about 30% of patients. Here, we present a patient who relapsed following transplantation and experienced an improvement in chimerism loss after salvage chemotherapy.

Methods: Here, we present a patient who relapsed following transplantation and experienced an improvement in chimerism loss after salvage chemotherapy and donor lymphocyte infusion (DLI).

Results: A 64-year-old male patient presented with fatigue and joint pain three years ago. He had no known chronic diseases, and the physical examination was unremarkable. Complete blood count revealed pancytopenia. Bone marrow sampling and flow cytometry results showed diffuse blastic infiltration, consistent with AML. The patient's cytogenetic analysis was compatible with a complex karyotype; therefore, he was classified as high risk. Complete remission was achieved after induction chemotherapy with 3+7 (idarubicin, cytarabine (ara-C)). Following consolidation with high-dose ara-C, the patient underwent sibling-matched allogeneic HCT with a myeloablative conditioning regimen (busulfan/fludarabine/ATG). Methotrexate, ATG, and cyclosporine were administered as graft-versus-host disease (GvHD) prophylaxis. No GvHD was observed during follow-up. In the 20th month post-transplantation, complete blood count showed leukocytes 132.7 $x10^3$/µl (3.9-10.9), neutrophils 5.49 $x10^3$/µl (1.8-6.9), monocytes 53.11 $x10^3$/µl (0.3-0.9), platelets 22 $x10^3$/µl (166-308), and hemoglobin 9.2 g/dl (13.5-16.9). Blastic infiltration was observed in the bone marrow, and chimerism was detected at 5%. No new mutations were identified in genetic tests. HAM (high-dose ara-C, mitoxantrone) chemotherapy was administered due to relapse of AML after transplantation. Remission was achieved following this salvage

chemotherapy, with chimerism at 97%. Subsequently, DLI was given to prolong the response and harness the graft-versus-leukemia (GvL) effect.

Conclusions: The prognosis for patients with relapsed AML after allogeneic SCT is poor, with a two-year overall survival rate below 20%. There is no established standard treatment for relapse post-transplantation. To reduce tumor burden, intensive chemotherapy is recommended for fit patients, while low-intensity chemotherapy or hypomethylating agents are suggested for unfit patients. If a mutation is identified through genetic testing, targeted therapies or venetoclax can be combined. Cellular therapies, particularly those that modulate the immune microenvironment and offer GvL effects, such as CAR-T or NK cell therapies, may improve survival when used in personalized combinations with chemotherapy and targeted agents (like FLT3, IDH, TP53). The relapse rate after allogeneic HCT remains high, and treatment options are limited. The absence of randomized controlled trials indicates that further research is necessary in this area.
This case illustrates the successful application of HAM chemotherapy and DLI in a patient with relapsed AML and loss of chimerism after hematopoietic stem cell transplantation. The recovery of nearly complete donor chimerism and ongoing remission underscores the potential of this approach in high-risk AML. Further research is needed to refine salvage treatments and immunotherapeutic methods in this context.

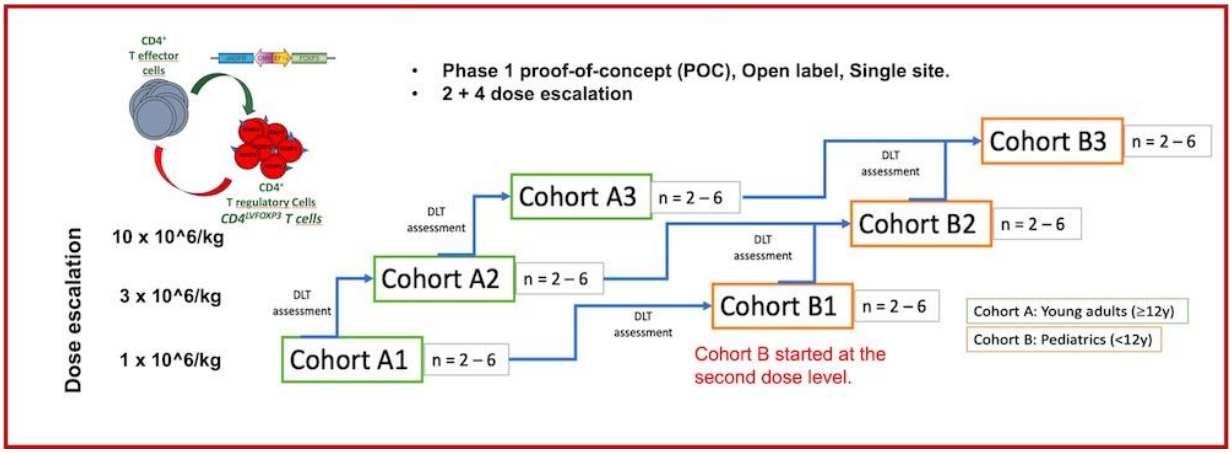
Background: We have developed a First-In-Human (FIH) Phase 1 clinical trial with a novel regulatory T (Treg) cell therapy product to treat IPEX syndrome (NCT05241444), a life-threatening monogenic autoimmune disorder classically associated with enteropathy, early-onset diabetes, and severe atopic dermatitis. The Orphan Drug product consists of engineered CD4^{LVFOXP3} Treg-like cells, obtained from autologous CD4+ T cells lentiviral vector (LV)-transduced with EF1a-FOXP3, fully resembling naturally occurring Treg, and expressing the membrane marker tNGFR (CD271).

Methods: The design is a 2+4 dose escalation in two different age cohorts, ≥12 years and <12 years of age (Figure 1).

Figure 1. Study Design



Results: Eight patients have been treated with a high-purity product (Table 1). Primary endpoints of feasibility and safety have been successfully achieved with the lowest ($1x10^6$/kg; n=2), intermediate ($3x10^6$/kg; n=2), and highest ($10x10^6$/kg; n=2) doses in the older patients and in two of the younger patients at the intermediate dose. There have been no significant or related adverse events. In nearly all patients, we observed a noticeable clinical response, including significant improvement in growth, gastrointestinal symptoms and disease biomarkers after treatment. $CD4^{LVFOXP3}$ are detectable in the blood after infusion with a clear dose-response relationship and persistence. $CD4^{LVFOXP3}$ Treg-like cells demonstrate phenotypic and functional stability at the single cell level by CITEseq on the product preinfusion and ex vivo. $CD4^{LVFOXP3}$ maintains the Thelper subsets' heterogeneity of the parental cells and expresses the transgene *FOXP3-lv* and Treg markers, including *CCR4, CTLA4* and *IL2RA* and low IL7R. After infusion, the patient's peripheral blood samples have exhibited lower expression of the inflammatory cytokines *IL17A, IL17F, IL22, IL15, IFNg*, constrained TCR clone expansion and cycling status, and contain a high proportion of cells that have stem cell memory features, most likely derived from naïve CD4+ T cells.

Conclusions: These findings show that $CD4^{LVFOXP3}$products are safe, preserve their Treg-like signatures, and persist after in vivo transfer, with evidence of clinical benefit. Successful completion of this trial will address a significant unmet medical need while also providing proof of safety and feasibility of this novel therapy. These data could expand the application of autologous $CD4^{LVFOXP3}$ to additional autoimmune disorders.

Background: Adapter CAR platforms critically depend on the pharmacokinetics and pharmacodynamic stability of their adapter molecules (AMs), specifically the integrity of the CAR-targeted epitope on these molecules. We investigated the pharmacokinetics of AMs in the full-size antibody format and the pharmacodynamic impact of the stability of the CAR-targeted epitope on the performance of two distinct adapter CAR technologies: one based on chemical conjugation with NHS-biotin and one based on a peptide tag. Our preclinical assessment provides insights into the rational selection of CAR-targeted epitopes and highlights the need for optimized dosing regimens to maintain stable antigen expression.

Methods: Adapter molecules (IgG1 antibodies) were produced through transient expression, purified, and conjugated to lysine residues using NHS chemistry with LC-LC-NHS-biotin. Separately, peptide tags were integrated into the amino acid sequence of the identical CD33-gemtuzumab-based AM. The pharmacodynamic stability and enzymatic cleavage kinetics of the CAR-targeted epitope of the linker-label-epitope (LLE-biotin) or peptide tag were evaluated both *in vitro* and *in vivo* by indirect flow cytometry in human and NSG mouse sera at various doses and time points. Both adapter CAR systems were based on third-generation CAR architectures. The adapter CARs were tested *in vitro* for cytotoxicity against AML and *in vivo* for leukemia control using longitudinal bioluminescence imaging in a cell line-derived U937 model and benchmarked against a conventional CD33-targeted CAR T.

Results: The adapter CAR technologies and the conventional CD33-CARs demonstrated excellent *in vitro* leukemia control. However, *in vivo* performance was critically dependent on the pharmacodynamic stability of the CAR-targeted epitope conjugated to or integrated into the AM. The enzymatic cleavage was identified as the key mechanism for inactivating the AM, with rapid deconjugation kinetics *in vitro* (ca. 2/3 of the AM deconjugated after 24 hours), and even more extensive deconjugation *in vivo*, reaching around 99% deconjugation four hours after subcutaneous injection and 99.9% three days post administration. Consequently, only a minimal portion of AML-bound AM remained functional, compared to AML-bound AMs that were deconjugated. In contrast, the integrated peptide tag proved to be

stable and resistant to enzymatic cleavage. In the U937 cell line-derived xenograft model, adapter CARs with pharmacodynamically unstable AMs failed to control leukemia *in vivo* and exhibited the same leukemic burden as adapter CARs without AMs or untransduced T cells. Advanced adapter CAR technologies with favorable pharmacodynamics, or conventional CAR T cells can facilitate *in vivo* leukemia control.

Conclusions: Our data demonstrate that the pharmacodynamic stability of the CAR-targeted epitope is essential for adapter CAR-mediated function. In addition to the loss of function when CAR-targeted epitope-devoid AMs are present, the competitive inhibition of functional AMs by the abundance of functionally inert AMs significantly disrupts overall performance of the conceptual framework. *In vivo* leukemia control strictly depends on the pharmacodynamic stability of the AM. Therefore, selecting the appropriate CAR-targeted epitope in adapter CAR technologies must acknowledge its *in vivo* pharmacodynamic stability.

A SINGLE-STEP STRATEGY FOR SIMULTANEOUS T-CELL ACTIVATION AND B-CELL ELIMINATION IN CAR-T PRODUCTION USING BISPECIFIC ANTIBODIES

Ivan Gaponenko[1], *Aminat Balaeva*[1], *Vladislav Markelov*[1], *Vladislav Sergeev*[1], *Alena Shakirova*[1], *Kirill Lepik*[1], *Alexander Kulagin*[1]
[1]*R.M. Gorbacheva Memorial Institute of Children Oncology, Haematology and Transplantation, Pavlov First Saint Petersburg State Medical University, Saint Petersburg, Russian Federation (the)*

Background: Chimeric antigen receptor T-cell (CAR-T) therapy shows promise for B-cell malignancies treatment. T-cell activation and expansion are crucial CAR-T production steps. The cost-effective method of T-cells stimulation directly from peripheral blood mononuclear cells (PBMCs) based on OKT3 is widely used. The most significant limitation of this approach is the presence of CD19-expressing leukemic cells susceptible to further transduction, leading to epitope masking [Ruella M. et al. 2018]. The aim of the current study is to test monoclonal bispecific anti-CD3/CD20 antibodies on PBMCs cell source acting as T-cell stimulator and B-cell depleting agent simultaneously.

Methods: PBMCs obtained from four healthy donors were cultured at 1×10^6 cells/mL and activated for 6 days in the presence of 150 IU/mL interleukin-2 (IL-2) and bispecific anti-CD3/CD20 monoclonal antibodies at concentrations of 0.5, 1, 5, and 10 pmol/mL. OKT3 (100 ng/mL) was used in control samples. In parallel, immunomagnetic selection of T cells and B cells was performed, followed by separate activation of selected T cells using the same activation conditions. Cumulative population doubling level (CPDL) was calculated to assess T-cell proliferation. CD3+ and CD19+ cell proportions, T-cell differentiation subsets (effector,

effector memory, central memory, naïve), and expression of activation and metabolic markers CD71 (transferrin receptor) and LDLR (low-density lipoprotein receptor) were analyzed by flow cytometry.

Results: All groups showed T-cells expansion at the end time point. CPDL values were significantly higher in samples treated with anti-CD3/CD20 antibodies at concentrations from 0.5 to 10 pmol/mL compared with controls ($p<0.05$). Complete elimination of B cells was achieved by day 3 in all anti-CD3/CD20-treated samples, whereas only partial reduction was observed in OKT3 controls (3.28±1.2%). B-cell depletion was dependent on the initial CD3:CD19 ratio and was not achieved when the ratio was below 4:1. T-cell immunophenotyping demonstrated a ≥2-fold reduction of effector cells and ≥1.5-fold decrease of effector memory cells, accompanied by an ≥8-fold increase of central memory T cells, with no significant changes in naïve T cells. Expression of CD71 remained stable across all conditions (mean 77±4%) and did not differ from controls, while LDLR expression was preserved, indicating adequate metabolic activation of T cells irrespective of the activation method.

Conclusions: Bispecific anti-CD3/CD20 antibodies provide efficient T-cell activation comparable to OKT3 while simultaneously eliminating CD20+ B cells and promoting a favorable central memory–enriched T-cell phenotype. Bispecific antibodies can also be used as an additional agent to standard activation in cases of poor T-cell selection in patients with a large number of blast cells in the blood. This approach represents a promising alternative CAR-T manufacturing strategy combining activation, depletion, and phenotypic optimization in a single step.

Disclosure: Nothing to declare.

Background: The rapid expansion of cellular immunotherapies has created strong incentives to discover new target antigens and develop related therapeutic strategies. Insufficient target validation can lead to ineffective treatments and setbacks in clinical translation. Robust validation should integrate orthogonal datasets, genetic perturbation, and matched functional assessment under standardized conditions, including multimodal antibody- and CAR-based testing. Here, we present a systematic validation framework and apply it to the ATP-gated ion channel P2RX7 (P2X7), which regulates cell proliferation, survival, and inflammatory signaling. A conformational "non-functional" P2X7 variant (nfP2X7) has been proposed as a pan-cancer and cancer-restricted antigen on the basis of a putatively unique epitope exposed only on tumor cells.

Methods: We established a multi-step validation pipeline for novel immunotherapy targets. First, we systematically mined public bulk RNA-seq datasets to evaluate tumor coverage and normal-tissue expression of candidate genes. Next, we quantified the surface expression of CD19, CD276, and P2X7 via indirect flow cytometry in well-characterized cell lines. For P2X7, we employed antibodies targeting both the functional P2X7 and the proposed non-functional conformational variant of P2X7 (nfP2X7). We compared these data with publicly available RNA-seq datasets and our qPCR measurements. Additionally, we generated genetic gain- and loss-of-function models using stable lentiviral overexpression and CRISPR/Cas9-mediated P2X7 knockout to demonstrate target-antigen–dependent antibody binding, receptor function, and target-cell recognition by the antibodies and the corresponding CAR-expressing T cells. Finally, we stimulated P2X7 with its natural ligand, ATP, to confirm that receptor function was preserved in the relevant model systems.

Results: Database mining showed that P2X7 is heterogeneously expressed across cancers, with high expression in melanoma, moderate expression in AML, and absent expression in prostate cancer, breast cancer, ovarian cancer, and soft tissue sarcomas. Immunoprofiling using flow cytometry correlated closely with P2X7 transcript levels and aligned with P2X7 knockout and overexpression in an antigen-dependent manner. The P2X7-, CD19-, and CD276-CAR T cells exerted antigen-specific cytotoxicity, consistent with their respective antibody counterparts. Conversely, antibodies designed to recognize the nfP2X7 epitope did not correlate with P2X7 mRNA levels or with P2X7 knockout or overexpression. nfP2X7-CAR T failed to induce antigen-dependent cytotoxicity and could not distinguish P2X7-positive from P2X7-negative targets, while P2X7-CARs retained expected specificity. We found no evidence to support P2X7 as a universal cancer target antigen, and cancer-specific nfP2X7 entity. Instead, the data indicate the recognition of non-specific or context-dependent epitopes unrelated to P2X7.

Conclusions: This systematic validation framework demonstrates that target antigen validation and antibody validation are essential steps in developing immunotherapeutics, especially for new, unvalidated target antigens. The proposed nfP2X7 antigen does not fulfill the criteria for a clinically appropriate, tumor-specific target, and P2X7 itself is not a pan-cancer target antigen. More broadly, our work highlights the importance of multimodal antigen and antibody validation, combining public datasets, orthogonal expression assays, genetic perturbation, and matched antibody-CAR reagents before advancing novel targets into translational immunotherapy efforts. We suggest this structured approach as a model to improve the standards for future target nomination.

Background: Chimeric antigen receptor T cells (CAR-T) have substantially improved outcomes in MM by targeting surface antigens such as BCMA and SLAMF7; however, their efficacy may be limited by antigen loss (like in MM) and restricted target availability (like in AML). T-cell receptor–engineered T cells (TCR-T) enable recognition of intracellular tumor antigens in an HLA-restricted manner and represent a complementary therapeutic strategy. Modular TCR designs incorporating PD-1-CD28 switch receptors and leucine zipper (LZ) domains have been proposed to enhance signaling and receptor stability, yet their functional impact remains incompletely defined.

Methods: $CD3^+$ T cells were transduced with a panel of TCR constructs recognizing the tumor-associated antigens WT1 or TERT. For each target, original and affinity-modified variants were generated, with or without incorporation of a PD-1-CD28 switch receptor and/or an LZ domain. A PD-1–only vector, MOCK (empty vector), and non-transduced (NV) T cells served as controls. CAR-T cells targeting BCMA or SLAMF7, established surface markers of MM, were produced in parallel for contextual comparison.
Phenotypic profiling was conducted by multiparameter flow cytometry assessing CD4/CD8 composition, memory differentiation (CCR7/CD45RO), and immune checkpoint expression (PD-1, TIM-3, LAG-3, TIGIT, BTLA, CD39). Functional activity was evaluated in co-cultures

with U266-Luc⁺ cells, a multiple myeloma cell line expressing WT1, TERT, BCMA and SLAMF7 using luciferase-based killing assays (24–72 h) and LDH release, with antigen-negative control conditions.

Results: Across TCR-T, CAR-T, MOCK, and NV products, phenotypic profiling revealed broadly comparable CD4/CD8 distributions, CCR7/CD45RO memory subsets, and immune checkpoint expression profiles; no statistically significant differences persisted after FDR correction. These findings indicate that, within this dataset, global phenotypic features were largely conserved across platforms. The limited and unequal number of CAR-T and control samples restricts the statistical power of phenotypic comparisons, which should therefore be interpreted as contextual rather than definitive.
WT1- and TERT-directed TCR-T constructs mediated robust, antigen-dependent cytotoxicity against U266-Luc⁺ cells, reflected by consistent reductions in luciferase signal and corresponding LDH release, with minimal activity toward control targets. Original TCR variants reproducibly outperformed affinity-modified counterparts, indicating reduced functional potency of mutated receptors. Incorporation of a PD-1-CD28 switch receptor was associated with increased tumor cell killing under conditions expected to engage inhibitory signaling, without evidence of increased off-target cytotoxicity in the applied in vitro assays. Addition of an LZ domain further augmented or accelerated effector responses in a subset of constructs.

Conclusions: TCR-engineered T cells targeting WT1 and TERT exhibit potent, antigen-specific cytotoxicity against MM cells in vitro, which can be fine-tuned through modular design elements such as PD-1-CD28 switch receptors and leucine zipper stabilization. While TCR-T and CAR-T products generated using the same expansion platform display broadly comparable phenotypic profiles, functional differences among TCR-T constructs are primarily driven by receptor architecture rather than baseline T-cell phenotype. Importantly, WT1 and TERT are tumor-associated antigens expressed across multiple malignancies, including acute myeloid leukemia, supporting the potential use of TCR-T therapies targeting these antigens either in additional disease settings or as subsequent lines of treatment in multiple myeloma.

IMPROVING LENTIVIRAL TRANSDUCTION EFFICIENCY OF CD34+ HEMATOPOIETIC STEM CELLS USING POLOXAMERS OR LENTIBLAST PREMIUM®: OPTIMIZATION TOWARD A GENE THERAPY PROCEDURE FOR SICKLE CELL DISEASE

Tizaanuo Ruth Marie Hien[1], Cécile Roudaut[1], Alice Girardot[1], Axelle Maulet[1], Tristan Rallon[1], Jean-Roch Fabreguettes[2], Olivier Zelphati[3], Florent Poulhes[3], Cédric Sapet[3], Ugo Chartral[1], Mégane Brusson[4], Annarita Miccio[4], Marina Cavazzana[1], ***Elisa Magrin***[1]

[3]OZ Biosciences, Parc Scientifique de Luminy, Marseille, France, [4]Laboratory of Chromatin and Gene Regulation during Development, Inserm, Imagine Institute, Paris, France

Background: Gene therapy is emerging as a curative strategy for sickle cell disease (SCD), relying on efficient lentiviral transduction of autologous CD34⁺ hematopoietic stem and progenitor cells (HSPCs). Optimizing transduction conditions while complying with academic GMP constraints is essential for the development of future clinical-grade protocols. We compared several transduction enhancers, including the poloxamers P338, P188, and P407 provided as reconstitutable powders, in combination with prostaglandin E2 (PGE2), as well as the ready-to-use reagent LentiBlast Premium®. We also assessed the specific impact of PGE2 on vector copy number (VCN).

Methods: CD34⁺ cells from healthy donors (HD) were thawed, pre-activated and transduced with a technical-grade bifunctional lentiviral vector designed to silence βS-globin expression while introducing an anti-sickling β-globin. Four sequential experiments were performed. Quality controls included viability assessment, immunophenotypic purity of CD34⁺, colony-forming unit (CFU) assays of progenitors and quantification of VCN in liquid cultures (LC) and progenitor colony counting on day 14. A VCN ≥ 2 in LC was defined as the minimal acceptable target.

Results: Firstly, the poloxamers P338, P188, and P407 were evaluated in CD34+ cells from HD1 as transduction enhancers. VCN in LC reached 4.86 with P407, 3.31 with P338, and 1.54 with P188. VCN in progenitors mirrored these results, identifying P338 and P407 as the most effective enhancers among the poloxamers tested. For all tests, no VCN was detected under mock conditions.
Secondly, we sought to validate these findings and evaluate the impact of increased cell density on transduction efficiency using the best-performing enhancer, P407. Raising the CD34⁺ cell density from 3×10^6 to 4×10^6 cells/mL further improved P407-mediated transduction, yielding VCN of 20.07 and 6.03 in HD2 and HD3, compared with 10.01 and 4.33 at 3×10^6 cells/mL. In the same experiment, we confirmed the superior performance of P338 and P407 over P188 and the no-enhancer control. VCN measured in progenitor colonies reproduced this hierarchy.
Thirdly, the LentiBlast Premium® was compared with P338 and P407 at different dilutions (1/1000, 1/100, 1/50) in HD3. LentiBlast Premium® demonstrated a dose-dependent increase in VCN, ranging from 4.82 to 6.48 in LC, but P338 and P407 achieved the highest VCN (7.17 and 10) in LC. These results indicate that although LentiBlast Premium® provides concentration-dependent VCN enhancement, its efficiency was lower than P338 and P407. However, these two poloxamers are not fully compatible with GMP use.
Finally, the effect of combining LentiBlast Premium® with PGE2 was evaluated in HD4. PGE2 added to a 1/100 dilution of LentiBlast Premium® lead to a marked increase in VCN (+110%), while the effect on P338, used as positive control, efficiency was more moderate (+60%). VCN in progenitors showed similar increases. Overall, this combination produced the highest and most consistent VCN values.

Conclusions: While P338 and P407 enhanced lentiviral transduction, the combination of LentiBlast Premium® and PGE2 delivered the highest VCN, together with full GMP compatibility. These results support the incorporation of LentiBlast Premium® plus PGE2 into

future GMP-compliant, academic-scale manufacturing protocols for SCD gene therapy. These experiments should also be tested on cells from SCD patients.

Background: Wiskott-Aldrich Syndrome (WAS) is a life-threatening platelet disorder and inborn error of immunity caused by WAS gene mutations. Allogeneic hematopoietic stem cell transplantation (HSCT) can be curative but is still hampered by limited donor availability and potential complications. Etuvetidigene autotemcel (etu-cel) is a gene therapy (GT) product composed of autologous CD34+ hematopoietic stem and progenitor cells (HSPCs) transduced *ex vivo* with a self-inactivating lentiviral vector encoding human WAS cDNA under endogenous promoter control. Recently, etu-cel received EMA CHMP positive opinion and FDA approval for the treatment of WAS patients ≥6 months for whom HSCT is appropriate and lacking a suitable HLA-matched related donor. We report the results of an integrated safety and efficacy analysis in 27 WAS patients treated with etu-cel.

Methods: Source of autologous HSPCs for drug product (DP) manufacturing consisted in mobilized peripheral blood (n=21), bone marrow (n=5) or both (n=1). Etu-cel was infused after rituximab and reduced-intensity conditioning. Patients received fresh [phase I/II trial, NCT01515462, n=8; expanded access program (EAP), n=9] or cryopreserved (phase III trial, NCT03837483, n=10) formulation. Safety endpoints comprehended adverse events (AEs), immune response to transgene, replication-competent lentivirus (RCL) and abnormal clonal proliferation (ACP). Primary efficacy endpoints were overall survival (OS), rate of severe infections from 6 to 18 months post-GT and rate of moderate and severe bleedings in the first 12 months post-GT. Secondary efficacy endpoints included gene-corrected cell engraftment, WASP expression, T-cell function, platelet count, autoimmunity and eczema over time.

Results: Age at treatment ranged between 1.0 and 35.1 years. OS was 96.3%; one EAP subject died 4.5 months post-GT due to deterioration of a pre-existing neurological condition. Median follow-up was 5.72 years (range: 2.31-13.26).
Etu-cel was well tolerated with absence of DP-related AEs, engraftment failure, evidence of ACP, RCL or immunogenicity. None of the treated patients required any secondary procedures after GT.
The rate of severe infections was reduced by 92.5% in the 6-18 months post-GT compared to the rate 12 months before GT. Similarly, moderate and severe bleedings were decreased by 60% in the first 12 months post-GT compared to the year prior to treatment. The majority of patients did not report moderate to severe bleeding after four years post-GT. Stable robust multilineage engraftment of gene-corrected HSPCs led to restoration of WASP expression in lymphocytes and platelets, which resulted in improved immune-cell function and platelet count. Immunoglobulin replacement could be stopped in all patients after GT and cessation of sustained antimicrobial treatment was achieved in 92.6% patients. All patients reached freedom from sustained platelet transfusions after GT and at last follow up, 92.6% reached platelet count $>50\times10^9$/L. After GT, immune dysregulation improved in most patients and eczema resolved in all. Hospitalization rate declined and quality of life ameliorated in all patients. Outcome was similar across different ages, disease characteristics, WAS mutations, and DP formulations.

Conclusions: Results from this integrated safety and efficacy analysis show sustained long-term significant clinical benefit of one single infusion of etu-cel for the treatment of WAS, demonstrating its favorable benefit-risk profile with up to 13 years follow-up.

ATIDARSAGENE AUTOTEMCEL IN METACHROMATIC LEUKODYSTROPHY: SAFETY CONSIDERATIONS FROM REAL-WORLD PRACTICE

Valeria Calbi[1,2], *Vera Gallo*[1,2], *Salvatore Recupero*[1,2], *Sara Mazza*[2], *Francesca Ciotti*[1], *Maddalena Fraschini*[1], *Marina Sarzana*[1], *Cristina Puricelli*[1], *Raisa Jofra Hernandez*[1], *Beatrice Volpe*[1,3], *Laura Passerini*[2], *Francesco Morena*[4], *Sabata Martino*[4], *Grazia Fazio*[5], *Giovanni Cazzaniga*[5], *Alexandra Kolenova*[6], *Silvia Gregori*[2], *Eugenio Montini*[2], *Alessandro Aiuti*[1,2,3], *Francesca Fumagalli*[1,2]
[1]*IRCCS San Raffaele Scientific Institute, Milan, Italy,* [2]*San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), Milan, Italy,* [3]*"Vita-Salute" San Raffaele University, Milan, Italy,* [4]*University of Perugia, Perugia, Italy,* [5]*Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy,* [6]*National Institute of Children's Diseases, Bratislava, Slovakia*

Background: Metachromatic leukodystrophy (MLD) is a rare, fatal lysosomal disease caused by biallelic *ARSA* gene mutations. Atidarsagene autotemcel (arsa-cel) is an autologous lentiviral haematopoietic stem cell (HSC) gene therapy that has demostrated durable clinical benefit and a favourable risk–benefit profile in 39 patients treated in the clinical development programme (CDP), with extended follow-up. Arsa-cel is currently approved as standard of care for presymptomatic late-infantile (PSLI) and early-juvenile (PSEJ), or early-symptomatic EJ MLD (ESEJ). We report real-world safety and efficacy in an expanded cohort treated outside the CDP.

Methods: We present a single-centre, real-world series of patients treated with arsa-cel between 2020 and 2025 under individual compassionate-use programmes or in the post-authorization commercial setting. Clinical and laboratory data, as well as adverse events (AEs) and serious AEs (SAEs), were collected.

Results: Thirteen patients were deemed clinically eligible for treatment; one could not be treated because gene-therapy product failed release testing; Twelve patients received arsa-cel: 8 PSLI, 2 PSEJ and 2 ESEJ. Mobilised peripheral blood (G-CSF + plerixafor) was used as the $CD34^+$ source in all cases, with a median collection of 37.6×10^6 $CD34^+$ cells/kg (range 19.2–62.9). All patients underwent myeloablative single-agent busulfan conditioning. Median age at treatment was 11.3 months (range 8.3–128.3). Neutrophil and platelet recovery occurred in all patients, and all remain alive after a median follow-up of 40.3 months (range 5.8–64.2).
Four severe adverse events (SAE) occurred following treatment that were assessed as potentially related to gene therapy or conditioning. One severe hepatic veno-occlusive disease and one severe immune-mediated thrombocytopenia occurred within 3 months post treatment and are solved. One PSLI patient experienced lack of gene-corrected cell engraftment (LoE) in the first month post-treatment. The patient, could not receive a rescue treatment because of rapid disease progression and he is now showing typical MLD neurological manifestations; exploratory T-cell assays suggested a possible immune-

mediated process underlying this event. One asymptomatic B-cell precursor acute lymphoblastic leukaemia was diagnosed 3 years post-therapy. The patient, 4 years of age at the time of the event, is receiving standard therapy and remains under follow-up. Causality assessment, including longitudinal integration-site analyses, is ongoing. No replication-competent lentivirus was detected. Low-titer anti-ARSA antibodies were observed in 9/12 patients early post-therapy, resolving spontaneously in 7/9.
At 1 year post-treatment, 8 evaluable patients showed a median VCN in peripheral blood mononuclear cells of 2.08 copies/cell (range 2.01–4.9), with 52.9–90.5% transduced bone marrow progenitors. As of today, except for the patient with LoE, ARSA activity has risen to supranormal levels in peripheral blood mononuclear cells and to normal levels in cerebrospinal fluid, and most patients continue to show age-appropriate acquisition of motor and cognitive skills.

Conclusions: The robust engraftment, sustained ARSA reconstitution and early outcomes seen in most patients in this real-world cohort of 12 patients with MLD treated with arsa-cel are consistent with those seen in the clinical development programme; however, this cohort highlights the critical importance of systematic, long-term post-therapy monitoring for the continued evaluation of the risk–benefit profile in the real world setting.

Background: Exagamglogene autotemcel (exa-cel) is an autologous gene therapy for patients aged 12 years and older with sickle cell disease (SCD) or transfusion-dependent thalassemia (TDT). Successful implementation of this therapy requires comprehensive

preparation, appropriate patient selection, efficient stem cell collection and manufacturing, and post-infusion care. Here, we present our center's experience with exa-cel therapy.

Methods: We describe the outcomes for nine patients who underwent autologous gene-edited hematopoietic stem cell transplantation (HSCT) using exa-cel for SCD or TDT. Data were collected retrospectively including demographics, indications for therapy, infused cell doses, engraftment timing, adverse events. The primary objectives included number of transfusions post infusion in TDT, number of painful crises post infusion in SCD. The secondary objective was the number of hospitalizations post engraftment.

Results: Nine patients received exa-cel therapy—three with TDT and six with SCD—with a median follow-up of 75 days (7–512 days). None had HLA-matched donors for allogeneic HSCT. The median age was 16 years (range: 13–32). All patients had acceptable organ function. Refer to the table for characteristics.
SCD Indications and Comorbidities:

- All six SCD patients had recurrent severe vaso-occlusive crises despite hydroxyurea.
- Acute chest syndrome occurred in 4/6 patients.
- Three had prior ICU admissions.
- Chronic pain and increased opioid use were reported in 2/6.
- Avascular necrosis was present in 4/6; one had osteomyelitis, and one had priapism.
- No patients had a history of stroke, CNS vasculopathy, or recurrent splenic sequestration.
- Median baseline HbF was 13% (range: 1.9–26.5%).

Iron Overload and Transfusion History:

- Iron overload (T2* MRI) was present in 2/6 SCD patients and all three TDT patients.
- Median liver iron concentration was 13 mg/g (range: 10–15), with no evidence of fibrosis.
- One TDT patient had alloimmunization.
- All patients with TDT had received >12 transfusions/year.

Stem Cell Collection, Preparation and Conditioning:

- All patients with TDT required one cycle of stem cell collection
- Stem cell collection was challenging in the first six SCD patients prior to implementing a modified G-CSF protocol; 2/6 received G-CSF with plerixafor.
- Multiple collection attempts were required over 3-12 months.
- Ovarian tissue preservation was done in two prepubertal girls.
- All adult male patients had sperm banking and adult female patients had oocyte cryopreservation.
- Median cumulative busulfan AUC was 80 mg·h/L (range: 70–85)

Outcomes:

- All patients achieved successful engraftment.
- Five patients required G-CSF post-infusion (median: 2 doses, range: 1–9).

- One TDT patient developed platelet refractoriness and delayed platelets engraftment (50 days), requiring HLA-matched transfusions and thrombopoietin receptor agonists.
- All three TDT patients became transfusion-independent, with hemoglobin levels >13–14 g/dL and HbF >95%. Phlebotomy was initiated around six months post-therapy.
- None of the SCD patients experienced pain crises or required hospitalization after initial discharge.
- Post-engraftment HbF% levels in SCD patients reached 50–60%, with sustained hemoglobin improvement.

Patient and Transplant Characteristics (n = 9)	Value median or N (range)	Adverse Events	Value (median or N (range or %)
Median age (years)	16 (13–32)	Mucositis	8 (88%) 2 required TPN
Comorbidity index scores	0: 6 1: 1 2: 2	Veno-occlusive disease	1 (moderate in TDT)
Gender (M/F)	5/4	Fever Neutropenia	4
Positive RBC antibody screen	1	Bacteremia	1
Median cumulative Busulfan AUC (mg·h/L)	80 (70–85)	ICU admission	0
Median infused CD34+ cell dose (×10⁶/kg)	6.9 (4–15)	CMV reactivation	0
Number of product vials	3 (2–5)	Survival	9
Neutrophil engraftment (days)	27 (21–32)	Median follow-up duration for TDT (days)	425 (356–512)
Platelet engraftment (days)	33 (26–50)	Median follow-up duration for SCD (days)	49 (7-94)

Conclusions: Exa-cel gene therapy for hemoglobinopathies is encouraging. With appropriate patient selection, preparation, and post-infusion care, outcomes have been favorable. However, initial CD34+ stem cell collection in SCD patients posed challenges, necessitating protocol optimization. Long-term follow-up is essential to evaluate the durability and safety.

Background: Etuvetidigene-autotemcel (Etu-cel), the first gene therapy (GT) to be approved by European Medicines Agency and Food and Drug Administration for the treatment of Wiskott-Aldrich Syndrome (WAS), has been developed in our Centre in the last 15 years. At present, after the completion of the clinical development program (trials NTC01515462 and NTC03837483), Etu-cel has been administered to 8 patients through an early access scheme in Italy.

Methods: Etu-cel is an autologous lentiviral hematopoietic stem and progenitor cell (HSPC) GT indicated for WAS patients aged 6 months and older who have a mutation in the WAS gene and no suitable Human Leukocyte Antigen (HLA) matched related stem cell donor. All the 8 patients treated in the early-access setting presented with severe thrombocytopenia (median platelet count pre-GT 22.75 x10^9/L, range 9-31). Five patients had significant autoimmunity/autoinflammation signs prior to treatment (inflammatory bowel disease, post-Covid-19 Multisystem Inflammatory Syndrome in Children, vasculitis). One patient, notably, was treated after the complete rejection of 3 unsuccessful and complicated allogeneic hematopoietic stem cell transplants, having been rescued with infusion of unmanipulated autologous back-up and without evidence of residual donor cells. All patients received the cryopreserved formulation of Etu-cel product, obtained from mobilized peripheral blood HSPC, after a reduced intensity conditioning based on rituximab, fludarabine and busulfan. Median age at treatment was 2.25 years (0.9-18.4). Vector Copy Number (VCN) on drug product and cell dose were in line with those of the clinical development program.

Results: Current follow-up ranges between 3 and 24 months (median 9 months). All patients are alive and in good clinical condition and did not present any product-related adverse events or reactions. Neutrophil engraftment was achieved at a median of 27 days (range 24-48 days) after infusion of drug product. Multilineage engraftment of gene-corrected cells was demonstrated in all patients and WASP expression increased both on platelets and lymphocytes.
In patients with a minimum follow-up (FU) of 6 months, median platelet count after treatment stably increased above 100 $x10^9$/L. In details, it was 129 $x10^9$/L at FU +6 months (n = 5) and 123.5 $x10^9$/L at +1 year (n = 4). All patients are currently transfusion independent and no bleeding events were recorded. Two patients received a thrombopoietin receptor agonist in the initial post-engraftment phase (PLT count censored).
Infection rate decreased and no moderate or severe infective events were registered after 6 months post-GT. Antimicrobial prophylaxis were stopped in 3 patients and immunoglobulin replacement in 4 patients at FU +1 year, approximately.
Eczema improved and resulted absent from the FU +1 year. No signs of new or previous autoimmunity were detected post-GT.

Conclusions: All patients are alive and experienced clinical benefit, with progressive resolution of WAS manifestations. In this early access scenario, Etu-cel has confirmed the effectiveness and safety already shown in the context of the clinical development program.

EXTENSIVE METABOLIC CORRECTION AND FAVOURABLE NEUROLOGICAL OUTCOMES MAINTAINED 5 YEARS AFTER TREATMENT WITH AUTOLOGOUS HAEMATOPOIETIC STEM CELL GENE THERAPY (OTL-203) IN MUCOPOLYSACCHARIDOSIS TYPE-I HURLER

Francesca Tucci[1,2], *Giulia Consiglieri*[1,2], *Matilde Cossutta*[1,2], *Francesca Fumagalli*[1,2], *Francesca Ciotti*[1,2], *Marina Sarzana*[1,2], *Cristina Puricelli*[1,2], *Emma Restelli*[1,2], *Maurizio Barbera*[1], *Cristina Baldoli*[1], *Rossella Parini*[1], *Vasileios Nikolaou*[3], *Jean Brooks*[3], *Marianna Lalla*[3], *Muska Yarzi*[3], *Su Syonmez*[3], *Laura Campbell*[3], *Bernhard Gentner*[2], *Alessandro Aiuti*[1,2,4], *Maria Ester Bernardo*[1,2,4]

Background: Mucopolysaccharidosis type I Hurler syndrome (MPS-IH) is a lysosomal storage disorder characterized by deficiency of the enzyme alpha-L-iduronidase (IDUA). The resulting accumulation of glycosaminoglycans (GAGs) causes a wide range of systemic abnormalities, progressive neurological disease and early death. As part of a phase 1/2 trial

(NCT03488394, EU CT 2024-514870-29-00), eight patients with MPS-IH were treated with OTL-203, an investigational autologous haematopoietic stem cell-based gene therapy (median age at treatment: 2.0 years [range: 1.2–2.8]). OTL-203 was associated with extensive metabolic correction and multisystemic improvements up to 4 years post-treatment. Here, we report biochemical and neurological outcomes in all patients 5 years after OTL-203 treatment (median [range]: 5 years [4.9–5.1]).

Methods: Vector copy number was quantified using digital droplet polymerase chain reaction. IDUA activity in the blood and cerebrospinal fluid (CSF) was measured using specific IDUA substrates. Tandem mass spectrometry was used to measure GAGs in the urine and CSF. Motor skills were assessed using the Peabody Developmental Motor Scales, while cognitive function was evaluated by the Bayley Scales of Infant and Toddler Development and the Wechsler Preschool and Primary Scale of Intelligence. Age of achievement for motor and cognitive milestones was compared to the ranges of healthy children defined by the World Health Organization. Brain and spinal abnormalities were measured using magnetic resonance imaging (MRI) and a specific neuroradiological scoring system developed for patients with MPS-IH who have been treated with allogeneic haematopoietic stem cell transplant (allo-HSCT). The parent-reported Pediatric Quality of Life (PedsQL) and the parent-reported PedsQL Family Impact Module were used to assess patient and caregiver quality of life.

Results: All patients are alive to date and continue to show sustained engraftment of gene-corrected cells. At their last evaluation, all patients had supraphysiological blood IDUA activity, resulting in substantial urinary GAG substrate reductions to normal**/**near normal levels. In the CSF, IDUA activity was detected 3 months after OTL-203 treatment and persisted over time, and was accompanied by extensive GAG reductions (to undetectable dermatan sulphate levels in all patients). Compared with baseline, most patients (7/8) had stabilization or improvement in total motor function scores to within low average/average ranges of healthy peers by their last evaluation. Over the follow-up period, most patients (6/8) acquired cognitive skills as expected for their age. By their last evaluation, all patients had experienced improvement or stabilization of brain MRI abnormalities (including perivascular space dilation, white matter abnormalities and subarachnoid space enlargement). Most patients (6/8) also experienced improvements in spinal MRI *abnormalities* (including dorsolumbar kyphosis and foramen magnum stenosis and ***ventriculomegaly***) between baseline and their last follow-up. For most patients, PedsQL scores for physical health (6/8), psychosocial health (6/8) and family impact (5/8) did not worsen markedly over time.

Conclusions: These results indicate sustained engraftment of gene-corrected cells, biochemical correction in the CSF and a favourable neurological response up to 5 years after OTL-203 treatment. Clinical outcomes were supported by the neuroradiological findings. An ongoing phase 3 trial (NCT06149403, EU CT 2022-500306-17-00) is prospectively comparing the clinical outcomes of OTL-203 with allo-HSCT, the current standard of care.

LONG-TERM CLINICAL OUTCOMES OF ATIDARSAGENE AUTOTEMCEL, AUTOLOGOUS HEMATOPOIETIC STEM CELL GENE THERAPY (HSC-GT) FOR EARLY-ONSET METACHROMATIC LEUKODYSTROPHY, WITH UP TO 13 YEARS OF FOLLOW-UP

*Vera Gallo[1,2], **Salvatore Recupero**[1,2], Alberto Zambon[1], Francesca Ciotti[1,2], Maddalena Fraschini[1], Sara Mazza[2], Marina Sarzana[1], Francesco Morena[3], Marcella Facchini[1,2], Maura Ruzhnikov[4], Andrew Shenker[5], Phil Weatherill[6], Philippa Nutkins[4], Jean Brooks[4], Laura Campbell[4], Sabata Martino[3], Alessandro Aiuti[2,7,8], Valeria Calbi[1,2], Francesca Fumagalli[1,2]*

Background: Metachromatic leukodystrophy (MLD) is a rare, autosomal recessive lysosomal disorder caused by arylsulfatase A (ARSA) deficiency, leading to progressive motor and cognitive decline. Atidarsagene autotemcel (arsa-cel) is an *ex vivo* autologous hematopoietic stem-cell gene therapy approved for pre-symptomatic late infantile (PSLI), pre-symptomatic early juvenile (PSEJ) and early-symptomatic early juvenile (ESEJ) MLD subtypes, collectively termed early-onset MLD.

Methods: We present long-term results from 39 patients with early-onset MLD treated with arsa-cel, excluding four patients outside the approved indication for the efficacy analysis. Outcomes in arsa-cel-treated patients were compared with a subtype-matched natural history (NHx) cohort of 49 patients.

Results: Data were collected April 2010–March 2024; median follow-up was 7.1 years (range 3.1–13.2) for PSLI (n=19), 4.0 years (range 1.1–11.0) for PSEJ (n=11), and 10.0 years (range 9.2–10.9) for ESEJ (n=5). All arsa-cel-treated patients achieved durable engraftment of gene-corrected cells and restoration of ARSA activity in peripheral blood and cerebrospinal fluid.
Arsa-cel-treated patients exhibited clinically meaningful preservation of motor function compared with the NHx cohort, demonstrating a significantly reduced risk of severe motor impairment (GMFC level ≥5) or death (PSLI: p<0.001; PSEJ: p=0.003; ESEJ: p<0.001) and motor impairment (GMFC level ≥3) or death (p<0.001 across subtypes). The estimated proportion of treated patients with PSLI MLD surviving without severe motor impairment or death up to age 6 was 100% (95% CI: 100.0, 100.0), whereas NHx LI patients experienced rapid loss of motor function and none were estimated to remain event-free up to age 6. For treated patients with PSEJ and ESEJ MLD, 90.9% (95% CI: 50.8, 98.7) and 80.0% (95% CI: 20.4, 96.9) were estimated to remain event-free up to age 13 and 14, respectively, while none were estimated to remain event-free in the NHx EJ cohort.
Overall survival improved in treated PSLI MLD patients compared with the NHx LI cohort (p<0.001). For PSEJ and ESEJ MLD, overall survival was similar to the NHx EJ cohort (PSEJ: p=0.967; ESEJ: p=0.177), likely due to the extended follow-up required to capture mortality in EJ MLD.
Arsa-cel treatment was associated with clinically meaningful preservation of cognitive abilities. At last follow-up, most treated patients with PSLI and PSEJ MLD (13/19 and 9/11, respectively) were alive with normal cognition (IQ scores ≥85) and with no AEs indicative of cognitive decline. For treated patients with ESEJ MLD, 2/5 maintained normal cognition, 2/5 had mild impairment (IQ scores ≥70), and 1/5 had severe impairment (IQ score ≤55). By contrast, severe cognitive impairment was seen in the NHx EJ cohort at similar ages.
At analysis, there had been no serious adverse events assessed as related to arsa-cel and no evidence of insertional oncogenesis or abnormal clonal expansion. Three patients died due to unrelated causes (two from disease progression and one from cerebral stroke). Transient, low anti-ARSA antibody titres occurred in six patients without clinical impact.

Conclusions: With up to 13 years of follow-up, arsa-cel continues to show a favourable benefit–risk profile, exhibiting a durable effect in slowing progression and preventing severe motor and cognitive impairment in most treated patients.

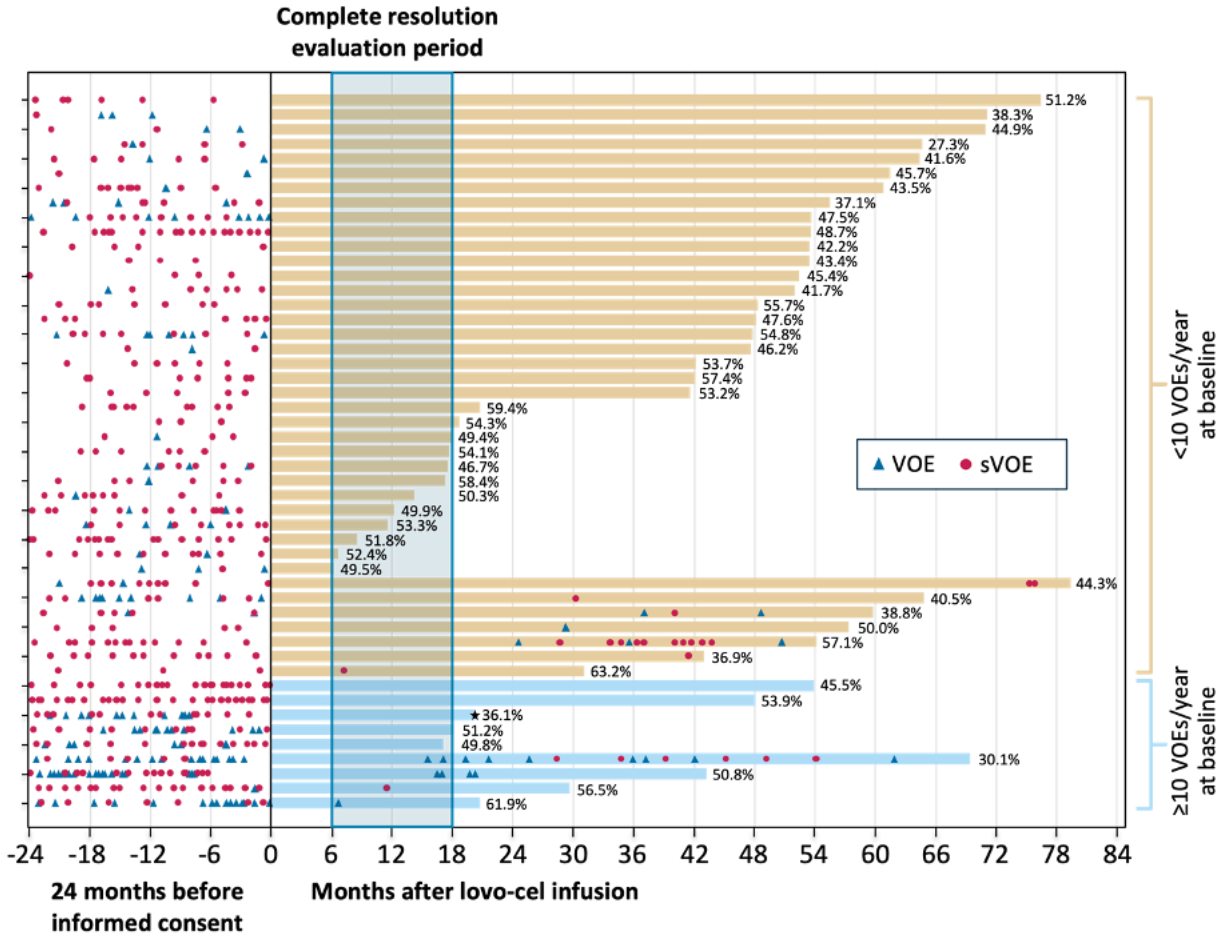
Background: Acute pain crises are the most common and often debilitating complication of sickle cell disease (SCD). Vaso-occlusion has historically been considered the primary cause, although the pathobiology of SCD pain is complex. Transformative therapies such as allogeneic hematopoietic stem cell transplant (allo-HSCT) and lovotibeglogene autotemcel (lovo-cel) gene therapy mitigate hemolysis and reduce vaso-occlusion, yet a subset of patients continue to report pain crises. We characterized pain patterns, risk factors, and outcomes after lovo-cel and compared them to allo-HSCT to better define the etiology of post-treatment pain.

Methods: Participants in HGB-206/210 (Kanter et al., 2022;2023) with ≥4 vaso-occlusive events (VOEs) at baseline and ≥18 months follow-up as of July 2024 (n = 38) were included; updated analyses will be presented. Comparable severe VOE data were obtained from lovo-cel participants (n = 32) and allo-HSCT recipients (n = 163; Leonard et al., 2023) using aligned definitions and follow up. In lovo-cel trials, VOEs were assessed by investigators using a standardized pain evaluation aid and characterized by frequency, hospitalization, and biomarkers; events also underwent independent adjudication. Treatment durability was assessed by transgene expression, hemolysis markers and red cell indices. Patient-reported outcomes (PROMIS-57) were evaluated using mixed-effects models, and predictors of post-treatment VOEs were examined with logistic regression.

Results: Severe VOEs were uncommon following both lovo-cel and allo-HSCT, occurring in 13% (4/32) of lovo-cel recipients and 27% (30/112) of engrafted allo-HSCT recipients without GVHD. Across all VOE event types, 27/38 (71%) lovo-cel participants experienced no post-treatment VOEs, contributing a total of 112 VOE-free patient-years (Figure 1). Opioid use declined from 76% (32/42) at baseline to 36% (15/42) >18 months post-infusion.
To characterize post-treatment acute pain events, a structured classification tool was developed. Forty-five events from 13 participants across 7 sites (May 2022–July 2025) were analyzed. Principal Investigators classified only 11% (5/45) as attributed solely to vaso-occlusion; 38% reflected non-VOE etiologies, and 51% had mixed attribution; however, investigators were only confident of these attributions in 36% of cases, underscoring diagnostic uncertainty. When laboratory assessments were available, biomarker patterns of inflammation and hemolysis did not align with established VOE signatures (Ballas et al., 2012), suggesting distinct causes of acute pain.
Baseline annualized VOE rate was the strongest predictor of post-treatment VOEs (odds ratio [OR], 1.21; 95% CI, 1.0-1.5; p=0.06). Age, sex, chronic pain history, and prior opioid use were not associated with risk, consistent with allo-HSCT findings. Participants with post-treatment VOEs had higher PROMIS pain scores at baseline (mean 6.2 vs 4.7; p=0.03) and after lovo-cel (3.8 vs 2.6; p=0.06). Despite this, substantial reductions in annualized VOE rates and hospitalizations were observed. HbAT87Q expression and red cell indices remained

stable.

Figure 1. VOE (blue) and severe VOE (pink) events prior to consent and after lovo-cel infusion.



Conclusions: Most individuals treated with lovo-cel or allo-HSCT became VOE-free; however, a minority continued to experience acute pain not consistent with traditional VOE. People with acute pain post-treatment need recognition, validation, and counseling; with a focus on long-term management. Improved classification frameworks are needed to optimize long-term approaches to pain management.

Department, University of Manchester, Manchester, United Kingdom of Great Britain and Northern Ireland (the)

Background: Neuronopathic mucopolysaccharidosis type II (nMPSII, Hunter Syndrome) is a lysosomal storage disorder that leads to intracellular accumulation of glycosaminoglycans, which manifests clinically as progressive multiorgan failure, neurodegeneration and death. Haematopoietic stem cell gene therapy (HSCGT) has been used in several inherited metabolic conditions to engraft gene-modified cells that can produce high quantities of previously deficient protein. However, immune responses to these proteins have been reported and early graft loss of modified cells in pre-clinical and clinical reports. We describe our first-in-world experience of HSCGT in nMPSII and including using additional immunomodulation in the peri-transplant period to reduce the risk of graft rejection in an ongoing clinical trial using a novel ex-vivo lentiviral platform (NCT05665166).

Methods: Three patients to date have undergone CD34+ cell collection via leukapheresis using G-CSF and plerixafor. CD34+ haematopoietic stem cells (HSCs) were then transduced ex-vivo using a lentiviral vector containing the human *IDS* gene tagged with ApoEII driven by a human CD11b myeloid-specific promoter. For two patients treated following protocol amendment, gene-modified HSCs were transplanted after busulfan-based conditioning with the addition of three doses of alemtuzumab at 0.1mg/kg on day -7 to -5 during conditioning and ongoing sirolimus from day -1 with a target therapeutic range of 5 – 10 micromol/L. Engraftment kinetics, biochemical parameters and adverse events were assessed at set time points.

Results: For the first patient, CD34+ leukapheresis was uneventful and the modified cell product met release criteria with a vector copy number of 3.63 copies per cell, cell viability of 73.89% and CD34+ purity of 98.87%. 10.78 $x10^6$ TNC/kg were infused following conditioning as above.
Neutrophil engraftment was achieved on day +19, reticulocyte engraftment was achieved on day +29, and platelet engraftment was achieved on day +30. Minimal supportive transfusion was required during admission. The patient did experience transient cytomegaloviraemia, detectable via PCR from day +6, following which they received foscarnet and ganciclovir and successfully cleared viraemia by day +24. Additional screening for invasive virology remained negative and no other significant adverse events were recorded.
Supraphysiological IDS activity >10x ULN was detectable post-transplant from engraftment onwards in both peripheral blood and bone marrow leucocyte samples. Additionally, plasma IDS activity was detectable at day +30, consistent with clearance of anti-IDS antibody. CNS IDS activity was also measurable from day +30 post-transplant.
A second patient has undergone successful leukapheresis and at time of writing has received the cell product following this modified conditioning protocol without concern. Engraftment kinetics and post-transplant disease monitoring assessments are awaited.

Conclusions: The first patient shows early and sustained biochemical correction of nMPSII, and the second patient has undergone the conditioning regimen without concern, confirming the tolerability of our immunomodulation protocol alongside HSCGT. Further follow-up is required to correlate biochemical correction with developmental and cognitive outcomes. Treatment of a further two patients on this trial using this methodology is planned and if

successful this approach may have wider applicability in inducing recipient immune tolerance to HSGCT products in a range of conditions.

Clinical Trial Registry: NCT05665166

GALLBLADDER ABNORMALITIES IN METACHROMATIC LEUKODYSTROPHY: PRELIMINARY ANALYSIS IN PATIENTS TREATED WITH HEMATOPOIETIC STEM CELL GENE THERAPY AND UNTREATED PATIENTS

Salvatore Recupero[1,2], *Vera Gallo*[1], *Paola Maria Vittoria Rancoita*[3], *Laura Luongo*[3], *Greta Spelta*[3], *Francesca Di Matteo*[3], *Michele Colombo*[1], *Mery Cardarelli*[4], *Alessandro Aiuti*[3], *Valeria Calbi*[1], *Francesca Fumagalli*[1]
[1]*IRCCS San Raffaele Scientific Institute, Milan, Italy,* [2]*University of Rome Tor Vergata, Rome, Italy,* [3]*Vita-Salute San Raffaele University, Milan, Italy,* [4]*Ospedale Maggiore Policlinico, Milan, Italy*

Background: Metachromatic leukodystrophy (MLD) is a fatal lysosomal neurodegenerative disorder caused by arylsulfatase-A deficiency. Atidarsagene autotemcel (arsa-cel), an autologous transplantation of $CD34^+$ cells transduced ex vivo with a lentiviral vector encoding the ARSA gene, represents the only approved treatment for pre-symptomatic late-infantile and early-juvenile MLD, or early-symptomatic early-juvenile MLD forms. MLD is also characterized by extra-neurological features, with gallbladder involvement being the most prominent. Despite the rarity of gallbladder abnormalities in pediatric populations, sulfatide accumulation in the gallbladder wall in MLD is associated with an increased risk of malignant transformation. This study analyzes gallbladder involvement in MLD, both in the natural history of the disease and in patients treated with arsa-cel, evaluating its role as an early diagnostic tool and the potential therapeutic effects on gallbladder abnormalities.

Methods: We retrospectively evaluated 104 patients with MLD (44 late-infantile, 40 early-juvenile, 16 late-juvenile, 4 adult), including 48 untreated and 56 treated with arsa-cel. The gene therapy cohort included 26 pre-symptomatic late-infantile, 24 early-juvenile (15 pre-symptomatic and 9 early-symptomatic), and 6 late-juvenile patients (4 pre-symptomatic and 2 early-symptomatic). Clinical data on the age of onset of neurological symptoms and history of cholecystectomy were collected for all patients, as well as ultrasound findings at baseline and throughout follow-up, specifically assessing wall thickening, gallbladder contraction, biliary sludge, and polyp characterization. In patients who underwent cholecystectomy, histopathological reports were analysed when available.

Results: Gallbladder abnormalities were observed at first available ultrasound in 88.6% (39/44) of late-infantile, 75.0% (30/40) of early-juvenile, 68.8% (11/16) of late-juvenile, and 75.0% (3/4) of adult patients. The earliest and most common alteration was wall

thickening: 68.2% (30/44) of late-infantile with Median Age at First Evaluation (MAFE) 13 months, 55.0% (22/40) of early-juvenile, MAFE 61 months, 50.0% (8/16) of late-juvenile, MAFE 189 months. Wall thickening was detected in the pre-symptomatic phase in 84.6% (22/26) of late-infantile, 73.3% (11/15) of early-juvenile, and 25.0% (1/4) of late-juvenile patients.
Longitudinal analysis showed progression of abnormalities over time in untreated patients, particularly in late-infantile and early-juvenile forms. Among arsa-cel recipients, longitudinal analysis of patients with at least one gallballder ultrasounds after treatment (n=50, median follow-up post arsa-cel 5 years) revealed resolution of baseline wall thickening in 61.5% (24/39) and polyposis in 50% (3/6) of patients. Histopathological analysis of removed gallbladders revealed cases of metaplasia, dysplasia, and even carcinoma in situ. These findings were sometimes undetectable by ultrasound, confirming the risk of malignant progression and supporting early cholecystectomy in the presence of suspicious features.

Conclusions: Our analysis confirms early and frequent gallbladder involvement across all MLD forms. Gallbladder wall thickening emerged as the earliest alteration and may represent the first precursor to more complex abnormalities such as polyps. The detection of ultrasound abnormalities as well as cases of cholecystectomy in patients before neurological symptom onset—including those with late-onset forms— suggests that visceral involvement may serve as an early diagnostic disease indicator. The possibility that treatment with arsa-cel prevents the occurrence of new lesions and partially regresses pre-exiting alterations will need to be assessed as long-term follow-up and real world data accumulate.

BRIDGING READINESS AND REALITY: U.S. PEDIATRIC HEMATOLOGISTS' PERSPECTIVES ON GENE THERAPY FOR SICKLE CELL DISEASE IN THE POST-APPROVAL ERA

*Cecile Karsenty[1], Titilope Fasipe[1], Venee Tubman[1], Anil George[1], Khaled Yassine[1], Allistair Abraham[2], John Horan[3], Helen Heslop[1], **Alexander Ngwube**[1]*
[1]Baylor College of Medicine, Houston, United States of America (the), [2]Children's National Hospital, DC, United States of America (the), [3]University of Rochester, Rochester, United States of America (the)

Background: United States Food and Drug Administration approval of two autologous gene therapy (GT) products exagamglogene autotemcel (Casgevy, CRISPR-based) and lovotibeglogene autotemcel (Lyfgenia, lentiviral-based) marks a watershed moment in curative options for sickle cell disease (SCD). However, the successful and equitable implementation of GT in pediatric care requires more than regulatory approval; it demands provider readiness, clear referral frameworks, and systemic alignment. We conducted a national survey to assess how pediatric hematologists are preparing to integrate GT into clinical practice.

Methods: A 35-item REDCap survey was disseminated to approximately 500 board-certified/eligible pediatric hematology/oncology providers across the US (July–September 2025) via the ASPHO and STAR networks. Eligible respondents provided care to pediatric patients with SCD. Survey assessed (1) referral intent across clinical scenarios, (2) structural and clinical factors influencing decisions, and (3) self-reported counseling confidence. Respondents were classified by practice focus (SCD-focused, general hematology/oncology, HSCT-focused). Comparative statistics used chi-square or Fisher's exact tests with a two-sided $p<0.05$ considered significant.

Results:

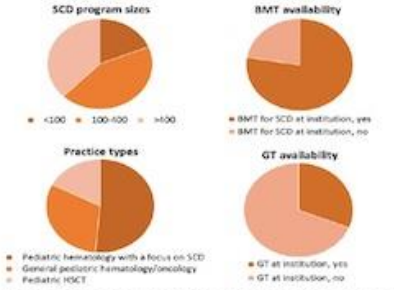

Figure 1a. Broad representation of program sizes, practice types, and institutional Allo-BMT and GT availability based on survey responses

Figure 1b. Most pediatric hematologists/oncologists do not offer product guidance when referring patients with SCD for GT

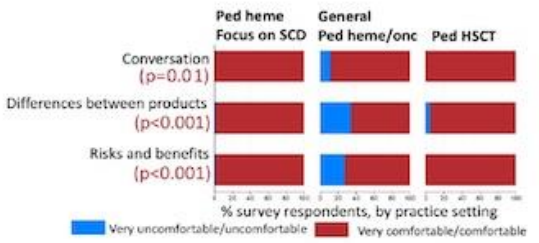

Figure 1c. General pediatric hematologists/oncologist are least comfortable discussing GT options with their patients

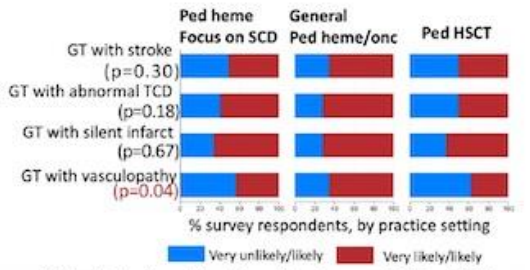

Figure 1d. Pediatric hematologists with a focus on SCD or HSCT are less likely to consider GT in individuals with pre-existing CNS complications

A total of 138 providers responded (27.6% response rate), with broad representation across program sizes, geographic regions, and clinical roles. Most respondents (86%) indicated they were likely or very likely to refer appropriate patients for GT. However, intent to refer varied by clinical scenario and specialty. General hematologists were significantly more likely than SCD-focused or HSCT providers to consider GT for patients with silent cerebral infarcts (63% vs 39%, p=0.01) or cerebral vasculopathy (59% vs 37%, p=0.04), despite reporting lower overall familiarity with GT products and protocols.

Institutional readiness was variable: 77.5% reported access to allogeneic BMT services, while 68.8% indicated GT onboarding capacity. Still, only 18% of providers routinely discussed specific GT products during referral. Among those who did, Casgevy was overwhelmingly favored (94%), though many acknowledged insufficient comparative data to justify a preference. Counseling confidence was uneven: 70% of SCD-focused hematologists felt comfortable discussing GT, compared to just 32% of general hematologists (p<0.001). Confidence was lowest regarding long-term risks (busulfan toxicity, clonal hematopoiesis, secondary malignancies) and mechanistic differences between Casgevy and Lyfgenia.

Insurance approval emerged as the most cited determinant of whether a patient would be referred (72%), ahead of disease severity, caregiver readiness, or institutional infrastructure. Open-text responses highlighted a lack of clear eligibility criteria, uneven payer policies, and limited availability of patient-friendly educational tools as key barriers.

Conclusions: U.S. pediatric hematologists are enthusiastic about GT for SCD, but implementation is constrained by inconsistent referral practices, limited product-specific

knowledge, and payer-driven access barriers. As GT expands globally, these findings offer both contrast and guidance for European systems. While Europe's nationalized health models may mitigate some structural hurdles, the variability in provider knowledge, absence of unified SDM protocols, and need for long-term safety data are universal concerns. Proactive investment in pan-European clinical education, registries, and harmonized counseling tools will be essential to translate gene therapy's promise into equitable, patient-centered care. The U.S. experience underscores that regulatory approval is only the beginning, implementation requires coordinated clinical, educational, and policy efforts to deliver on gene therapy's curative potential for all.

A CASE OF LACK OF ENGRAFTMENT OF GENE-CORRECTED CELLS AFTER LENTIVIRAL HEMATOPOIETIC STEM CELL GENE THERAPY FOR METACHROMATIC LEUKODYSTROPHY: AN INTEGRATED CLINICAL AND IMMUNOLOGICAL INVESTIGATION

Valeria Calbi[1,2], *Laura Passerini*[1], *Salvatore Recupero*[1,2,3], *Vera Gallo*[1,2], *Sara Mazza*[1], *Raisa Jofra Hernandez*[2], *Beatrice Volpe*[2,4], *Francesco Morena*[5], *Sabata Martino*[5], *Ana Lg Rodriguez*[6], *Francesca Fumagalli*[1,2], *Silvia Gregori*[1], *Alessandro Aiuti*[1,2,4]
[1]*San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), Milano, Italy,* [2]*IRCCS Ospedale San Raffaele, Pediatric Immunohematology Unit, Milano, Italy,* [3]*University of Rome Tor Vergata, PhD Program in Immunology, Molecular Medicine and Applied Biotechnologies, Department of Biomedicine and Prevention, Rome, Italy,* [4]*"Vita-Salute" San Raffaele University, Milan, Italy,* [5]*Department of Chemistry, Biology and Biotechnologies, University of Perugia, Perugia, Italy,* [6]*Hospital do Divino Espírito Santo, Ponta Delgada, Portugal*

Background: Atidarsagene autotemcel (arsa-cel) is an autologous lentiviral haematopoietic stem cell (HSC) gene therapy indicated for the treatment of early-onset metachromatic leukodystrophy (MLD). We report the first case of complete lack of engraftment of gene-corrected cells after arsa-cel administration and describe a preliminary integrated clinical and immunological investigation into causality of the event.

Methods: A male infant with presymptomatic late-infantile MLD (homozygous *ARSA*c.465+1G>A, null mutation) received arsa-cel at 15 months of age. Mobilization, $CD34^+$ cell yield, drug-product characteristics and busulfan exposure were comparable to that in other patients successfully treated with arsa-cel. Longitudinal laboratory assessments included vector copy number (VCN) and ARSA activity in peripheral blood (PB), bone marrow (BM) and cerebrospinal fluid (CSF), and anti-ARSA antibodies (AAA) determination complete HIV serology. Immune assessments comprised ARSA-specific T-cell assays,

immunophenotyping, immune activation markers, autoantibodies/autoimmunity investigations.

Results: Haematologic recovery was within the anticipated range of arsa-cel successfully treated patients. However, VCN remained below the limit of quantification in all PB and BM samples up to day +180, and ARSA activity was undetectable in PB/BM with minimal CSF activity, indicating lack of engraftment of gene-corrected cells with haematological recovery driven by untransduced autologous HSCs. No deviations in manufacturing, cell dose or conditioning were identified. No anti-HIV antibodies were detected. AAA were negative at baseline, became detectable at day ~30, peaked at day ~60 and declined by day ~180. The patient showed a strong recombinant ARSA-specific $CD4^+$ T cell response from day +30, persisting at day +60 and at 6 months; $CD8^+$ T cell analysis showed no ARSA-specific activation and IFNg release. Other patients with AAA positivity in the clinical development program and post marketing experience, including two with the same *ARSA* genotype, did not show decreases in ARSA activity or VCN. The immune milieu in this highlighted patient displayed a pro-inflammatory profile with eosinophilia, elevated IgE and broad anti-HLA class alloantibodies, in the context of prolonged *Candida parapsilosis* candidemia during aplasia. By the time the lack of engraftment became evident, the patient started to develop typical overt signs of MLD neurological disease and could not undergo further treatment.

Conclusions: This case represents the first failure of engraftment of gene-corrected cells after arsa-cel administration secondary to immune response. A null ARSA genotype (absence of baseline tolerance), in the presence of active infection along with a pro-inflammatory context, sustained ARSA-specific $CD4^+$ T cell responses and humoral activation support a potential multifactorial, T-cell-driven rejection of transduced cells. Individual genetic predisposition, potentially including specific HLA backgrounds, may modulate the risk of immune rejection and warrants comparative analyses with other treated patients. Early monitoring of engraftment of gene-corrected cells may help identify patients in whom immunomodulatory strategies could be considered

STEM CELL MOBILISATION FOR GENE THERAPY IN ADOLESCENT PATIENTS WITH SICKLE CELL DISEASE: EXPERIENCE FROM THE FIRST THREE PATIENTS IN THE UK

Olya Oconnor[1], Hannah Ezard[1], Melanie Rooney[1], Angela Burns[1], Kelly Watts[2], Kiera Whitworth[2], Sandra Jones[2], Ramya Hanasoge-Nataraj[2], ***Sarah Lawson***[1]
[1]*Birmingham Children's Hospital, Birmingham, United Kingdom of Great Britain and Northern Ireland (the),* [2]*The Royal Manchester Children's Hospital, Manchester, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Gene therapy for sickle cell disease (SCD) offers curative potential without the risks of allogeneic transplantation. However, autologous stem-cell mobilisation in SCD is difficult due to endothelial activation, hyperviscosity, vaso-occlusive risk and a pro-thrombotic state. Plerixafor-only mobilisation often yields suboptimal CD34^+ cell numbers and may increase viscosity leading to circuit clotting. Some centres have reported improved yields when combining granulocyte colony-stimulating factor (G-CSF) with plerixafor, but published data remain limited. We describe the first UK experience using this combined approach in three adolescents undergoing mobilisation for autologous gene therapy.

Methods: Three teenagers (ages 14, 15 and 16) with severe SCD were referred for exagamglogene autotemcel (Casgevy®). Each underwent two initial mobilisation cycles: **Cycle 1** with plerixafor alone, and **Cycle 2** with plerixafor + G-CSF (dosed for 3–4 days until WBC >50 × 10^9/L). Both cycles produced insufficient CD34^+ yields for manufacture.
A modified **Cycle 3** protocol was therefore implemented, consisting of:
• G-CSF 5 mcg/kg twice daily for four days prior to apheresis
• Plerixafor 0.24 mg/kg pre-collection
• Increased G-CSF threshold to WBC 75 × 10^9/L
Supportive measures included red cell exchange (RCE) 1–3 days before apheresis, targeting HbS <15%, addition of Aspirin 75 mg to routine LMWH thromboprophylaxis and IV hydration.

Results: Across all patients, CD34^+ yields improved substantially with the modified protocol.

CD34^+ cell yield (×10^6/kg) following three collection cycles

Patient	Cycle 1	Cycle 2	Cycle 3
1	9.0	13.5	26.66
2	9.84	6.79	20.50
3	3.3	7.0	20.0

Mobilisation was well tolerated in all three patients. Patient 1 and Patient 2 experienced circuit clotting during Cycle 1, and Patient 3 had two G-CSF doses omitted in Cycle 2 because of the mild pain, successfully managed with oral morphine.
Peak WBC counts during Cycle 3 were 89.9 × 10^9/L, 103.2 × 10^9/L and 70.9 × 10^9/L for Patients 1, 2 and 3 respectively. Despite recognised concerns that G-CSF may precipitate VOC in SCD, no VOC episodes occurred, and all patients tolerated mobilisation exceptionally well. Other than transient leukocytosis (all patients) and manageable pain (one patient), no significant adverse events were observed. All adolescents returned promptly to school and normal activities, supporting both feasibility and acceptability of this regimen.

Conclusions: The combination of G-CSF and plerixafor with an elevated WBC threshold, preceded by RCE and supported by targeted thromboprophylaxis with LMWH and Aspirin, proved safe, well tolerated, and markedly more effective than plerixafor alone in adolescents

undergoing mobilisation for SCD gene therapy. This modified protocol achieved consistently adequate CD34^+ yields after prior mobilisation failures.
We propose this approach as a potential first-line mobilisation strategy for SCD patients preparing for autologous gene therapy, with the aim of minimising repeated collections, central line procedures and associated anaesthetic exposure. Further multicentre evaluation is warranted to confirm safety and generalisability across broader patient cohorts.

Disclosure: Nothing to declare

THE USE OF GCSF FOR STEM CELLS MOBILIZATION IN PATIENTS WITH SICKLE CELL DISEASE TREATED WITH GENE THERAPY

*Mohsen Alzahrani[1], Bader Alahmari[1], Shahbaz Memon[1], Nada Alshaikh[1], Husam Alsadi[1], Ayman Almozaini[1], Mohammed Bakkar[1], Tahani Elfadul[1], Rahaf Salem[1], Ahmed Youssef[1], Mazin Abdulsalam[1], Khalid Mohamed[1], Mohamad Mohamed[1], Rasha Taher[1], Rodaina Abujoub[1], Tahani Alanazi[1], Suha Alkhraisat[1], Isam Mahasneh[1], Amani Alharbi[1], Elham Alanazi[1], Afnan Alzaidi[1], Hamzah Alquraan[1], Wadha Al Salh[1], Noha Needy[1], Ohoud Albaqmi[1], Hoda Alshammari[1], Eman Anizi[1], Ghada Alyousif[1], Norah Al Shuraym[1], Mashael Almutairi[1], Maybelle Belili[1], Zoha Zakir[1], Walid Mashaqbeh[1], Saad Almalki[1], Sami Gammah[1], Dunia Jawdat[1], Khalid Batarfi[1], Ahmed AlSuhaibani[1], **Mohammed Essa**[1]*
[1]King Abdulaziz Medical City, Riyadh, Saudi Arabia

Background: Hematopoietic stem cell transplantation (HSCT) remains the only curative option for sickle cell disease (SCD), yet it's constrained by donor scarcity and transplant-related complications. Gene-editing technologies like CRISPR/Cas9—targeting the BCL11A erythroid enhancer—have shown potential in increasing fetal hemoglobin (HbF) expression. This approach demands robust mobilization of autologous $CD34^+$ hematopoietic stem and progenitor cells (HSPCs), ideally $\geq 20\times10^6$/kg, a threshold challenging to achieve in SCD patients.
Standard granulocyte-colony stimulating factor (G-CSF)-based mobilization is generally avoided due to the associated risk of inducing VOCs and acute chest syndrome (ACS), particularly in the presence of high HbS levels. In this study we report the use of GCSF + plerixafor for mobilization of stem cells from patients with SCD.

Methods: The objective is to assess the safety, feasibility, and effectiveness of combining GCSF with plerixafor in stem cell mobilization for Exa-cel gene therapy in SCD patients.
Retrospective analysis of 13 SCD patients undergoing autologous $CD34^+$ cell collection.
Mobilization Protocols:
Group A (n=2): Plerixafor alone.
Group B (n=4): Initial plerixafor, then added G-CSF.
Group C (n=7): G-CSF + plerixafor from outset.
Hydroxyurea held for 8 weeks; exchange transfusions targeting HbS <30% (Group A/B) or <20% (Group C).
Inpatient management included hydration and aspirin prophylaxis.

Results: A total of 13 patients with sickle cell disease (SCD) were enrolled for gene therapy and underwent stem cell mobilization. The median age was 16 years (range: 12–32), with 6 males and 7 females.
The median number of mobilization cycles was 1 (range: 1–6). Seven patients collected with one cycle, one with 2 cycles, 2 with 4 cycles, 1 with 5 cycles and 2 with 6 cycles. In Group A, both patients failed to collect an adequate number of cells after 2 cycles for the first patient and 6 cycles for the second patient. In Group B, the median number of mobilization cycles was 4 (range: 2–6), while in Group C, all 7 patients successfully collected sufficient cells after only one cycle.
The overall median total CD34+ cell count collected was 71 × 10^6/kg, with 27 × 10^6/kg in Group A, 80 × 10^6/kg in Group B, and 74.6× 10^6/kg in Group C. The median manufactured dose was 6.75 × 10^6/kg overall, with 1.5 × 10^6/kg in Group A, 6.35 × 10^6/kg in Group B, and 14.4 × 10^6/kg in Group C.
There was no VOCs, prolonged pain symptoms, or ACS secondary to G-CSF administration. There were no ICU admissions and no reported mortality. Median duration of hospitalization was 6 days for all admissions and 6 days in patients mobilized with G+plerixafor.

Outcome	Group A	Group B	Group C	Overall
Median $CD34^+$ collected ($\times 10^6$/kg)	27	80	74.6	71
Median manufactured dose ($\times 10^6$/kg)	1.5	6.35	14.4	6.75
Median mobilization cycles	2.5	4	1	1
VOC / ACS / ICU admissions	0	0	0	0
Median hospital stay (days)	6	6	6	6

Conclusions: The combination of G-CSF with plerixafor resulted in improved collection of the target cell dose for gene therapy compared to plerixafor alone. No safety concerns were observed with G-CSF use in SCD patients managed under a specific protocol. Further evaluation in a larger cohort, including detailed analysis of the cellular characteristics of collected cells, is planned.

Disclosure: Non to disclose.

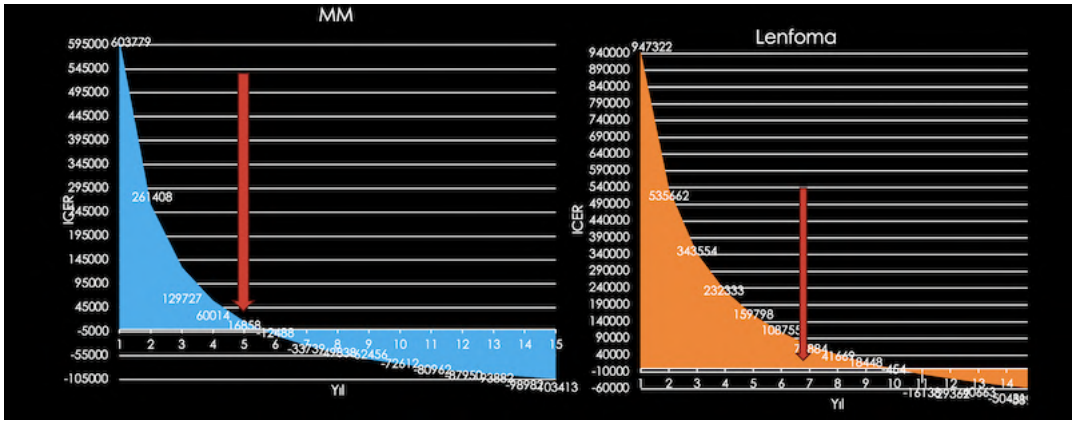
EXPLORING THE REIMBURSEMENT OF CAR-T CELL THERAPY FOR MULTIPLE MYELOMA AND B-CELL LYMPHOMA PATIENTS UNDER TURKIYE'S SOCIAL SECURITY SYSTEM (SGK)

Meltem Kurt Yuksel[1], *Serhat Çelik*[1], *Cemal Kocak*[1]
[1]*Ankara University, Ankara, Turkey*

Background: CART therapies are indicated in MM and BCLs. Some countries reimburse CART therapies; most, especially low- and middle-income countries (LMICs), lack access due to high manufacturing costs. Cost-effectiveness analysis guides resource allocation by governments and insurers. Quality-Adjusted Life Year (QALY) measures health quality from 0 to 1, with 1 indicating perfect health; World Health Organization (WHO) considers it very cost-effective if it equals per capita gross domestic product (GDP). Incremental Cost-Effectiveness Ratio (ICER) compares costs and benefits of new technologies; if the ICER is less than three times GDP, it's cost-effective and reimbursable. This study assesses the likelihood of reimbursement by the Social Güvenlik Kurumu (SGK) for CAR-T in Turkiye. It compares the cost-effectiveness of autologous stem cell transplantation (ASCT), CAR-T, and Bi-specific T-cell Engagers (BITEs) over 15 years.

Methods: Fifteen patients, including those with Multiple Myeloma (n=10) and B-cell lymphoma (n=5), were evaluated retrospectively. All had undergone autologous stem cell transplantation (ASCT). The costs of mobilization, stem cell apheresis, and autologous stem cell transplantation at the unit were calculated in TL and converted to USD based on the exchange rates at the time. Costs of CART cell therapy and bispecific antibody treatments (BITEs) were estimated from the literature. In line with World Health Organization (WHO) recommendations, the cost-effectiveness threshold was set at three times the nominal GDP per capita in Turkey (15,147.84 USD). QALYs: The responsible physician determined separate QALYs for MM and BHL for the first three months and the following period, based on the Karnofsky performance scale. QALY values from the literature were used for CART and BITE treatment costs. Monthly costs for followed-up patients were calculated by dividing median treatment costs by the median follow-up periods (83 months or 22 months). Cost and QALY calculations and graphing were performed using Microsoft 365 Excel.

Results: The figure shows the ICER per year for Multiple Myeloma (MM) and B-cell Lymphoma (BCL). The red arrows show the time point of the cost-effective cut-off in 15 years.



The median costs and QALYs of each ASCT, CART, and BITE for MM and BCL are given in Table 1. Considering the median cost, CART therapy is not cost-effective for MM patients in the first years after transplantation (>$45,442), but it becomes cost-effective after the 4th year (including the 5th year), and this effectiveness continues for the next 10 years. In B-cell lymphomas, CART becomes cost-effective after the 7th year post-transplant (including the 8th year), and this effectiveness persists for up to 15 years. BITE treatments were not found to be cost-effective during the 15-year follow-up period. Therapies such as CAR-T become cost-effective compared to BITE after the 2nd month in multiple myeloma and after the 10th month in lymphoma.

		MM (n=10)	Lymphoma (n=5)
		n (%)	n (%)
Female sex		2 (20,0)	5 (100,0)
Age median (min–max)		63 (48-75)	54 (29-73)
Follow-up duration, median (min–max)		83 months (11-110)	22 months (10-72)
QALY coefficient (1)	post-transplant, first 3 months	0,5	0,5
	after 3 months post-transplant	0,7	0,8
QALY CAR-T (2)	post-transplant, first 3 months	0,9	0,9
	after 3 months post-transplant	0,9	0,9
QALY BITE (3)	post-transplant, first 3 months	0,9	0,9
	after 3 months post-transplant	0,9	0,9

Treatment cost (4)	median (USD)	230.401,13	33.869,69
CAR-T cost (USD) (5)	mean (USD)	184.255,75	184.255,75
BiTE cost (6-8)	mean (USD, monthly	64.500 USD	12.721 USD

J Med Econ. 2025 Dec;28(1):910-920. doi: 10.1080/13696998.2025.2514909. Epub 2025 Jun 14. PMID: 4049570.

Conclusions: The limited number of patients and the retrospective design of our study are our main limitations. Uncertainties in the QALY and ICER calculations for CART and BITE treatments in the literature, along with the fact that these studies cover only a two-year time frame, make it challenging to interpret their long-term effects and treatment costs.

UM171-EXPANDED CORD BLOOD AS A SAFE AND POTENT GRAFT SOURCE FOR HIGH-RISK LEUKEMIAS AND MYELODYSPLASTIC SYNDROMES WITH DURABLE LONG-TERM SURVIVAL

Sandra Cohen[1,2], *Imran Ahmad*[1,2], *Elisa Tomellini*[3], *Nadia Bambace*[4], *Lea Bernard*[2,1], *Jean Roy*[1,2], *Jonathan Gutman*[5], *Jurjen Versluis*[6], *Pierre Caudrelier*[3], *Gabrielle Thauvette*[3], *Guy Sauvageau*[1,2], *Filippo Milano*[7,8]
[1]*Université de Montréal, Montréal, Canada,* [2]*Hopital Maisonneuve Rosemont, Montréal, Canada,* [3]*ExCellThera, Montreal, Canada,* [4]*Miami Cancer Institute, Miami, United States of America (the),* [5]*University of Colorado School of Medicine, Aurora, United States of America (the),* [6]*Erasmus Medical Center, Rotterdam, Netherlands (the),* [7]*Fred Hutchinson Cancer Research Center, Seattle, United States of America (the),* [8]*University of Washington School of Medicine, Seattleun, United States of America (the)*

Background: Patients with high (H) and very high (VH)–risk acute leukemia (AL) or myelodysplastic syndrome (MDS) have high relapse rates and poor overall survival (OS) after conventional allogeneic transplantation (alloT). Cord blood (CB) transplantation (T) offers a lower relapse risk in high risk diseases but is limited by low cell dose, delayed engraftment, and high non-relapse mortality (NRM). UM171 is a small molecule that expands hematopoietic stem cells ex vivo and may overcome these limitations.

Methods: We analyzed outcomes of 60 adults with high (H) or very high (VH)–risk AL or MDS who received a single UM171-expanded CB graft in two prospective phase II trials: ECT-002 (Canada) and ECT-004 (United States and the Netherlands). H-risk AL/MDS was defined as disease with an expected 2-year progression-free survival (PFS) <40% after conventional alloT. VH-risk disease was defined as a second allo transplant, AL with active disease, acute myeloid leukemia (AML) with TP53 mutation and complex karyotype, AML with EVI1 mutation, or MDS with multi-hit TP53 mutation. To maximize graft-versus-leukemia activity, we purposely aimed for 5/8 HLA-matched CB units, accepting lower allele-level matching even when better-matched units were available. The primary endpoints were safety and non-relapse mortality (NRM); secondary endpoints included PFS, OS, relapse incidence, engraftment, and graft-versus-host disease (GVHD).

Results: Sixty patients (median age 43 years; range 19–66) were transplanted; 87% had AL (63% myeloid, 37% lymphoid) and 13% had MDS. Thirty percent had failed a prior allogeneic transplant and 57% met VH-risk criteria. As designed, 75% received a 5/8 HLA-

matched graft, and 43% received a CB unit with a pre-expansion cell dose below the minimal threshold required for unmanipulated CBT. Neutrophil engraftment occurred in 92% of patients at a median of 17 days. One primary graft failure occurred in the presence of high-titer donor-specific anti-HLA antibodies. All patients completed planned follow-up (3 years in the Canadian study and 2 years in the U.S. study).
At 24 months, OS was 63.7% and PFS was 57.0%. The cumulative incidences of relapse and NRM were 22.5% and 20.5%, respectively. Age was the strongest predictor of NRM: patients <43 years experienced 0% NRM, with 24-month OS and PFS of 82.8% and 79.3%,respectively. Older patients (≥43 years) had comparable relapse rates but significantly higher NRM. Grade III-IV acute GVHD occurred in 20%, while moderate to severe chronic GVHD was infrequent at 7% at 2 years.

Conclusions: UM171-expanded CBT provides rapid and durable engraftment and achieves promising long-term survival in adults with high and very high–risk AL/MDS, even when using intentionally selected 5/8 HLA-matched and low–cell-dose grafts. Particularly notable were the outcomes observed in patients with VH–risk features such as AL not in remission, TP53-mutated AML/MDS, or 2nd allo transplant. These VH-risk groups are historically associated with extremely poor post-transplant survival. These findings highlight UM171-expanded CB as a safe and potent graft source in H and VH-risk AL/MDS. However, a prospective randomized trial is needed to confirm these results and define the role of UM171-expanded CB relative to other graft sources.

Background: Plerixafor (Plex), a reversible CXCR4 antagonist, has currently no formal indication in healthy allogeneic donors (HD), although its efficacy and safety profile have been proved in autologous donors. An off-label use of Plex is widely increasing as pre-emptive or therapy, according with peripheral CD34+ after at least 4 days of GCSF or CD34+ level in apheresis, respectively. Failure mobilization can lead to subsequent apheresis procedures or urgent bone marrow harvest. As there is a need for clarifying its potential indication in HD with problems in mobilization, we addressed a nationwide retrospective study from Spanish Bone Marrow Donor Registry (REDMO) within Spanish Group for Haematopoietic Transplantation and Cellular Therapy.

Methods: We included healthy related (RD) and unrelated donors (UD) classified as poor (peripheral $CD34^+$ 11–20/μL on day +4/+5 of G-CSF and/or $CD34^+$/kg $<4\times10^6$ in 1st apheresis) or very poor (peripheral $CD34^+$ ≤10/μL on day +4 or +5 and/or those yielding $<2\times10^6$ $CD34^+$/kg in 1st apheresis) mobilizers between January 2013 and June 2025, regardless the use of Plex. We compared general and mobilization characteristics between Plex and non-Plex group. Plex was used as "off label" pre-emptive or therapy strategy according with each center policy. We used SPSS for statistical descriptive analysis. The study was approved by local Ethical Committee (HCB/2024/0690).

Results: Seventeen Spanish centers reported a total of 343 adult and pediatric (n:19) healthy donors classified as poor (69.4%) or very poor mobilizers (30.6%) according with definitions reported above. Mean follow up was 2.8 years (0.1-12.5). General and mobilization characteristics are reported in table 1. All donors received a median G-CSF dose of 10 μg/kg/day administered twice daily for at least 4 days, with no statistically differences in the use of original or biosimilar formulation of GCSF between groups. The most frequent donor comorbidities were HTA and smoking. Overall, 92 donors (27%) received Plex (89 RD, 3 UD), and 14 out of them were pediatric. The use of pre-emptive Plex (n:40) was successful in all but one that required a second dose, whereas 52 donors received it as therapy after 1st apheresis (one donor needed 2 Plex doses). Non- Plex group (202 RD, 49 UD) required mostly two apheresis (95.6%). Remarkably Donors receiving Plex achieved a significantly higher median total $CD34^+$ collected (6.6 vs 4.9×10^6/kg $p<0.001$) with respect no Plex group. If a second apheresis was needed, collected CD34+ was significantly higher in Plex group. Consequently, fewer apheresis and lower total volume was processed in Plex group. No final failure mobilization was reported in the whole group. Adverse events were uncommon, and particularly in Plex Group (8%) described as mild (gastrointestinal,

headache and asthenia), with no adverse events reported in pediatrics.

Table 1 general Characteristics

Variables n(%)	**Total n:343**	**Plex (92)**	**No plex (251)**	**p**
Donor Sex Male/Female	117(34)/216 (63)	36 (39)/56(61)	81 (32)/170(68)	0.2

Donor comorbidities	132 (38.4)	41(44.5)	91(36.2)	0.05
Median GCSF dose (µg/kg/day)	11.45 (6.7–26)	10.6(8-26)	11(6-22)	0.5
GCSF type Original Biosimilar	 232(68) 41(32)	 78 (85) 14 (15)	 156 (85) 27(15)	 0.9
Apheresis number 1 2 3	 38 (11) 290 (84) 16 (5)	 38 (40) 49 (54.4) 5 (5.6)	 - 240(95.6) 11(4.4)	0.02
Total Median CD34+ ×10^6/ kg collected First Apheresis Second Apheresis	5 (1.2–54) 2.6 (0.3-20) 1.9(0.5-9.4)	6.6 (2.2-54) 2.4 (0.3-20) 4.2 (0.5-9.4)	4.9 (1.2-13) 2.8 (0.6-7.5) 1.8 (0.4-9.4)	0.001 0.7 0.001
Median Total volume (ls) processed (range)	25(2.7-58)	23(2.7-42)	25 (6-58)	0.02

Mobilizer type				
Poor	237 (69)	40(44.3)	197 (78.4)	0.02
Very poor	106 (31)	52(55.7)	54 (21.6)	

Conclusions: Plex can be used safely in both adult and pediatric healthy donors with a significant better efficacy in mobilization. A pre-emptive strategy with Plex can avoid extra apheresis procedures in poor mobilisers, of special interest for unrelated voluntary donors. Next step will be to design a homogenous protocol including Plex in allogeneic donors.

Background: TCRαβ/CD19 depletion is an *ex vivo* graft-engineering strategy for haploidentical hematopoietic stem cell transplantation (haplo-HSCT) that removes TCRαβ$^+$ T cells and CD19$^+$ B cells while preserving key innate/adaptive effectors (NK cells and γδ-T cells) supporting engraftment, infection control and graft-versus-leukemia activity. Although extended from pediatric non-malignant to malignant indications, its technical complexity, cost and regulatory burden limit implementation to a few specialized centers. We established a national single-center model for real-time distribution of fresh TCRαβ/CD19-depleted grafts, bringing cells to patients rather than patients to cells. In this abstract, we aimed to evaluate this innovative national centralized fresh-manufacturing strategy, achieving a vein-to-vein time <36 hours.

Methods: We developed an end-to-end logistics and quality framework covering on-site and off-site apheresis, graft collection, fresh-product transport to Necker or external centers (n=10), in-process and final quality controls, graft transformation (TCRαβ/CD19 depletion), and shipment (car, train, plane) to the transplant center. We retrospectively assessed the feasibility of this pathway in patients receiving a TCRαβ/CD19-depleted haplo-HSCT manufactured at Necker since 2014 (n=55). Diagnoses were grouped into major categories: bone marrow failure/DNA-repair syndromes (33%), inborn errors of immunity (62%), hematological malignancies (5%).

Results: The national single-center model was logistically feasible and delivered standardized products. Twenty productions (36%) were performed for external centers, and all grafts met the targeted logistics constraints, achieving a vein-to-vein time <36 h and being infused within the within the product shelf-life (<6 h post-release). Final cellular composition was comparable whether apheresis was performed on-site at Necker or off-site in referring centers. Despite variability in apheresis product composition, 53 (96%) of the products met predefined quality specifications. Two transplants required a second apheresis and CD34+ selection due to low CD34+ mobilization. The median CD34+ cell recovery was >88%, with a median TCRα/β depletion of −3.9 log. Importantly, clinical outcomes were not impacted by the logistics pathway, as time to neutrophil recovery and platelet reconstitution were similar whether grafts were infused at Necker or shipped and infused at the referring transplant center.

Conclusions: This national fresh-product strategy bridges point-of-care and centralized cryopreserved manufacturing. It demonstrates that a centralized academic platform for TCRαβ/CD19 depletion can reliably support nationwide activity, delivering comparable graft quality and post-transplant hematologic recovery regardless of collection or infusion site, enabled by robust logistics (rail/air) and short turnaround times. Activity increased approximately ten-fold between 2014 and 2024, underscoring the growing demand for this platform. Establishing a second authorized center is therefore a logical next step: a structured tech-transfer program with Institut Paoli-Calmettes (IPC, Marseille) was initiated, transferring Necker's experience in manufacturing, stability, transport and regulatory interactions through joint meetings and document reviews.

CILTACABTAGENE AUTOLEUCEL OUT-OF-SPECIFICATION MANUFACTURING OUTCOMES IMPROVE WITH EARLIER LINES OF THERAPY

Maximilian Merz[1], Robert Bowden[2], Juan Carlos Araque[3], Gourav Choudhary[3], Lisa Kallenbach[3], Victoria Alegria[4], Octávio Costa Filho[5], Matthew Perciavalle[5], James Salmon[5], Jay Kang[5], Michael Mondon[5], Jill Vanak[6], Daniel Ciccone[3], Peter Millili[3], Monica Onorata[3], ***Hannelore Van Eeckhoutte***[3]*, Vicki Plaks[6]*

[2]Janssen Research and Development, Spring House, United States of America (the), [3]Johnson & Johnson Innovative Medicine, New Brunswick, United States of America (the), [4]Janssen Scientific Affairs, Horsham, United States of America (the), [5]Legend Biotech USA Inc, Somerset, United States of America (the), [6]Johnson & Johnson, Spring House, United States of America (the)

Background: Ciltacabtagene autoleucel (cilta-cel) is a B cell maturation antigen–directed chimeric antigen receptor-T cell therapy approved for adults with lenalidomide-refractory multiple myeloma as early as first relapse. Cilta-cel is manufactured using autologous T cells, resulting in variability in the initial starting material and subsequent manufactured product, which may not meet health authority specifications (out-of-specification [OOS]). Quality attributes of T cells obtained from patients are the predominant contributors to OOS manufacturing outcomes. Moreover, manufacturing of in-specification drug products is associated with the enrichment of naive and central memory T cell subpopulations, which are more abundant in material collected from patients with relatively fewer prior lines of therapy (pLOTs). This study examined cilta-cel manufacturing outcomes across multiple pLOTs.

Methods: Commercial cilta-cel manufacturing data were analyzed to identify determinants of manufacturing outcomes, define biomarkers predictive of manufacturing success and assess results following OOS-driven remanufacturing or recollection.

Results: Rates of first-time manufacturing success significantly improved using T cells from patients with fewer pLOTs (≥1 versus ≥4 pLOT: 93% versus 89%; N=~3000). CD3+ cell recovery at manufacturing initiation was less favorable in patients with ≥4 versus fewer pLOTs. The initial cellular CD4:CD8 ratio improved by 54% with fewer pLOTs (average CD4:CD8 ratio, 1 versus ≥4 pLOT: 1.0 versus 0.65); these data also suggest that CD4:CD8 ratio >0.5 may contribute to better in-specification, first-time manufacturing outcomes. Recovery of viable cells before lentiviral vector transduction and cumulative population doubling level of cells improved (≤7%) with relatively fewer pLOTs (P<0.05 for both). Markers of metabolic activity were significantly improved with fewer pLOTs (10% average improvement for material from patients with 1 versus more pLOTs).
Across OOS outcomes from all pLOTs (n=317), 63% were released through an expanded access program without remanufacturing. Of the remaining 37%, 8.6% were cancelled. An additional 28.6% (n=90) underwent remanufacturing, 60% (n=54) resulted in OOS or cancellation and 40% (n=36) resulted in within-specification outcomes. Material from patients with ≥4 pLOTs undergoing remanufacturing resulted in the same or additional OOS results or cancellations as the first manufacturing outcome (67% of attempts [n=36]). Remanufacturing new apheresis material was requested in 14% of initial OOS cases due to insufficient remaining material or concerns about effects of prior therapies, suggesting long-lasting impact of prior treatments and/or disease characteristics. Remanufacturing attempts using new apheresis material (n=45) resulted in similar or worse outcomes in 31% of cases and cancellation in 20% of cases. Cancellation and OOS outcome rates for remanufacturing with ≥4 pLOTs were 39.5% and 35.5%, respectively (n=29). The manufacturing success rate improved to 99% when using cells from patients with ≥1 pLOT (6.5% received OOS product) versus 97% for ≥4 pLOTs (9.2% received OOS product).

Conclusions: First and overall manufacturing success rates were higher using cells collected from patients with ≥1 versus ≥4 pLOTs. T cell attributes associated with manufacturing

outcomes were improved in starting material collected from patients with ≥1 versus ≥4 pLOTs. Remanufacture of product often results in additional OOS outcomes, which may further delay treatment. © *American Society of Hematology (2025). Reused with permission*.

HEMATOPOIETIC STEM CELL DONATION IN FAMILY DONORS UNDER 18 YEARS OF AGE. EXPERIENCE OF THE ITALIAN SECOND OPINION COMMITTEE SIMTI / SIDEM FOR DONOR PROTECTION

Aurora Vassanelli[1], *Angelo Ostuni*[2], *Ornella Iuliani*[3], *Giulia Pucci*[4], *Monica Castelli*[5], *Simona Pollichieni*[6], *Nicoletta Sacchi*[6]
[1]*University Hospital of Verona - Policlinic Hospital, Verona, Italy,* [2]*Policlinico Hospital of Bari, Bari, Italy,* [3]*Hospital of Pescara, Pescara, Italy,* [4]*Hospital Melacrino Morelli of Reggio Calabria, Reggio Calabria, Italy,* [5]*Hospital "San Bortolo" of Vicenza, Vicenza, Italy,* [6]*Italian Bone Marrow Donor Registry, Genova, Italy*

Background: In allogeneic transplantation, a compatible donor is initially selected from within the family. If the most suitable HLA-matched family donor is <18 years of age, to protect the donor and avoid the administration of growth factors, in Italy a bone marrow donation is permitted as a standard donation, but peripheral blood stem cell donation is not, according to the SIMTI GIMTO Recommendations (Blood Transfusion 2013). In very specific cases, the SIMTI/SIDEM Committee to donor protection, designated by the relevant scientific societies, may be consulted as a "Second Opinion" to assist the Donor Center (DC) and the Transplant Program (TP) in assessing donor suitability, with the aim of protecting the donor's well-being and safety.
We have evaluated all requests for "second opinions" to the SIMTI/SIDEM Committee, analyzing the impact of the number of donation requests from donors under 18 years of age.

Methods: The possibility of evaluating a donor <18 years of age for the donation of peripheral HSC is provided for by Italian law (State-Regions Agreement 231/2022), but is assessed by the SIMTI/SIDEM Commission only in the absence of comorbidities, associated with one of the following criteria: absence of other compatible related or unrelated donors, urgent transplantation for the recipient, or the need for a second donation from the same donor who has already donated Bone Marrow. The TP sends a request to the SIMTI/SIDEM Commission through the IBMDR (Italian Bone Marrow Donor Registry), with centralized and shared management of Second Opinion requests, both for related and unrelated donations.

Results: From 2009 to 2025, 364 requests were received by the SIMTI/SIDEM Commission, of which 21 were for minor donors (6%), received after 2013. Of these, 16/21 (76% of requests) were sent to assess suitability for peripheral HSC donation, in 13 donors as a first donation, in 3 donors as a second donation (after a previous donation of Bone Marrow), due to graft failure.
Donors were distributed according to the following age groups: <14 years: 1 donor (6.3%); 14-15 years: 8 donors (37.5%), 16-18 years: 9 donors (56.2%).
All requests met the aforementioned appropriateness requirements.
The SIMTI-SIDEM Commission responded with an "affirmative opinion" to all these requests, with the following recommendations: the donor must express his or her "willingness" to donate; consent must be given by both parents; CVC placement is not permitted (it is considered a contraindication to peripheral HSC donation in a minor); follow-up must be conducted for at least 10 years after donation, according to the Recommendations.
All donations proceeded normally, and no adverse events or serious reactions were recorded; no significant problems were reported during follow-up.

Conclusions: Peripheral HSC donation is not considered standard for donors <18 years of age. However, under very select conditions and with Second Opinion approval, it is possible to safely evaluate the donation of growth factor-mobilized peripheral HSC, particularly in the 16-18 age group, ensuring accurate pre-donation hematological and immunological evaluation and follow-up for at least the next 10 years.

[1]*DKMS Group gGmbH, Clinical Trials Unit, Dresden, Germany,* [2]*University Hospital TU Dresden, Medical Clinic I, Dresden, Germany,* [3]*Translational Science and Therapeutics Division, Fred Hutchinson Cancer Research Center, Seattle, United States of America (the),* [4]*Division of Medicine, University of Washington, Seattleun, United States of America (the),* [5]*Flow and Immune Analysis Shared Resource, Roswell Park Comprehensive Cancer Center, Buffalo, United States of America (the),* [6]*Center for International Blood and Marrow Transplant Research, NMDP, Minneapolis, United States of America (the),* [7]*DKMS Donor Center gGmbH, Tübingen, Germany,* [8]*City of Hope Los Angeles and City of Hope National Medical Center, Los Angeles, United States of America (the)*

Background: In an international collaboration between DKMS (Germany) and NMDP (USA), we are comprehensively characterizing the immune effector cell composition of 2,000 donor Peripheral Blood Stem Cell (PBSC) products. Our goal is to correlate the cellular composition of PBSC grafts with patient outcome of allogeneic hematopoietic cell transplantation (alloHCT). As part of this project, we investigated the effect of cryopreservation on the cellular composition of PBSC products. Cryopreservation is thought to influence cellular composition of the graft, but comprehensive data are lacking. Here, we present an analysis on how cryopreservation followed by short-, medium- and long-term storage affected the graft composition.

Methods: A 34-color flow cytometry panel was used to determine the graft immunophenotype in terms of specialized immune effector cells. We analyzed 20 fresh grafts and compared them to their frozen and thawed counterparts after storage in liquid nitrogen for 2 weeks, as well as 2, 6 and 24 months, respectively. Cryopreservation of product samples followed routine clinical procedures using a 10% DMSO containing cryo-medium and a controlled rate freezing. After thawing at 37°C, cells were washed, stained, fixed and analyzed immediately by high dimensional full spectrum flow cytometry. Our panel is designed to capture the major immune cell subsets, hematopoietic stem cells (HSCs) and an extensive set of phenotyping markers focused on the activation and differentiation status of T-cell and dendritic cell (DC) subsets.

Results: We observed significant changes in cell composition after cryopreservation: (i) As known, granulocytes showed a pronounced decline. (ii) Analyzing nine main cell populations (excluding granulocytes) we observed a marked reduction of mDCs following freezing and short-term storage (1.9% of all live cells fresh vs 1.4% two weeks storage, $p<0.001$). Specifically within the mDCs compartment, the CD16+ mDCs was significantly reduced (1.6% vs 0.8%, $p<0.001$) in frozen and thawed samples. After two years of storage, grafts showed ongoing significant decrease of mDCs (1.4% vs 1.0%, $p<0.001$) and especially of CD16+ mDCs (0.8% vs 0.6%, $p<0.04$).

Conclusions: In this longitudinal analysis, we observed a significant decrease of mDCs frequencies within two years of storing in the vapour phase of liquid nitrogen. This population may have a role in the development of chronic GVHD after alloHCT. The results provide further insight into the influence of cryopreservation on PBSC graft composition and warrant further efforts to explore mechanisms behind differential outcomes observed using fresh vs cryopreserved PBSCs.

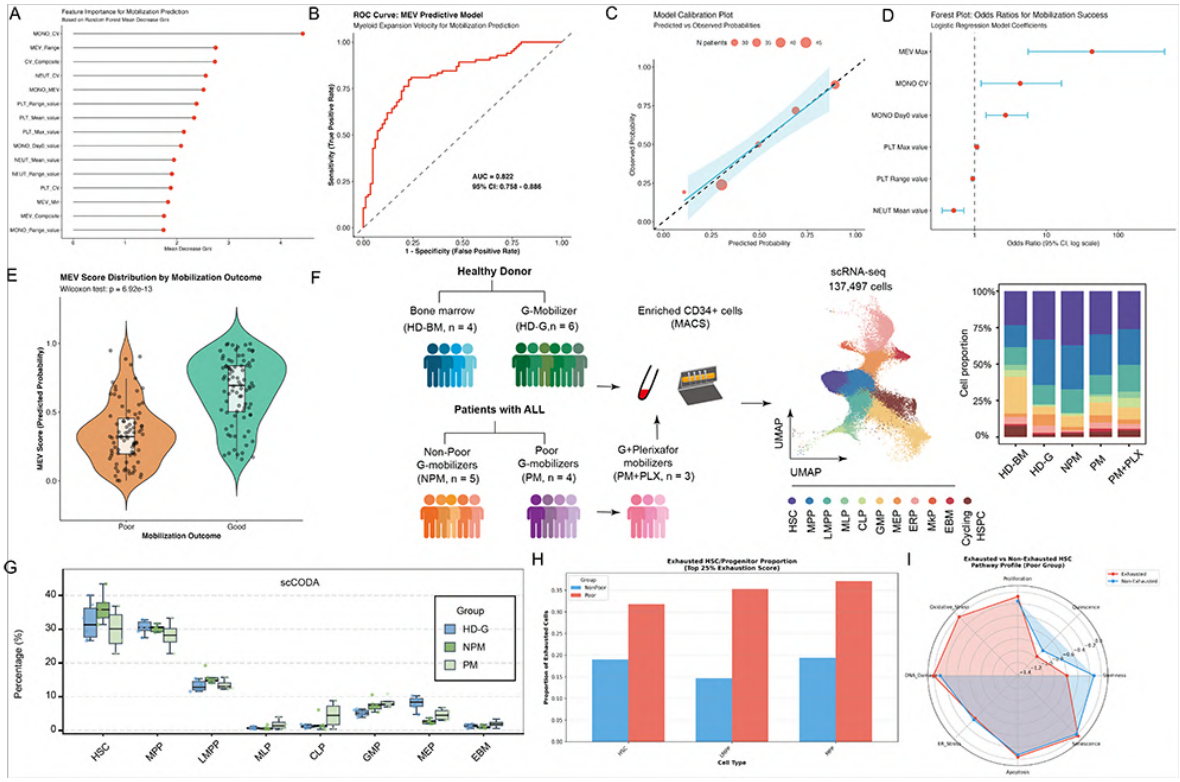
MYELOID EXPANSION VELOCITY: A NOVEL KINETIC BIOMARKER FOR PREDICTING HEMATOPOIETIC STEM CELL MOBILIZATION FAILURE IN ACUTE LEUKEMIA

*Hongye Gao[1], Yawei Zheng[1], Lisha Wang[1], Shihui Ma[1], Jiali Sun[1], Xina Song[1], Weihua Zhai[1], **Erlie Jiang**[1], Fang Dong[1]*
[1]Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Tianjin, China

Background: Failure to collect adequate hematopoietic stem cells (HSCs) remains a critical bottleneck for autologous transplantation in acute leukemia. Current prediction methods rely on static "snapshots" of peripheral blood counts, which frequently fail to capture the dynamic nature of hematopoietic recovery. We hypothesized that the trajectory of myeloid recovery during G-CSF priming—specifically the Myeloid Expansion Velocity (MEV)—serves as a superior surrogate for underlying stem cell fitness compared to isolated measurements.

Methods: We analyzed 167 B-ALL patients with complete daily blood count monitoring during mobilization. MEV was defined as the slope of myeloid marker recovery, with additional features capturing trajectory variability and acceleration. A multivariable predictive model was constructed and internally validated. To decode the cellular drivers of these kinetic patterns, we performed single-cell RNA sequencing (scRNA-seq) on 137,497 $CD34^+$-enriched cells from 22 subjects, comparing healthy donors to patients stratified by mobilization outcome.

Results: MEV emerged as a robust predictor, fundamentally outperforming static measurements. The MEV-based kinetic model achieved an AUC of 0.822 (sensitivity 79.8%, specificity 77.1%). Three key kinetic insights highlighted the unique value of MEV. (i) Velocity drives success: Maximum MEV was the strongest individual predictor (OR = 43.2, $p < 0.001$), indicating that the speed of expansion is more critical than absolute counts. (ii) Stability matters: Monocyte variability emerged as a top-ranked feature, suggesting that erratic recovery signals poor outcomes. (iii) The "High-Count" Paradox: High but erratic neutrophil trajectories were inversely associated with success, a phenomenon invisible to static testing but captured by MEV. Mechanistically, scRNA-seq provided the biological rationale for these kinetic failures. Poor mobilizers exhibited genuine HSC depletion (scCODA log-ratio −0.415). Crucially, the residual HSC pool displayed an "Exhausted-like" phenotype, characterized by hyper-proliferation, high oxidative stress, and DNA damage. This exhaustion led to premature myeloid skewing, explaining the clinical observation of transient, ineffective neutrophil surges (high kinetic volatility) that fail to yield harvestable stem cells.



Conclusions: MEV represents a paradigm shift from static to kinetic monitoring. By quantifying the velocity and stability of recovery, MEV identifies at-risk patients earlier and more accurately than conventional methods. The biological basis of low MEV—oxidatively stressed and exhausted HSCs—offers mechanistic clarity, suggesting that interventions targeting oxidative stress could restore stem cell fitness.

TRANSFORMING TIMELY ACCESS TO STEM CELL COLLECTIONS: EARLY IMPACT OF ANTHONY NOLAN'S FIRST DEDICATED CELL COLLECTION CENTRE

Dawn Hart[1], *Laura Dalling*[1], *Elizabeth King*[1], *Nic Alderson*[1]
[1]*Anthony Nolan, London, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Stem cell transplantation is a vital curative therapy for blood cancers and blood disorders, but persistent apheresis capacity constraints in the UK have limited timely

access to donor cells. In 2023/24, only 15% of requests for stem cell collections were fulfilled on the clinician's or researcher's "first-choice date," risking delays to life-saving transplants. The UK Stem Cell Strategic Forum has highlighted the urgent need to expand domestic collection capacity and future-proof infrastructure for emerging cell and gene therapies. In response, Anthony Nolan launched England's first dedicated Cell Collection Centre (CCC) at Nottingham University Hospitals NHS Trust, hosted within the NIHR Nottingham Clinical Research Facility at Queen's Medical Centre, with the aim of increasing donation capacity, reducing delays, and supporting research.

Methods: We performed a descriptive analysis of operational performance before and after the CCC launch. The primary metric was the proportion of donor collections completed on the requested "first-choice date," a key driver of successful transplant outcomes and of customer service for both clinicians and researchers. Historical data from 2022/23 and 2023/24 served as baseline comparators. Early post-launch data from July to November 2025 were reviewed, including procedural and patient/donor characteristics, to ensure that apheresis capacity was maximised. Qualitative feedback from donors and operational learnings was also collected. Published reports on UK apheresis capacity were referenced to contextualise the national challenge.

Results: Prior to CCC implementation, the lack of apheresis capacity across the UK meant that only 17% (2022/23) and 15% (2023/24) of requests facilitated by Anthony Nolan were fulfilled on the first-choice date. Following the CCC launch, preliminary data to the end of November 2025 show an increase to 53% for collections facilitated at the CCC, reflecting a substantial improvement in scheduling flexibility and capacity. In its first five months, the CCC facilitated 78 collections from 70 donors, including 46 donors for transplant patients (8 required two-day collections,) and 24 donors for medical research and treatments. The CCC adds up to 1,300 new donation slots annually, directly addressing UK infrastructure gaps. Early feedback suggests an excellent donor experience and streamlined logistics. The CCC also supports collections for research, enabling the development of novel cell-based therapies; quantitative data on research collections will be reported in future analyses. Strategic Forum modelling suggests that expanding domestic donor provision to 45% of UK supply could save the NHS £1.1 million per year and reduce reliance on overseas donors. Operational innovation includes predictive modelling to optimise one-day versus two-day collections, freeing capacity for additional donors.

Conclusions: Establishing a dedicated cell collection centre significantly improves the ability to meet optimal collection dates, a key factor in reducing transplant delays and supporting innovation. These early results underscore the value of targeted infrastructure investment and collaborative models in future-proofing cell supply for both clinical and research needs. Further evaluation will explore the longer-term impact on transplant outcomes, donor satisfaction, and scalability across the UK.

TYPE OF INDUCTION CHEMOTHERAPY INFLUENCES STEM CELL MOBILIZATION CAPACITY IN MULTIPLE MYELOMA PATIENTS – COMPARISON OF VCD VS DARA-VTD IN A LARGE MULTICENTER COHORT

Christa Unger[1], *Song-Yau Wang*[2], *Juliana Wiegandt*[2], *Hartmut Gläser*[1], *Sebastian Böttcher*[1], *Frauke Theis*[1], *Johannes Lakner*[1], *Christoph Machka*[1], *Elisabeth Weiss*[1], *Christina Grosse-Thie*[1], *Larissa Henze*[1], *Simone Heyn*[2], *Georg-Nikolaus Franke*[2], *Enrica Bach*[2], *Klaus Metzeler*[2], *Madlen Jentzsch*[2], *Maximilian Merz*[2], *Vladan Vucinic*[2], *Christian Junghanss*[1], *Wolfram Pönisch*[2]
[1]*Rostock University Medical Center, Rostock, Germany,* [2]*University Leipzig Medical Center, Leipzig, Germany*

Background: Treatment of multiple myeloma (MM) has evolved rapidly over the last decades and consequently the choice of induction therapy for patients eligible for autologous stem cell transplantation (ASCT). Incorporating an anti-CD38 monoclonal antibody and immunomodulatory drugs into the induction regimen has resulted in deeper response before ASCT and better overall outcomes as reported recently. However, clinical observation and early reports hints on influences of the induction regimen on subsequent peripheral blood stem cell (PBSC) mobilization.

Methods: This retrospective multicenter cohort analysis collected data from MM patients who underwent ASCT between 2009 and 2025. Patients had to receive first line induction treatment of MM containing of either bortezomib, cyclophosphamide and dexamethasone (VCD) or daratumumab, bortezomib, thalidomide and dexamethasone (D-VTD). The stem cell mobilization regimen consisted of cyclophosphamide followed by G-CSF administration. Evaluated parameters included amongst others: patient characteristics such as age, sex, cytogenetic risk profile, additional use of plerixafor, day of first apheresis, pB $CD34^+$ cells/µL on first day of apheresis, total number of aphereses, cumulative yield of $CD34^+$ cells.

Results: Of 299 patients included, 140 were treated with VCD (median 61 [29-72] yrs) and 159 with D-VTD (median 63 [35-73] yrs) as induction therapy. In the VCD cohort, 20% of patients (n=23) and 22% (n=32) of the D-VTD were to be categorized as high risk cytogenetic profile. All patients could eventually successfully mobilize PBSC. However, additional use of plerixafor became necessary in 4% (VCD, n=5) in contrast to 23% (D-VTD, n=37; $p<0.001$) due to insufficient PBSC mobilization. First day of apheresis did not differ between the cohorts. In terms of pB $CD34^+$ cells/µL on first day of apheresis, VCD patients had significant higher counts compared to the D-VTD patients (104.9/µl vs. 44.0/µl, $p<0.001$) as well as lower total numbers of aphereses, respectively (mean 1.22±0.20 vs. 1.55±0.51, $p<0.001$). Furthermore cumulative yield of $CD34^+$ cells in the VCD group was significantly higher compared to the D-VTD patients ($10.65x10^6$/kg vs. $6.09x10^6$/kg, $p<0.001$).

Conclusions: Our real-world data shows significant differences in PBSC mobilization outcomes between VCD and D-VTD induction therapies in transplant-eligible MM patients. Whether this effect can be attributed to novel drug classes included or antibody

pharmacokinetics is currently unclear. Optimal settings for PBSC mobilization in these have to be determined in the future.

Disclosure: Nothing to declare.

A292

LESS INFLAMMATION, SAME SURVIVAL: PLERIXAFOR MOBILIZATION REDUCES ENGRAFTMENT CRS IN PAEDIATRIC HSCT COMPARED TO GCSF ALONE

Vijayshree Muthukumar[1], Krithika Krishnakumar[1], Ravindra Prasad[1], Usha Surianarayanan[1], Indira Jayakumar[1], Kavitha Ganesan[1], Ramya Uppuluri[1], ***Revathi Raj***[1]
[1]*Apollo Speciality Hospital, Chennai, India*

Background: Effective peripheral blood stem cell mobilization is critical for successful paediatric allogeneic haematopoietic stem cell transplantation (HSCT). While granulocyte colony-stimulating factor (G-CSF) remains the standard mobilization approach, a subset of donors exhibit inadequate $CD34^+$ release and may require plerixafor rescue. Although plerixafor use is well characterized in adults, paediatric data, particularly linking mobilization biology to graft composition and transplant outcomes, remain limited. Understanding whether plerixafor influences graft quality, immune reconstitution, toxicity profiles or survival is essential for optimizing donor selection, mobilization strategy, and post-transplant management.

Methods: We conducted a retrospective comparative study of 87 paediatric HSCT recipients transplanted over the past 1 years at our Hospital. Donors were mobilized either using G-CSF alone (n=45) or G-CSF plus plerixafor (n=42). Donor variables included age, sex, mobilization regimen, $CD34^+$ and $CD3^+$ yields, and stem cell collection volume. Recipient outcomes evaluated included engraftment kinetics, CRS, engraftment syndrome, acute GVHD, mortality, relapse, TATMA, secondary graft dysfunction requiring romiplostim, SOS, day +15/+30 chimerism, viral reactivation, and immune reconstitution across CD4 subsets, NK and B cells at days +30, +60 and +90. Statistical testing used t-test/Mann-Whitney for continuous variables and Fisher's exact testing for categorical outcomes, with $p<0.05$ considered significant.

Results: Recipient demographics were balanced between groups, whereas plerixafor donors were younger (24.0 vs 33.6 years). Stem cell volume collected (167.9 vs 178.4 mL; p=0.41) and infused (97.4 vs 90.6 mL; p=0.56) were comparable. CD34 yields were significantly higher in G-CSF-only donors both at collection (p=0.048) and infusion (p=0.03), whereas CD3 yields did not differ significantly. The CD34:CD3 ratio was significantly higher in G-CSF donors, indicating stem-cell–dominant grafts, whereas plerixafor grafts were more T-cell enriched.
Infusion CRS severity was similar (p=0.96), but engraftment CRS was significantly higher in the G-CSF group (p=0.047). Although Anakinra use was numerically higher in the G-CSF cohort (13 vs 6 total doses), differences were not significant. Relapse (p=0.71), mortality

(p=0.20), TATMA (p=0.24), romiplostim requirement (p=0.51) and SOS (trend p=0.07) did not differ significantly between cohorts. Immune reconstitution profiles of effector CD4, memory CD4, total CD4, NK and B-cells were equivalent at all assessed time points (all p>0.05). Neutrophil engraftment was faster in the plerixafor group by ~1 day, but non-significant (p≈0.07). Chimerism at days +15 and +30 demonstrated robust donor engraftment (>98%) in both groups without significant differences.

Conclusions:

- The CD34:CD3 ratio differed significantly between mobilization strategies. G-CSF–only mobilization yielded grafts richer in CD34⁺ stem cells, whereas plerixafor-mobilized grafts were more T-cell enriched. These differences in graft biology did not translate into inferior clinical outcomes in the plerixafor group.
- Engraftment CRS was significantly lower in the plerixafor cohort and anakinra requirement for cytokine control was numerically reduced, indicating a lower inflammatory burden despite graft compositional differences.
- Immune recovery, survival, and complication profiles remained equivalent between mobilization strategies.
- Overall, plerixafor is a safe and effective adjunct for suboptimal mobilizers, permitting adequate graft collection while mitigating engraftment inflammatory toxicity.

Disclosure: No Disclosures

Background: Cord blood transplantation (CBT) is an established alternative source of hematopoietic stem cells for pediatric patients with both malignant and non-malignant disorders. While outcomes after unrelated CBT (UCBT) are well characterized, comparatively less evidence is available for related CBT, particularly sibling cord blood transplantation (SCBT). Existing reports indicate favorable outcomes of HLA-identical SCBT in bone marrow failure syndromes and hemoglobinopathies. However, systematic evaluation across broader pediatric populations remains limited. Furthermore, the role and utilization of SCBT in malignant diseases, as well as its evolution over the past two decades, remain insufficiently documented.

Methods: The SIBCORD survey was distributed to European Society for Blood and Marrow Transplantation (EBMT) Centers via an emailed link. The survey aimed to capture current patterns of sibling cord blood (SCB) utilization, primary clinical indications, and cord blood banking (CBB) practices across countries, with particular attention to heterogeneity in accessibility and resource allocation.

Results: A total of 71 Centers (71/172, 41.3%) responded. Of these, 43 (60.6%) reported active use of CBT as an alternative hematopoietic stem cell source, most frequently for non-malignant diseases (24/43, 55.8%). Notable geographic variation was observed among countries with the highest response rates: continued CBT use was reported by 6/12 Italian Centers, 7/8 in the United Kingdom, 5/7 in France, and 5/6 Centers in Spain. Among CBT Centers, 22 (51.2%) indicated that the CBTs performed involved sibling donors.
Regarding CBB options offered to families at the time of delivery, donation to a public bank was the most common option (18/65, 27.7%), followed by directed donation through a public bank (11/65, 16.9%). Most Centers (32/43, 74.4%) reported never using CBT units originating from hybrid or private/family banks; however, when such units were used, the process was described as straightforward by the majority (13/24, 54.2%). The primary reason for avoiding CB from private banks was lack of trust or concerns about product quality (18/29, 62.1%), followed by ethical concerns (11/29, 37.9%).
Practices related to donor assessment and unit qualification also varied. Nine Centers reported conducting postnatal assessments for genetic abnormalities; however, a substantial proportion (6/34, 17.6%) indicated that this information was unknown at their institution. The date of collection and total volume were considered essential by 20 (46.5%) and 17 (40.5%) Centers, respectively. Total nucleated cell count (36/43, 83.7%) and $CD34^+$ cell

count (34/43, 79.1%) were most often deemed absolutely necessary, as were high-resolution 6-allele HLA typing (28/41, 68.3%) and blood group determination (22/42, 52.4%).

Conclusions: By integrating these preliminary survey findings with existing evidence, our analysis highlights substantial heterogeneity in CBT utilization and banking practices across EBMT Centers and underscores the continued relevance and potential future role of SCBT. The observed country-specific differences suggest opportunities for harmonizing guidelines and optimizing access to this alternative stem cell source. Further investigation, together with recently published literature, is needed to better define the optimal clinical use of SCBT and its role within contemporary HSCT and gene-therapy frameworks.

Disclosure: Nothing to declare.

WORLD MARROW DONOR ASSOCIATION WORLDWIDE SURVEY ON PLERIXAFOR USE IN HEALTHY RELATED AND UNRELATED DONORS

Tania Dexter[1], *Kalinga Perera*[2], *Alejandra Martínez Trillos*[3], *Jesús Fernandez Sojo*[4], *Sylvie Lachance*[5], *Jane Ward*[6], *Eefke Van Eerden*[7], *Mats Bengtsson*[8], *Simona Pollichieni*[9], *Yen-Michael Hsu*[10], *Thilo Mengling*[11], *Jonas Rieping*[12], *Chloe Anthias*[1], *Alison Bermis*[13], *Meghann Cody*[13]
[1]*Anthony Nolan, London, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Welsh Bone Marrow Donor Registry, Pontyclun, United Kingdom of Great Britain and Northern Ireland (the),* [3]*Spanish Bone Marrow Donor Registry, Barcelona, Spain,* [4]*Barcelona Cord Blood Bank, Barcelona, Spain,* [5]*Héma-Québec Stem Cell Donor Registry, Saint-Laurent, Canada,* [6]*South African Bone Marrow Registry, Cape Town, South Africa,* [7]*World Marrow Donor Association, Leiden, Netherlands (the),* [8]*Tobias Registry, Stockholm, Sweden,* [9]*Italian Bone Marrow Donor Registry, Genoa, Italy,* [10]*Gift of Life Registry, Florida, United States of America (the),* [11]*DKMS Group, Tübingen, Germany,* [12]*DKMS Collection Centre, Cologne, Germany,* [13]*National Marrow Donor Program, Minneapolis, United States of America (the)*

Background: Several prospective studies have investigated the use of plerixafor in healthy stem cell donors, either alone or in combination with granulocyte colony stimulating factor (G-CSF). Despite local guidelines and practices being developed, there is no formal World Marrow Donor Association (WMDA) guidance on its use. Plerixafor use in healthy donors remains an off-licence indication in many countries; therefore, a worldwide consensus will support registries in its use and ensure that practice remains universal and safe for donors. The group began drafting the consensus with a survey of institutions worldwide, the results of which are presented here.

Methods: The survey was disseminated via the WMDA monthly newsletter "Stem cell matters" and via email. The electronic survey in English was open for responses between August 11, 2025, and October 9, 2025. The primary aims were to understand current practices and experience with the use of plerixafor in healthy related and unrelated donors as

well as to understand the safety measures in place, barriers to use, scheduling and billing. Not all questions were compulsory.

Results: 51 responses were received from 17 countries worldwide. This included responses from donor registries (21.6%), collection centres (CC) (17.6%), transplant centres (TC) (11.8%), 1 individual, and institutions that were registries and CCs (3.9%), CCs and TCs (41.2%) and 1 donor and patient registry.
Two institutions had used plerixafor in a total of > 100 healthy donors, 4 reported using it 10-99 times and 6 reported using plerixafor 1-9 times.
Twirty-one (60.8%) institutions do not currently endorse plerixafor in healthy donors but would consider it and 13 (25.5%) are already using it. Seven (13.7%) reported that they would not consider it. Twenty-six (51%) institutions did not have experience with plerixafor in healthy donors, 2 (3.9%) had used in unrelated only, 12 (23.5%) in related only and 7 (13.7%) in related and unrelated healthy donors.
A table of responses is shown in appendix 1.

Question	**Response**	**Number of institutions**
Which country is your institution from?	Germany, Portugal, Czech Republic, Poland, Greece, Norway, Spain, UK, Belgium, Denmark, France, Netherlands, Algeria, South Africa, Canada, Israel, US	N/a
Is plerixafor approved by pharmaceutical legislation and available for use in healthy unrelated donors in your country?	Yes, available but not approved Yes, available and approved Not available	25 2 14
Is GCSF approved by pharmaceutical legislation and available for use in healthy unrelated donors in your country?	Yes, available but not approved Yes, available and approved	3 47

Does your registry/institution have any experience using plerixafor mobilization alone (without G-CSF) in healthy donors?	No, and we would not consider No, but we would consider Yes	22 19 1	
Which indications are you currently or considering using plerixafor for?		Currently	Considering
	Emergency use following a poor day one collection after G-CSF mobilization	19 2	31 13
	Pre-emptive use for unrelated donors with an unfavourable donor-patient weight discrepancy	9 5	20 9
	Pre-emptive use with a low pre-apheresis peripheral blood CD34+ count	0 3	0 14
	Pre-emptive use to collect high cell doses for patients	3	11
	Pre-emptive use to collect high cell doses for research	2 0	20 5
	Pre-emptive use for a subsequent donation from donors who have mobilized poorly on a previous donation	0 0	6 7
	Pre-emptive use for donors who have not tolerated the full course of G-CSF	1	0
	Pre-emptive use for donors with G-CSF allergy		
	Pre-emptive use for plerixafor induced immunological profile of the stem cell graft		

	Pre-emptive use of plerixafor according to donor preference Pre-emptive use for stem cell donors to research for clients who specifically request mobilization using plerixafor Access / flow issues		
Does your registry ever use more than one dose of plerixafor?	Yes No, but we would consider No, and we would not consider	5 1 7	
Does your registry/institution always check a WBC/CD34+ count prior to administration?	Yes No	8 1	
What time do you administer plerixafor?	<6 hours 6-12 hours 12-18 hours >18 hours	4 6 2 0	
Does your institution administer prophylactic anti-diarrhoeal and anti-emetics?	Yes No	2 9	
Does your registry/institution monitor WBC and/or CD34+ counts after plerixafor?	Yes No	11 2	
How often does your registry/institution find supportive medications (e.g.,	Rarely (1/100) Sometimes (< 1/10) Often (>1/10) Never	4 1 1 3	

antidiarrheals, antiemetics, analgesics) are required?		
Does your registry/institution monitor the donor after 1st plerixafor administration?	Yes </= 1 hour Yes, overnight No	7 3 3
How long do donors report symptoms usually last for after the last dose of plerixafor?	< 24 hours 24-72 hours Unsure	5 3 5
Has your institution experienced any other concerning side effects from plerixafor apart from the gastrointestinal side effects?	No Yes	12 1 - allergy, 1 – SOB
Has your registry/institution recorded any side effects >/= CTCAE Grade 3?	No Yes	13 0
Who incurs the cost of the plerixafor?	Transplant centre Other Collection centre Donor registry	3 1 7 1

Respondents specified cut offs for the administration of plerixafor and mentioned CD34+ cut offs between 5-20/µL or significant weight discrepancy between the donor / recipient. It may also be considered if the target is not reached (2x10*6 CD34+/kg recipient body weight) after the first day of apheresis or if they estimate a poor mobilization on a second apheresis that will compromise the recipient's product.
Respondents highlighted barriers to the use of plerixafor in healthy donors including that it is unlicensed so there is some apprehension and that it is hard to access in some CCs. They

also mention the cost (prior to generic availability) and the requirement in some institutions for a hospital admission to receive it early in the morning before apheresis or the delay to apheresis after administration.

Conclusions: There is clear interest in the use of plerixafor in healthy related and unrelated donors worldwide with varying practices with scheduling, dosing and indications for its administration. A WMDA recommendation collating the published evidence and the results of this survey will be published to guide institutions and most importantly ensure the safety of healthy donors worldwide.

CENTER- AND DEVICE-RELATED VARIABILITY IN TCRAB/CD19 DEPLETION OF HEMATOPOIETIC PROGENITOR CELL APHERESIS PRODUCTS

Joaquín Gomez-Medina[1], Guzman Lopez de Hontanar[2], Cira Asin[1], Juan Antonio Blázquez-Soto[1], Raquel de la Calle[2], Trinidad Garcia-Ramos[1], Mireya Homs[2], Ana Martin de Ana[2], Alfredo Minguela[1], Marta Perez-Laencina[1], Elena Sebastian[2], Ana Castillo[2], Josune Zubicaray[2], Ana María García-Hernández[1], Julian Sevilla[2], ***Miguel Blanquer***[3]
[1]*Hospital C.U. Virgen de la Arrixaca, Murcia, Spain,* [2]*Hospital Universitario Infantil Niño Jesús, Madrid, Spain,* [3]*Hospital C.U. Virgen de la Arrixaca. IMIB. Universidad de Murcia, Murcia, Spain*

Background: TCRαβ/CD19 depletion in haploidentical hematopoietic stem cell transplantation aims to reduce graft-versus-host disease (GVHD) while preserving engraftment success by retaining CD34⁺ cells, TCRγδ T cells, and NK cells.

Methods: We performed a retrospective, comparative, analytical study evaluating quantitative cell processing outcomes in TCRαβ/CD19 depletion procedures performed at two medical centers, *Hospital Clínico Universitario Virgen de La Arrixaca* (HCUVA) and *Hospital Infantil Universitario el Niño Jesús* (HIUNJ). The objective was to determine whether differences existed in the efficacy of the depletion process between centers and between two depletion platforms, CliniMACS Plus and CliniMACS Prodigy. All calculations were performed by comparing the starting apheresis product with the final graft after TCRαβ/CD19 depletion. Results are reported as median (range).

Results: A total of 247 TCRαβ/CD19 depletion procedures were performed across the two centers.
Center comparison: The first analysis assessed the impact of the cell processing system: bag centrifugation at HIUNJ vs. the Sepax system at HCUVA. Bag centrifugation was used in 68.84% of the procedures and achieved TCRαβ and CD19⁺ cell depletion log reductions of 5.98 (3.16–6.68) and 5.27 (2.14–6.09), respectively. Recovery rates of CD34⁺, TCRγδ, and NK cells were 81.1% (38.6–100), 76.8% (23.5–100), and 75.4% (27.6–100), respectively.

In contrast, procedures using the Sepax system (31.16%) resulted in TCRαβ and CD19⁺ depletion log reductions of 4.83 (2.09–6.24) and 3.42 (1.61–5.64), respectively, with recovery rates of 74.9% (27.6–100) for CD34⁺ cells, 60.8% (17.5–100) for TCRγδ T cells, and 63.4% (20.7–96.7) for NK cells. All variables differed significantly between the two approaches.
Device comparison: The second analysis compared the CliniMACS Plus and CliniMACS Prodigy systems. Among the 225 (91.1%) procedures performed with CliniMACS Plus, TCRαβ and CD19⁺ log depletion levels were 5.81 (2.09–6.68) and 4.87 (1.6–6.09), respectively, with recovery rates of 79.2% (27.6–100) for CD34⁺ cells, 71.3% (17.5–100) for TCRγδ cells, and 71.4% (20.7–100) for NK cells. For the 22 (8.9%) procedures performed using CliniMACS Prodigy, TCRαβ and CD19⁺ log depletion levels reached 6.06 (4.16–6.48) and 5.23 (3.19–5.81), respectively, while cell recovery rates were 71.2% (37.4–100) for CD34⁺ cells, 47.3% (19.4–95) for TCRγδ cells, and 50.5% (24.4–70.2) for NK cells. Significant differences were observed only in recovery rates, not in depletion efficiency.

Conclusions: In this retrospective comparative analysis of 247 procedures, cell processing performed at HIUNJ using bag centrifugation demonstrated superior TCRαβ/CD19 depletion efficiency and better recovery of key cell populations compared with procedures performed at HCUVA using the Sepax system. Additionally, no significant differences were found in TCRαβ or CD19⁺ depletion between the CliniMACS Plus and Prodigy devices. However, CliniMACS Plus was associated with improved cell recovery.

Disclosure: The authors report no conflicts of interest and no external funding was received for this study.

A296

SAFE EMERGENCY TRANSFER OF CORD BLOOD UNITS AFTER CRYOGENIC TANK MALFUNCTION: A RARE OPERATIONAL EVENT

Jesus Fernandez-Sojo[1], *Carmen Azqueta*[1], *Nerea Castillo-Flores*[1], *Monica Linares*[1], *Elena Valdivia*[1], *Laura Medina-Boronat*[1], *Sergio Arteaga*[1], *Nuria Rubio*[1], *Sonia Poyatos*[1], *Alexander Guterres*[2], *Ana Garcia-Buendia*[1], *Joan R. Grifols*[1]
[1]*Banc de Sang i Teixits, Barcelona, Spain,* [2]*Concessus, Portugal, Portugal*

Background: Loss of vacuum in BioArchive cryogenic tanks is an exceptional but high-risk event that accelerates liquid nitrogen (LN) evaporation, reduces LN levels, and may expose stored cord blood units (CBUs) to transient warming if no corrective action is taken. At the Concordia public cord blood bank (Banc de Sang i Teixits), a malfunctioning BioArchive tank containing 2,880 CBUs—including 14 directed units—showed progressive LN consumption suggestive of a structural fissure leading to vacuum loss. Repair was not feasible with the units in place, and manual removal of more than 2,000 CBUs was not possible. An emergency rescue transfer was therefore planned in collaboration with the tank provider (Consensus). To date, only two rescue transfers have been reported worldwide over more than 30 years.

Methods: A backup BioArchive-compatible tank was prefilled to 50% capacity with LN. In an outdoor elevated parking area, a crane was used to lift the BioArchive structure, laterally remove the malfunctioning tank, and position the backup tank beneath the robotic indexing system (Figure 1). According to the Consensus technician—who performs this manoeuvre annually during training without real CBUs—the transfer could be completed in under one minute. A temperature probe was placed in the vapor phase of the failing tank to monitor temperature stability throughout the procedure.
To evaluate the potential impact of vapor-phase exposure and rapid mechanical transfer, six CBUs stored in the highest tank levels (worst-case scenario) and with available pre-event segment analysis data were selected for post-thaw assessment. Cell recovery, viability and colony-forming unit (CFU) assays were performed.

HELI

Results: The rescue transfer was successfully completed in 40 seconds. Continuous temperature monitoring confirmed stable vapor-phase conditions throughout the procedure. The characteristics of the six selected CBUs are shown in Table 1. CBUs had been stored for more than 20 years. Post-thaw analyses demonstrated high cell recovery, preserved cell viability and functionality (clonogenic capacity, eClone), in all CBUs evaluated, meeting established criteria for release for transplantation (Table 1).

Variables	Cord Blood Units (N=6)	
Storage time, years	25,9 (22,8-26,6)	
TNC (E8), pre-freezing	9,2 (6,4-41,4)	
CD34 (E6), pre-freezing	2,7 (1,3-21,1)	
7-AAD, CD45, pre-freezing, %	94,9 (94,8-98,0)	
7-AAD, CD34, pre-freezing, %	98,8 (96,6-99,6)	
	Segment thawed prior event	Bag (80%) thawed after emergency transfer
TNC recovery after thawing, %	88,3 (84,3-105,7)	94,5 (87,9-110,9)
Total CD34 recovery after thawing, %	N.A	64,7 (47,6-80,6)
7-AAD, CD45, after-freezing, %	N.A	44,9 (13,9-61,8)
7-AAD, CD34, after-freezing, %	N.A	78,9 (54,8-85,0)
eClone, %	25,1 (18,4-35,2)	16,0 (12,0-38,0)

Quantitative variables are shown as median (range); N.A, not available

Conclusions: Emergency rescue transfer of a BioArchive cryogenic tank experiencing vacuum failure is feasible, rapid, and safe when performed by trained personnel under controlled conditions. In this rare operational event—the third reported worldwide—no detrimental impact on CBU viability or functionality was observed. This report provides

practical, real-world evidence to guide cord blood banks in the management of critical cryogenic tank failures.

Clinical Trial Registry: Not applicable.

FROM ACCESS TO YIELD: PROCEDURAL INSIGHTS INTO PAEDIATRIC STEM CELL APHERESIS

Andrea Espasa[1], *Mercé Albert-Bayo*[1,2], *Marina Rierola*[1,2], *Sofia Alonso*[1,2], *Violeta Vidal*[1], *Shiomara Quiñones*[1], *Julia Ayats*[2,3], *Mònica Linares*[2,4], *Juan Manuel Porras*[1,2], *Carmen Montanero*[1,2], *David Gómez-Vives*[1,2], *Maria Teresa Contijoch*[1,2], *María Isabel Benítez-Carabante*[5], *M Luz Uria–Oficialdegui*[5], *Cristina Díaz de Heredia*[5], *Verónica Pons*[1,2]
[1]*Blood and Tissue Bank of Catalonia – University Hospital Vall d'Hebron, Barcelona, Spain,* [2]*Transfusional Medicine Group – VHIR, Barcelona, Spain,* [3]*Blood and Tissue Bank of Catalonia – University Hospital Germans Trias i Pujol, Badalona, Spain,* [4]*Blood and Tissue Bank of Catalonia – Cell Therapy Service, Barcelona, Spain,* [5]*Department of Pediatric Hematology and Oncology – University Hospital Vall d'Hebron, Barcelona, Spain*

Background: Autologous peripheral blood stem cell transplantation can be essential in treating some paediatric solid tumours. Collecting adequate CD34+ cells is challenging in young children due to low body weight, limited blood volume, and vascular access constraints. Optimising mobilisation, apheresis settings, and catheter choice is essential for safe and effective collection, but data on procedural aspects in pediatric patients are limited. This study reviews the experience of a single centre in order to assess practical outcomes and safety.

Methods: We retrospectively analysed autologous peripheral blood stem cell collections performed in paediatric patients (<18 years) at a single centre between 2023 and 2025. Apheresis procedures were performed using a Spectra Optia® (Terumo) machine with an ACD and heparin combination solution as the anticoagulant. CD34+ collection efficiency (CE) was evaluated using pre- and post-collection CD34+ counts (CE1) and pre-collection count alone (CE2). Results are reported as median [minimum–maximum].

Results: The analysis included 21 procedures performed on 18 patients. All of the patients had a solid tumour diagnosis, and 83% of them were under five years old. Patient demographics and procedure- and product-related characteristics are presented in Table 1. Blood priming was required in 18 apheresis procedures (85.7%). The collection preference was initially set at 50 but was subsequently reduced in 57% of procedures to optimise stem cell collection, while it remained unchanged in most of the remaining cases (28%). Prophylactic calcium was administered in all apheresis procedures except those performed in two adolescent patients (90%); no hypocalcaemia-related adverse events were reported. Two patients experienced hypotension during and after apheresis; in both patients, it was resolved with fluid infusion. In the first patient, apheresis was resumed once hypotension

resolved.
Eight-French (Fr) non-tunneled central venous catheters (CVCs) were used in most of the patients (72%). Ultrasound-guided peripheral venous access were inserted in the only two adolescent patients in our cohort. Tunneled CVCs were introduced at our centre for apheresis last year (N=3), but two experienced flow issues. A patient's 6.5-Fr CVC collapsed on the day of apheresis and had to be replaced; apheresis was successfully performed the next day using a 7-Fr CVC.
Platelet loss after apheresis was observed in all procedures (-38.6% [-18% - -71.1%]), while haematocrit did not significantly change.
All patients met stem cell collection target for subsequent transplantation, although three patients required two apheresis sessions. CE1 was significantly higher than CE2 (p=0.01), as it considers a generalised drop in CD34+ cells during the apheresis process. CE1 was lower in very low-weight patients (under 20 kg) (p=0.03).

	Parameter	Values
Subject Characteristics (N=18)	Age (years)	2.5 [0.42–16]
	Sex - Female / Male n (%)	10 (56%) / 8 (44%)
	Weight (Kg)	13.4 [7.5-61.5]
	Total blood volume (TBV) (mL)	1020 [683–4116]
	Diagnosis (Neuroblastoma / Ewing sarcoma / Medulloblastoma / Other solid tumours [a])	8 / 3 / 2 / 5
	Subjects undergoing stem cell collection (Once / Twice)	15 / 3
	Stem cell mobilization[b] (G-CSF alone / G-CSF +	13 / 4 / 1

	Plerixafor / G-CSF + chemotherapy)	
	Venous access (Non-tunneled CVC / Tunneled CVC / Ultrasound-guided peripheral venous access)	13 / 3 / 2
Process Parameters (N=21)	Time of the process (min)	241 [168–379]
	TBV processed	4.0 [2.5–5.6]
	AC in the patient (mL)	186 [114–557]
	Collection volume (mL)	117 [76–436]
	Collection volume as percentage of TBV (%)	11.1 [6.2–16.2]
	Maximum flow rate (mL/min)	21 [12–50]
CD34+ Determination and Collection Efficiency (CE) (N=21)	CD34+ cells collected (x10^6/kg of patient)	6.47 [0.56-24.8]
	CE1 (%)	50.4 [17.7–85.8]
	CE2 (%)	36.5 [10.7–65.2]

[a] Other tumours included Wilms tumour, chordoma, retinoblastoma, rhabdoid tumour and embryonal brain tumour

[b] Dose of G-CSF was 10 µg/kg/12 hours; dose of plerixafor was 240 µg/kg.

Conclusions: This retrospective analysis shows that paediatric stem cell apheresis is safe and effective, despite technical challenges. Minor complications, such as hypotension and catheter flow issues, occurred but were successfully managed. CE was lower in patients under 20 kg, likely due to the longer time required to stablish the interface. Overall, the procedure is feasible in children, highlighting the importance of careful vascular access management and specific attention to low-weight patients.

Disclosure: Nothing to declare.

A298

UNIVERSAL GENERIC PLERIXAFOR FOR STEM CELL MOBILIZATION IN MULTIPLE MYELOMA: CLINICAL OUTCOMES COMPARISON WITH RISK-ADAPTED STRATEGY AND INTERNATIONAL BENCHMARKS

Sreeraj Vasudevan[1], *Ritu R Menon*[1], *Dona Liza Thampan*[1], *Vinu Vipin*[1], *Rakesh S Nair*[1], *Nandakumar R*[1], *Advait M K*[1], *Unnikrishnan P*[1], *Ashwin Oommen Philip*[1], *Sunu Lazar Cyriac*[1], *Raman Kutty*[1], *Anil Jose Thazath*[1]
[1]*Amala Institute of Medical Sciences, Thrissur, India*

Background: Plerixafor combined with granulocyte colony-stimulating factor (G-CSF) enhances stem cell mobilization in multiple myeloma (MM) patients undergoing autologous stem cell transplantation (ASCT). International studies report optimal harvest rates of 84-94% with upfront plerixafor strategies, while risk-adapted approaches achieve 29-85% depending on patient selection. We evaluated clinical outcomes of universal generic plerixafor administration, comparing results with a published Indian risk-adapted cohort and international benchmarks.

Methods: We analyzed 53 consecutive MM patients receiving universal generic plerixafor (24mg fixed-dose) with G-CSF (10 µg/kg/day for 5 days) at a tertiary care center in Kerala, India (2022-2024). All patients received single subcutaneous plerixafor 12 hours before day-5 apheresis without prior CD34 testing. Primary outcomes were compared with: (1) All India Institute of Medical Sciences (AIIMS), New Delhi data (n=105) using risk-adapted plerixafor for patients with day-4 CD34+ <20 cells/µL (44.8% received plerixafor); and (2) published international studies including MSKCC (USA), Italian multicenter, and recent meta-analyses.

Results: Universal generic plerixafor achieved significantly superior outcomes compared to risk-adapted strategy: mean CD34+ yield was 2.6-fold higher (9.56±6.31 vs 3.63±1.75 $\times 10^6$/kg, $p<0.001$), optimal harvest rate ($\geq 4\times 10^6$/kg) was markedly improved (86.8% vs 29.5%, $p<0.001$), and single-session apheresis completion was substantially higher (96.2% vs 56.2%, $p<0.001$). These results align with international upfront plerixafor outcomes: MSKCC reported 94% optimal harvest ($\geq 5\times 10^6$/kg), Italian multicenter achieved 84.6%, and Emory reported 92.8%. Minimal harvest ($\geq 2\times 10^6$/kg) was comparable across strategies

(98.1% vs 96.2%, p=0.865), consistent with international rates of 94-100%. Engraftment kinetics showed favorable trends (neutrophil: 9.77±0.97 vs 10.30±2.19 days; platelet: 11.23±1.93 vs 12.25±3.37 days) and IV antibiotic duration was significantly reduced (4.28±3.14 vs 7.7±4.29 days, p=0.001). Universal plerixafor negated the adverse effect of prior lenalidomide exposure (exposed: 9.61±6.99 vs unexposed: 9.50±5.70 $\times 10^6$/kg, p=0.948). Cost-effectiveness analysis comparing the two Indian cohorts demonstrated an incremental cost-effectiveness ratio of $9.15 per 1% increase in optimal harvest rate.

Table-1:International Mobilization Comparison

tudy / nstitution	Country	N	Strategy	Study Period	Minimal Harvest ≥2×10⁶/kg	Optimal Harvest ≥4–5×10⁶/kg	Mean Apheresis Sessions	Plerixafor Use		Mean CD34+ Yield ×10⁶/kg	Comparato Yield

hio State Andritsos)	USA	156	Pre-emptive vs Standard	2016–2018	NR	NR	NR	-		NR	NR
mory (Li et .)	USA	138	Upfront P+G-CSF	2010–2014	NR	92.8%*	NR	100%		NR	NR

Footnotes*94% and 92.8% = Optimal harvest defined as ≥5×10⁶ CD34+ cells/kg.NR = Not Reported; POD = Plerixafor On-demand; MD = Mean Difference.

Conclusions: Universal generic plerixafor achieves clinical outcomes comparable to high-resource international centers and significantly superior to risk-adapted strategies. The approach delivers 2.6-fold higher CD34+ yields, nearly 3-fold improvement in optimal harvest rates, and marked reduction in apheresis requirements while effectively overcoming adverse prognostic factors. These findings support universal plerixafor as a clinically superior and cost-effective mobilization strategy for MM patients in diverse healthcare settings.

A299

IMPACT OF VENOUS ACCESS IN THE APHERESIS PERFORMANCE

Sara Lopes[1], *Raquel Ferreira*[1], *Lúcia Vieira*[1], *Tânia Cardoso*[1], *Ana Raquel Almeida*[1], *Maria Graça Braz*[1], *Susana Roncon*[1]
[1]*Portuguese Oncology Institute of Porto (IPO Porto), Porto, Portugal*

Background: Apheresis performance in cell collections is strongly influenced by venous access type and the expertise to maintain stable vascular strategies across multi-day procedures. Understanding how these factors interact in real-world practice is essential for optimising efficiency and safety, particularly in high-volume centres with a wide age range of patients.

Methods: All apheresis procedures performed at the Cell Therapy Department of IPO Porto between 01/July/2024-31/October/2025 were retrospectively analysed. Collections were categorised as extracorporeal photopheresis (ECP), haematopoietic progenitor cell (HPC) collection or lymphocyte/mononuclear cells (MNC) apheresis procedures. This study evaluated venous access patterns, collection speed, calibre usage, multi-day access stability and repuncture events in a large single-centre cohort supported by a specialised apheresis team.
Venous access was classified as central venous catheter (CVC), peripheral venous access (PV), combined CVC+PV or peripherally inserted central catheter (PICC). Collection speed was defined as processed blood volume per minute. Peripheral catheter calibres ranged from 20-16G, while central catheters ranged from 7-11Fr. Multi-day collections were identified using the institutional patient identifier, grouping all attempts on the same date as a single collection day and evaluating access changes and repuncture events.

Results: Of the 1,069 procedures analysed, ECP accounted for 782 procedures, HPC for 224 and lymphocyte/MNC collections for 63; 978 were performed in adults and 91 in paediatric patients.
Paediatric procedures relied almost exclusively on CVCs, with low and tightly controlled flow rates (M=11.2mL/min; range 4.9–17.1). In this group, CVC calibre selection was highly standardised (mean calibre 10Fr; range 8-11Fr), reflecting a preference for central access adapted to patient size.

In adults, PV produced substantially higher flow rates than CVC in ECP (24.1 vs 16.1mL/min); HPC achieved the highest efficiencies overall, with CVC collections reaching a mean of 68.3mL/min (40.5–82.4) and PV a mean of 57.9mL/min (20.1–76.5); Lymphocyte/MNC collections showed consistently high flows with both CVC (54.4mL/min) and PV (51.1mL/min). Peripheral catheter calibre displayed a clear gradient: 20G (M=22.9mL/min; n=875), 18G (M=43.0; n=319), 17G (M=57.9; n=86) and 16G (M=56.6; n=183). PICC lines produced markedly lower flows. Among 280 patients, 56 (20%) required more than one collection day. In 45 multi-day courses beginning with PV, the peripheral approach was maintained in most cases, with identical calibres used across all PV days in 28 patients (62%). Alterations in access or calibre typically followed reduced flow or tolerance during the initial day.
Repuncture occurred in 149 collection-days, predominantly in ECP (n=94), followed by HPC (n=44) and lymphocyte/MNC procedures (n=11); however, it had limited impact on the ability to maintain peripheral access in adults and did not significantly compromise flow safety thresholds.

Conclusions: This study demonstrates that apheresis success is strongly dependent on the expertise of a dedicated team. In ECP procedures, protocolled vascular strategies were consistently maintained. In cell collections, target yields were achieved with a low proportion of multi-day procedures, minimal repuncture rates and no major adverse events. The ability to select appropriate venous access, optimise catheter calibre and preserve stable access across consecutive days directly translates into safe, efficient and reproducible apheresis outcomes.

Disclosure: Nothing to declare.

A301

OUTCOMES AND PREDICTORS OF HEMATOPOIETIC STEM CELL MOBILIZATION STRATEGIES IN AUTOLOGOUS TRANSPLANTATION: A REAL-WORLD ANALYSIS

*Juliana Castro[1], **Manuela Estrada-Schweineberg**[2], Juliana Pardo-Aljure[1], Stefania Pantoja[2], Paula Perez[2], Federico Ramos-Marquez[2], Juan Camilo Vásquez[2], Gabriel Ayala-Carrascal[3], Mateo Gutiérrez Pérez[1], Dana Taub-Sánchez[1], Alejandra Melo[1], Andrés Guerra[1], Laura Ortiz Valderruten[2], Ana María Molano[2], Karen Chaves[2], Carmenza Camargo[2], Claudia Agudelo López[2], Beatriz Wills[2], Guillermo Quintero[2]*
[1]Universidad de los Andes, Bogotá, Colombia, [2]Fundación Santa Fé de Bogotá, Bogotá, Colombia, [3]Universidad Nacional de Colombia, Bogotá, Colombia

Background: G-CSF is the most commonly used agent for hematopoietic stem cell mobilization, yet up to 30% of patients fail to achieve adequate CD34+ yields. Alternative strategies combining G-CSF with chemotherapy, including cytarabine-based regimens, have shown promising results, but real-world comparative data remain limited.

Methods: We conducted a retrospective single institution analysis including 91 patients undergoing auto-HSCT. Mobilization strategies (G-CSF + cytarabine low-dose vs G-CSF alone) were compared using the CD34+ cell dose normalized by weight (×10⁶/kg), with successful mobilization defined as ≥2.0 ×10⁶ CD34+/kg. Toxicities and patient characteristics were analyzed.

Results:

The most frequent diagnoses were multiple myeloma (n = 55, 58.5%), mantle cell lymphoma (n = 12, 12.8%) and acute myeloid leukemia (n = 3, 3.2%). Of the 91 patients who underwent a mobilization regimen, 68 (74.73%) received G-CSF alone and 23 (25.27%) received cytarabine plus G-CSF. Overall, 41 patients (45.05%) were female, the median age was 58 years (IQR, 17).

The mean peripheral blood CD34⁺ cell count (PBCD34) prior to apheresis was 45.74 ± 50.1 /uL. No significant differences in PBCD34 were observed between the G-CSF–only group and the chemotherapy plus G-CSF group (Mann–Whitney U test, p = 0.51).

Following mobilization, the median CD34⁺ cell yield in the group of G-CSF alone was 4.47 × 10⁶ cells/kg (IQR, 3.7 × 10⁶) compared to 7.06 × 10⁶ cells/kg (IQR, 1.08 × 10⁶) in patients that received cytarabine plus G-CSF. CD34+ count differed significantly between mobilization strategies (Mann–Whitney U test, z = −2.30, p = 0.021). Patients mobilized with chemotherapy plus G-CSF showed higher total cell counts compared with those receiving G-CSF alone measured after 5 days.

Of the 91 patients, 7 (7.7%) failed to achieve the target CD34⁺ cell dose of ≥2.0 × 10⁶ CD34⁺ cells/kg. Among these, 4 patients (4.4%) underwent a second mobilization regime with repeated doses of C-GSF, achieving a successful collection, while 3 patients (3.3%) were deemed ineligible for autologous HSCT.

Mobilization-related toxicities differed according to mobilization strategy. Bone pain was common in both groups, occurring in 43.3% of patients receiving G-CSF alone and 30.4% of those receiving cytarabine plus G-CSF. Mucositis was infrequent and did not significantly differ between groups (3.0% vs 8.7%). In contrast, hematologic toxicities were significantly more frequent with cytarabine plus G-CSF, including neutropenia (43.5% vs 4.5%, p < 0.001) and thrombocytopenia (30.4% vs 6.0%, p = 0.001). Both differences were statistically significant (p = 0.0001)(p = 0.001).

Rescue mobilization with plerixafor was required in 27 patients (29.7%). Among patients mobilized with G-CSF alone, (n=23, 33.8%) required rescue mobilization, compared with (n=4, 17.4%) in the cytarabine plus G-CSF group. No statistically significant association was observed between mobilization strategy and the need for rescue mobilization with plerixafor (Pearson $\chi^2 = 4.76$, p = 0.093; Fisher's exact test p = 0.116).

Table 1. Mobilization outcomes and toxicity according to mobilization strategy

Variable	G-CSF alone	G-CSF + chemotherapy

Table 1. Mobilization outcomes and toxicity according to mobilization strategy

Number of patients, n (%)	68 (74.73%)	23 (25.27%)
Total CD34+ collected (×10⁶/kg), median (IQR)	4.47 × 10⁶ cells/kg (IQR, 3.7 × 10⁶)	7.06 × 10⁶ cells/kg (IQR, 1.08 × 10⁶)
Requirement of rescue mobilization	23 (33.8%)	4 (17.4%)
Adverse events during mobilization, n (%)		
Bone pain	29 (43.3%)	7 (30.4%)
Mucositis	2 (2.99%)	2 (8.70%)
Neutropenia	3 (4.48%)	10 (43.5%)
Thrombocytopenia	4 (5.97%)	7 (30.43%)

Conclusions: Mobilization with intermediate-dose cytarabine plus G-CSF resulted in significantly higher CD34⁺ cell yields compared with G-CSF alone. Nevertheless, this regimen was associated with a higher incidence of hematologic toxicities, specifically neutropenia and thrombocytopenia. No significant differences were observed in the requirement for rescue mobilization.

POOR MOBILIZATION IN B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: CLINICAL CHARACTERIZATION, RESCUE STRATEGIES, AND THE LIMITED UTILITY OF CONVENTIONAL PREDICTORS

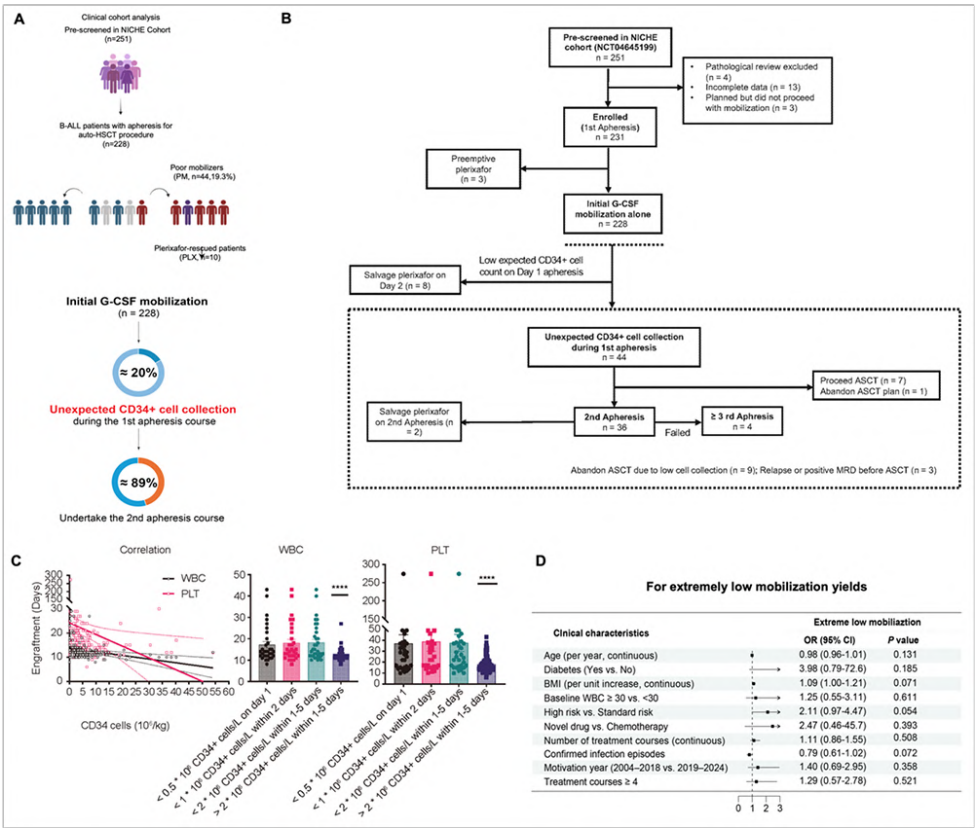
Hongye Gao[1], Yawei Zheng[1], Lisha Wang[1], Linjie Wu[1], Mengnan Lv[1], Shihui Ma[1], Jiali Sun[1], Xina Song[1], Weihua Zhai[1], Fang Dong[1], ***Erlie Jiang***[1]
[1]*Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Tianjin, China*

Background: While mobilization failure is well-documented in multiple myeloma and lymphoma, affecting 23–40% of patients, data regarding poor mobilization (PM) in acute lymphoblastic leukemia (ALL) remains scarce. As autologous stem cell transplantation (ASCT) relies on adequate graft collection, defining the epidemiology of PM and evaluating the efficacy of rescue strategies in ALL is critical for clinical decision-making.

Methods: We analyzed mobilization outcomes in 231 patients with B-ALL from the NICHE cohort undergoing their first G-CSF mobilization (10 μg/kg/day for ≤5 days) between 2004 and 2024. Three patients receiving preemptive plerixafor were excluded from the primary

analysis. We applied a hierarchical definition for poor mobilization: PM-I (<2×10⁶ CD34⁺ cells/kg within 5 days), PM-II (<1×10⁶ CD34⁺ cells/kg within 2 days), and Extreme Poor Mobilization (EPM; mean <0.5×10⁶ CD34⁺ cells/kg/day on day 1). Univariate logistic regression evaluated potential predictors of EPM, including age, sex, diabetes, prior chemotherapy exposure, and disease status. We further tracked rescue strategies and subsequent ASCT attrition rates.

Results: Among 228 patients managed with G-CSF alone, PM rates were unexpectedly high: 19.3% (44/228) met PM-I criteria, 17.5% (40/228) met PM-II, and 18.9% (43/228) were classified as EPM. These figures highlight a distinct mobilization challenge in ALL compared to other hematologic malignancies.
Of the 44 patients in the PM-I group, 36 (88.6%) attempted a second collection course using alternative strategies, primarily steady-state collection (52.8%) and bone marrow harvest supplementation (27.8%). Plerixafor was utilized in only 2.1% of cases. Ultimately, 9.1% of PM-I patients required ≥3 courses. Notably, ASCT attrition due solely to collection failure occurred in 3.9% (9/231) of the total cohort, exceeding attrition due to relapse or MRD positivity (1.3%).
Crucially, univariate analysis indicated that standard clinical variables—including age (P=0.38), diabetes (P=0.38), and number of prior chemotherapy cycles (P=0.52)—failed to predict EPM.



Conclusions: Poor mobilization is a frequent and significant barrier in B-ALL, often requiring complex rescue strategies such as bone marrow supplementation. The failure of conventional clinical factors to predict EPM suggests that mobilization outcomes in ALL may be driven by intrinsic marrow microenvironment dysfunction rather than broad systemic parameters.

MANUAL RED CELL DEPLETION IN PAEDIATRIC BONE MARROW TRANSPLANTATION: APPLICATIONS IN ALLOGENEIC AND AUTOLOGOUS SETTINGS

Ivana Ferrero[1], *Deborah Rustichelli*[1], *Sara Castiglia*[1], *Alessandra Mandese*[1], *Aloe Adamini*[1], *Roberto Albiani*[1], *Manuela Spadea*[1], *Valeria Ceolin*[1], *Vincenzo Apolito*[1], *Francesco Saglio*[1], *Franca Fagioli*[1]
[1]*Regina Margherita Children's Hospital, Turin, Italy*

Background: While mobilized hematopoietic stem cell (HSC) transplantation has largely supplanted bone marrow (BM) as the primary source of healthy progenitor cells, BM remains the preferred choice for unrelated donor transplantation in children and adolescents undergoing transplantation(1,2), due to a lower risk of graft-versus-host disease compared to peripheral blood stem cells, especially in children.
Red blood cell depletion (RBCD) is a critical step in AB0-incompatible transplantation, particularly in paediatric patients, where weight discrepancies can be an issue. Moreover, RBCD is essential in case of cryopreservation of autologous BM.
There are a few applicable methods for RBC and plasma depletion in BM as hydroxyethyl starch (HES/HAES) with centrifugation; Ficoll/ hypaque (F/H) gradient centrifugation, blood cell automatic processor (previous COBE system or newer Spectra Optia) (3). CD34+ recovery, product quality, and small collection volumes must be carefully balanced, especially in paediatric setting.
References

2. Passweg JR, et al. 2025.
3. Sawa M, et al. 2023.

Methods: We herein describe our experience with manual RBCD procedures in a paediatric Cell Processing Laboratory. Manual RBCD was carried out by density gradient centrifugation followed by controlled RBC/plasma removal. The method was previously validated according to a failure mode and effect analysis (FMEA) risk assessment.
The BM was transferred to a CPDA-1 (Citrate, Phosphate, Dextrose, and Adenine) quadruplex bag for whole blood collection with a preassembled Composampler system. The volume of RBCs to be removed was calculated based on the haematocrit, but allowing 10-20 ml of

residual RBCs to be safe. After centrifugation (2000 rpm for 15 minutes without brake), the bag was kept upright and the RBC were drained by gravity from the bottom tube. When necessary, some volume of plasma was removed by the upper tube. After manipulation, the process was evaluated in terms of feasibility, cell recovery, product quality, and suitability for paediatric patients. Cell viability and CD34+ recovery were determined by flow cytometry (DxFleX, Beckman Coulter) according to ISHAGE method. TNC recovery and RBC depletion were evaluated by automated haematology analysis (Xn-1000, Dasit).

Results: We analysed 52 BM allogeneic (related and unrelated) grafts, manipulated and infused in 40 patients, and 9 BM autologous grafts cryopreserved as a backup and not infused, collected from 2020 to 2025. After manual RBCD, the mean TNC recovery was 92.96% (SD 8.80), the mean CD34+ recovery was 93.65 %(SD 8.94) and the mean of RBC depletion was 75.08% (SD 8.32).

Conclusions: Although RBCD values are higher with automatic methods, up to 85% (3), compared to our data of 75.08%, the manual procedure allows for obtaining better results in terms of TNC and CD34+ recovery.
While the automated system offered advantages in terms of standardisation and reduced operator dependency, manual RBCD demonstrated greater flexibility and reliability when processing small-volume products. In several cases, manual RBCD provided superior control over product handling and recovery, particularly for collections below the optimal volume range of the automated system.
The manual RBCD technique remains a valuable and adaptable option when dealing with small or suboptimal volumes, often encountered with paediatric patients.

A304

IMPACT OF PRIOR DARATUMUMAB USE ON CD34+ CELL MOBILIZATION IN MULTIPLE MYELOMA PATIENTS ELIGIBLE FOR AUTOLOGOUS TRANSPLANTATION: SINGLE-CENTER EXPERIENCE

Carmen Gil Barroso[1], *Antonio José Palma Vallellano*[1], *Rocío Zapata Bautista*[1]
[1]*Hospital Juan Ramón Jiménez, Huelva, Spain*

Background: The use of Daratumumab in first-line therapy for multiple myeloma (MM) patients eligible for autologous transplantation has substantially improved the depth of response. However, some studies suggest lower mobilization efficacy or a greater need for rescue strategies (such as plerixafor) after its use. Our objective is to analyze the impact of prior Daratumumab treatment on CD34+ cell mobilization and collection performance, as well as the need for plerixafor.

Methods: We conducted a retrospective analysis of 100 MM patients undergoing 119 mobilization episodes between December 2013 and November 2025. The mean age was 57.63 ± 7.21 years, with 50% (N=50) men. We evaluated the impact of prior Daratumumab

exposure on CD34+ mobilization performance, number of apheresis sessions, and success rate (>2×10⁶ CD34+/kg). Daratumumab began to be used in our patients in 2022. Statistical tests used included Chi-square, Fisher's exact test, and Mann-Whitney U test.

Results: Of the 119 mobilization episodes analyzed, 22.7% (n=27) corresponded to patients who had received Daratumumab during induction (mean 3 ± 1.4 prior cycles), while 77.3% (n=92) had been treated with another chemotherapy regimen. There were no differences in sex or age distribution between groups (p=1; p=0.19). The clinical characteristics of each group can be seen in Table 1.
The distribution of mobilization regimens differed significantly between cohorts (p=0.001), mainly due to greater use of etoposide + G-CSF after its introduction in May 2022, a date close to the approval of Daratumumab in the first-line setting.
There were no differences in the number of mobilizations attempts between the two subgroups (p=0.079). However, patients exposed to Daratumumab required fewer apheresis sessions (p=0.034). Pre-apheresis CD34+/µL counts were similar between groups (p=0.44). Nevertheless, CD34+×10⁶/kg collected after the first apheresis was significantly lower in the Daratumumab group (p=0.007), with a lower success rate (p=0.004). In the subgroup mobilized with etoposide + G-CSF - where the distribution between patients exposed to Daratumumab and those not exposed was balanced (N = 11 vs 10) - no differences in success rate were observed (p=0.58). Plerixafor use was 44.4% in the Daratumumab group, with no significant difference vs controls (p=0.1).

DARATUMUMAB	YES	NO	p
Number of mobilizations	N = 27	N = 92	
Number of patients	N = 20	N = 82	
SEX - Male - Female	 N = 10 N = 10	 N = 41 N = 41	1
Mean Age	59.06 ± 5.31	56.52 ± 7.83	0.19
Mobilization Regimens - G-CSF - Cyclophosphamide 1.5 g/m² + G-CSF - Polychemotherapy + GCSF - Etoposide 375 mg/m² + G-CSF	 N = 13 N = 2 N = 1 N = 11	 N = 51 N = 30 N = 1 N = 10	< 0.001
Number of Mobilizations - 1 - 2	 N = 15 N = 4	 N = 74 N = 6	0.079

DARATUMUMAB	YES	NO	p
- 3 - 4	N = 0 N = 1	N = 2 N = 0	
Mean Pre-apheresis CD34/uL	59.02±64.54	54.8±38.06	0.44
Number of apheresis procedures - Not performed - 1 - 2 - 3	N = 5 N = 21 N = 1 N = 0	N = 10 N = 56 N = 24 N = 2	0.034
Mean CD34×10⁶/kg collected after the first apheresis	3.55±3.02	4.99±2.8	0.007
Number of CD34+ > 2×10⁶/kg - Yes - No	N = 16 N = 11	N = 78 N = 14	0.004
Plerixafor - Yes - No	N = 12 N = 15	N = 25 N = 67	0.102
Venous Access - Apheresis not performed - Central - Peripheral	N = 5 N = 1 N = 21	N = 10 N = 27 N = 55	0.009

Conclusions: According to our study, prior treatment with Daratumumab has not affected mobilization performance or increased the need for plerixafor, but it has been associated with a significant reduction in the success rate of CD34+ collection. Those exposed to Daratumumab required fewer apheresis sessions, probably due to the time difference between the two subgroups and the availability of a wider range of therapeutic options other than transplantation in recent years, which reduces the need to repeat apheresis to ensure success. Larger studies with the same median follow-up are needed due to sample size imbalance and temporal differences between groups.

ALLOGENEIC BONE MARROW HARVEST IN ADULT AND PEDIATRIC DONORS: A SINGLE-CENTRE EXPERIENCE

Jorge Verdejo de Antonio[1], *Paula Berigüete*[2], *Alba Gómez de la Flor*[1], *Montserrat Barrilero*[1], *Josune Zubicaray*[1], *Guzmán López de Hontanar*[1], *Alejandro Sanz Ruiperez*[3], *Ana Castillo*[1], *Ana de la Cruz*[1], *Almudena Galán*[1], *Mireya Homs*[1], *Raquel de la Calle*[1], *Ana Martín*[1], *Marta González Vicent*[1], *Julián Sevilla Navarro*[1], *Elena Sebastián*[1]
[1]*Hospital Infantil Universitario Niño Jesús, Madrid, Spain,* [2]*Hospital Clínico San Carlos, Madrid, Spain,* [3]*Hospital Universitario Puerta de Hierro, Majadahonda, Madrid, Spain*

Background: Bone marrow is the preferred graft source for non-neoplastic diseases because a graft-versus-tumor effect is not required and the goal is to minimize the risk of graft-versus-host disease (GVHD). Although this procedure has been standardized, differences in product quality still persist, influenced by technical aspects, collected volume and donor characteristics. We present the experience of a pediatric centre, focusing on safety and differences in product quality between pediatric and adult donors.

Methods: We retrospectively reviewed all allogeneic bone marrow harvests performed in our centre between 2009 and 2025. Demographic and clinical variables from donors and patients were collected, along with the different cellular subtypes of the product. A descriptive analysis of the data was performed, expressing quantitative variables as median and interquartile range and qualitative variables as frequencies and percentages. Comparison of variables by age was done using the Mann–Whitney U test, with $p < 0.05$ considered statistically significant. Data analysis was conducted in Python.

Results: Twenty-five collection procedures were done in that period but 22 were finally included in the analysis (3 were excluded because some data was missing). The median donor age was 16.5 years (10.75-25.75) with a median weight of 59 kg (37.5-78.5); 54.5% were male and 45.5% female. Fourteen donors (64%) were <18 years old. All donors were related (63.6% identical); 27.3% had minor ABO incompatibility, with none having major incompatibility. The most frequent indication for the procedure was acquired aplastic anemia (SAA) (54.5%). Most donors did not experience relevant adverse events (AEs), but 22.7% had AEs during the procedure and 10% after it, most of them being mild AEs. Only one donor required auto-transfusion after the procedure.
The median collected volume was 686.5 ml (533.25-965.75), with a median of 14.7 ml per donor´s kg (10.4-19.2). The median values for the different cell subtypes were total nucleated cells (TNC) 15,035/µl (12,039-19,568), 213.25 CD34+/µl (179.5-332.5), 2,370 CD3+/µl (1,940-2,827) and 1,152 CD19+/µl (669-1,486). Table 1 shows all demographic and technical variables.
Comparing the quality of the final product between the pediatric (<18-year-old) and adult populations, there were significant differences in the number of CD19+ cells in favour of the pediatric population (1337/µl vs 832/µl, $p=0.03$), whereas no differences were observed for CD3+, CD34+ and TNC. Figure 1.
All patients engrafted except for two: both of them had SAA and required an additional CD34+ boost.

Table 1. Demographic and technical characteristics (n=22)	
Age, median (range) **Pediatric donors (<18-y-o),** n (%)	16.5 (10.75-25.75) 14 (64%)
Weight, median (range)	59 (37.5-78.5)

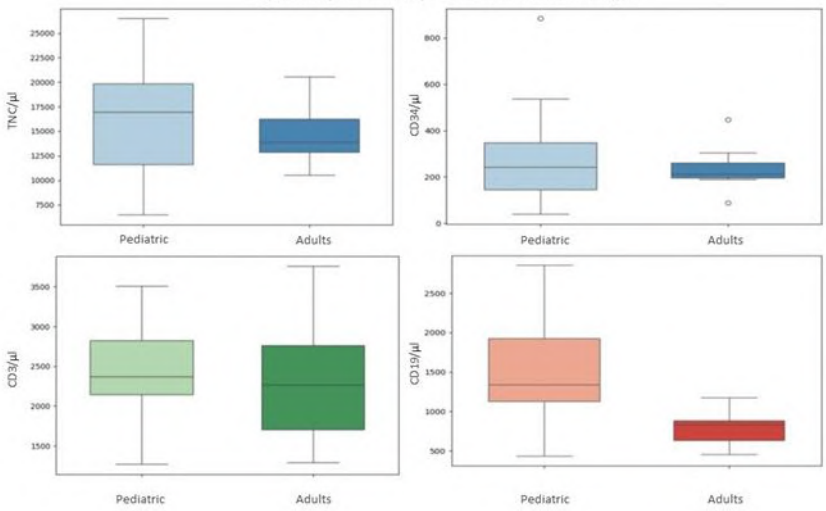
Adverse events during procedure, n (%) • Any • Hypotension • Minor bleeding • Anemia	 17 (77.3%) 3 (13.7%) 1 (4.5%) 1 (4.5%)
Adverse events after procedure, n (%) • Any • Back pain • Anemia	 20 (91%) 1 (4.5%) 1 (4.5%)
Positive harvest culture	1 (4.5%)
Harvest volume (ml), median (range)	686.5 (533.25-965.75)
Cell subtypes/µl, median (range) • TNC • CD34+ • CD3+	15,035 (12,039-19,568) 213.25 (179.5-332.5) 2,370 (1,940-2,827) 1,152 (669-1,486)

• CD19+			
Comparison between pediatrics and adults/µl, median	**<18 y**	**>18 y**	**P-value**
• TNC	16,960	13,882	0.616
• CD34+	242.15	213.25	0.868
• CD3+	2,370	2,266	0.860
• CD19+	1,337	832	0.030

Figure 1. Comparison between pediatric and adult harvest cell subtypes



Conclusions: This study describes the safety and characteristics of bone marrow harvests in a donor cohort at a pediatric centre. The procedure was safe in both pediatric and adult donors. Results show that there is a higher number of CD19+ cells/µl in the harvest product of the pediatric population compared with adults, with no differences observed in the other cell types analysed. However, studies with larger, multicentre cohorts are needed to determine the clinical significance of these findings.

Disclosure: Nothing to declare

A307

THE ROLE OF GRAFT CD3 AND TNC DOSES IN TRANSPLANT OUTCOMES: DOES IT STILL MATTER IN THE PTCY ERA?

*Asena Dikyar[1], **Emine Merve Savaş**[1], Cengiz Seven[1], Şahika Zeynep Akı[1], Ahmet Kürşad Güneş[1]*
[1]Etlik City Hospital Department of Hematology, Ankara, Turkey

Background: Graft cellular composition, particularly infused $CD3^+$ T-cell and TNC doses, has been implicated in transplant outcomes such as GVHD, relapse, and survival. Prior studies—largely from the pre-PTCy era—suggested a higher risk of GVHD with increasing $CD3^+$ cell doses, but their relevance in contemporary PTCy-based GVHD prophylaxis remains uncertain. We therefore evaluated the impact of infused $CD3^+$ and TNC doses on post-transplant outcomes in patients receiving PTCy-based GVHD prophylaxis.

Methods: Between May 2023 and October 2025, 116 allo-HSCT were performed at our center. Among these, 56 patients received PTCy-based GVHD prophylaxis with MUD, MMUD, or haploidentical grafts; after excluding three patients who died within the first 30 days, 53 patients were included in the analysis. Patients were stratified into low and high groups according to the median infused $CD3^+$ and TNC doses. Study endpoints included acute and chronic GVHD, CMV and BK virus reactivation, engraftment times, relapse rates, and overall survival.

Results: A total of 53 patients receiving PTCy-based GVHD prophylaxis were included, with a median age of 44 years (38–59). Transplant characteristics are summarized in Table 1. The median infused $CD34^+$, $CD3^+$, and TNC doses were 6×10^6/kg (5.4–6.5), 19×10^7/kg (13–26), and 11.7×10^8/kg (8.5–17.6), respectively. When stratified by the median CD3 dose, the incidence of CMV reactivation was similar between CD3-low and CD3-high groups (64% vs 67.9%), as were acute GVHD (48% vs 46.4%), chronic GVHD (24% vs 17.9%), and cumulative incidence of relapse (8% vs 17.9%). Platelet engraftment occurred earlier in the CD3-high group (median 13 vs 15 days; p=0.02) (Table 2).

TNC-based stratification likewise showed no significant differences in CMV reactivation (73.1% vs 59.3%), BK viruria (42.3% vs 33.3%), acute GVHD (38.5% vs 55.6%), chronic GVHD (19.2% vs 22.2%), or relapse (11.5% vs 14.8%) (Table 3). Figure 1 shows overall survival rates according to CD3 and TNC groups. Median OS was not reached in any subgroup, and no survival difference was observed between groups. Mean OS was 585 vs 552 days for CD3-low vs CD3-high (p=0.761) and 594 vs 542 days for TNC-low vs TNC-high (p=0.560).

Conclusions: In this study, infused $CD3^+$ and TNC doses were not associated with the incidence of acute or chronic GVHD, relapse, or overall survival. At our center, graft cell doses are maintained within a narrow target range. While pre-PTCy studies reported an increased GVHD risk with higher $CD3^+$ cell doses, and limited PTCy-era data suggest that extreme low or high $CD3^+$ or TNC doses may influence GVHD or relapse outcomes, our results suggest that, when extreme $CD3^+$ or TNC levels are avoided, PTCy-based GVHD prophylaxis may provide protection against GVHD largely independent of infused $CD3^+$ or TNC dose.

Disclosure: Nothing to declare.

A308

COMPARATIVE EVALUATION OF ADAMII IMAGE CYTOMETRY WITH TWO FLOW CYTOMETRY PLATFORMS FOR $CD34^+$ HEMATOPOIETIC STEM CELL ENUMERATION

Mirjana Milinković[1], *Zorana Kozić*[1], *Tamara Jovanović*[1], *Marija Vukčevic*[2], *Ivan Stanojević*[3], *Ivana Majstorovic*[3], *Milica Ćućuz*[3], *Dušan Vučetić*[1]
[1]*Institute for Transfusiology and Hemobiology, Military Medical Academy, Belgrade, Serbia,*

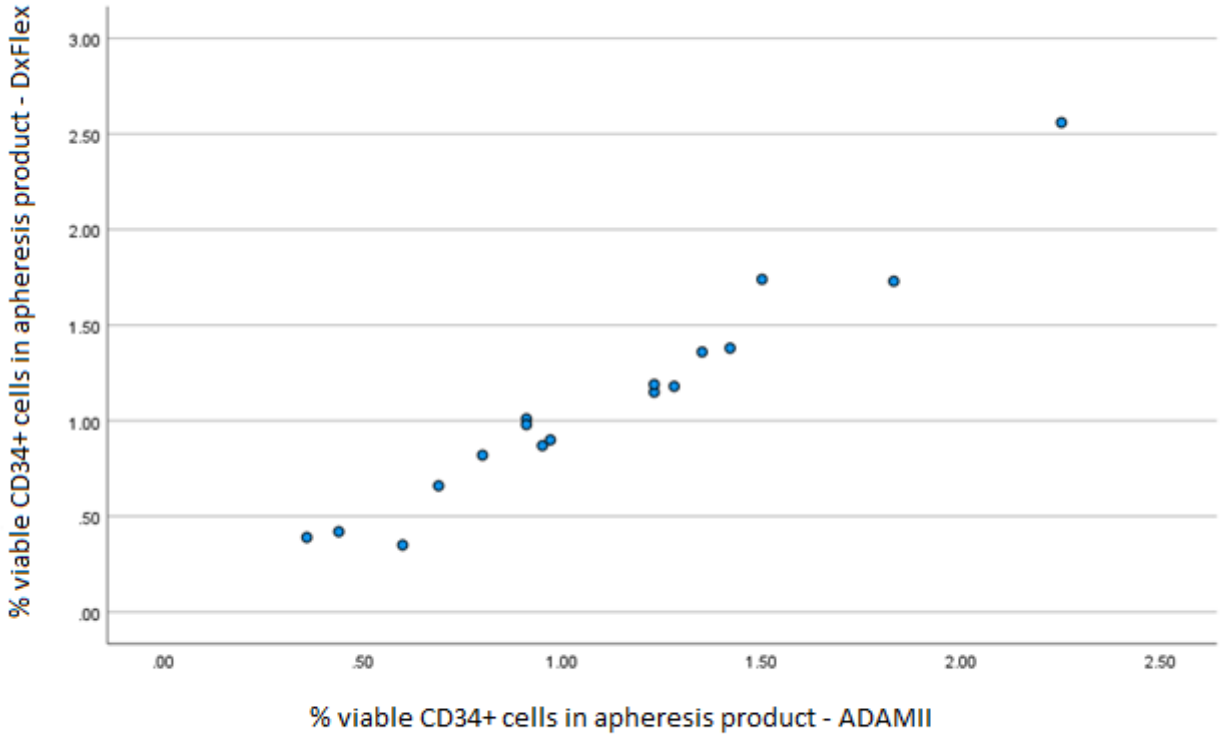
[2]Institute for Biocides and Medical Ecology, Belgrade, Serbia, [3]Institute for Medical Research, Military Medical Academy, Belgrade, Serbia

Background: Precise measurement of $CD34^+$ cells is essential for ensuring an adequate hematopoietic stem cell (HSC) dose for transplantation. The measurement should be performed quickly to predict the appropriate volume of apheresis product. The minimal number of CD34+ cells needed for Hematopoietic Stem Cell Transplantation (HSCT) to be successful is $2x10^6$ cells/kg of recipient body weight for autologous, and $4x10^6$ cells/kg for allogenic HSCT.

Methods: We quantified $CD34^+$ cells using the ADAMII image cytometer (NanoEntek, South Korea) in 14/11 peripheral blood samples and 22/17 apheresis products obtained from HSCT donors for comparison with Navios EX/DxFlex, Beckman Coulter Flow Cytometry platforms, USA. The viable $CD34^+$ cell counts enumerated on ADAMII were compared with the corresponding values from DxFlex flow cytometry, and total CD34+ counts were compared with corresponding values from BC Navios EX. The comparison between each of the two methods was done using Spearman or Pearson correlation analysis. The data were statistically processed in the IBM SPSS v27.0 program. The Shapiro Wilk test was used to determine the normality of the data distribution. Pearson's correlation analysis, Spearman's correlation analysis and the Mann Whitney U test were used to determine the statistical significance at the $p<0.05$ level.

Results: ADAMII demonstrated excellent correlation with both flow cytometry methods. Spearman's correlation analysis was performed ($p<0.05$), demonstrating a statistically significant, moderately strong, positive correlation between the percentage of total CD34+ cells measured by ADAMII and the percentage of total CD34+ cells in peripheral blood ($\rho=0.676$, $p=0.008$), and a statistically significant, strong, positive correlation between the percentage of total CD34+ cells in the apheresis product when compared with Navios EX ($\rho=0.973$, $p=0.000$). Spearman's correlation analysis was performed ($p<0.01$) showing statistically significant, strong, positive correlation between the percentage of viable CD34+ cells measured by ADAMII and the percentage of viable CD34+ cells in peripheral blood ($\rho=0.91$, $p=0.000$), and a statistically significant, strong, positive Pearson's correlation between the percentage of viable CD34 in the apheresis product when compared with BC DxFlex ($\rho=0.978$, $p=0.000$). The average number of CD34+ was $4,41x10^6$ cells/kg BW±0.46 per collection ($n=46$). Patients with multiple myeloma have significantly higher values of CD34+ cells in peripheral blood after mobilization, compared with patients suffering from lymphoma (Mann Whitney $U=6.00$, $p=0.047$). Female patients showed a significantly higher number of CD34+ cells in apheresis product per kg of body weight when compared to male

patients (Mann Whitney U=251.00, p=0.002).



Conclusions: The ADAMII image cytometry platform can be reliably employed for point-of-care quantification of CD34⁺ cells, enabling accurate prediction of the CD34⁺ cell number in samples of peripheral blood and apheresis products, prior to and throughout peripheral stem cell collection.

Disclosure: Nothing to declare.

DONOR SELECTION FOR HLA HAPLOTYPE-HOMOZYGOUS PATIENTS UNDERGOING CORD BLOOD TRANSPLANTATION

Noriyoshi Yoshinaga[1], *Junya Kanda*[1], *Makoto Iwasaki*[1], *Tomomi Toubai*[2], *Satoko Morishima*[3], *Makoto Murata*[4], *Naoyuki Uchida*[5], *Yoshiko Matsuhashi*[6], *Masatsugu Tanaka*[7], *Atsushi Wake*[8], *Fumihiko Ishimaru*[9], *Yoshiko Atsuta*[10], *Hideki Nakasone*[11]
[1]*Kyoto University, Kyoto, Japan,* [2]*Clinical Research and Trials Center, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo, Japan,* [3]*Central Japan*

Cord Blood Bank, Seto, Japan, [4]Shiga University of Medical Science, Otsu, Japan, [5]Federation of National Public Service Personnel Mutual Aid Associations TORANOMON HOSPITAL, Tokyo, Japan, [6]Kawasaki Medical School Hospital, Kurashiki, Japan, [7]Kanagawa Cancer Center, Yokohama, Japan, [8]Federation of National Public Service Personnel Mutual Aid Associations, Toranomon Hospital, Kawasaki, Japan, [9]Japanese Red Cross Blood Service Headquarters, Tokyo, Japan, [10]Japanese Data Center for Hematopoietic Cell Transplantation, Nagakute, Japan, [11]Jichi Medical University Saitama Medical Center, Saitama, Japan

Background: HLA haplotype homozygosity occurs in more than 1% of the Japanese population. For these patients undergoing cord blood transplantation (CBT), the optimal donor selection strategy remains unclear. Specifically, clinical outcomes have not been clearly compared among HLA-matched cord blood units (CBU), HLA-mismatched CBU without mismatch in the graft-versus-host (GVH) direction, and HLA-mismatched CBU with mismatch in the GVH direction.

Methods: We conducted a retrospective analysis using registry data from the Japanese Society for Transplantation and Cellular Therapy. The study included patients aged 16 years or older with HLA haplotype homozygosity who underwent their first CBT. We compared transplant outcomes among three donor groups: HLA-matched CBU (homo-to-homo), HLA-mismatched CBU without GVH-direction mismatch (hetero-to-homo GVH=0), and HLA-mismatched CBU with GVH-direction mismatch (hetero-to-homo GVH>0).

Results: The study cohort comprised 40 patients in the homo-to-homo group, 58 in the hetero-to-homo GVH=0 group, and 33 in the hetero-to-homo GVH>0 group. The 5-year overall survival rates were 25.6%, 38.7%, and 20.1%, respectively, with no statistically significant differences observed. However, multivariate analysis revealed that the hetero-to-homo GVH>0 group was associated with a significantly higher risk of non-relapse mortality (NRM) compared to the homo-to-homo group (adjusted hazard ratio [aHR] 2.27, p=0.034). Conversely, the risk of relapse was significantly lower in the hetero-to-homo GVH>0 group (aHR 0.46, p=0.031). No significant differences were observed in the incidence of acute GVHD, chronic GVHD, or neutrophil and platelet engraftment.

Conclusions: These findings suggest that donor selection for HLA haplotype-homozygous patients in CBT may be considered based on the patient's risk of relapse. In high-risk cases, selecting a donor with a mismatch in the GVH direction might offer a protective effect against relapse. However, the potential increase in NRM warrants careful consideration.

A310

COMPARATIVE CHARACTERISTICS OF CD3 DEPLETION AND ALPHA/BETA T CELL DEPLETION AS A GRAFT MANUFACTURING PLATFORM

Svetlana Glushkova[1], *Viktoria Vedmedskaya*[1], *Maria Fadeeva*[1], *Elvira Musaeva*[1], *Oyuna Lodoeva*[1], *Tatiana Sozonova*[1], *Maria Igonina*[1], *Vladislav Belchikov*[1], *Yakov Muzalevskii*[1], *Alexei Kazachenok*[1], *Larisa Shelikhova*[1], *Dmitriy Pershin*[1], *Michael Maschan*[1]
[1]*Dmitry Rogachev National Medical Research Center of Pediatric Hematology, Oncology and Immunology, Moscow, Russian Federation (the)*

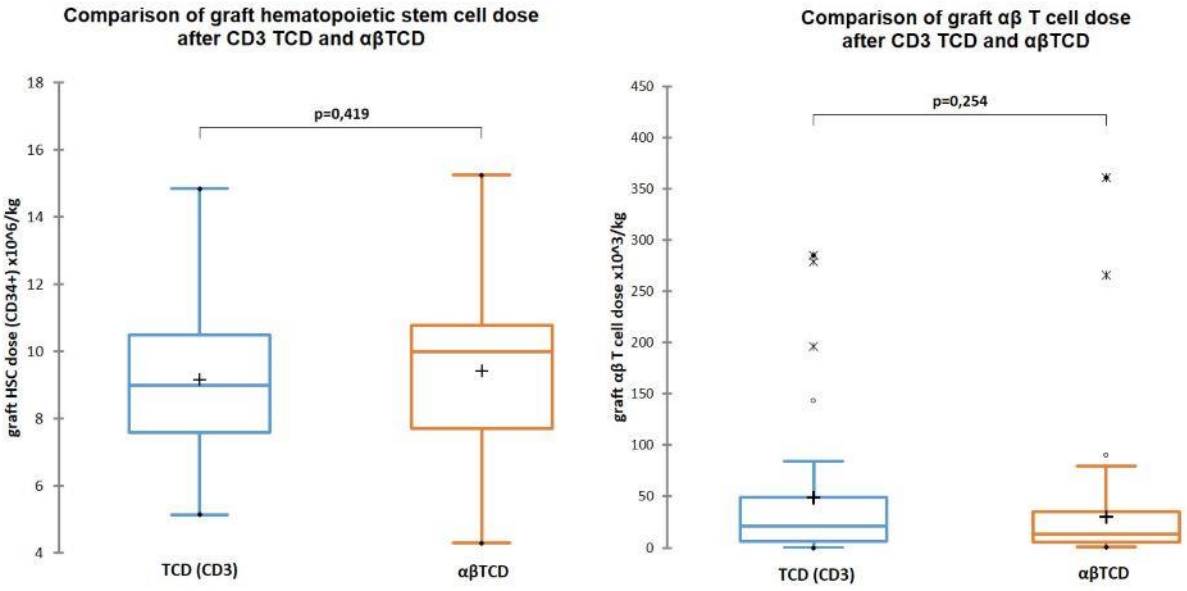
Background: T cell depletion method was developed to reduce the risks of severe graft-versus-host disease and other complications after the hematopoietic stem cell transplantation (HSCT). αβ T cell depletion (αβTCD) was implemented as a platform approach across different indications and donor types at the Dmitry Rogachev National Medical Research Center. Historically, CD3 T cell depletion (CD3TCD) was associated with somewhat inferior results in terms of depth of target population removal. Since 2024, we have used CD3TCD procedure based on reagent from CytoSinct™ to prepare grafts. The aim of this study was to investigate applicability and technical feasibility of CD3TCD in comparison to αβTCD.

Methods: The study cohort includes 33 patients transplanted from 06.2024 to 09.2025 with the help of CD3TCD method (CD3TCD group). CD3TCD group included patients with both malignant (27 patients, 82%) and non-malignant indications (6 patients, 18%). The median age at HSCT was 9.8 years (0.7-17.8). Donors were either haplo-identical related (28 HSCTs) or fully-compatible unrelated (4 HSCTs), one patient received HSCT from fully-compatible related donor. The grafts were processed using magnetic monoclonal antibodies CytoSinct™ CD3 Nanobeads (human) and CytoSinct™ 1000 Depletion Tubing Set (GenScript, China). CD3TCD was performed on a CliniMACS® Plus device (Miltenyi Biotec, Germany) using the standard Depletion 3.1 program. The starting material was prepared by the peripheral blood leukocyte apheresis. CD3TCD quality control was carried out by standardized flow cytometry. We compared the results with the retrospective data of 68 grafts processed by αβTCD with Miltenyi Biotec reagents and tubing set on CliniMACS® Plus device from 2015 to 2020 (αβTCD group). The number of graft cells per kg were compared by Mann–Whitney U-test.

Results: CD3TCD method demonstrated high reproducibility; all grafts were processed successfully without technical failures. The graft cells had high viability – 98% (93%-99%), the yield viable hematopoietic stem cells (HSC) was 89% (58%-100%), the median CD3 cells depletion logarithm was 3.5 (2.3-5.1). The median cell dose per kilogram was $9*10^6$ ($5*10^6$-$15*10^6$) for HSC and $21*10^3$ (0-$286*10^3$) for αβ T cells. The graft composition is shown in Table1. The residual T cell population was dominated by γδ+ T cells, while αβ+ T cells content was lower ($p<0.0001$). The comparison of the CD3TCD group graft composition with αβTCD group showed no significant difference in cell dose of HSC and αβ T cells per kilogram (the median cell dose per kilogram was $10*10^6$ ($4.3*10^6$-$15*10^6$) for HSC and $13*10^3$ ($1*10^3$-$361*10^3$) for αβ T cells in αβTCD group), p-value was 0.419 and 0.254, respectively, Picture1. No episodes of acute toxicity were identified at transplant transfusion.

The engraftment characteristics were consistent with the expected time for the ex-vivo depletion method.

	GRAFT COMPOSITION /kg				
Statistic	NC x 10^8	HSC x10^6	T cells x10^6	αβ T x10^3	
Minimum	1.7	5.2	0.003	0.000	
Maximum	17.9	14.8	7.2	285.5	
1st Quartile	5.8	7.6	0.05	6.2	
Median	7.6	8.9	0.13	21.0	
3rd Quartile	10.5	10.5	0.42	49.0	



Conclusions: CD3TCD with CytoSinct™ detection reagent and CytoSinct™ tubing set by GenScript on the CliniMACS® Plus device by Miltenyi Biotec is implementable and ensures the production of a graft product with target CD3 content. αβ T cell and HSC graft dose after CD3TCD are comparable with αβTCD.

A311

ANALYSIS OF CLINICAL AND PROCEDURAL FACTORS ASSOCIATED WITH SUCCESSFUL COLLECTION OF CD34+ HEMATOPOIETIC PROGENITOR CELLS

Carmen Gil Barroso[1], *Antonio José Palma Vallellano*[1], *Rocío Zapata Bautista*[1]
[1]*Hospital Juan Ramón Jiménez, Huelva, Spain*

Background: Despite therapeutic advances in multiple myeloma (MM), high-dose chemotherapy followed by autologous hematopoietic stem cell transplantation remains the first-line treatment for eligible patients. Mobilization of CD34+ cells may be performed with G-CSF alone or combined with chemotherapy, without conclusive differences between regimens according to the literature. Our objective was to analyze the potential influence of mobilization regimens, complementary use of plerixafor, and type of vascular access on collection success.

Methods: A retrospective analytical study included 119 mobilization attempts in 100 MM patients between 2013 and 2025 in a single center. Mobilization failure was defined as a pre-apheresis peripheral blood CD34+ count below 10 CD34+/µL. Apheresis was performed using the Amicus Femwall separator, with success defined as collection of >2×10⁶ CD34+/kg post-apheresis. We evaluated the influence of mobilization regimen, plerixafor use, and vascular access type. Statistical analyses included Kruskal-Wallis for nonparametric data, Wilcoxon for paired comparisons, and Fisher's exact or Chi-squared tests for categorical variables.

Results: The mean age was 57.63 ± 7.21 years, with 50% (N=50) men. Mobilization regimens were: G-CSF in 53.8% (N=64), cyclophosphamide 1.5 g/m² + G-CSF in 26.9% (N=32), poly-CT + G-CSF in 1.7% (N=2), and etoposide 375 mg/m² + G-CSF in 17.6% (N=21). First mobilizations accounted for 83.2% (N=99). Mean pre-apheresis CD34+/µL was 55.7 ± 45.14, with no significant differences between regimens (p=0.053).
Apheresis was not performed in 12.6% (N=15) of cases due to CD34+ <10/µL. Among the remaining 104 episodes, 21% (N=25) required two apheresis procedures and 1.7% (N=2) three. Mean CD34+ collected in the first apheresis was 4.69 ± 2.89 ×10⁶/kg, with a maximum of 15.43 ×10⁶/kg. Overall success rate was 79% (N=94). No association was found between mobilization regimen and number of apheresis sessions (p=0.757) or final success (p=0.075).
Significant differences were found regarding plerixafor use (p=0.047), with less use in the etoposide + G-CSF group. Although plerixafor use was not associated with final success (p=0.55), paired analysis showed a significant increase in pre-apheresis CD34+/µL following administration (p<0.001), with a mean increment of 31.78 ± 25.94 CD34+/µL. Regarding vascular access, 73% (N=76) used peripheral access and 26.9% (N=28) central access. No significant differences were found in success based on venous access (p=0.059).

	TOTAL MOBILIZATIONS	G-CSF	CYCLOPHOSPHAMIDE + G-CSF	POLYCHEMOTHERAPY + G-CSF	ETOPOSIDE + G-CSF	p
Nº of mobilization episodes	100% (N = 119)	53.8% (N = 64)	26.9% (N = 32)	1.7% (N = 2)	17.6% (N = 21)	
Mean pre-apheresis CD34+ count (CD34+/ µL)	55.7 (DS 45.14)	50.54 (DS 36)	53.37 (DS 41)	11.5 (DS 12)	79.53 (DS 65)	0.053
Nº of apheresis: - Not performed - 1 - 2 - 3	12.6% (N = 15) 64.7% (N = 77) 21% (N = 25) 1.7% (N = 2)	10.9% (N = 7) 62.5% (N = 40) 23.4% (N = 15) 3.1% (N = 2)	15.6% (N = 5) 62.5% (N = 20) 21.9% (N = 7) 0% (N = 0)	50% (N = 1) 50% (N = 1) 0% (N = 0) 0% (N = 0)	9.5% (N = 2) 76.2% (N = 16) 14.3% (N = 3) 0% (N = 0)	0.75
Mean CD34+ Yield from 1st apheresis (CD34+ x10^6 /Kg)	4.69 (DS 2.89)	4.45 (DS 2.81)	5.15 (DS 2.24)	0.6	4.96 (DS 3.8)	0.15
Apheresis Success - Yes - No	79% (N = 94) 21% (N = 25)	76.6% (N = 49) 23.4% (N = 15)	84.4% (N = 27) 15.6% (N = 5)	0% (N = 0) 100% (N =2)	85.7% (N = 18) 14.3% (N = 3)	0.075

	TOTAL MOBILIZATIONS	G-CSF	CYCLOPHOSPHAMIDE + G-CSF	POLYCHEMOTHERAPY + G-CSF	ETOPOSIDE + G-CSF	p
Plerixafor Use - Yes - No	31.1% (N = 37) 68.9% (N = 82)	39.1% (N = 25) 60.9% (N = 39)	31.3% (N = 10) 68.8% (N = 22)	0% (N =0) 100% (N =2)	9.5% (N = 2) 90.5% (N = 19)	0.047
Venous access - Not performed - Central - Peripheral	(N = 15) 26.9% (N = 28) 73% (N = 76)	(N = 7) 28% (N = 16) 72% (N = 41)	(N = 5) 33.3% (N =9) 66.6% (N = 18)	(N = 1) 0% (N = 0) 100% (N =1)	(N = 2) 15.7% (N = 3) 84.3% (N = 16)	0.53

Conclusions: Mobilization in MM showed a high success rate regardless of regimen, supporting decisions based on logistics and tolerability. Plerixafor demonstrated utility as a rescue strategy by significantly increasing CD34+ counts, though without direct impact on apheresis success. Finally, although approaching statistical significance, we did not demonstrate any differences according to the type of venous access. Overall, results highlight the importance of an individualized approach to optimize collection in autologous transplant programs.

DIRECTED SIBLING CORD BLOOD BANKING : FOURTEEN YEAR EXPERIENCE IN NHS BLOOD AND TRANSPLANT (NHSBT)

Rachel Pawson[1], *Adaora Chukwu*[1], *Olga Cetnik*[1], *Steve Bowen*[1], *John Girdlestone*[1], *Kirsty Sharplin*[1], *Beki James*[2], *Jon Smythe*[1], *Gurman Kaur*[1]
[1]*NHS Blood and Transplant Oxford Centre, Oxford, United Kingdom of Great Britain and Northern Ireland (the),* [2]*Leeds Children's Hospital, Leeds, United Kingdom of Great Britain and Northern Ireland (the)*

Background: Matched related donors remain the preferred source of stem cells (SCs) for transplantation. However, paediatric donors cannot donate until they are above a certain

weight or age allowing safe bone marrow (BM) collection. Delaying transplants is not feasible for haematological malignancies and may worsen outcomes for non-malignant conditions. Directed cord blood (DCB) collection provides an alternative source of SCs from siblings. NHSBT has offered DCB collection, processing and storage since 1997. We describe the experience of the programme from 2010 - 2023.

Methods: 531 DCB collections were received in NHSBT processing facilities.

Results: Main disease indications were: acute leukaemia (155), haemoglobinopathy (129), primary immune deficiencies (114), bone marrow failure syndromes (59). 75 DCB units (DCBUs) were discarded because of low volume (<50mls) or cell count (TNC <2.5 x 10^7). 38 bacterially-contaminated collections were banked to be considered for concessionary release if needed for transplant.
Of the banked collections (n=456), medians were: volume 74 mls (range 18-243); TNC 61 x 10^7 (range 1-347); CD34 count 14.2 x 10^5 (range 0.1-243); CD34 viability 99.2% (range 66.9-100%).
Twenty-one DCBUs (4.6% of banked DCBUs) were issued for SC transplantation. Recipients from 3 months to 11 years (median 6 yrs) had haemoglobinopathy (11), bone marrow failure (BMF) (5), myeloproliferative disease (2), ALL (2) and inherited disorders of metabolism (1). Median time of DCBs in storage prior to transplant was 25 months (range 56 days - 61 months). All were 10/10 HLA matches. The cell content of DCBUs transplanted is shown in Table 1. In 10/21 (48%) cases (8 haemoglobinopathy, 2 BMF), BM from the DCB sibling donor was infused at the same time as the DCBU.
Outcome data was available in 17 cases, all alive after median follow up of 9 years (range 2 yrs-12 yrs). Neutrophil engraftment occurred at median of 19 days (range 10-32) and platelet engraftment at median of 32 days (range 16-68 days) in 14 cases. A further 3 cases were reported to have engrafted. PB chimerism was reported in 8 cases, all being 100% donor. All haemoglobinopathy patients were transfusion independent. One patient with myeloproliferative disease relapsed at 9 months and had a mismatched unrelated donor transplant and is in remission 5 years on. Two patients with thalassaemia had grade 3 acute GVHD, one progressing to mild chronic GVHD which fully resolved.

Table 1. Characteristics of DCBUs and Recipients Receiving DCBUs Alone or in Combination with Sibling Donor BM

	Source of Stem Cells Infused *	
	DCBU alone (n=6)	**DCBU plus BM (n=10)**
Recipient age	3.5 yrs (2 to 10 yrs)	9 yrs (3 - 11 yrs)
Recipient weight	17.2 kg (15.2 to 44.6 kg)	24.6 kg (13.2 to 45.8 kg)
DCBU TNC dose infused: median (range)	7.8 x 10^7/kg (3.8-21.2)	1.64 x 10^7/kg (0.66-7.2)
DCBU CD34 dose infused: median (range)	1.26 x 10^5/kg (0.98-11.5)	0.48 x 10^5/kg (0.11-1.8)

Neutrophil engraftment: median (range)	18 days (15-32) (n=3)	16 days (10-28) (n=10)
Platelet engraftment: median (range)	42 days (21-50) (n=3)	31 days (16-68) (n=10)
Sibling donor age at BM donation	Not applicable	26 months (16-30 months)
*Data missing in 4 cases; 1 further case – DCBU given with mesenchymal stromal cells.		

Conclusions: DCB donations can provide a useful number of TNC and viable CD34 cells comparable to CBUs available in public banks. Overall usage was low as most were collected for a sibling with acute leukaemia, the majority of whom will not need a transplant. A higher proportion (11/129 = 8.5%) of collections for haemoglobinopathy was used, some supplemented with a BM donation. Additional information to assess the contribution of the DCBU will be sought. Transplants using DCBUs demonstrated favourable outcomes, with no graft failures and minimal GVHD, underscoring the utility of the collection programme.
Thanks to: transplant teams for outcome data; NHSBT laboratory colleagues.

A313

COMPARATIVE ANALYSIS OF MOBILIZATION REGIMENS AND THEIR IMPACT ON STEM CELL YIELD AND ENGRAFTMENT KINETICS IN PATIENTS UNDERGOING AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION: RETROSPECTIVE STUDY

Sidra Zafar[1], Hammad Javed[1], Tariq Ghafoor[1], ***Bushra Ahsan***[2]*, Nighat Shahbaz[1], Mehreen Ali Khan[1], Tariq Khattak[1], Jahanzeb Rehman[1], Raheel Iftikhar[1]*
[1]Armed Forces Bone Marrow Transplant Center, Rawalpindi, Pakistan, [2]Shaukat Khanum Memorial Cancer Hospital & Research Centre, Lahore, Pakistan

Background: For successful autologous stem cell transplantation sufficient mobilization of CD34+ is required, still some of the patients responds poorly to GCSF alone. Plerixafor can improve mobilization, but still local data on its efficacy is limited that emphasizes the necessity for real-world outcome studies. Therefore, the aim of the study is to compare the effectiveness of plerixafor based and non plerixafor based mobilization to achieve optimal stem cell yield and engraftment kinetics among various hematological malignancies.

Methods: For the following retrospective cross-sectional study, purposive sampling technique was performed. The study was conducted at Armed forces bone marrow transplant center where, patients who underwent autologous stem cell transplant between 2021-2025 were included. Patients mobilized with plerixafor based protocol or without plerixafor-based protocol were both eligible. Clinical records were reviewed to record observational data, diagnosis, mobilization regimen, stem cell yield, and engraftment outcomes. For stem cells

yield ≥2 × 10^6 $CD34^+$ cells/kg and ≥2–3 × 10^8 MNC/kg was considered successful engraftment. Neutrophil engraftment was defined as an ANC ≥0.5 × 10^9/L for three consecutive days usually achieved during 9 to 12 days whereas platelet engraftment was with counts ≥20 × 10^9/L without transfusion support is considered to achieve during 12 to16. Ethical approval was obtained from the institutional review board, and informed consent was taken from all participants. Statistical analysis was performed using SPSS version 27.

Results: A total of 137 patients were included in the study who underwent autologous stem cell transplantation with mean age 41.3±16 years, among them 66% were males and 34% were females. Multiple myeloma (54%) was the most common diagnosis followed by HL (28.5%), NHL (8.8%) and DLBCL (8.8%). Plerixafor based mobilization was used in 72.3% of the patients in comparison to non Plerixafor based mobilization 27.7%. Mean neutrophil engraftment was achieved at 11.2±1.9 days while platelet engraftment was achieved at 15.5±9.3 days respectively. The Plerixafor group achieved higher CD34+ yields (5.34±3.36 vs. 4.15±1.72; p=0.003) and higher MNC doses (7.41±2.94 vs. 5.26±2.43; p=0.46) **(Table 1)**. However there was a trend towards early Neutrophil engraftment (p=0.09) in plerixafor arm, while platelet engraftment occurred earlier with plerixafor (p=0.001) across diagnostic groups.

Table 1: Comparison of Engraftment Kinetics and Stem Cell Yield Between Patients Mobilized with and without Plerixafor.

Stem cells and engraftment kinetics	Mobilization with no plex	Mobilization with Plex	p-value	95% Confidence Interval of the Difference	
				Lower	Upper
Engraftment Kinetics					
Day-Neutrophil Engraftment	11.24±1.383	11.23±2.075	0.613	-0.720	0.744
Day-Platelet Engraftment	16.84±13.668	14.99±6.856	**0.051***	-1.775	5.473
Stem cells Yield					
MNC Dose given (x10^8/Kg)	5.26±2.435	7.41±2.945	0.465	-3.577	-0.725
CD34 Dose given (x10^6/Kg)	4.157±1.727	5.341±3.362	**0.003***	-2.31700	-0.04964

Engraftment patterns varied by diagnosis, with DLBCL showing the slowest platelet recovery

and MM achieving the highest CD34+ cell dose. Overall survival among the participants was 91% while disease free survival was observed as 81.9% across all disease groups **(Figure 1)**

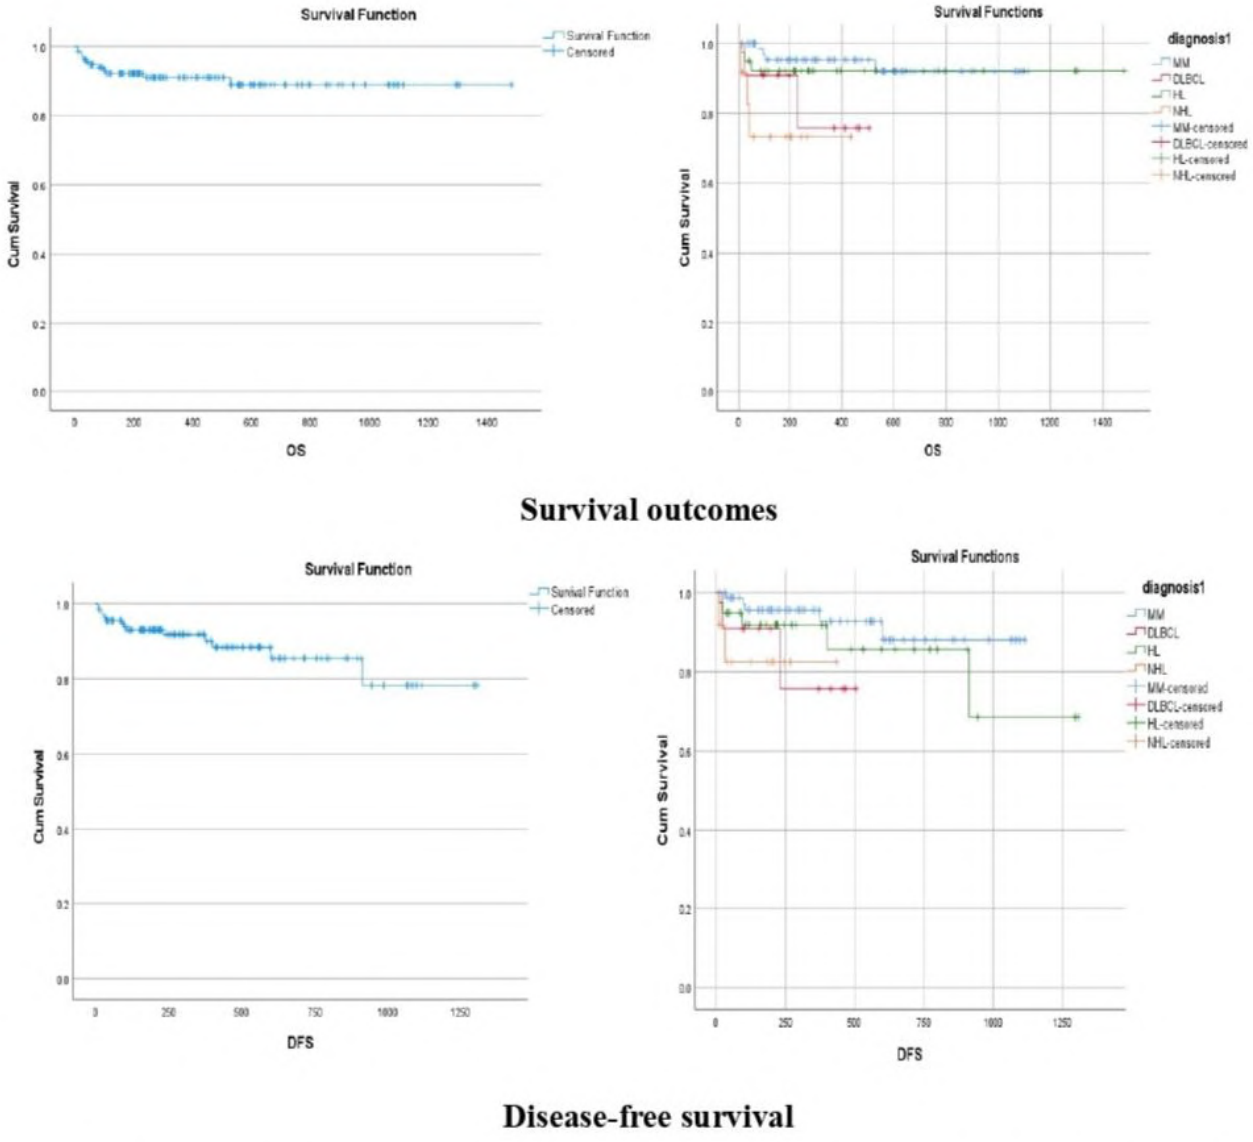

Figure 1. Survival and disease-free survival outcomes among patients with different diagnoses.

Conclusions: Compared to non plerixafor based mobilization, plerixafor based mobilization significantly increased the stem cell production and accelerated the platelet recovery. Overall, both strategies produced high survival rates for all disease groups and equivalent neutrophil engraftment.

Disclosure: Nothing to declare

A314

LEUKAPHERESIS FOR PROGENITOR CELL COLLECTIONS IN LOW WEIGHT CHILDREN: REPORT FROM A SINGLE PEDIATRIC CENTER

Jorge Verdejo de Antonio[1], *Guzmán López de Hontanar*[1], *Josune Zubicaray*[1], *Elena Sebastián*[1], *Ana Torre*[1], *Josefa Navarrete*[1], *Rocío Rico*[1], *Ana Castillo*[1], *Blanca Molina*[1], *Sara Vinagre*[1], *Ana de la Cruz*[1], *Almudena Galán*[1], *Álvaro Lassaletta*[1], *Manuel Ramirez Orellana*[1], *Marta González - Vicent*[1], *Julián Sevilla*[1]
[1]*Hospital Infantil Universitario Niño Jesús, Madrid, Spain*

Background: The aim of this study was to assess the performance of the Spectra Optia Apheresis System for collecting peripheral blood progenitor cells (PBPC) in low weight children with respect to collection variables, and CD34+ cells harvest prediction.

Methods: We retrospectively analyzed all procedures performed with that device in our institution, in children with a body weight below or equal to 20 kilograms, collect variables related with the procedure, and adverse events reported. Collection efficiencies were calculated as follows: CE1(%)= CD34+cells collected/((CD34+cells pre-apheresis in PB + CD34+cells post-apheresis)/2)×total blood volumen processed ×100; and CE2(%)= CD34+cells collected/(CD34+cells pre-apheresis in PB×total blood volumen processed) ×100. Apheresis were performed on a Spectra Optia device (Terumo BCT) using either the continuous mononuclear cell collection program (CMNC) or the mononuclear cell collection program (MCN). Central venous catheters were used for all procedures. Adverse events related to the mobilization and the collection were recorded by the nurse in charge during the process.

Results: A total of 105 apheresis from 82 children (62.2% male) were included (diagnosis presented in table 1). The median age was 2 years (interquartilic range (IQR) 1 – 4). The median weight was 14 kg (IQR 11.5 – 16), with the lower weight being 6 kg, and the median total blood volume (TBV) was 1107 mL (IQR 900 – 1284). The median number of TBV processed was 3.2 (IQR 2.8 – 4). The median CD34+ cell count per microliter pre-apheresis was 53 (IQR 26 – 98.5). Median CD34+ cell/kg collected was 4.98×10^6 (IQR 2.69×10^6 – 9.23×10^6). Median CE1 was 49.4% (IQR 39.35 – 60.05), and median CE2 was 39.6% (IQR 31.85 – 47.85).
As previously reported, CD34+ cell/kg collected were related to higher CD34+ cells pre-apheresis ($p<0.0001$), prior chemotherapy and radiotherapy, mobilization schedule (with higher collections using chemotherapy as mobilization agent), and healthy donor or patient status ($p<0.05$).
CE1 and CE2 were related to CD34+ cells pre-apheresis with those procedures with lower counts before the collection having better CEs. CE1, although not statistically related with prior purging of the device, showed clear trend toward significance ($p=0.053$).
Adverse events (AEs) were mostly related to the mobilization with 25.7% of children suffering some; 3% of children had more than 3 AEs related to the mobilization with low

grade fever being the most frequent one (11.9%). During the apheresis, children only presented mild cardiovascular manifestations; these AEs were recorded in 53.9% of children with mild tachycardia in all of them, and in 13.7% presenting with paleness. Median platelet loss was 40.6% (IQR 35.45 – 48.93), and median hematocrit loss was 1% (IQR -1.5 – 4). No procedures had to be canceled or interrupted due to AEs.

Table 1. Diagnosis of the 80 children

Diagnosis	N	**%**
Healthy donor	15	18.3
Neuroblastoma	21	25.6
Central nervous system tumor	20	24.4
Hurler syndrome	8	9,8
Fanconi Anemia	6	7,3
Nefroblastoma	4	4.9
Osteopetrosis	3	3.7
Non Hodgkin Lymphoma	2	2.4
Manosidosis	1	1.2

Conclusions: The Spectra Optia Apheresis System for collecting PBPC is safe for low weight children. Collection efficiencies are related to the peripheral blood CD34+ cell count before the procedure. CD34+ cells/kg can be predicted by several patient characteristics.

Disclosure: Nothing to declare.

A315

NO SIGNIFICANT IMPACT OF GRAFT CD34+/CD3+ RATIO ON TRANSPLANT OUTCOMES AFTER POST-TRANSPLANTATION CYCLOPHOSPHAMIDE-BASED HAPLOIDENTICAL PERIPHERAL BLOOD STEM CELL TRANSPLANTATION

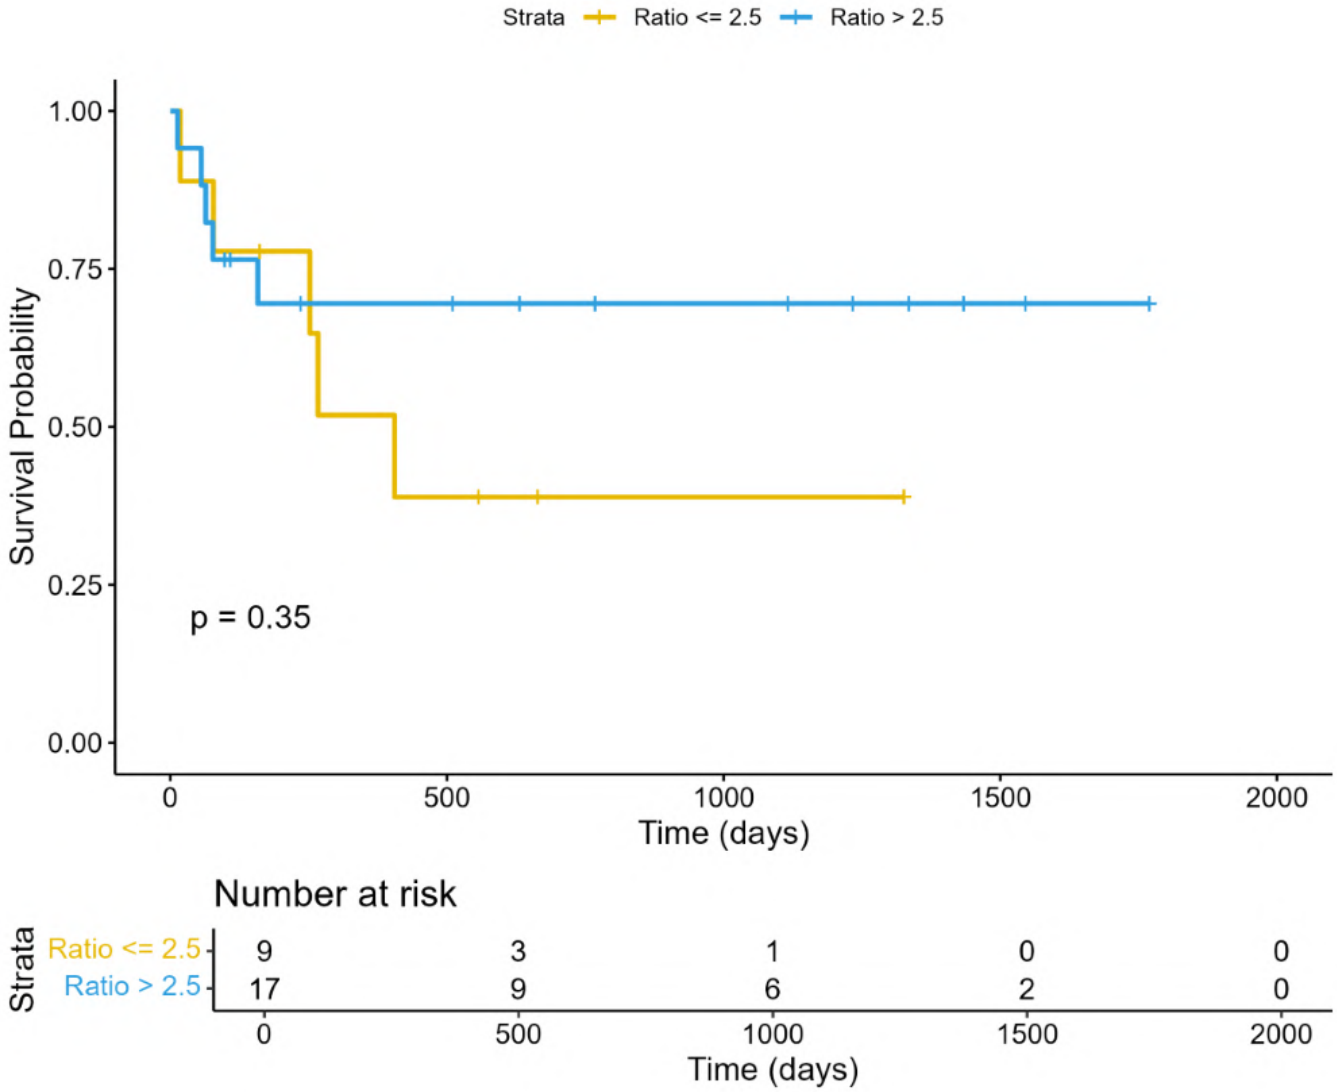
Nadia Bambace[1], *Ariel Perez Perez*[1], *Lyle Feinstein*[1], *Yuliya Linhares*[1], *George Nahas*[1], *Marco Ruiz*[1], *Tiba Al Sagheer*[1], *Munnezzah Khan*[1], *Rafael Barrero Ravelo*[1], *Ning Sun*[2], *Guenther Koehne*[1], *Harold Alvarez*[1]
[1]*Miami Cancer Institute, Miami, United States of America (the),* [2]*Baptist Health South Florida, Miami, United States of America (the)*

Background: Post-transplantation cyclophosphamide (PTCy)-based haploidentical peripheral blood stem cell transplantation (PBSCT) is widely used for patients lacking HLA-matched donors. The optimal graft composition and cell doses for this alloHSCT platform remains an unanswered question. We sought to investigate the impact of graft composition variables including CD34/CD3 ratio on major clinical transplant outcomes.

Methods: We retrospectively analyzed consecutive adults who underwent related haploidentical PBSCT at our institution between December 2020 and September 2025. Patients received peripheral blood stem cell (PBSCs) grafts and uniform GVHD prophylaxis with post-transplant cyclophosphamide (40-50 mg/kg/day on day +3-4), tacrolimus (n=25) or sirolimus (n=1) and mycophenolate mofetil. Graft composition was quantified by flow cytometry. Cox regression analyses were performed to evaluate the effect of cell doses (CD34 reported as x 10^6/kg and CD3 as x 10^8/kg) and CD34/CD3 ratios on clinical outcomes. For CD34/CD3 ratio a cut-off of > 2.5 versus ≤ 2.5 was used based on prior report by Katagiri et. al. (Blood 2024). Given the paucity of grade III/IV acute GVHD events in this small cohort, a modified GVHD-free, relapse-free survival (GRFS) definition was utilized. A GRFS event was defined as Gr>=2 acute GVHD, chronic GVHD warranting immune suppressive therapy, disease relapse or death from any cause. Time-to-event outcomes were measured from graft infusion (day 0). OS, RFS and GRFS were estimated by the Kaplan–Meier method.

Results: A total of 26 alloHSCT recipients were included. Median age was 61 years (range 19–74), and 20 patients (77%) were male; 17 patients (65%) were Hispanic. Underlying diagnoses included AML (n = 15), ALL (n = 5), MDS (n = 3), CMML (n = 1) and T-cell lymphoma (n = 2); 22 patients (85%) were in complete remission at transplant. Fifteen patients (55%) received reduced-intensity conditioning of which 67% received Fludarabine-Melphalan +TBI 200cGy. Median CD34+ and CD3+ doses were 7.39 ×10^6/kg (range 6.29–9.37) and 1.95 ×10^8/kg (range 1.81–2.96), with median CD34/CD3 ratio 4.10 (range 2.37–4.97). Median follow-up was 11 months. One-year OS and RFS for the entire cohort were 63% (95% CI 46–86) and 80% (95% CI 64–100); modified GRFS at 1 year was 20% (95% CI 9–47). Patients with CD34/CD3 ratio > 2.5 had numerically higher 1-year RFS (84% vs 71%; p= 0.57) and OS (70% vs 52%; p= 0.36) than those with CD34/CD3 ≤ 2.5, but these differences were not statistically significant. The CD34/CD3 ratio did not influence modified GRFS (HR 1.40, 95% CI 0.53-3.71; p=0.5).

Figure I: Overall survival according to graft CD34/CD3 ratio



Conclusions: In this predominantly Hispanic cohort of PTCy-haplo-PBSCT, a higher graft CD34/CD3 ratio was not significantly associated with superior 1-year OS, RFS or modified GRFS. Within the range of graft doses delivered at our institution, higher CD3+ content, reflected in lower CD34/CD3 ratios, did not appear to adversely affect transplant outcomes, supporting the concept that PTCy abrogates the adverse impact of high CD3 graft content. Larger multicenter analyses are required to define optimal graft composition in PTCy haploidentical PBSCT.

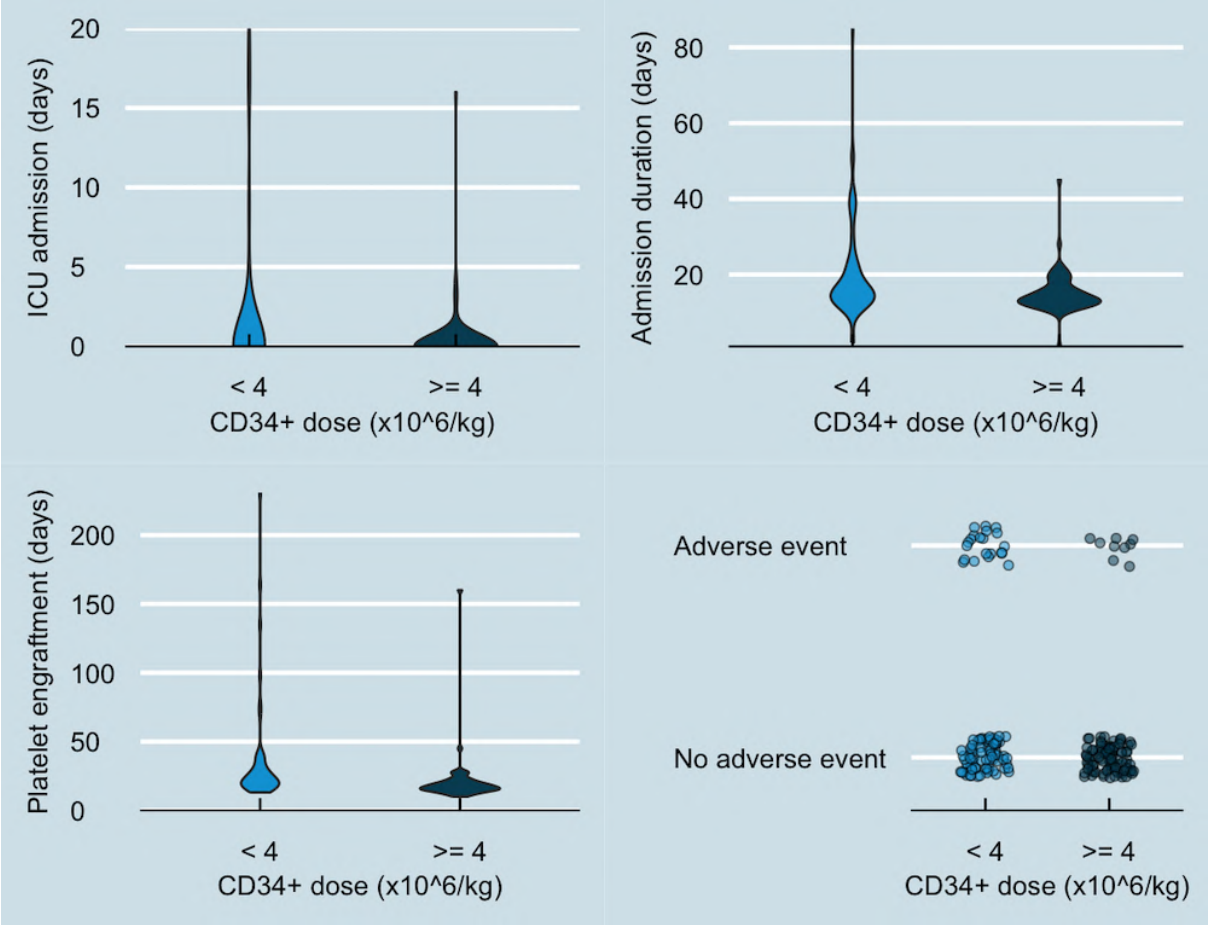
IMPACT OF CD34⁺ CELL DOSE AND GROWTH FACTOR SUPPORT ON EARLY MORBIDITY AND NON-RELAPSE MORTALITY AFTER AUTOLOGOUS STEM CELL TRANSPLANT FOR LYMPHOMA

*Ferdaws Abu Jabal[1], **Shahjehan Hanif**[1], Eduardo Deliyannis[1], May Htet Naing[1], Lara Gracie[1], Sakthi Kannan[1], Madapura Shashidhara[2], Sridhar Chaganti[1], Triantafillos Liloglou[3], Bernard Maybury[1]*
[1]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom of Great Britain and Northern Ireland (the), [2]Wrightington, Wigan and Leigh NHS Foundation Trust, Wigan, United Kingdom of Great Britain and Northern Ireland (the), [3]Edge Hill University, Ormskirk, United Kingdom of Great Britain and Northern Ireland (the)

Background: In autologous stem cell transplantation (ASCT), a CD34⁺ progenitor cell dose below 2×10^6/kg is associated with adverse outcomes, including delayed hematopoietic recovery, inferior progression-free survival, and higher non-relapse mortality (NRM). Above 2×10^6/kg, increasing CD34⁺ doses are associated with faster hematopoietic recovery, but the impact on early morbidity and NRM is poorly defined.

Methods: We conducted a retrospective single-center cohort study of adult lymphoma patients undergoing high-dose chemotherapy followed by ASCT between 2020–2024. The primary outcome was 180-day NRM. Secondary outcomes included neutrophil, platelet and lymphocyte engraftment, length of hospital stay, intensive care (ICU) admission, duration of intravenous antibiotics, and a composite of adverse outcomes. Associations were assessed using descriptive statistics and Fisher's exact test.

Results:



Data were collected on 162 patients with diagnoses of Hodgkin lymphoma (26%), primary CNS lymphoma (PCNSL; 15%), low-grade non-Hodgkin lymphoma (19%), and high-grade non-Hodgkin lymphoma (40%). The median CD34+ dose was 4×10^6/kg (range 2 – 27). 33% of patients received plerixafor and/or an additional cycle of cytarabine or cyclophosphamide to mobilise progenitor cells. Overall 180-day NRM was 4.3%. NRM occurred in 2.5% of patients receiving $CD34^+$ doses $\geq4\times10^6$/kg (2/81) compared with 6.2% among those receiving $<4\times10^6$/kg (5/81), which was not statistically significant (Fisher's exact test p=0.443).

Patients receiving a CD34+ dose $\geq4\times10^6$/kg had lower rates of delayed hospital discharge >25 days (3% vs 19%, p=0.002), a trend towards lower rate of ICU admission (6% vs 15%, p=0.06), and no difference in platelet engraftment by day 100 (98% vs 94%, p=0.3). $CD34^+$ dose $\geq4\times10^6$/kg was significantly associated with decreased rate of a composite adverse outcome consisting of any of 180-day NRM, ICU admission, delayed hospital discharge or failure of platelet engraftment by day 100 (9% vs 22%; odds ratio 0.34, 95% CI 0.13–0.83; p=0.01).

Filgrastim was used in 64% of the cohort, while pegfilgrastim was used in 36%. Among patients receiving pegfilgrastim, 90% received additional supplementary filgrastim for a median 5 days (range 0–28). There were no significant differences in haematopoietic

recovery, length of hospital stay, and duration of intravenous antibiotic therapy, between filgrastim and pegfilgrastim.

Conclusions: We did not demonstrate a significant association between CD34+ dose in ASCT and 180-day NRM. CD34+ doses <4×10⁶/kg were associated with a higher rate of ICU admission and a composite adverse outcome. We found similar clinical outcomes with pegfilgrastim compared with filgrastim. CD34+ doses for ASCT in lymphoma should be >4×10⁶/kg where this can be attained without additional risk to the patient. Further health economic analysis is required to determine whether additional apheresis procedures would be cost-effective.

P099

MOTIXAFORTIDE AND G-CSF TO MOBILIZE HEMATOPOIETIC STEM CELLS FOR AUTOLOGOUS TRANSPLANTATION IN HIGH-RISK MULTIPLE MYELOMA: TWO CASES CLINICAL REPORT

Min Dong[1], *Yongwei Guo*[1], *Jie Meng*[1], *Lihua Hu*[1]
[1]*Department of Hematology, The Second Affiliated Hospital of Hainan Medical University, Haikou, China*

Background: Approximately 5% to 30% of multiple myeloma (MM) patients experience stem cell mobilization failure when undergoing autologous transplantation. Motixafortide, a novel high-affinity CXCR4 antagonist, works by blocking the SDF-1/CXCR4 axis to synergize with G-CSF, particularly reversing the microenvironmental retention effect caused by high-risk factors such as del(17p). Compared to plasmaphorin, motixafortide can be administered once daily for full-day collection. The mobilized products are rich in pre-pDCs (plasma cell-like dendritic cells), which are beneficial for immune reconstruction, while avoiding the common gastrointestinal and cardiac toxicity risks associated with plasmaphorin.

Methods: This study reports two multiple myeloma (MM) patients with high-risk mobilization difficulties, including advanced age, multiple-line therapy, and cytogenetic abnormalities, who received a combination of Motixafortide and Granulocyte colony-stimulating factor (G-CSF) for cell mobilization. Case 1: G-CSF8 μg/kg/day (days 1-4) and Motixafortide 0.83 mg/kg/day (day 4); Case 2: G-CSF10 μg/kg/day (days 1-4) and Motixafortide 2.06 mg/kg/day (day 4). CD34+ stem cell collection was performed using a blood cell separator 10-16 hours after motilferomide administration. All patients underwent daily blood routine tests and venous CD34+ cell counts on days 4-7, with CD34+ cell counts also measured in the collected samples.

Results: Motixafortide significantly enhanced the release efficiency of peripheral blood stem cells, with the peak $CD34^+$ cell counts increasing from 16/μL and 0.49/μL to 56/μL and 90/μL, respectively. Both patients achieved optimal collection targets (total $CD34^+$ cells:

5.66×10⁶/kg and 7.8×10⁶/kg) within 1-2 single draws. The patients demonstrated good tolerance, with only mild injection site reactions and no serious adverse events. Post-transplant hematopoietic reconstitution was rapid, with neutrophil implantation occurring at +9 days and platelet implantation at +10 days.

Conclusions: The combination of Motixafortide and G-CSF provides a new and effective option for the mobilization of high-risk or plethasafu-intolerant MM patients with its excellent mobilization efficiency, convenient administration and good safety.

Disclosure: The authors declare no conflict of interest.

THE COMPARISON OF BONE MARROW PLUS PERIPHERAL BLOOD VERSUS PERIPHERAL BLOOD AS GRAFT SOURCE IN HAPLOIDENTICAL STEM CELL TRANSPLANTATION FOR PATIENTS ≥55 YEARS

Yuqian Sun[1,2], *Wei Zhao*[1], *Yu Wang*[1,2], *Lanping Xu*[1,2], *Xiaohui Zhang*[1,2], *Daihong Liu*[3], *Qifa Liu*[4], *Xi Zhang*[5], *Depei Wu*[6], *Xiaojun Huang*[1,2]
[1]*Peking University People's Hospital; Peking University Institute of Hematology, Beijing, China,* [2]*National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China,* [3]*Department of Radiology, Chongqing University Cancer Hospital, Chongqing, China,* [4]*Department of Hematology, Nanfang Hospital, Southern Medical University, Guangzhou, China,* [5]*Department of Hematology, Xinqiao Hospital, Chongqing, China,* [6]*National Clinical Research Center for Hematologic Diseases, Jiangsu Institute of Hematology, The First Affiliated Hospital of Soochow University, Institute of Blood and Marrow Transplantation of Soochow University, Suzhou, China*

Background: Haploidentical stem cell transplantation (haplo-HSCT) has become increasingly common in elderly patients; however, standardized protocols for selecting the optimal graft source are lacking. It is known that peripheral blood (PB) grafts were associated with faster engraftment while higher risk of graft-versus-host disease (GVHD) compared to bone marrow (BM) grafts. We hypothesize that the combination of BM and PB (BM+PB) grafts might reduce the incidence of GVHD without changing the engraftment speed, but relevant data is very insufficient. Therefore, this study aimed to compare the clinical outcomes of PB-alone grafts versus BM+PB grafts in elderly recipients aged 55 years and older.

Methods: This was a retrospective multicenter study from 6 Chinese centers. Patients were enrolled if they were (1) received first haplo-HSCT; (2) age ≥55 years; and (3) diagnosed with acute myeloid leukemia (AML), acute lymphoblastic leukemia (ALL) or myelodysplastic syndromes (MDS). The primary endpoint was 5-year DFS. Secondary endpoints include engraftment, GVHD, TRM, relapse and OS. The OS and DFS were estimated using the Kaplan–Meier method. The cumulative incidences of engraftment, GVHD, TRM, and relapse were estimated using a competing risk model. Prognostic factors were analyzed using Cox regression.

Results: From September 27, 2010 to March 10, 2025, a total of 936 patients were enrolled, including 679 patients received PB-alone grafts and 289 patients received BM+PB grafts. Details of the patients, disease, transplant characteristics and donor characteristics are shown in Table 1.

The median time to neutrophil engraftment was 12 days in both the PB-alone and BM+PB groups (P=0.47), and the median time to platelet engraftment was also identical (14 days in both groups, P=0.43). The cumulative incidences of acute GVHD at 100 days and chronic GVHD at 5 years were comparable between PB-alone group and BM+PB group, 33.8% versus 37.4% (*P*=0.39) and 37.7% versus 42.2% (*P*=0.36), respectively. (Figure 1A, B). The survival outcomes, overall survival (OS) and disease-free survival (DFS) at 5 years, were comparable, 62.1% versus 60.9% (*P*=0.47) and 56.8% versus 57.3% (*P*=0.40). (Figure 1C, D). The cumulative incidences of relapse (CIR) and transplant related mortality (TRM) at 5 years were 17.6% versus 14.9% (*P*=0.39) and 25.8% versus 27.6%(*P*=0.83). (Figure 1E, F). After adjusting for baseline differences in patient age, donor age, and other relevant covariates, multivariate analysis revealed no statistically significant differences between the groups in OS (HR 0.87, 95% CI: 0.66–1.14; *P*=0.30), DFS (HR 0.86, 95% CI: 0.67–1.11; *P*=0.24), TRM (HR 1.01, 95% CI: 0.56–1.83; *P*=0.61), or CIR (HR 0.80, 95% CI: 0.55–1.18; *P*=0.27).

Table 1|Characteristics of patients, donor and transplantation.

Characteristics	All (n=936)	PB (n=679)	BM+PB (n=289)	*P*
Patients' age at HSCT, median (range)	58 (55–75)	59 (55–75)	58 (55–73)	0.01
Donors' age, median (range)	33(15–62)	33 (15–62)	32 (16–62)	<0.01

P101

QUALITATIVE AND QUANTITATIVE CHARACTERISTICS OF CD34+ HEMATOPOIETIC STEM CELLS AND THEIR ASSOCIATION WITH HEMATOPOIETIC RECOVERY FOLLOWING ASCT

Anamarija Vrkljan Vuk[1], *Željko Prka*[1], *Branimir Gizdić*[1], *Vlatko Pejša*[1,2], *Anamarija Jularić*[1], *Biserka Orehovec*[1], *Suzana Ivoš*[1], *David Čičić*[1], *Ena Sorić*[1], *Ozren Jakšić*[1,2]
[1]*Dubrava University Hospital, Zagreb, Croatia,* [2]*University of Zagreb School of Medicine, Zagreb, Croatia*

Background: Qualitative and quantitative characteristics of mobilized CD34+ hematopoietic stem cells reflect the biological diversity of autologous grafts and may influence hematopoietic recovery following autologous stem cell transplantation (ASCT). While CD34+ cell dose remains the standard parameter for graft adequacy, integrating phenotypic and functional features of CD34+ cells may enable a more refined assessment of graft quality.

Methods: We prospectively analyzed 29 patients with lymphoma or plasma cell dyscrasia undergoing ASCT. Mobilized peripheral blood stem cells collected by apheresis were assessed by multicolor flow cytometry for Ki-67, CD38, CD90, and Notch1 expression on CD34+ cells. Colony-forming capacity was evaluated using methylcellulose assays (CFU-GM, BFU-E, CFU-Mix). Clinical endpoints included neutrophil and platelet recovery. Multivariable linear regression analyses were performed (n = 29).

Results: Twenty-nine patients were included (median age 60 years, range 27–73; 52% male), including 14 with non-Hodgkin lymphoma and 15 with plasma cell dyscrasia. Median times to neutrophil and platelet recovery were 10 (8–12) and 12 (9–18) days, respectively, and median graft viability was 85% (70–97%). Total CD34+ yield correlated inversely with time to neutrophil recovery ($\rho = -0.43$, $p = 0.02$) and showed a trend toward faster platelet recovery ($\rho = -0.36$, $p = 0.06$). Higher BFU-E counts correlated with delayed neutrophil recovery ($\rho = 0.42$, $p = 0.03$). CD34+ dose per apheresis correlated positively with total CD34+ yield ($\rho = 0.70$, $p < 0.001$) and inversely with the number of apheresis procedures ($\rho = -0.68$, $p < 0.001$).
In multivariable analysis including graft, functional, and phenotypic parameters, the neutrophil recovery model showed an R^2 of 0.57 (overall $p = 0.0679$), with total collected CD34+ cells independently associated with faster recovery ($p = 0.043$) and BFU-E independently associated with slower recovery ($p = 0.017$). Biomarker expression on CD34+ cells (Ki-67, CD38, CD90, Notch1) was not independently associated with engraftment kinetics; however, Ki-67 correlated inversely with graft viability and number of apheresis procedures, while CD38 showed a trend toward faster platelet recovery. Within the CD34+ compartment, Ki-67 correlated positively with CD38 and infused CD34+ dose, whereas CD38 and CD90 were inversely correlated. No variables independently predicted platelet recovery.

Conclusions: This exploratory analysis confirms total collected CD34+ cell dose as a key determinant of neutrophil recovery following ASCT, while CFU assays and CD34+ biomarker expression highlight additional biological heterogeneity of mobilized grafts. Although CD34+-associated biomarkers were not independently predictive in this cohort, their associations with graft characteristics and progenitor output support further investigation. Larger, adequately powered studies integrating phenotypic, functional, and immune reconstitution endpoints are warranted to further define the clinical relevance of biomarker-based CD34+ profiling and its integration with CFU assays in predicting post-transplant recovery.

Disclosure: Nothing to declare.

P102

INTRA-APHERESIS RECRUITMENT OF CD34⁺ CELLS IN G-CSF VERSUS G-CSF PLUS PLERIXAFOR MOBILIZATION: ASSOCIATION WITH COLLECTION EFFICIENCY AND FINAL HPC(A) YIELD

Yandy Marx Castillo-Aleman[1,2], *Carlos Agustin Villegas Valverde*[1], *Shinnette Lumane*[1,2], *Charisma Castelo*[1,2], *Jay Mary Rose-Roque*[1,2], *Marlene Cato*[1,2], *Nameer Al Saadawi*[1,2], *Mohamed Abu-Haleeqa*[1,2], *Inas El-Najjar*[1,2,3], *Mansi Sachdev*[1,2], *David Dennison*[1,2], *Aseel Suleiman Alsaid*[1,2], *Sakher Ahmad Obeidat*[1,2], *Ruaa Mousa Ali*[1,2], *Fatma Abdou*[1], *Shadi Shamat*[1], *Muhammad Touseef Haider*[1], *Anil Kumar Sarode*[1], *Rene Antonio Rivero-Jimenez*[1,3], *Antonio Alfonso Bencomo-Hernandez*[1], *Fatema Mohammed Al-Kaabi*[1,2], *Yendry Ventura-Carmenate*[1,3]
[1]*Abu Dhabi Stem Cells Center, Abu Dhabi, United Arab Emirates (the),* [2]*Yas Clinic Khalifa City, Abu Dhabi, United Arab Emirates (the),* [3]*United Arab Emirates University, Abu Dhabi, United Arab Emirates (the)*

Background: Circulating CD34⁺ hematopoietic progenitor cell (HPC) counts before apheresis [HPC(A)] are routinely used to guide the timing of collection, yet they do not fully account for the marked variability seen in collection efficiency (CE) or final yield. The intra-apheresis recruitment (IAR) of CD34⁺ cells, defined as the proportional increase in available progenitors during the procedure relative to baseline, may be an underappreciated biological factor influencing harvest performance. This study aims to characterize the IAR during HPC(A) through the recruitment ratio (RR) of CD34⁺ cells and examines its relationship with mobilization using G-CSF alone versus G-CSF plus plerixafor.

Methods: A retrospective analysis of HPC(A) procedures was performed between January 2023 and November 2025 at Abu Dhabi Stem Cells Center (ADSCC)/Yas Clinic Khalifa City (YCKC) Hospital in Abu Dhabi, United Arab Emirates. Pre- and post-apheresis CD34⁺ cell counts were recorded together with collection-bag CD34⁺ concentrations and a range of donor and procedure variables. Donors were grouped by mobilization regimen (G-CSF or G-CSF plus plerixafor). For each regimen, CE_1, CE_2, crude CE (cruCE), RR, performance ratio (PR), and total CD34⁺ cell yields were compared. All metrics were calculated using standard formulas.

Results: A total of 265 HPC(A) procedures were performed in 214 donors using the Spectra Optia® Apheresis System (Terumo BCT) with software version 11.0. Mobilization with G-CSF alone was used in 112 donors (55 autologous and 57 allogeneic), while 102 autologous donors received G-CSF plus plerixafor. Donors mobilized with G-CSF plus plerixafor were slightly older and had significantly lower total blood volume (TBV) and lower pre-apheresis CD34⁺ counts compared with those mobilized with G-CSF alone. Sex distribution and the use of MNC versus cMNC protocols were similar between groups. Procedure duration did not differ, although donors receiving G-CSF plus plerixafor had a higher TBV-processed ratio. CE metrics (CE_1, CE_2, crude CE, and PR) and RR were comparable, with no statistically significant differences. However, the final CD34⁺ cell yield was significantly lower in the G-CSF plus plerixafor group (p= 0.006). Table 1 summarizes the donor characteristics and apheresis outcomes.

Table 1. Comparison of donor characteristics and HPC(A) collection outcomes in G-CSF and G-CSF plus plerixafor mobilization

Donor characteristics	**G-CSF (n = 136) Median (IQR) †**	**G-CSF + plerixafor (n = 129) Median (IQR) †**	***p*-values [a]**
Age (years); median (range)	38 (2 – 64)	43 (2 – 67)	0.008 **

$CD34^+$ AY (× 10^6 cells/kg)	5.5 (3.7 – 10.6)	4.7 (2.8 – 7.7)	0.006 **

† Median and IQRs (25^{th}–75^{th} percentiles) unless otherwise specified.
[a] *p*-values calculated using the Mann–Whitney *U*-test unless otherwise specified; [b] *p*-values calculated using the Fisher's exact test. Asterisks indicate levels of statistical significance: * $p < 0.05$ and ** $p < 0.01$.
AY: apheresis yield; *CE:* collection efficiency; *cruCE:* crude CE; *IQR:* interquartile range; *NS:* not significant; *PR:* performance ratio; *RR:* recruitment ratio; *TBV:* total blood volume.

Conclusions: Similar RR and CE outcomes were observed between the two mobilization groups, likely reflecting the inclusion of a substantial proportion of allogeneic donors in the G-CSF cohort, while the G-CSF plus plerixafor group consisted exclusively of autologous donors. Because autologous donors often have varying degrees of bone marrow impairment, some impact on $CD34^+$ cell recruitment before and during HPC(A) was evident in our cohort, although this seemed partly overcome by adding plerixafor to the mobilization protocol.

Clinical Trial Registry: Not applicable.

Disclosure: Nothing to declare.

P103

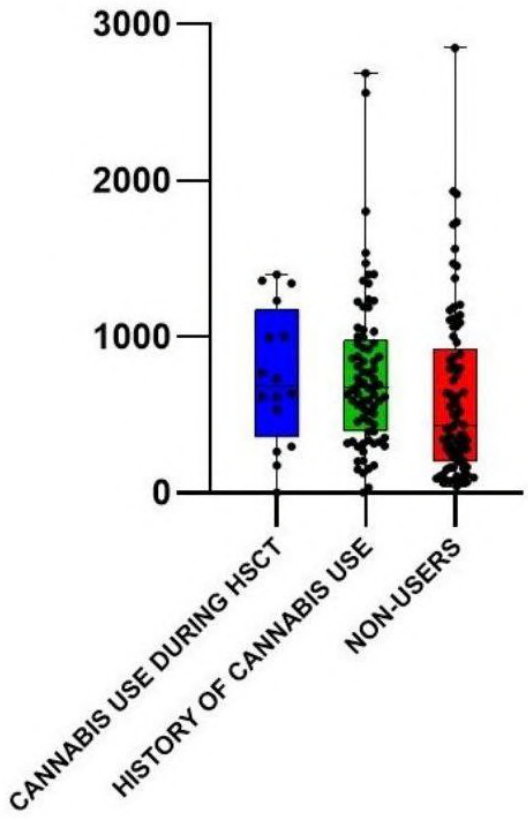
CANNABIS USE AND ITS RELATIONSHIP WITH MOBILIZATION EFFICIENCY TIME AFTER HSCT IN PATIENTS WITH MULTIPLE SCLEROSIS. A SINGLE CENTER EXPERIENCE IN MEXICO

Guillermo J. Ruiz-Argüelles[1], *Paola Andrea Anaya-Valdés*[1], *Miguel Angel Gómez-Cabrera*[1], *Oscar Emigdio Melchor-Melo*[1], *Lidia Joanna Alberto-Lopez*[1], *Jose Rodrigo Velasco-Padilla*[1], *Juan Pablo Ramirez-García*[1], *Max Robles-Nasta*[1], *Juan Carlos Olivares-Gazca*[1], *Guillermo J. Ruiz-Delgado*[1]
[1]*Centro de Hematología y Medicina Interna, Clínica Ruiz, Puebla, Mexico*

Background: Cannabis use is increasingly common among patients with multiple sclerosis (MS), yet its potential impact on hematopoietic stem cell mobilization and engraftment following autologous transplantation remains largely unexplored. Autologous hematopoietic stem cell transplantation (HSCT) is an effective therapeutic strategy for highly active or treatmentrefractory MS.

Methods: This retrospective single-center study included patients with MS who underwent autologous HSCT between 2018 and 2025. Participants were stratified into three groups according to cannabis exposure: (1) active users during HSCT, (2) patients with a prior history of cannabis use, and (3) non-users. $CD34^+$ cell counts were compared across groups using the Kruskal–Wallis test followed by Dunn's multiple comparison test with Bonferroni correction.

Results: A total of 177 patients were analyzed (16 active users, 76 former users, and 92 non-users). The Kruskal–Wallis test revealed significant overall differences in $CD34^+$ counts among the three groups ($H = 6.53$, $p = 0.038$). Post hoc analysis showed that patients with a history of cannabis use had significantly higher $CD34^+$ mobilization compared with non-users ($p = 0.0478$). No significant differences were found between active users and the other groups, likely due to the smaller sample size of the active-user subgroup ($n = 16$).



Conclusions: A history of cannabis use may be associated with enhanced CD34⁺ progenitor cell mobilization in patients with MS undergoing autologous HSCT, whereas active consumption during transplantation does not appear to confer additional benefit. These findings warrant further investigation in larger, prospective studies to elucidate the underlying biological mechanisms linking cannabis exposure to hematopoietic outcomes.

P104

HEMATOLOGIC SHIFTS DURING HPC(A) AND THEIR INFLUENCE ON COLLECTION EFFICIENCY AND CD34⁺ CELL YIELD

Background: $CD34^+$ hematopoietic progenitor cell apheresis [HPC(A)] induces measurable hematologic changes, including hemoconcentration, redistribution of leukocyte subsets, and platelet loss. These shifts are routinely captured in pre- and post-procedure complete blood counts but remain underutilized as predictors of apheresis performance. This study aims to characterize hematologic changes during HPC(A) and determine their association with collection efficiency (CE) metrics: CE_1, CE_2, crude CE (cruCE), captured cells (CA), and $CD34^+$ apheresis yield (AY).

Methods: A retrospective analysis of HPC(A) procedures was performed between January 2023 and November 2025 at Abu Dhabi Stem Cells Center (ADSCC)/Yas Clinic Khalifa City (YCKC) Hospital in Abu Dhabi, United Arab Emirates. Pre- and post-apheresis $CD34^+$ cell counts were recorded together with collection-bag $CD34^+$ concentrations and a range of donor and procedure variables. CE metrics were calculated using standard formulas. After excluding extreme outliers using the 1.5 × IQR rule, multiple linear regression models were fitted for CE_1, CE_2, cruCE, CA, and AY, including intraprocedural changes in hematocrit, white blood cells, neutrophils, mononuclear cells, and platelets (ΔHCT, ΔWBC, ΔNEU, ΔMNC, and ΔPLT, respectively) as standardized predictors. Δ values were calculated as post- minus pre-apheresis measurements. Standardized regression coefficients (β), 95% confidence intervals, adjusted R^2, and variance inflation factors (VIFs) were also estimated.

Results: A total of 289 HPC(A) procedures were performed in 214 donors using the Spectra Optia® Apheresis System (Terumo BCT) with software version 11.0. The majority of aphereses (n = 264, 91.3%) were performed after mobilization with either G-CSF alone (n = 136) or G-CSF plus plerixafor (n = 128) at standard doses. In the cleaned cohort (n = 225), models explained a modest proportion of outcome variability (adjusted R^2 0.02–0.09). As shown in Table 1, greater platelet decrease was the only consistent independent determinant of CE and AY, being positively associated with CE_1 and CE_2 (β 2.74, 95 % CI 0.38–5.11, p = 0.023; β 3.19, 95 % CI 0.70–5.68, p = 0.012, respectively) and inversely associated with AY (β −0.70, 95 % CI −1.17 to −0.23, p = 0.004). No Δ-variable independently predicted cruCE or CA. Marked collinearity among leukocyte-related predictors (ΔWBC, ΔNEU, ΔMNC; VIF > 700) limited the interpretation of their individual regression coefficients.

Table 1. Multiple linear regression coefficients for CE_1, CE_2, cruCE, CA, and AY of $CD34^+$ cells †

Predictor	CE_1 β (p)	CE_2 β (p)	cruCE β (p)	CA β (p)	AY β (p)
ΔHCT	0.28 (0.804)	-0.71 (0.551)	0.63 (0.181)	3.42 (0.441)	0.17 (0.475)
ΔWBC	-35.70 (0.256)	-37.06 (0.263)	3.51 (0.786)	18.80 (0.878)	-0.08 (0.990)

ΔNEU	35.40 (0.231)	37.77 (0.225)	-3.32 (0.785)	-6.30 (0.956)	-0.07 (0.990)
ΔMNC	3.60 (0.522)	7.60 (0.200)	-2.94 (0.204)	-4.22 (0.847)	-0.46 (0.685)
ΔPLT	2.74 (0.023) *	3.19 (0.012) *	-0.19 (0.700)	4.64 (0.330)	-0.70 (0.004) **

† Predictors were standardized as z-scores, and outcome models were adjusted for ΔHCT, ΔWBC, ΔNEU, ΔMNC, and ΔPLT. Asterisks denote statistical significance: * $p < 0.05$ and ** $p < 0.01$.
AY: apheresis yield; *CA:* captured cells; *CE:* collection efficiency; *cruCE:* crude CE; *HCT:* hematocrit; *MNC:* mononuclear cells; *NEU:* neutrophils; *PLT:* platelets; *WBC:* white blood cells.

Conclusions: ΔPLT emerged as the only robust predictor across all models, showing a positive association with CE_1 and CE_2 and an inverse association with AY. The remaining Δ-variables offered no independent contribution once multicollinearity was accounted for. Intra-apheresis platelet dynamics may therefore serve as a practical biomarker of apheresis system performance. Moreover, these findings may support further investigation into the emerging "G-CSF steal" phenomenon in donors mobilized with filgrastim.

Clinical Trial Registry: Not applicable.

EFFICACY AND SAFETY OF PLERIXAFOR SALVAGE HEMATOPOIETIC STEM CELL MOBILIZATION IN B-CELL ACUTE LYMPHOBLASTIC LEUKEMIA: A STUDY OF HETEROGENEOUS RESPONSES

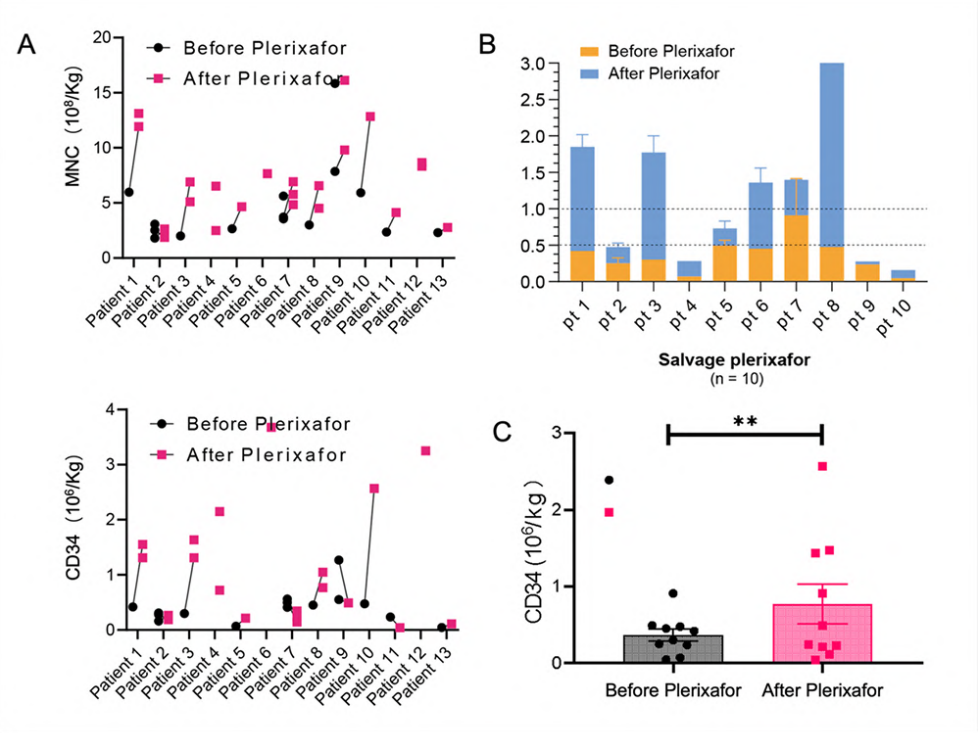
Yawei Zheng[1], Hongye Gao[1], Lisha Wang[1], Linjie Wu[1], Mengnan Lv[1], Shihui Ma[1], Jiali Sun[1], Xina Song[1], Weihua Zhai[1], Fang Dong[1], ***Erlie Jiang***[1]
[1]*Institute of Hematology and Blood Diseases Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Tianjin, China*

Background: Hematopoietic stem cell mobilization failure remains a challenge for autologous stem cell transplantation (ASCT) in B-cell acute lymphoblastic leukemia (B-ALL). While Plerixafor is a standard rescue agent for mobilization in other malignancies, its efficacy in B-ALL is less defined, and theoretical concerns regarding leukemic cell mobilization persist. This study evaluates the clinical utility of Plerixafor in B-ALL, focusing on response variability and relapse safety.

Methods: We analyzed B-ALL patients from the NICHE cohort (NCT04645199) mobilized between 2004 and 2024. Patients received standard G-CSF-based regimens. Plerixafor was administered as a salvage strategy in patients failing to achieve sufficient $CD34^+$ yields

(n=10) or preemptively in high-risk cases who are predicted to have poor mobilization (n=3). We assessed CD34⁺ collection yields, individual response patterns, and post-transplant relapse rates.

Results: Preemptive use of Plerixafor in 3 high-risk patients resulted in successful collection in all cases. In the salvage setting (n=10), responses to Plerixafor were heterogeneous but statistically beneficial overall. As shown in Figure 1, Plerixafor administration significantly increased the mean CD34⁺ cell yield compared to pre-treatment levels ($P < 0.01$). However, individual outcomes varied: while a subset of patients (responders) achieved substantial yield improvements (e.g., >3-fold increase) enabling successful transplantation, others showed limited incremental benefit, highlighting the biological heterogeneity of mobilization failure in B-ALL. Importantly, despite concerns about tumor contamination, the cell collection following plerixafor administration did not exhibit an increased MRD-positive rate as determined by flow cytometry-based MRD assessment, and Plerixafor usage was not associated with an increased risk of disease recurrence. Long-term follow-up confirmed that patients receiving Plerixafor did not exhibit higher rates of relapse compared to standard mobilization controls.



Conclusions: Plerixafor serves as a viable salvage option for B-ALL patients with mobilization failure. While pharmacological interventions is variable, with distinct subgroups of responders and non-responders, its application leads to a statistically significant overall improvement in stem cell yields. Furthermore, Plerixafor appears safe in this context, offering a potential pathway to ASCT without elevating relapse risk.

INCREASED RISK OF POOR MOBILIZATION AFTER QUADRUPLE THERAPY IN MULTIPLE MYELOMA

*Matei Coliță[1,2], Iuliana Iordan[1,3], Sorina Bădeliță[4], Lavinia Lipan[1,4], Sânziana Barbu[4], Alexandra Ichim[4], Radu Florescu[4], Alexandra Marcoci[1], Cătălin Șerban[4], Daniel Coriu[1,4], **Alina Tănase**[1,4]*
[1]University of Medicine and Pharmacy "Carol Davila", Bucharest, Romania, [2]Colțea Clinical Hospital, Bucharest, Romania, [3]National Registry of Voluntary Hematopoietic Stem Cell Donors, Bucharest, Romania, [4]Fundeni Clinical Institute, Bucharest, Romania

Background: The use of quadruple induction regimens in first-line therapy has improved outcomes in transplant-eligible patients with multiple myeloma (MM). However, increasing evidence suggests that intensified induction, particularly daratumumab-containing regimens, may adversely affect peripheral blood stem cell (PBSC) mobilization, mainly when granulocyte colony-stimulating factor (G-CSF) alone is used. This study evaluates PBSC mobilization outcomes and apheresis efficiency in MM patients undergoing autologous hematopoietic stem cell transplantation after quadruple versus triple induction therapy.

Methods: The study was performed by the Hematopoetic stem Cell Clinic from Fundeni Clinical Institute in collaboration with the Multiple Myeloma National Registry and included patients mobilized between January 2020 and December 2025. The inclusion criteria were patients with MM in first-line treatment mobilized with G-CSF. The lot was divided into two categories: patients who received triple (proteasome inhibitor, an immunomodulatory agent, or cyclophosphamide, and dexamethasone) or quadruple therapy (daratumumab in addition to triple therapy). Poor mobilizer was defined as a patient mobilizing fewer than 20 CD34+ cells/μL into the peripheral blood after G-CSF, or collecting fewer than 2 × 106 CD34+ cells/kg.Statistical analysis was performed using IBM SPSS Statistics Version 25 (IBM Corp., Armonk, NY, USA). The categorical data were analysed with a chi-squared test. Continuous data were reported as the median and interquartile range (IQR). The differences between groups were analysed with the Mann-Whitney test.

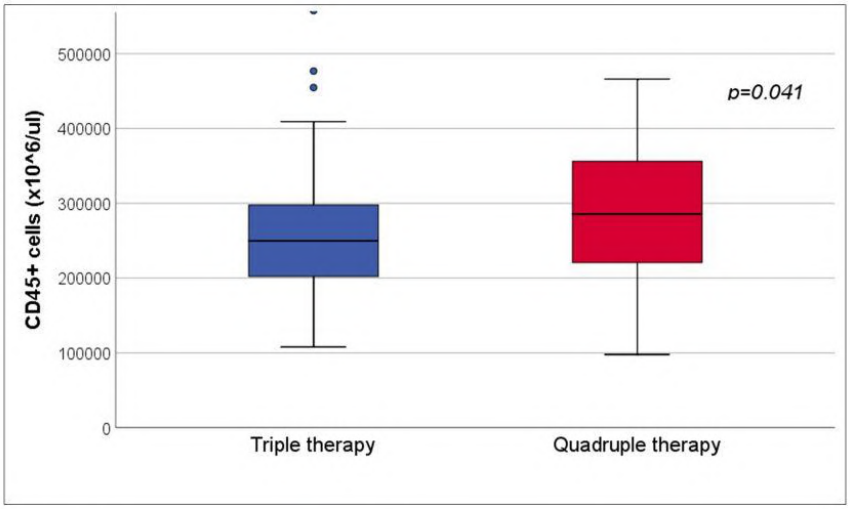
Results: We analyzed 150 patients, including 72 males (48%), with a median age of 57.3 years; 65.7% had cytogenetic high risk. Triple therapy (TT) was administered to 80 patients (53.3%), while 70 patients (46.7%) received quadruple therapy (QT).
In both groups, the CD34+ peak was reached on the fifth day after G-CSF initiation. In the QT group, higher peripheral leukocyte counts were observed (p=0.021), but fewer CD34+ cells in peripheral blood compared to patients treated with TT (p=0.000) (Table 1). Poor mobilizers were more frequent among patients who received QT than those who received TT (36.25% vs. 14.28%, p=0.002).
Regarding the apheresis product, the number of CD45+ cells was lower in the TT group

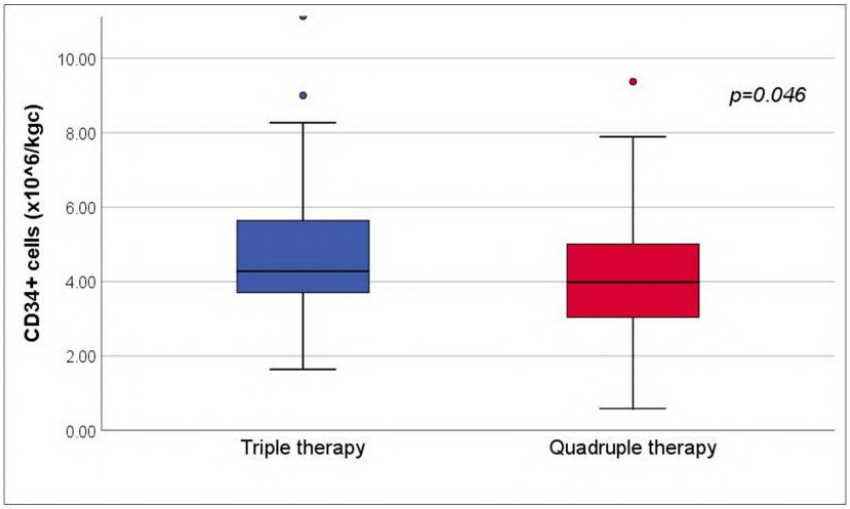
compared with the QT group (p=0.041). However, the number of collected CD34+ cells/kg was significantly lower in patients treated with QT compared with the TT group (median 3.45 vs. 4.28 CD34+ cells/kg, p=0.046) (Figure 1).

Table 1. Mobilization outcomes

	Triple therapy (n=70)	**Quadruple therapy (n=80)**	**p**
Poor mobilizers	10 (14.28%)	29 (36.25%)	0.002
CD34+ peak day - median (IQR)	5 (0)	5 (1)	0.008
Maximum PB CD34+/µl - median (IQR)	36 (27)	27 (22)	0.000
WBC PB (x10^9/L) on apheresis day - median (IQR)	50.87 (17.55)	53.68 (23.19)	0.021

Abbreviations: IQR=interquartile range; PB=peripheral blood; WBC=white blood cell count





Conclusions: In this cohort, quadruple induction therapy was associated with poorer peripheral blood stem cell mobilization compared with triple therapy. Despite similar CD34+ peak timing, patients receiving quadruple therapy showed lower peripheral blood CD34+ counts, a higher rate of poor mobilizers, and fewer CD34+ cells/kg collected by apheresis. These findings are consistent with previously published data suggesting that daratumumab-containing induction regimens may negatively impact PBSC mobilization, particularly when G-CSF alone is used. Further prospective studies are required to define optimal mobilization strategies in this setting better and to determine how to mitigate the adverse effects of quadruple therapy on stem cell collection.

SUCCESS OF HEMATOPOIETIC ENGRAFTMENT AFTER LONG-TERM CRYOPRESERVATION OF PERIPHERAL BLOOD HEMATOPOIETIC STEM CELLS

Marta Fonseca Santos[1,2,3], *Maria Luisa Martín Mateos*[1,2,3], *Pablo García Jaén*[1,2,3], *Rocío Sánchez Carrera*[1], *Estrella Arnes Moreta*[1], *Mercedes Gonzalez del Rio*[1], *Sara Marcos Asensio*[1,2,3], *Maria Belen Vidriales Vicente*[1,2,3], *Borja Puertas*[1,2,3], *Lourdes Vazquez Lopez*[1,2,3], *Lucía López Corral*[1,2,3], *Fermín Sánchez-Guijo*[1,2,3], *Olga López Villar*[1,2,3], *Miriam López Parra*[1,2,3]
[1]*Hospital Universitario de Salamanca, Salamanca, Spain,* [2]*IBSAL, Salamanca, Spain,* [3]*Universidad de Salamanca, Salamanca, Spain*

Background: Autologous Stem Cell Transplantation (ASCT), using apheresis-collected cells after mobilization, remains a relevant treatment for several hematological malignancies. These cells are immediately cryopreserved for storage until transplant. In some cases, allogeneic cells also require cryopreservation for subsequent infusion (Allo-SCT).
The efficacy of these cells in reconstituting hematopoiesis is well-established, with a target dose of CD34+>2×10^6/kg ensuring a reliable engraftment, including neutrophil recovery and platelet transfusion independence by day +14. Standard cryopreservation (using 5-10% DMSO and controlled-rate freezing) has minimal impact on engraftment when cells are short-term stored.
Transplant is usually performed in a short period of time after cryopreservation. However, due to complications or the need for a second ASCT, infusion may be significantly delayed, requiring the use of long-term stored cryopreserved cells. While successful bone marrow engraftment and cellular viability in long term cryopreserved hematopoietic stem cells (HSC) have been reported, data on the long-term engraftment outcomes of cryopreserved Peripheral Blood HSC (PB-HSC) remain scarce. Therefore, the objective of this work was to evaluate the engraftment results of long-term stored PB-HSC.

Methods: This study included data from 13 consecutive patients who underwent ASCT or allo-SCT between 2013 and 2025 using PB-HSC long-term stored (more than 1 year). Variables analyzed included cryopreservation time (months), infused cell dose (CD34x10^6/kg), pre- and post-thaw viability, transplant and disease characteristics and engraftment (days to absolute neutrophil count (ANC) and platelet recovery).

Results: With a median age of 54 years (range 31-68). The most common underlying disease was multiple myeloma (38.5%). The majority of patients were in complete response (69.2%) and underwent autologous transplantation (92.3%). All patients (100%) were mobilized using only G-CSF. The median collected cell dose was CD34+ 3.77×10^6/kg (range 2.09–32.5), and the median pre-cryopreservation viability was 99%.
The median cryopreservation time for the infused products was 38 months (range 12 – 58 months), with some products stored for nearly five years. The median infused dose was CD34+ 3.50×10^6/kg. While median post-thaw viability was 81%. No primary engraftment failure was reported. Median time to achieve ANC >0.5×10^9/L was 11 days (range 10-16), and the median time to achieve platelet recovery >20×10^9/L was also 11 days (range 9-42).

These times are consistent with results typically reported for fresh or short-term cryopreserved PB-HSC. Table 1 and Figure 1.

Table 1. Transplant characteristics

Variable	**N=13**

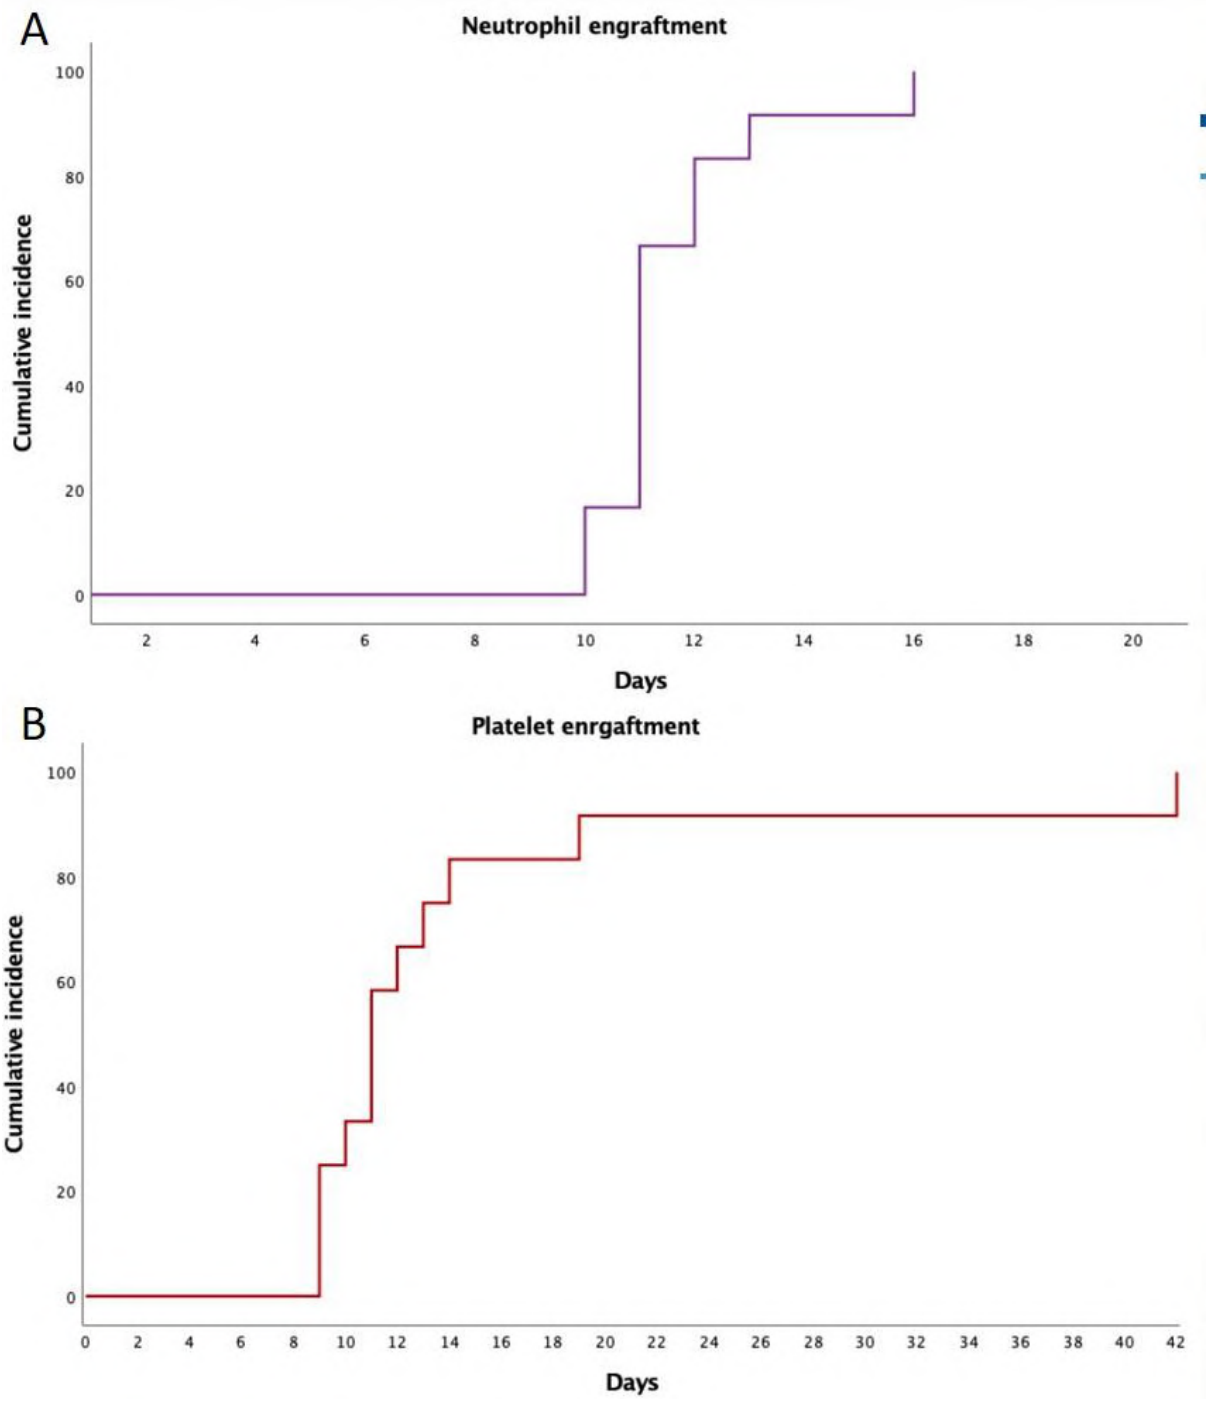
Conditioning, n (%) BEAM BuMel Mel200 Z-BEAM Rt+Cy	 4 (30,8) 3 (23,1) 3 (23,1) 2 (15,4) 1 (7,7)

G-CSF days after infusion, median (range)	5 (0-12)
Graft failure, n (%)	0 (0)
Engraftment Neutrophils >0,5 x10^3/µL, median (range) Platelets > 20 x10^3/µL, median (range) Platelets > 50 x10^3/µL, median (range)	 11 (10-16) 11 (9-42) 20 (11-91)

Figure 1. Engraftment. A) Neutrophil engraftment (ANC >0.5×10^9/L) and B) Platelet

engraftment (Platelets >20×10^9/L)



Conclusions: This study confirms the safety of long-term stored PB-HSC, with no reported cases of graft failure and rapid recovery of neutrophils and platelets similar to the results with those cryopreserved for a short period, indicating that prolonged storage does not

significantly compromise the clinical efficacy of the graft. These findings need to be confirmed in longer series.

Disclosure: Nothing to declare.

P108

MANAGING STEM CELL MOBILISATION FAILURE: LITERATURE REVIEW AND A CASE OF HIGH-DOSE PLERIXAFOR WITH TWICE DAILY G-CSF MOBILISATION STRATEGY FOR AUTOLOGOUS STEM CELL TRANSPLANTATION

Linda Lingxu Li[1], *Kirsten Watkins*[1], *Clinton Lewis*[1]
[1]*Te Whatu Ora Auckland City Hospital, Auckland, New Zealand*

Background: High dose chemotherapy followed by autologous stem cell transplant (ASCT) is a curative therapy for a number of haematologic and non-haematologic malignancies. This requires successful mobilisation and collection of a sufficient dose of peripheral blood stem cells. Standard approaches for mobilisation involve the use of granulocyte colony-stimulating factor (G-CSF) either alone or in combination with chemotherapy. In patients who fail mobilisation, the addition of plerixafor can significantly increase the peripheral blood $CD34^+$ cell count. However, literature guidance on management when plerixafor fails is limited. Furthermore, plerixafor access is often limited by cost or reimbursement criteria. This presents a clinical challenge in patients dependent on adequate mobilisation and collection in order to proceed to curative ASCT.

Methods: A literature review was undertaken to inform management of a 43-year-old man with relapsed germ cell tumour (GCT) who was referred for ASCT. He failed two mobilisation attempts with combined chemotherapy, G-CSF and plerixafor at standard dosing of 240mcg/kg/day. Bone marrow biopsy and cytogenetic studies did not reveal a cause for mobilisation failure. He had previously received pelvic irradiation which was felt to be the mechanism. PubMed and Google Scholar were searched for relevant studies evaluating plerixafor and G-CSF dosing regimens. Key findings are summarised in Table 1. The patient provided informed consent to proceed with additional mobilisation attempts using a novel high dose mobilisation regimen.

Table 1: Plerixafor and G-CSF study summary

Plerixafor			
Study	Study design & participants	Drug regimen	Outcomes
Pantin et al. 2017[1]	Phase 2, open-label, randomised trial;	480 mcg/kg vs 240 mcg/kg; subcutaneous; n = 24.	Higher $CD34^+$ AUC over 24 h with 480 mcg/kg

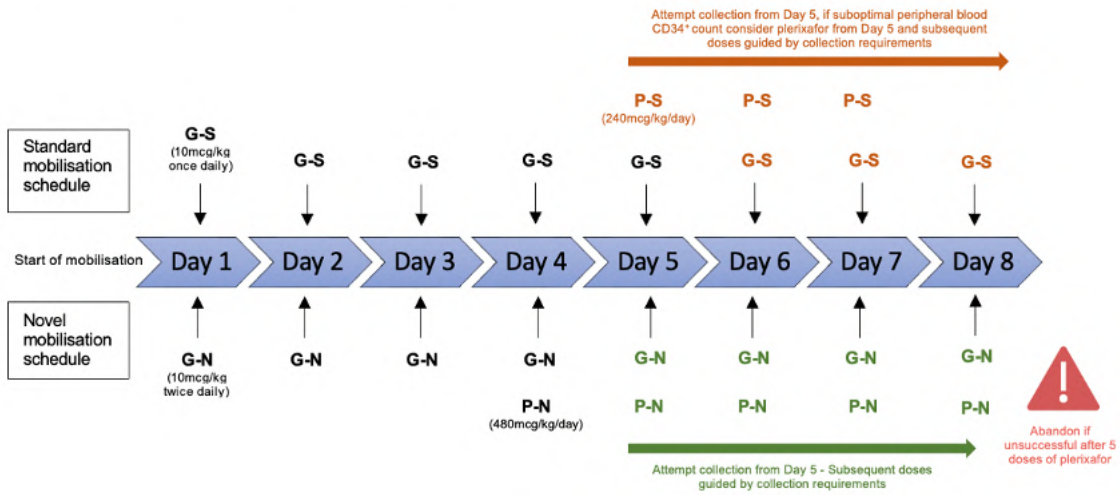
	healthy donors; n = 24		dose. No grade 3 – 4 adverse reactions.
Schroeder et al. 2017[2]	Phase 1/2, open-label trial; healthy donors. Phase 1: n = 21; Phase 2: n = 29	Phase 1: Escalating IV doses 80 – 480 mcg/kg + 240 mcg/kg SC on day 6. Phase 2: 320 mcg/kg IV.	Optimal IV dosing: 320 mcg/kg.
Cashen et al. 2017[3]	Phase 1/2 trial; autologous donors with lymphoma/myeloma. Phase 1: n = 25; Phase 2: n = 36	Phase 1: Plerixafor 160 – 400 mcg/kg IV+ G-CSF. Phase 2: Plerixafor 400 mcg/kg IV + G-CSF.	No efficacy difference between 160 – 400 mcg/kg. Similar adverse reactions rates.
G-CSF			
Study	Study design & participants	Drug regimen	Outcomes
Martinez et al. 1999[4]	Randomised trial; healthy donors; n = 40	10 mcg/kg every 12 h (n = 20) vs 10 mcg/kg every 24 h (n = 20) Apheresis from day 5; PBSC.	Higher $CD34^+$ cells collected in 12 h dosing vs 24 h dosing group ($5.9x10^6$/kg vs $3.1x10^6$/kg) after single apheresis. No discontinuation due to intolerance.
Seggewiss et al. 2003[5]	Retrospective analysis; autologous donors with underlying malignancy; n = 113	300 - 480 mcg/day (n = 55) vs 600 - 900 mcg/day (n = 58); SC.	Higher $CD34^+$ cells/L in 600 – 900 mcg/day vs 300 - 480 mcg/day group ($174x10^6$/L vs $92x10^6$/L).

AUC: Area Under Curve; G-CSF: Granulocyte colony-stimulating factor; IV: intravenous, SC: subcutaneous; PBSC: peripheral blood stem cells.

Results: Mobilisation was successful with the use of high-dose plerixafor (480 mcg/kg/day) and twice daily G-CSF (10 mcg/kg). Adequate $CD34^+$ stem cells were collected for three consecutive transplants over three days of leukapheresis (Spectra Optia), yielding a total volume of 815 mL and stem cell dose of $6.09x10^6$ $CD34^+$ cells/kg. The patient did not experience any adverse reactions related to this dosing regimen. In vitro assessment of viability demonstrated adequate function with an average post-cryopreservation viability of 50% and CFU-GM ranging from 0.23 to 2.25 $x10^4$/kg. The patient proceeded to the first cycle of high-dose therapy, receiving approximately 2.15 $x10^6$ $CD34^+$ cells/kg. Neutrophil and platelet engraftment were achieved by day 23 and 30, respectively, with the delayed engraftment attributed to prior pelvic irradiation. Unfortunately, the patient died from progressive disease. Contemporary literature suggests higher plerixafor doses may be effective in healthy donors and non-GCT patients; however, evidence supporting its use

specifically in GCT are lacking. The optimal dose and duration of plerixafor in difficult mobilisers are also poorly defined[1–3]. Based on data in healthy volunteers and haematology patients, we developed a novel mobilisation schedule incorporating high-dose plerixafor and G-CSF (Figure 1).

Figure 1: Novel versus standard mobilisation schedule.



Conclusions: This case highlights a significant mobilisation challenge in those undergoing ASCT. It provides valuable reassurance that successful mobilisation can be achieved using a novel approach with high-dose plerixafor in combination with twice-daily G-CSF, even in demonstrated poor mobilisers. However, access to this intensified regimen required extraordinary funding approval, which may limit its feasibility and broader implementation in resource-constrained settings.

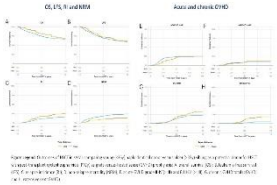
Background: Allogeneic hematopoietic stem cell transplantation (HSCT) is a curative therapeutic option for secondary acute myeloid leukemia (sAML). Whether a young haploidentical donor (yHaplo) is preferred over an older sibling donor (oMSD) for HSCT with post-transplant cyclophosphamide (PTCy) in sAML is unknown.

Methods: The study aimed to assess whether a yHaplo (<35 y)median 27.7y is preferential to oMSD (≥ 35 y) median 57.9y for sAML patients (pts) undergoing HSCT in first complete remission (CR1) with PTCy, between 2012 and 2022. Statistical tests included a multivariable analysis (MVA).

Results: 406 pts were included (yHaplo=306, oMSD=100). Median follow-up was 2.4 y, and the median year of transplant was 2019 (interquartile range [IQR], 2017-2021), with no significant difference between the two donor groups. Median pt age was 58.9 y (IQR, 52.9-63.4), and 61.6% were male, comparable between the groups. The antecedent hematological disease was myelodysplastic/myeloproliferative disorder in both groups, 86.3% vs. 82%(p=0.92). The cytogenetic risk was categorized as intermediate (65.2% vs. 61.4%), adverse (33.6% vs. 37.5%), and favorable (1.2% vs. 1.1%) in the yHaplo and oMSD groups, respectively (p = 0.79) (data missing for 71 pts). Median time from diagnosis to transplant was significantly longer for yHaplo vs. oMSD, being 5.1 vs. 4.1 months, respectively (p<0.001). Bone marrow was the stem cell source in 19% of the yHaplo vs. 5% of the oMSD grafts (p<0.001), following myeloablative conditioning (MAC) in 56.4% vs. 51% (p=0.35). PTCy was most frequently combined with cyclosporine A /mycophenolate mofetil-based immunosuppression as graft-*versus*-host disease (GvHD) prophylaxis. Thiotepa/busulfan (Bu)/Fludarabine (Flu) was the most frequent conditioning in yHaplo pts, while it was Bu/Flu in the oMSD group. Day +30 absolute neutrophil count ($\geq$0.5 x 10^9/L) was inferior in yHaplo compared to oMSD 83.9% vs. 93.8%, hazard ratio (HR) 0.6 (95% CI, 0.43-0.82, p=0.002). Day +60 platelet count (>20,000) was 78.2% vs. 90.4%, respectively. Day +180 incidence of acute (a) GvHD II-IV was 24.5% vs. 25.2 % and of III-IV it was 8.3% vs. 11.6%, respectively. The 2-y total and extensive (ext) chronic (c) GvHD were 26.2% vs. 36.5% and 5.4% vs. 20.2 %, respectively. In MVA analysis, ext cGvHD was significantly lower in the yHaplo compared to the oMSD groups, with an HR 0.38 (95% CI, 0.18-0.78, p=0.008), while aGvHD II-IV and III-IV and total cGvHD did not differ significantly. The 2-y non-relapse mortality (NRM) was higher in HSCTs from yHaplo compared to those from oMSD, being 24.6% vs. 19% (HR 1.86; 95% CI, 1.07-3.2, p=0.028). The main cause of death was sAML, accounting for 40.2% vs. 66.7% of deaths, respectively. The 2-y overall survival (OS:59.6% vs. 49.4%), GvHD-free, relapse-free survival (GRFS: 45% vs. 33.5%), leukemia-free survival (LFS: 53.6% vs. 45.4%), and relapse incidence (RI: 21.8% vs. 35.7%) (Figure) did not differ significantly between the two groups.



Conclusions: HSCT with PTCy for sAML in CR1, from yHaplo vs oMSD, resulted in similar transplantation outcomes, besides a higher incidence of NRM and slower neutrophil engraftment, while a lower incidence of ext cGvHD in the yHaplo compared to the oMSD.

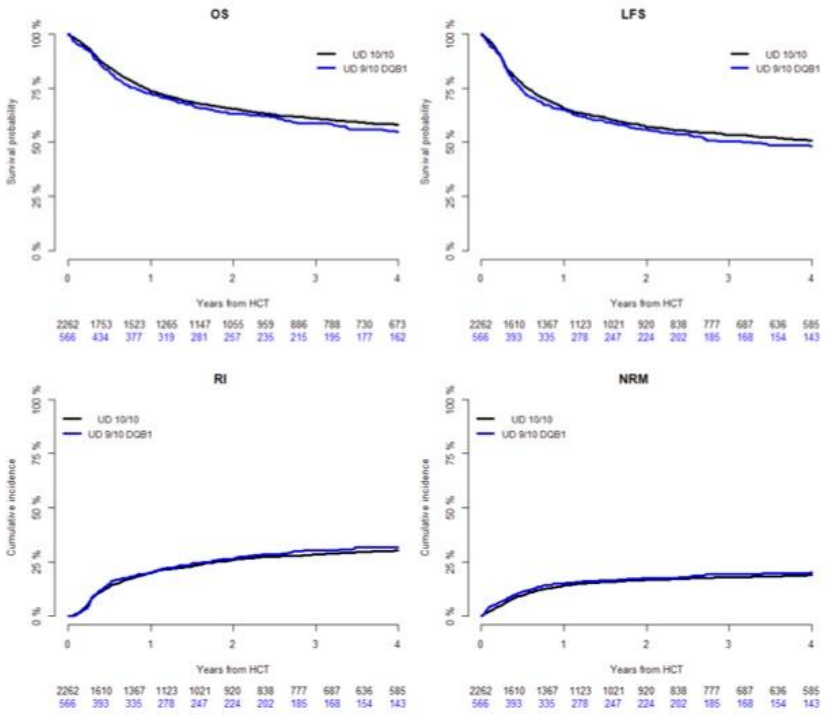
Background: In 8/8 matched unrelated donor (MUD) transplants (HCT), strong linkage disequilibrium between HLA-DRB1 and HLA-DQB1 results in concordance at the DQ locus, yielding a 10/10 match, although isolated DQB1 mismatches still occur. The clinical impact of isolated single HLA-DQB1 mismatching in otherwise fully MUD (UD 9/10) HCT remains uncertain. While disparities in HLA-DQB1 have been reported to be permissive, EBMT guidelines still consider DQB1 during donor selection. With increasing use of reduced-intensity conditioning and evolving GvHD prophylaxis the contemporary significance of DQB1 mismatching warrants re-evaluation.

Methods: We conducted a registry-based study on behalf of the ALWP on adult AML patients in CR undergoing first allogeneic HCT from UD between 2010–2024, with full high-resolution HLA typing at A, B, C, DRB1, and DQB1. HCT from UD 10/10 or UD 9/10 with isolated DQB1 mismatch were included. 16,083 MUD and 627 9/10 were available. A pair-match analysis (1:4) between UD 9/10 with isolated DQB1 mismatch and UD 10/10 was performed based on age at HCT, year of HCT, stem-cell source, disease status, ELN2022 cytogenetics, KPS, patient sex, regimen intensity, use of PTCY and invivo TCD, female-to-male sex matching.

The primary objective was the impact of isolated HLA-DQB1 mismatching on post-transplant outcomes.

Results: Among the 16,710 patients included, the median age at transplant was 57.7 years. Disease status at HCT included 82.5% in CR1. Peripheral blood was the predominant graft source (94.6%). MAC regimen was performed in 42.7%. GvHD prophylaxis included ATG, PTCy and Campath respectively in 68.3%, 9.6% and 7.9% of patients. Median donor age was 28.9 years, 28.8 in UD 10/10 and 31.5 in UD 9/10 DQB1.After matching, 2,828 patients were included (UD10/10 n=2,262; UD9/10 DQB1 n=566). Median donor age remained lower in the UD 10/10 group (28.8 vs 31.5).
With a median follow-up of 4.1 years, HCT outcomes did not differed by HLA matching (figure). In UD 10/10 and in 9/10 DQB1-mismatched recipients, 2y-OS was 65.6% (95%CI 63.4–67.6) and 63.1% (58.7–67.2) (HR 1.09, 0.95–1.27; p=0.23), 2y-LFS was 57.2% (55.0–59.4) and 56.0% (51.5–60.3), (HR 1.06, 0.93–1.22; p=0.38), 2yRI was 26.0% and 26.4% (HR 1.06, 0.89–1.27; p=0.48), and 2y-NRM was 16.7% and 17.6% (HR 1.06, 0.86–1.32; p=0.57), respectively.
The cumulative incidence of grade II-IV aGvHD by day 100 was 26.6% (95%CI 24.7–28.5) and 22.5% (95%CI 19.1–26.1) (HR 0.86, 0.72–1.03; p=0.11), while grades III–IV was 9.5% and 6.9% (HR 0.77, 0.56–1.06; p=0.11). cumulative incidence of 2y cGvHD was 34.4% (32.2–36.6) and 29.4% (25.3–33.7) (HR 0.81, 0.68–0.98; p=0.03), and extensive/severe cGvHD 10.0% and 5.7% (HR 0.55, 0.37–0.81; p=0.002), respectively.



Conclusions: This study demonstrates that isolated HLA-DQB1 mismatching does not affect 2y OS, LFS, RI, or NRM after unrelated donor HCT in AML in CR, confirming its limited clinical relevance when high-resolution matching at A, B, C, and DRB1 is performed. Cumulative

incidence of cGvHD was lower among DQB1-mismatched recipients. This findings may be related to different practice among centers in immunosuppression tapering or experience and deserve further investigations.

Clinical Trial Registry: Not applicable.

A MACHINE LEARNING APPROACH COMBINING HLA AND NON-HLA FACTORS TO SUPPORT SELECTING THE "BEST" DONOR: ANALYSIS ON 7,609 TRANSPLANTS AND A READY-TO-USE INTERACTIVE TOOL

Roberto Crocchiolo[1,2], *Raffaele Scorza*[3], *Stefania Cacace*[3], *Elena Oldani*[1], *Davide Chizzoniti*[1], *Luca Castagna*[1], *Michele Malagola*[1], *Barbara Sarina*[1], *Simona Piemontese*[1], *Nicola Polverelli*[1], *Giovanni Rombolà*[2], *Nicoletta Sacchi*[4], *Quirico Semeraro*[3], *Massimo Martino*[1]
[1]*GITMO, Gitmo, Italy,* [2]*AIBT, Aibt, Italy,* [3]*Politecnico di Milano, Milano, Italy,* [4]*IBMDR, Genova, Italy*

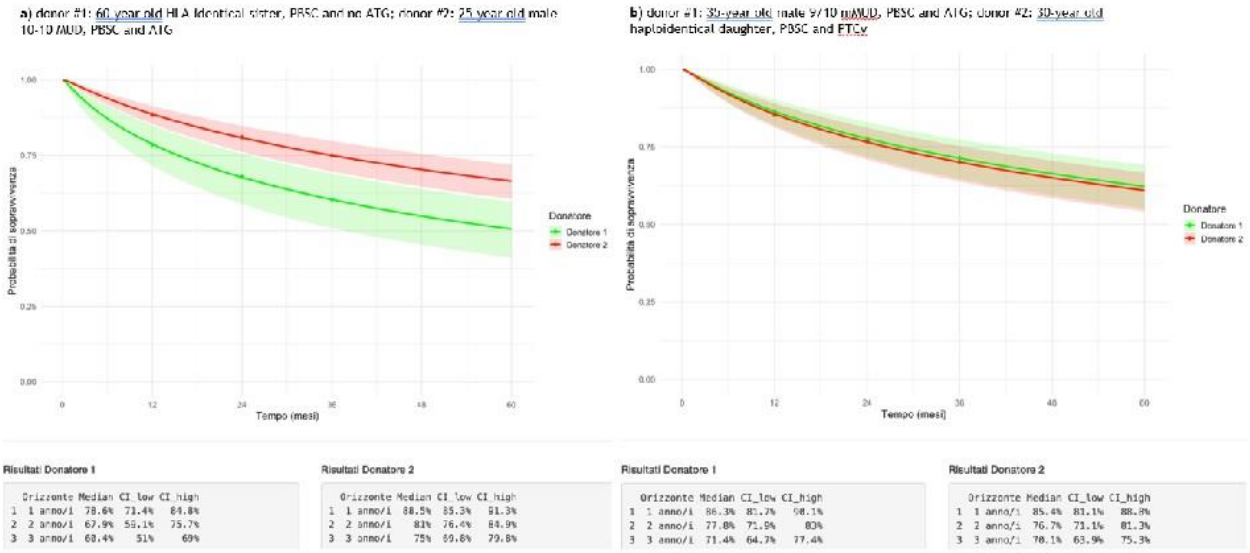
Background: The selection of a donor for allogeneic HSCT is a complex, multi-factorial challenge that requires balancing HLA compatibility with non-HLA factors, including more recent pharmacological advances like PTCy for GvHD prophylaxis. We addressed here the need for interpretable and data-driven decision support by developing a comprehensive framework based on a Bayesian hierarchical Accelerated Failure Time (AFT) model, built on 7,609 HSCTs perfomed in Italy between 2014 and 2024.

Methods: Anonymous data on adult patients were collected on behalf of the Gruppo Italiano per il Trapianto di Midollo Osseo, cellule staminali emopoietiche e terapia cellulare (GITMO). After the selection of those informative from over 24,000 HSCTs, the final dataset maintained comprehensive information on patient demographics, donor characteristics, HLA compatibility, transplantation procedures and post-HSCT outcomes. The final model provides the risk of post-transplant mortality according to the donor type taking into account the main non-HLA factors and importantly, the patients' and disease characteristics. The use of PTCy, anti-thymocyte globulin (ATG) or calcineurin (CNI)-based prophylaxis is also considered.

Results: HLA compatibility between patients and their respective donors was categorised into four donor groups: HLA-identical siblings, haploidentical, 10/10-matched (MUD) and 9/10-mismatched unrelated donors (mMUD). Estimates coefficients are calculated for each of the following variables: patients' and donors' age, disease status, conditioning regimen, performance status at HSCT, stem cell source, donor type; interaction effects between donor type and GvHD prophylaxis were identified. External validation was performed using a held-out test set created through random split (80% training, 20% testing) with stratified sampling to preserve event rate proportion. The robustness and interpretability of the model led us to start to build up an interactive tool to support the donor search, i.e. between an older HLA-identical sibling vs. a younger MUD or a mMUD vs. a haploidentical. The current

version is tailored for two donor options. After having provided baseline input information on patient's status, disease and HSCT, and then information on donor options #1 and #2, the model gives back two survival curves, one associated with each donor for direct comparison between the two options (see Figure 1).

Figure 1. Predicted survival curves for two donor candidates for the same patient type, a 55-year old man with acute leukemia in CR1



Conclusions: In conclusion, our model trained on a large multicenter dataset showed to efficiently combine HLA and non-HLA factors across different donor types and GvHD prophylaxis, for the prediction of post-transplant survival. The output might be used to support the choice of the "best" stem cell donor during the selection process. At the time of writing, a web-based tool is under evaluation for research or clinical purposes.

Background: Haplo-identical allogeneic cell transplantation (haploHCT) is increasingly used if no matched related or unrelated donor (MUD) is available. Retrospective studies suggest a stronger GvL effect after haploHCT

Methods: To test the hypothesis that haploHSCT reduces the risk of relapse by 10% we performed an open label, two-arm, multicenter, multinational, randomized phase II trial comparing anti-leukemic activity of HCT for patients with acute leukemia in CR between a MUD and a haploidentical donor using identical GvHD prophylaxis consisting of PTCy, Tacrolimus and MMF. Major inclusion criteria were AML intermediate and adverse risk according ELN and ALL and MDS high risk in CR, age 18-70 years , and availibility of 10/10 HLA MUD and haplo-identical (≥ 5/10 and ≤8/10 HLA) relative donor.
To detect a difference of 10% in relapse incidence at 2 years, 220 patients per arm are needed. A planned interim and futility analysis was performed after 171 patients were included and 158 pts were randomized to MUD (n=78) or HaploHCT (n= 80).

Results: The median age of the pts was 56 years (range 18-70), Disease and patient characteristics were well balanced in both arms. Due to the unavailability of the donor assigned by randomization, 6/69 pts randomized to MUD received a Haplo HSCT and 5/71 pts randomized to HaploHSCT received a MUD; thus, according to Intention to treat (ITT), 78 pts were assigned to MUD while 68 pts received MUD according per protocol (PPP), and in the Haplo HSCT group 80 pts were analyzed acc. ITT and 72 pts according PP, respectively. The cumulative incidence of relapse at 2 years for MUD and Haplo was 33% (95%CI: 20-46) und 28% (95% CI: 17-42) acc. ITT (p=0.9) and 25% (95%CI:13-39) and 29% (95%CI:17-42) acc. PP (p=0.4), respectively. The NRM at 1 year for MUD vs Haplo was 3% (95%CI: 0.5-9) vs 5% (95% CI:2-12) acc. ITT and 5% (95%CI: 1-12) vs 4% (95%CI:1-11) acc. PPP (p=0.9), respectively , resulting in an EFS of 60% vs 64% acc. to ITT- and 65% vs 65% to PPP (p=0.7) and a 2 year OS of 68% vs 77% in the ITT – and 74% vs 75% acc PP (p=0.77), respectively. The GRFS at 2 years acc. to PP was 61% (95% CI: 48-78) for MUD and 60% (95%CI: 47-75) for HaploHCT (p=0.5).
PGF occurred in 3 pts, all after Haplo-HCT, and the median time to neutrophile and platelet engraftment was 18 and 16 days after MUD (p=0.16) and 19 and 23 days after HaploHCT (p= 0.03). The incidence of any acute and cGvHD and SAE did not differ between both arms.

The DSMB recommend stopping recruitment because it is unlikely to show a 10% superiority of HaploHCT to MUD regarding relapse incidence with the planned sample size.

Conclusions: The planned interims analysis of the randomized study comparing 10/10 MUD with haplo-identical HCT using identical PTCy based GvHD prophylaxis showed similar relapse incidence, comparable GvHD incidence, low NRM and favourable outcome in both arms and further recruitment will unlikely show superiority regarding 10% reduction in relapse after HaploHCT.

Clinical Trial Registry: The study was registered under ClinicalTrial.gov: (NCT04232241

[1]*Department of Stem Cell Transplantation, University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

Background: Recipient cytomegalovirus (CMV) seropositivity has historically been associated with increased non-relapse mortality (NRM) following allogeneic stem cell transplantation (allo-SCT). Previous studies have also demonstrated meaningful differences in outcomes across specific recipient/donor CMV serostatus combinations (R+/D+, R+/D-, R-/D+, R-/D-). With the introduction of letermovir prophylaxis into routine clinical practice, it is unclear whether these historically relevant serostatus-related risk differences persist. This study evaluates the impact of letermovir on overall outcomes and, in particular, on the heterogeneity between CMV serology combinations.

Methods: We conducted a retrospective study of 1,353 adult patients undergoing matched unrelated donor (MUD) allo-SCT between 2010 and 2024. Letermovir prophylaxis was implemented in 2022. Patients were divided into a pre-letermovir era (2010-2021; n=1,062) and a post-letermovir era (2022-2024; n=291). The pre-letermovir era was further divided into early (2010-2015) and late (2016-2021) cohorts to account for temporal improvements in supportive care. Outcomes assessed included NRM, relapse, overall survival (OS), progression-free survival (PFS), and acute and chronic GVHD. Subgroup analyses compared all four recipient/donor CMV serostatus combinations.

Results: In the post-letermovir era, 1-year NRM was similar between CMV-seronegative (14%) and CMV-seropositive patients (18%; p=0.41), with multivariate analysis showing no independent effect of CMV serostatus (HR 1.04, p=0.91). In contrast, during the entire pre-letermovir era, CMV-seropositive patients demonstrated significantly higher NRM compared with CMV-seronegative patients (16% vs. 11%; p=0.002; multivariate HR 1.46, p=0.02). This effect was most pronounced in the early pre-letermovir period (17% vs. 12%; p=0.07; HR 1.78, p=0.023), while attenuated in the late pre-letermovir period (15% vs. 11%; p=0.16).
Subgroup analysis revealed substantial heterogeneity among recipient/donor CMV combinations in the pre-letermovir era. One-year OS ranged from 68% in R+/D+ to 76% in R-/D-, and 1-year PFS ranged from 57% in R+/D+ to 69% in R-/D-. NRM varied from 10% in R-/D+ to 20% in R+/D-, while relapse incidence ranged from 16% in R-/D- to 28% in R-/D+. These differences were statistically significant across all combinations. Although some effects lost significance on multivariate analysis, the unadjusted findings confirm that CMV pairing was a meaningful determinant of outcomes before letermovir.
In the post-letermovir era, these differences disappeared entirely. Across all four CMV serostatus combinations, 1-year OS ranged from only 66% to 76% (p=0.52), NRM from 14% to 22% (p=0.67), PFS from 57% to 71% (p=0.28), and relapse incidence from 10% to 22% (p=0.44). Recipients with negative CMV serology receiving grafts from CMV-positive donors (R-/D+) demonstrated outcomes fully comparable to all other combinations. Historically high-risk combinations such as R+/D- also showed no differences after letermovir implementation.

Conclusions: Letermovir prophylaxis was associated with elimination of the historically observed survival differences across all recipient/donor CMV serostatus combinations in MUD allo-SCT. These findings suggest a profound reduction in CMV-related risk heterogeneity and support routine letermovir use in CMV-seropositive recipients, with implications for donor selection and post-transplant risk stratification.

IMPACT OF DONOR CHARACTERISTICS ON THE OUTCOMES FOLLOWING HAPLO-HSCT IN PATIENTS AGED 55 YEARS AND OLDER

Wei Zhao[1], *Rui Ma*[1,2], *Xueyi Luo*[1,2], *Wei Sun*[1,2], *Wei Han*[1,2], *Xiaodong Mo*[1,2], *Yu Wang*[1,2], *Xiaohui Zhang*[1,2], *Lanping Xu*[1,2], *Xiaojun Huang*[1,2,3], *Yuqian Sun*[1,2]
[1]*Peking University People's Hospital, Peking University Institute of Hematology, Beijing, China,* [2]*National Clinical Research Center for Hematologic Disease, Beijing Key Laboratory of Hematopoietic Stem Cell Transplantation, Beijing, China,* [3]*Peking-Tsinghua Center for Life Sciences, Beijing, China*

Background: Haploidentical haematopoietic stem cell transplantation (haplo-HSCT) provides curative potential for older patients with haematological malignancies. Since multiple haploidentical donors may be available for a given patient, identifying factors that influence transplant outcomes, particularly donor-related characteristics, is critical. This study aimed to identify donor factors that are associated with transplant outcomes.

Methods: This retrospective study was conducted at Peking University People's Hospital. Patients were eligible if they: (1) underwent their first haplo-HSCT between January 2019 and June 2024; (2) were aged ≥55 years; and (3) had a diagnosis of acute myeloid leukaemia (AML), myelodysplastic syndromes (MDS), or acute lymphoblastic leukaemia (ALL).

Results: Between January 2019 to June 2024, a total of 460 patients were enrolled. The last follow-up was 9 October 2025. Detailed characteristics are presented in **Table 1**.

Table 1|Characteristics of patients, donor and transplantation.

Characteristics	N = 460
Patients' age at HSCT, median (range)	59 (55,74)
Donors' age, median (range) < 33, n (%) > = 33, n (%)	 184 (40.0) 276 (60.0)
Donor-recipient gender matching, n (%) Female to Male Others	 109 (23.7) 351 (76.3)
Donor-recipient ABO blood type, n (%) matched major dismatch minor dismatch Bidirectional mismatch	 235 (51.1) 100 (21.7) 93 (20.2) 32 (7.0)
Donor-recipient CMV status, n (%) +/+ +/- -/+ -/- missing	 377 (82.0) 7 (1.5) 13 (2.8) 2 (0.4) 61 (13.3)
Diagnosis, n (%) AML ELN (low/median/high) MDS ALL	 232 (50.4) 47/99/86 148 (32.2) 80 (17.4)

Matched HLA loci at A, B, C, DRB1 and DQB1, n (%) 5/10 >5/10	 351 (76.3) 109 (23.7)
Conditioning regimen, n (%) Bu/Cy+ATG Bu/Cy/Flu+ATG	 54 (11.7) 406 (88.3)
Stem cell source PB BM+PB	 398 (86.5) 62 (13.5)
Median CD34+ count, $\times 10^6$/kg (range)	3.72 (0.37—31.22)
Median MNC count, $\times 10^8$/kg (range)	8.96 (1.96—22.42)
Follow-up for survivors post-transplant, days, median (range)	746 (38—2343)

"-"=negtive; "+"=positive; AML=Acute Myeloid Leukemia; MDS=Myelodysplastic Syndromes; ALL=Acute Lymphoblastic Leukemia; MRD=Minimal Residual Disease; CR=Complete Remission; NR=Non-Remission; HCT-CI=hematopoietic cell transplant-comorbidity index.

The median follow-up time for survivors was 746 days. At the last follow-up, 340 patients (73.9%) were alive. The cumulative incidence of grade II–IV acute graft-versus-host disease (GVHD) and moderate-to-severe chronic GVHD were 22.9% and 26.0%. The 2-year overall survival (OS) and disease-free survival (DFS) were 72.8% (95% CI: 68.6–77.2) and 66.8% (95% CI: 62.4–71.5), respectively. At the last follow-up, 66 patients (14.3%) had relapsed, the 2-year cumulative incidence of relapse (CIR) and transplant-related mortality (TRM) were 13.1% (95% CI: 10.0–16.5) and 21.2% (95% CI: 17.4–25.2). Univariate regression was performed for all potential predictors, including donor and patient parameters, disease

characteristics and treatment-related variables. Variables with P<0.1 from non-donor categories, together with all donor factors (regardless of significance), were included in the multivariate Cox regression. Multivariate analysis showed that increasing donor age was significantly associated with inferior OS (HR 1.22, 95% CI: 1.10–1.36; P<0.001), poorer DFS (HR 1.20, 95% CI: 1.09–1.32; P<0.001), and higher TRM (HR 1.20, 95% CI: 1.07–1.34; P=0.001). Subgroup comparisons was conducted in different donor age, with the optimal threshold by maximally selected rank statistics. Compared with donors aged ≥33 years, younger donors (<33 years) were associated with better OS (80.8% vs. 67.6%, P=0.002), improved DFS (73.8% vs. 62.6%, P=0.002), and lower TRM (16.6% vs. 24.2%, P=0.03), not CIR. (**Figure 1A-D)**

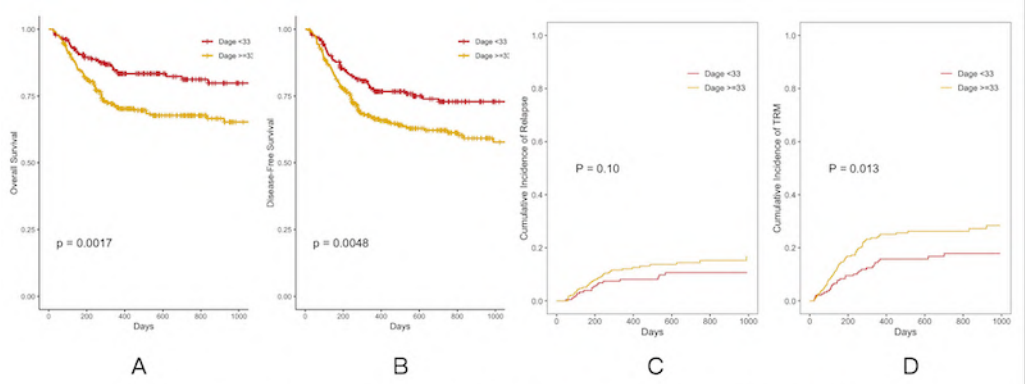

Figure 1. Comparison between Donor age <33 and ≥33 groups. (A) OS, (B) DFS, (C) TRM, (D) CIR.

Dage = Donor Age

Conclusions: This study indicated that donor age significantly influences the outcomes of haplo-HSCT in patients ≥55 years. Younger donors, particularly those aged < 33 years, were associated with better OS and DFS and lower TRM, suggesting that younger donors may be preferred for older patients undergoing haplo-HSCT.

Clinical Trial Registry: NA

Background: Allogeneic stem cell transplantation (alloHSCT) from fully HLA-matched (10/10) donors is safest treatment but often limited by donor availability. This study evaluates whether first-field (antigen-level) or second-field (allele-level) mismatches (MMs) at the five major HLA loci (HLA-A, -B, -C, -DR, -DQ) affect transplantation outcomes versus fully matched pairs. All analyzed mismatches were 9/10 HLA matches. Since HLA-DQ mismatches are considered more tolerable and data on DQB1 mismatches are relatively limited, the study focused on this locus.

Methods: This registry-based, retrospective study analyzed adults undergoing first alloHSCT from 2010–2021. We evaluated 3772 fully matched (10/10) and 1071 single HLA-mismatched (9/10) transplants, including 122 DQB1 mismatches. Patients receiving post-transplant cyclophosphamide as graft-versus-host disease prophylaxis (GVHD) were excluded. Endpoints were overall survival (OS), progression-free survival (PFS), graft-versus-host disease-free/relapse-free survival (GRFS), relapse incidence (RI), non-relapse mortality (NRM), grade III–IV acute GVHD (aGVHD), and chronic GVHD (cGVHD). Cox proportional hazard models assessed associations of MM status with OS, PFS, and GRFS; cause-specific Cox regression for competing risks evaluated RI, NRM, aGVHD, and cGVHD.

Results: Univariable analysis demonstrated that HLA-Class I mismatches (HLA-A, -B, -C) were associated with significantly reduced survival compared with 10/10 matches. Especially HLA-A first-field mismatches had consistently negative effects: 5y-OS (32% vs. 46%, $p < 0.001$), 5y-PFS (24% vs. 32%, $p = 0.003$), and 5y-GRFS (14% vs. 21%, $p < 0.001$). Notably, HLA-DQB1 first-field mismatches showed a detrimental impact on outcomes comparable to Class I mismatches, with 5y-OS (27% vs. 46%, $p = 0.011$), 5y-PFS (8.4% vs. 32%, $p < 0.001$), and 5y-GRFS (7.4% vs. 21%, $p = 0.032$). Multivariable analyses confirmed the impaired survivals, specifically for HLA-DQB1, with OS (HR 1.50, $p = 0.022$) and PFS (HR 1.50, $p = 0.009$). HLA-DRB1 mismatches also showed a negative impact, observed only for OS (9/10 second-field HR 1.46, 95% CI 1.05–2.04, $p = 0.025$; 9/10 first-field HR 1.87, 95% CI 1.10–3.17, $p = 0.02$).

HLA-Class I first-field mismatches were consistently linked to higher aGVHD risk, increasing over time compare to 10/10 matches (HLA-A: 6.7% → 23% → 25%; HLA-B: 6.5% → 26% → 26%; HLA-C: 4.4% → 21% → 23% at 28, 100, 365 days; all $p < 0.001$). Cox regression showed significantly increased aGVHD risk for HLA-A (HR 2.27), HLA-B (HR 2.20), and HLA-C (HR 1.91) mismatches (all $p < 0.001$), while Class II mismatches had no significant effect. Except for HLA-A first-field mismatches, we could neither detect an effect on cGvHD for first- nor second-field 9/10 mismatches.
Lastly and interestingly, among the five major HLA loci, only HLA-DQB1 first-field mismatches were found to be significantly associated with increased RI (HR 1.62, 95% CI 1.14–2.31, $p = 0.007$), and not significant for NRM and this effect was not related with DQA1 mismatches.

Conclusions: First-field DQB1 mismatches, similar to HLA Class I mismatches, significantly compromise survival outcomes, whereas second-field mismatches appear to have no impact. These findings underscore the importance of complete HLA matching, including DQB1, in donor selection for alloHSCT. In the absence of a fully matched donor, second-field mismatches may be preferable to first-field mismatches.

MODELING SUFFICIENCY AND GROWTH OF THE AUSTRALIAN AND NEW ZEALAND HSC DONOR REGISTRIES TO MEET PATIENT POPULATION REQUIREMENTS IN AN ERA OF MISMATCHED TRANSPLANTATION

*Carmel O'Brien[1], **Garth Healey**[1], Carolyn Crump[2], Heather Dunckley[3], Lisa Smith[1], Martin Maiers[4]*
[1]Stem Cell Donors Australia, Sydney, Australia, [2]New Zealand Bone Marrow Donor Registry, New Zealand Blood Service, Auckland, New Zealand, [3]New Zealand Transplantation and Immunogenetics Laboratory, New Zealand Blood Service, Auckland, New Zealand, [4]CIBMTR® (Center for International Blood and Marrow Transplant Research), NMDP, Minneapolis, United States of America (the)

Background: Access to suitably HLA-matched unrelated donors for allogeneic hematopoietic cell transplantation (HCT) in Australia and New Zealand is constrained by registry size and the underrepresentation of some ancestries. We used population-based modeling to quantify current match likelihoods across ancestry groups, evaluate the contribution of international donors, and explore growth strategies that improve equity in donor access for Australasian patients.
